In the other two cases, both coaches used their visions of high-quality teaching to assess the instructional changes their partner teachers had made and then simply told the teachers that the changes were improvements. To illustrate, we focus on a coaching cycle in which the coach and teacher worked to improve students' engagement by making the task more "relatable" to students. To do so, the coach and teacher decided to start the lesson with an introductory task about her recent experience buying strawberries at a grocery store. However, the primary task for the lesson focused on estimating the cost of oranges. In the debriefing conversation following the lesson, the coach and teacher observed that the teacher "kind of lost [students] after a while" because it took a long time to discuss her trip to the store to buy strawberries. Despite this, the coach told the teacher that "making [the launch] personal was really good" She then went on to note that this kind of personal connection is an effective teaching strategy, and thus constituted an improvement. Unfortunately, their decision to include a personal story both increased the time the teacher spent introducing the task and appeared to be confusing for many of the students who then struggled to begin working on the task. Our assessment of whether the instructional change was an improvement therefore differed from that of the coach.

Discussion and Conclusion

The goal of this analysis was to clarify how mathematics coaches can support teachers in determining whether the instructional change(s) they made during the lesson benefitted students' learning and their engagement and were thus improvements. We found that in the cases in which coaches succeeded in supporting teachers in making this kind of determination, they connected changes in students' thinking and their engagement to changes in instruction. In contrast, we found that in the unproductive cases, the coaches and teachers either concluded that making the intended instructional change was a sufficient reason for the change to be an improvement or the coaches used their visions of high-quality teaching to assess whether the changes were improvements for teachers. It therefore appears unproductive for coaches to focus only on the teacher's actions without considering the consequences of those actions for students' thinking and engagement.

The results of our analysis make a significant contribution to research on one-on-one mathematics coaching. Specifically, our findings extend prior research examining one-on-one debriefing conversations in mathematics coaching (Russell et al, 2017; Cross Francis et al., 2021; Saclarides, 2022). Several recent studies of one-on-one coaching have examined the focus and nature of coaches' and teachers' talk during debrief conversations descriptively (Amador et al., 2024; Cross Francis et al., 2021; Gillespie & Amador, 2024; Saclarides, 2022). Our study builds on and extends this primarily descriptive work by clarifying how coaches can accomplish the retrospective purpose of debriefing conversations, thereby advancing our understanding of how coaches can facilitate productive debriefing conversations. Specifically, we highlight the importance of linking students' learning opportunities to instructional changes. While prior research points to the importance of connecting students' learning to instruction during co-planning conversations (Russell et al., 2020; Witherspoon et al., 2020) and when observing a lesson to identify instructional improvement goals for teachers (Kochmanski & Cobb, 2023b), this is the first study to highlight the importance of this connection in debriefing conversations.

Regarding implications for future research, it appears important for coaches to support teachers in connecting students' learning and instruction in all three phases of coaching cycles. Future research might investigate in greater detail how coaches can be supported to see this underlying principle as a central tenet of productive one-on-one coaching cycles. Further, we suspect that coaches who support teachers in connecting students' learning (or lack thereof) to their instruction might also be supporting teachers in coming to view instructional limitations as the primary source of students' learning difficulties (Jackson et al., 2017). This would be a significant development as prior research indicates many mathematics teachers attribute the difficulties of students they perceive are struggling primarily to inherent characteristics of the students (Jackson et al., 2018). Future research might investigate whether this is the case. Finally, while we investigated the retrospective function of debriefing conversations in the context of one-on-one coaching cycles, we anticipate that our findings will prove relevant to other settings in which teachers analyze their instruction with a colleague, such as mentor-mentee relationships in pre-service teacher education and when teachers work with a peer to improve their instruction. However, this conjecture requires further investigation.

EXAMINING RELATIONSHIPS BETWEEN ELEMENTARY TEACHERS' REFLECTIVE JOURNAL ENTRIES AND MATHEMATICS TEACHING PRACTICES

B. Sumeyye Kurutas
University of Delaware
sumeyyek@udel.edu

Keywords: Instructional Activities and Practices, Professional Development

Professional learning programs are designed to promote teacher learning to foster improved instructional decision-making to achieve better student learning outcomes (Borko et al., 2010; Darling-Hammond et al., 2017). One way to investigate teachers' professional learning experiences is to incorporate reflective journals into professional development. Reflecting in journals affords opportunities for teachers to document their experiences and make sense of their professional learning (Brown et al., 2011; Henderson et al., 2004). In this study, I examined relationships between two elementary teachers' intentions, as documented in reflective journals kept during a professional learning experience, and their mathematics teaching practices one year later. This descriptive case study investigates how elementary teachers made sense of their professional learning in their reflective journals, and then, a year later, which aspects of teaching from reflective journals appeared to translate into their mathematics teaching. The research question that guided this study: *In what ways do elementary teachers' reflective journaling about their professional learning translate into their mathematics teaching practices a year later?*

The main finding is that two elementary teachers' thinking in their reflective journals translated into their mathematics teaching practices, based on both reported and observed data. The aspects of mathematics teaching that teachers intended to improve – identifying the key learning goals of the lesson and creating intentional questions – were key aspects of effective mathematics teaching (NCTM, 2014; Smith & Stein, 2018). Figure 2 summarizes both participants' intentions and their mathematics teaching practices. This study has implications for teacher educators and professional learning designers to consider embedding reflective journaling as part of their professional learning programs. Reflection can be an important tool that supports professional learning and teacher education (Cimer et al., 2013; Schön, 1983).

FRAMING EVAN'S ERROR AS WORTH UNDERSTANDING: HOW TEACHERS NEGOTIATED THEIR NOTICING

Sarah Larison
Northwestern University
slarison@u.northwestern.edu

Examining how teachers notice students' errors is one part of understanding how teachers can learn to respond to errors productively. This paper explores how teachers notice student errors. Across one discussion, teachers negotiated their noticing by seeking, offering, and sharpening accounts of video evidence, and by offering, extending, and contesting interpretations of video evidence. Together, these moves constituted their shared framing of the error as worth understanding. This research contributes to our understanding of how teachers notice and can co-construct their noticing in the context of video-based professional development.

Keywords: Professional Development, Teacher Noticing

Mathematical errors — students' contributions that are not mathematically complete, precise, or correct (Baldinger et al., 2021) — are resources that can be leveraged to support students' learning (Borasi, 1987; NCTM, 2000). Teachers can work with students to examine errors to extend and deepen their mathematical thinking (Tulis, 2013). Yet, dominant deficit discourses in mathematics education typically value correctness over meaning, making productively engaging students' errors difficult for teachers (Adiredja & Louie, 2020). Indeed, teachers often ignore or simply correct errors (Santagata, 2005). Even teachers who report believing that errors are resources do not consistently use them as such in the classroom (Alvidrez et al., 2022). How, then, can teachers approach errors in more productive ways?

Every decision and response a teacher makes is, in part, an extension of something they *noticed* (Mason, 2002). Noticing has been conceptualized as the dynamic interplay of teachers' attention, interpretations, and framing (Louie et al., 2021), where framing is understood as the process of activating or developing schemas that both construct and are constructed by what teachers see and their sense of its meaning (Sherin & Russ, 2014). These schemas represent a "framework of frameworks" for a participant in an activity, reflecting a key element of the broader participant group's culture (Goffman, 1974, p. 27). Students running and shouting may be interpreted favorably by a teacher monitoring recess, and less favorably by a teacher monitoring silent reading time. The teacher's understanding of the nature of either activity (her framing) influences her attention to and interpretations of students' running and shouting, and, in turn, her attention to and interpretations of their running and shouting influences her understanding of the nature of either recess or silent reading time.

Teachers can learn to notice students' mathematical thinking (Dindyal et al., 2022), and noticing students' thinking has been linked to improved student learning outcomes (Kersting et al., 2010). Less is known about how teachers notice errors specifically. With this in mind, I unpack a discussion among three teachers about one student's mathematical error, tracing how they negotiated what happened in the video and what it meant to reach a well-supported and shared conclusion, asking: In one productive discussion about one student's mathematical error, how did teachers frame Evan's error as worth understanding?

Methods

Data come from a nine-week, online, professional development course for in-service K-2 mathematics teachers. Nine teachers participated in the course. One goal of the course was to support teachers to notice strengths in students' thinking. On alternating weeks, teachers recorded and uploaded video clips of their students trying new tasks to an online platform, then watched and marked moments of students' thinking in their own and their peers' videos using a video annotation tool (Larison, Richards, and Sherin, 2022). The other weeks, teachers met virtually on Zoom in small groups to discuss their videos. I facilitated the virtual video clubs (Sherin & van Es, 2009), working to maintain our focus on students' thinking in the videos. Here I explore part of one video club between a differentiation support teacher, Bea, and two second-grade teachers, Casey and Glenda (all names are pseudonyms).

A ~four-minute-long video clip from Bea's classroom formed the basis for the teachers' discussion. In the clip, three students shared their thinking about what goes in the blank in the equation 8 + 5 = __ + 7. Evan, a first grader who had historically attained high test scores, originally wrote "4" in the blank. Bea asked, "Why did you put a four there?" He responded, "Because eight plus…" pausing mid-sentence. After ~five seconds, Bea asked, "What are you thinking?" Evan told her, "I got mixed up…I thought the seven was more than eight." He concluded that "six" should go in the blank rather than four.

I examine one ~five-minute discussion segment among the three teachers as a case (Yin, 2009) of a productive discussion about a student's error to unpack teachers' noticing. Productive discussions about students' thinking have been conceptualized as focused on students' thinking, concerned with mathematically substantive ideas, and involving joint sensemaking among teachers (Sherin et al., 2009). I conceptualize a productive discussion about a student's *error* as also reaching a well-supported and shared conclusion about the meaning in the student's error. I do not suggest that teachers reaching a well-supported or shared conclusion is always possible or preferable; rather I use this approach to examine the work teachers did to reach their conclusion.

To begin to unpack teachers' *noticing* (Louie et al., 2021) related to the error in the video, I coded what they *attended* to, or evidence from the video mentioned in conversation, and their *interpretations* of that video evidence. To explore how teachers *negotiated* what happened in the video and what it meant, I used a constant comparison method (Glaser, 1965) to locate and characterize instances in which teachers interacted with video evidence their peers brought forward (a proxy for their *attention*), and engaged their peers' ideas about video evidence (a proxy for their *interpretations*). Finally, I looked across the teachers' discussion of video evidence and its meaning to infer the *framings* that organized and were organized by their attention and interpretations (Sherin & Russ, 2014). In practice, attention, interpretation, and framing are closely related. I separate them here for analytic purposes only.

Findings

Bea, Casey, and Glenda *negotiated* their noticing about the video in six different ways — by seeking, offering, and sharpening evidence, and offering, extending, and contesting interpretations (see Table 1). To understand the relationship between their negotiations, their *framing* of Evan's error, and how together they functioned to support the teachers in reaching shared meaning about the error, consider the following examples within the trajectory of their discussion.

Table 1: How Teachers Negotiated Salient Video Evidence and Its Meaning

	Type of Negotiation	Example
Attending	Seeking Evidence	Casey asked, "I think he says… 'I'm trying to think about how eight plus five, what would make it the same,' *does he say that*?"
	Offering Evidence	Glenda said, "I heard this time, *'would make the same.'*"
	Sharpening Evidence	Responding to Glenda's offering, Casey said, "Yeah he says, *'8 plus 5. I was thinking 8 plus 5 would make the same as 4 plus 7.'*"
Interpreting	Offering	Casey conjectured, "I think he was really thinking…six plus five equals four plus seven..."
	Extending	Adding to Bea's interpretation, Glenda said, "Yeah 'cause then…his pointing of the marker, too…he was saying since eight and five are further apart, seven and six should be closer together in terms of 'the same as.'"
	Contesting	Bea, responding to Casey, asked, "*Or* he got mixed up on which one (seven or eight) was bigger, right?"

In the initial part of their discussion, the teachers established the shared goal of figuring out the meaning of Evan's error by their careful and sustained engagement with it. This goal reflects their framing of Evan's error as worth understanding. They offered and contested a few interpretations about why Evan stated that four should go in the blank. More specifically, the discussion began when I asked, "What did you notice about Evan's thinking?" Casey **offered an interpretation** that the source of Evan's error was related to his sense of the numbers seven and eight, saying, "...he was thinking, 'okay seven is more than eight," so he needed a number more than five." She followed up, **offering another interpretation** that perhaps Even confused the eight with a six, thinking, "…six plus five equals four plus seven." Bea, **contesting Casey's second interpretation and extending** her first, replied, "Or he got mixed up on which one was bigger, right?" After a couple of talk turns between Bea and Glenda, Casey added, "I think he says… 'I'm trying to think about how eight plus five, what would make it the same,' does he say that?" both **offering and seeking evidence** from her colleagues. Bea responded, **sharpening the evidence**, "...He was pointing to the eight plus five, and he would say, 'This would need one smaller number.'" Glenda responded, "I was trying--I still need to listen. I want to think about it more because…I honestly think he has a far more sophisticated understanding of these numbers than I do….I'm like, 'what is he getting that I'm not figuring out?' and I know that it's working in his head," to which Casey and Bea immediately agreed, prompting me to ask if they would like to rewatch the video, to which all three teachers agreed. Together, these moves reflect the teachers' continued framing of Evan's error as worth understanding.

After rewatching the video, Glenda **offered evidence**, saying, "I heard this time, 'would make the same.'" **Casey sharpened the evidence**, adding, "Yeah, he says…eight plus five would make the same as four plus seven." Bea shifted back to the error specifically, **offering a new interpretation**, "...He realized that those were one away from each other and so that's why he had the four at first was because he knew that was one away from five. He just went the other way." Casey and Glenda responded, "Ooh!" in tandem. This series of talk turns signaled an "Aha! moment" for the group. Glenda **extended this interpretation**, offering additional evidence about Evan tapping his marker.

Together, Bea, Casey, and Glenda concluded that Evan, having drawn on his relational reasoning skills, knew that "something one away" from five should go in the blank, and his error was located in his having compensated "the other way" from five when he originally answered six, rather than four. Their conclusion reflects the shared interpretation that Evan had drawn on his sense of the numbers seven and eight, and their relation to five and the blank. The teachers' conclusion can also be understood as the result of their negotiating video evidence and its meaning within their shared framing of Evan's error as worth understanding.

Discussion

This research contributes to our understanding of how teachers notice students' mathematical errors and how teachers co-construct their noticing of classroom videos together in discussion. Here I have begun to explore the social dimension of one teacher group's noticing by tracing how teachers took up, contested (Goodwin, 1994), and otherwise engaged one another's attention, interpretation, and framing of one student's thinking in a classroom video. Note that teachers negotiated video evidence (a proxy for their attention) and its meaning (a proxy for their interpretations), but appeared to frame Evan's error in the video in parallel and seemingly productive ways across the duration of their talk. Future work can explore what happens when teachers bring different frames, perhaps more and less productive, to their noticing together.

Finally, recall that Bea was a differentiation support teacher, not a self-contained classroom teacher. Bea's job was to meet with small groups of (usually three) students, which allowed her to focus more carefully on individual students' thinking, rather than feel rushed to notice a classroom of different students' thinking. She was not bound by a curriculum or accountable to test scores because she was not the students' primary teacher. Evan was selected for differentiated instruction based on his *high* test scores. Indeed, Bea introduced him at the beginning of the course, writing, "Evan consistently scores high…" Framing has been conceived as the coordination of teachers' resources specific to the context, such as their knowledge, beliefs, and perceptions of environmental constraints (Richards et al., 2020). We can reasonably infer that Bea's knowledge (and by extension, Casey and Glenda's knowledge) of Evan's achievement history was salient to framing his error as worth understanding from the outset of the discussion. Teachers also likely perceived *few* environmental constraints for noticing Evan in the context of Bea's classroom, and the video club, where they could slow down to make sense of Evan without the pressure of deciding how to respond.

Let us suppose, then, that the teachers noticed Evan's error particularly carefully because of, in part, his achievement history and their perception of the affordances of the environment of

Bea's classroom and the video club itself. Many questions remain: To what extent did Evan's thinking having been an *error* influence their noticing? How did these teachers engage other students' thinking, with different achievement histories and in other classroom contexts? Did teachers routinely frame Evan's thinking in seemingly productive ways? In our final video club, Bea shared "frustration" with Evan, and "confusion," at his incorrect use of the equal sign, despite having been exploring it for weeks. Future research can continue to explore the complex relationships between teachers' noticing and who and what they notice.

EXAMINING LEARNING IN A FACILITATOR PROFESSIONAL DEVELOPMENT CENTERED AROUND THE TRU-PG FRAMEWORK

Helene S. Leonard
Montclair State University

Keywords: Professional Development, Instructional Leadership

Effective professional development is critical for growth and change within American education (Darling-Hammond et al., 2017). Therefore, those leading the professional development (facilitators) must be prepared to "successfully facilitate newly developed PD models that offer high-quality learning opportunities for teachers" (Borko et al., 2014, p. 14). To do so effectively, facilitators must be adequately prepared and supported (Borko et al., 2014; Koellner et al., 2011; Roth et al., 2017). Facilitators must draw from a rich knowledge base to make decisions and take action in planning and enacting their professional development sessions (Rodgers et al., 2017). Few empirical studies have been explicitly designed to study the facilitation of professional development or facilitator learning. Lesseig et al. (2017) noted that, as a field, we "lack research-based principles to guide the design of leader preparation" (p. 592). Therefore, studying how facilitators learn and enact effective PD is imperative.

This poster aims to describe the emergent findings of a study to address the needs of preparing, supporting, and researching facilitation by investigating facilitator learning in a facilitator professional development (FPD) designed to prepare and support facilitators as they enact a high-quality, effective mathematics PD program. This study focused on five facilitators and one facilitator educator as they participate in an FPD focused on reflective facilitation (adapted from Smith, 2001) and TRU for Professional Growth (TRU-PG) (Schoenfeld, 2015) to support their enactment of the Analyzing Instruction in Mathematics Using the TRU Framework (AIM-TRU) PD model. Each participant had various facilitation experiences and was from the same region in the Northeast United States.

This FPD was centered around Schoenfeld's (2015) Teaching for Robust Understanding for Professional Growth (TRU-PG) framework. This framework depicts five dimensions that characterize powerful learning environments: Professionalism, Room to Grow, Equitable Access, Agency, Ownership, and Identity, and Uses of Assessment. These dimensions have been posited by Schoenfeld as a framework for PD based on abstraction from the Teaching for Robust Understanding (TRU) framework, which has been shown to create powerful mathematics learning environments (Schoenfeld, 2015). Participants meet for seven FPD sessions throughout the school year. Each of the seven sessions focused on one dimension of TRU-PG or reflective facilitation practices. Each of these sessions was video recorded and transcribed. The research questions driving this study are: *How does the facilitator professional development model support facilitator learning?* and *How does the discourse in a facilitator professional development align with the TRU- PG framework?*

Drawing on situated learning perspective and community of practice (CoP) theoretical frameworks (Wenger, 1999), I use frame analysis (Bannister, 2015) to examine participation changes and how the discourse aligns with the TRU PG framework. This poster will report on preliminary findings of facilitator learning in this FPD, including an analysis of the problems of practice faced by participants and how they changed over time. The poster will also report on how the problems of practice align with the TRU-PG framework.

Mathematics teacher leadership is promising, yet complex work. This systematic review takes stock of the current research landscape on mathematics teacher leadership, specifically mathematics specialists as teacher leaders (MSTL). This study's findings provide further evidence that mathematics-specific teacher leadership is on the rise. Further, in considering the research design, the trends surrounding the methods, research questions and framing also illuminate future research directions and complexities.

Keywords: Instructional Leadership, Research Methods

Perspective on Teacher Leadership

As early as the 1970s, a teacher-leadership model was established to position teachers as educational change agents (Andrew, 1974). Within this model, the teacher leader position is an "in-school position" that moves beyond supervision responsibilities or those of a master teacher and is a "front line leadership role for improvement of curriculum and instruction" (p. 2). This teacher leader positioning allows for career growth and advancement while allowing teachers to remain in classrooms (Andrew, 1974), a promising aspect given current teacher retention issues (Yow et al., 2021a). Content-specific professional learning has proven to be an essential component of effective professional development (PD; Darling-Hammond et al., 2017; Desimone, 2009). Research indicates teacher leaders also believe that expertise in subject-matter and pedagogical content knowledge is important for them to engage effectively in teacher leadership (e.g., Snell & Swanson, 2000).

We define a mathematics-specific teacher leader as a type of mathematics specialist who has primary responsibilities within a P-12 classroom and provides formal and/or informal support for teaching and learning mathematics to in-service teachers through mentoring and other support structures (Baker et al., 2022). Thus, we refer to this individual as a mathematics specialist as teacher leader (MSTL, p. 31). Mathematics-specific teacher leadership is promising (Yow et al., 2021a), yet complex work (Klein et al., 2018), and research interest in this form of leadership is on the rise (Rigelman & Lewis, 2023).

Purpose

The purpose of this systematic review is to understand the current MSTL research landscape and explore the following research questions: (1) What are the historical publication trends for MSTLs? and (2) What are the various methods, research questions, and framing used in research design for MSTLs?

Methods

We explored the historical publication trends for MSTLs and the various methods, research questions and framings used in research design. Below we outline the systematic procedure we used to investigate the research related to MSTL between 1981-2021 and describe the methodological parameters of our data identification and analysis. We drew on Cooper et al.'s (2019) comprehensive steps to achieve a high-quality literature synthesis (Sandelowski & Barroso, 2007) to inform research and practice.

Data Collection

For the purpose of this analysis, we targeted the articles in which mathematics specialists served as teacher leaders from a larger body of work (Baker et al., 2022), wherein we explored empirical research to examine the positioning of mathematics specialists (see Baker et al., 2022 for a detailed process of inclusion and exclusion criteria). Within that larger analysis on mathematics specialists, 57 articles were identified with the MSTL code. To evaluate study quality, we used the appraisal criteria of Risko et al. (2008). This evaluation tool has seven quality criteria that enables the appraisal of articles from various methodologies. Of the 57 articles, 34 received an overall score of "3", meeting all seven criteria and producing a 60% inclusion rate.

Data Analysis

To answer our research question about historical publication trends for MSTLs, we began by isolating the 34 unique articles that featured a MSTL, and completed counts to determine the frequency of publications between our target dates of 1981–2021. The lower date range was based on the call for mathematics specialists from National Council of Teachers of Mathematics (NCTM) in 1981 (Dossey, 1984), a catalyzing event noted by Fennell (2017), and the upper date range was the last complete year of research available at the time analyses began. We then represented this data in a line graph to help illustrate publication trends over time. Next, we identified the journal title for each article that was published during this time frame and determined the frequency with which each journal published an MSTL article. We then examined the title to determine if the journal was a mathematics-specific education journal or a general education journal. The code "math" was used if only mathematics appeared in the journal title and the code "general" if there was no mention of mathematics in the title, or the journal focused on research across content areas (e.g., literacy, social studies). We then completed frequency counts of the journals that published one of the 34 MSTL articles.

To determine trends in research methods, we coded each article with an overarching description of the methodological approach (mixed methods, qualitative, quantitative) and determined the frequency of the approaches. We first searched the full article to identify how the author(s) described the study. In instances in which the author(s) did not identify a description of the methodology, we made inferences based on the data collection tools identified in the study. For example, if the article mentioned using interviews or observations, we coded the article as "qualitative." If the article mentioned using statistical analysis of scores on an assessment, we coded the article as "quantitative." If an article mentioned both qualitative and quantitative data sources, we coded it as "mixed methods."

To determine trends in research questions, we compiled each article's question(s). While some articles (e.g., Insuander et al., 2019) had multiple research questions, other articles featured a single research question that guided the investigation (e.g., Yow et al., 2021b). Nevertheless, all questions from one article were inserted into a single cell of our matrix. One member of the research team open-coded (Saldaña, 2021) the questions to determine what concepts emerged, and then made a preliminary categorization key. Two research team members then independently categorized the research questions into one or more of the following categories: "teacher leader characteristics", "teacher leader interactions", and "teacher leader professional learning". Only the presence of a category was recorded for each research article. Upon coming together to obtain consensus, a fourth category "systems" emerged. We also further refined "teacher leader interactions" to encompass the interactions a teacher leader has with any K-12 partner and "teacher leader professional learning" to illuminate that the PD was *for* the teacher leaders.

Beginning with a list of the headings and notes about codes for concepts and theories of the studies compiled by four authors, one author created an initial coding framework. A second author then referred to the articles themselves to apply the coding framework as a validation of the conceptual topics and to confirm the interpretation of the headings. As with the research questions, two authors met to come to consensus on the coding. Based on the research question coding and reviewing the literature review sections, a distinction between PD for teachers and PD for teacher leaders was made in the framework.

To determine the type of framing of MSTL research, we identified the articles with a clear heading that outlined a theoretical or conceptual framework. The next step was to consider the introduction and literature review sections to identify a conceptual or theoretical framework. This process yielded additional articles where the framework was identified by the authors embedded within text (often the literature review) and not within an independent section, which meant most of the articles had an identified theoretical or conceptual framework. The remaining articles were deemed to use a practical framework and their literature review constructs were analyzed to determine the practical frameworks for these studies.

Results

Research Question 1: Publication Trends

We examined the 34 unique studies that were coded as MSTL. Overall, there was an increasing trend in publications featuring an MSTL. Although the period we examined spanned over 40 years, the publication range was 2004-2021, with the majority published in the last decade. Between 2012-2021, there were 30 articles published which represent 88% percent of the total MSTL-focused subset, and 24 (71%) of the 34 articles being published during the most recent five years span of 2016-2021.

MSTL articles were published within 23 journals. Of those 23 journals, eight were mathematics-specific education journals and 15 were general education journals. Seven journals published more than one MSTL article. In the sub-set of seven journals, there were 16 MSTL articles of which four were housed in mathematics-specific education journals and three were in general education journals. The mathematics-specific education journals housed 10 of the 16 articles (63% of this subset; 29% of the entire data set).

Research Question 2: Research Design Trends

Methods

The 34 research articles include 24 qualitative studies, one quantitative study, eight mixed methods studies and one article focused on tool development. Common approaches to data collection included surveys (e.g., Yow et al., 2021b); interviews (e.g., Webel et al., 2018); and observational data (e.g., Gerstenschlager & Barlow, 2019). Many studies used case study approaches (e.g., Roberts, 2020) to analyze teacher leaders' development individually (e.g., cross-case analysis) or collectively over time.

Research Questions

Four categories of research questions emerged from the analysis: (a) leader characteristics, (b) leader interactions with others, (c) leader reactions to PD programs, and (d) systems-level analysis. The first three categories characterize aspects of the MSTLs' experience, roles, practices, and leader development. These questions capture their transition from teacher-to-teacher leader, the roles they play in schools, the kinds of knowledge and practices they need, and the influence of PD on their development as leaders.

While each article could include multiple questions with a specific categorization, we only coded for the presence or absence of the category. It was somewhat arbitrary as to the number of research questions as well as whether specific categorizations were present across one or multiple research questions. For instance, Cassata and Allensworth (2021) stated "RQ1. What were the practices teacher leaders used to support instructional change? RQ2. In what ways did school-level factors shape the practice of the teacher leaders?" (p. 2). In this example the first question is about the influence of MSTL on others and the second question is a systems question because it centers on the influence of the school on the MSTL. However, other articles might have multiple, related questions about a MSTL's interactions. For example, Borko et al. (2021) state "(1) How did the Teacher Leadership Preparation sessions evolve over time? (2) What key Problem-Solving Cycle ideas did the Teacher Leaders adopt and how did they adapt them over 3 years of planning and facilitating workshops?" (p. 130). The greatest number of articles are about PD programs for teacher leadership. Fewer studies are about MSTL characteristics or their interactions with others. While a clear pattern of research question categories did not emerge, it is important that the field is studying MSTLs in concert with the influences of either PD for them or their work within a system.

Framing

There was a total of 18 articles (53%) with a clearly identified theoretical framework with two specific theories used in two different articles: (a) professional noticing, and (b) situative learning. Three of the 18 articles did not have an identified section outlining the theoretical framework but instead embedded the framework within the literature review (e.g., Cwikia, 2004; Lu et al., 2020) or the introduction (e.g., Insulander et al., 2019). As we documented the theories used to study mathematics-specific teacher leadership, we also analyzed each article to determine if certain themes were evident across the 18 articles. Within some articles, researchers leveraged more than one theory and sought to answer multiple questions. For this reason, an article may be represented more than once within the identified themes. There were seven articles (21%) with a clearly identified conceptual framework. While one of these articles had a clearly labeled conceptual framework heading, it was also referred to as a theoretical framework elsewhere in the article (Boylan, 2018). All seven articles also used their conceptual frameworks in the analysis of their data. The conceptual frameworks used by studies of teacher leadership within mathematics education included frameworks about conceptualizing and defining informal mentors, communities of practice, induction, images of a teacher, and systems of teacher leadership. Others used formalized conceptual frameworks like Three-Tetrahedron (3-T) Model of Professional Development (Prediger et al., 2019) and The PRIME Leadership Framework (National Council of Supervisors of Mathematics [NCSM], 2008).

After determining whether an article had an author-identified theoretical or conceptual framework, we identified ten articles (29%) that used a practical framework to frame their study within known and successful practices (Eisenhart, 1991). For this analysis, we examined each article's introduction, literature review headings, and background sections to identify the practical frameworks. These were compiled into the following categories: mentors/ mentoring, mathematics coaching/specialists, teacher leadership, and instructional practice. The framing of mathematics coaching/specialists included background information, responsibilities, roles and their development and support. An instructional practice framing included exploring flipped classrooms, synchronous online teaching and blending learning, and data informed practices. Articles with a mentoring framing explored mentoring relationships and influence. A teacher leadership framing included influence, learning environments, data-informed decisions, and program components. One feature that seemed to distinguish the conceptual frameworks from the practical frameworks was that conceptual frameworks used a more general construct of mentoring, while the practical frameworks explored mathematics-specific literature around coaching and specialists, which was highlighted as an individual theme.

While the previous section explored the frameworks more holistically, this section examines the concepts that make up the background literature portions of each study and which are used to situate the studies in the research literature. Four categories of framing concepts emerged from the coding process: (a) practices, (b) positioning, (c) purpose, and (d) PD. Due to the complexity of the research questions surrounding mathematics-specific teacher leadership, an article could be assigned more than one framing category. The first framing category included types of practice and how studies described the type of actions, behaviors, strategies or approaches MSTLs should employ. The second category included two different positionings for leadership. One positioning is "teacher leadership" referring to general teacher leadership framed as: the influence on other teachers, informal or formal leadership roles, and taking up activities beyond classroom teaching. The second positioning was specific framing as content-specific leaders (in this case, mathematics) where the practices, standards, content, and knowledge of the discipline is positioned as critical to the role. The third category was about the purpose of the study itself including the intervention the authors might suggest or the teacher leadership itself. This category included teaching induction, teaching practice, professional knowledge, and instructional change as what might be influenced or changed by the teacher leadership process. The final category included two framings of PD: teacher PD and teacher leadership PD.

The three practices included formal and informal leadership practices and roles. The codes were used to describe the language authors used to situate their research via the literature or other frameworks. So, while Knapp (2017) was an often-cited article about mathematics coaching and the findings include coaching as a term, the literature review is framed around teacher leadership. Other articles framed specific aspects of teacher leadership practice in their findings, thus providing a window into how the research was theorized and supported.

The two categories of content-specific/mathematics leader and teacher leaders displayed how the role might be defined in the school, how the leadership work might be framed, and the complexity of teacher leadership overall. Content-specific teacher leadership (i.e., mathematics-specific) might emphasize mathematics classroom practices, mathematics standards, or how the leadership is situated in the content domain. For instance, Borko et al. (2021) described a model driven by a problem-solving cycle using mathematics tasks. Myers et al. (2020, 2021) and Webel et al. (2018) described elementary mathematics specialists focused on the teaching and learning of mathematics. In contrast, Boylan (2018) described “adaptive leadership” as a teacher leadership framework that could be applicable for multiple kinds of teacher leaders or school leaders. Smith et al. (2017) used ecological systems theory to understand teacher leadership as part of a network of influences and interactions. We have described this as positioning because it is about how the article positions the work and the research that supports it.

The purpose category of codes described the kinds of literature that frame the purpose of the leadership or the study. Teacher leadership was desirable in these studies for some purpose or goal. So, the goal might be to improve teacher induction, spur instructional change, describe teaching practice(s) or professional knowledge without a particular PD or intervention.

Professional knowledge included different types of knowledge for teaching and may also include teacher leadership knowledge. It was difficult to draw a clear distinction in the literature review sections between these, so it remained one category of professional knowledge. In addition, many of the teacher leaders were continuing to teach in classrooms so their knowledge of teaching and knowledge of leadership were likely intertwined. The final category came about after the coding of the research questions where PD for leadership became a clear category. These articles emphasize how they are drawing on findings about teacher PD to inform teacher leadership PD. However, a large number of articles distinguished features of teacher leadership that required different PD (e.g., adult learning, conducting research about teaching practices) than might be expected of a teacher.

We examined how the categories might be related to research question types, specific theoretical frameworks, and other categories. We also looked for patterns in how the categories might connect to one another. While there are consistent categories of the types of concepts and research that articles reference in their studies, there is not a clear relationship about when the categories might be connected to one another. For instance, we expected some connection between teacher induction and mentoring. However, articles might refer to both (n=12), mentoring only (n=5), or induction only (n=2).

It is important that studies are making a distinction between PD for teachers and PD for leadership. Some articles (e.g., Borko et al. 2021; Myers et al., 2021) referred to both. The literature review sections that focus on the design or goals for PD were complex because the design of leadership PD understandably draws upon the design of teacher PD. These sections brought in findings about the duration, structure, and organization of PD that have been long-standing. Despite the complexity, it is an important finding that the specific needs and interests of teacher leadership were recognized as needing different content, such as adult learning theories, adaptive school leadership (Boylan, 2018), and the perspective on content.

Discussion

For the current investigation, we analyzed 34 research articles that centered the work of MSTLs. We remind the reader that we had initially identified 57 research articles but excluded 23 because they did not meet some aspect of the Risko et al. (2008) appraisal criteria. In particular, some articles were eliminated because of inadequate participant description, not linking findings back to research, and/or not linking the findings to the research questions. Some articles had more than one of the Risko et al. (2008) criteria missing from their study.

Our findings revealed that research on and about MSTL is increasing. Nearly 90% of the MSTL research originated in the last decade and 70% of the articles were published during the most recent five years span (2016-2021). Two-thirds of the MSTL articles were published in general education journals. These publication trends highlight a need for the field to consider how to expand research on MSTLs and depict a real tension that scholars face when choosing publication outlets. From our experiences, we have learned that if the mathematics in the manuscript is not prominent enough, scholars tend to shy away from mathematics-specific journals and instead submit to general education journals to face less reviewer push back about "where is the math?" The implication is that mathematics-specific journals are not the predominant outlet for published work about MSTLs. We encourage the research community to consider the ways in which we might elevate work about MSTLs and MS more broadly in mathematics-specific or STEM-specific journals.

Future directions are also evident in the results regarding the research design, the trends surrounding the methods, framing, and research questions. The most frequent research design across the 34 articles was qualitative. Because MSTL is a growing field (Rigelman & Lewis, 2023; Yow et al., 2021a) and there are very few MSTLs working in schools, this makes sense. As a community we are trying to understand the boundaries of these individuals as they navigate their unique P-12 contexts.

To study everyday leadership and support for P-12 school initiatives (Fennell, 2017), it will be essential for future research to continue to address the contextual nature of both P-12 education and teacher leadership. There is then a parallel needed to clearly define the roles, responsibilities, and contextual nuances of MSTL work. Similar to research calls to action around mathematics specialists (Baker et al., 2021), more specificity is required in how we speak about and define MSTLs so that "the field of mathematics education can not only come to a common understanding, but advance both policy and practice" (p. 9). MSTLs can be one part of a coherent system for PD (Cobb et al., 2018). Further research is needed about the interactions between leadership at multiple levels: classroom, grade-level, school, and district.

To design research questions around MSTLs, it is important to recognize the complexities of teacher leadership broadly (Klein et al., 2018) as well as the need for MSTLs to possess specialized knowledge around leadership (e.g., AMTE, 2013) and the teaching, learning, and leading of mathematics (NCTM, 2014). This is amplified by the fact that most of the research questions in the current body of research center on leader interactions with others and leader reactions to PD programs, speaking to the complexity of the work and the need to understand an MSTL's influence and how that might inform MSTL professional learning. It also signals that the mathematics and teacher leadership research communities are wondering about the influence of these positions and the professional learning required. Further research on the MSTL positioning will be essential to understanding how these individuals take on or reject particular roles or responsibilities (Hunt & Handsfield, 2013) and the ways they position themselves or are positioned by others (Davies & Harré, 1990). Not surprisingly, there were fewer research questions around systems-level analyses. System-level work is even more complex, dynamic, and multifaceted as there are additional layers within and beyond an individual school community. It will be essential for future research to consider how MSTLs "develop long-term goals advocating for systematic instructional change and/or short-term goals providing small, measurable successes that serve as milestones" (Hjalmarson & Baker, 2020, p.555).

When analyzing the framing of MSTLs, we noticed a variety of theories and constructs. Although potentially alarming, this is logical as the field of mathematics-specific teacher leadership is emerging (Rigelman & Lewis, 2023; Yow et al., 2021a). The field is also multifaceted as there are many theories in play beyond those associated with teaching and learning: leadership theories, adult learning theories, mathematics-specific theories, and systems-level change theories to name a few. These theories are alluded to within the *Teacher Leader Model Standards* (2011) and the *Mathematics Specialist Standards* (AMTE, 2013) and illuminate the layers of complexities teacher leaders and MSTLs face.

However, while past research has illuminated that teacher leadership is either atheoretical (York-Barr & Duke, 2004) or partially theoretical (Wenner & Campbell, 2017), we see this space of mathematics-specific teacher leadership framing as a potential foundation from which to build. Considering that the field of mathematics-specific teacher leadership is new, the findings from our study illuminate four possible categorizations from which to frame future studies: (a) practices, (b) purpose, (c) positioning, and (d) PD. There is even a similar distribution of construct categorization across the research questions asked. This is a positive sign for the field. If we were focused too heavily on one or two of these categorizations, then we would likely be missing important aspects of mathematics-specific teacher leadership. However, we are not stating that these are the only categorizations, just we are seeking the foundation from which future research can build and new theories can emerge for a fledgling field.

Research is needed about mathematics specialist and their work. There are questions of policy and practice that need instrument design and development to advance research about the nuanced work of mathematics specialists. This systematic literature review will identify the gaps and need for the development of rigorous, quantitative measures.

Keyword: Measurement, Mathematics Specialist

With the increased use of mathematics coaches and specialists and an increase in related research (MCSs; Baker et al., 2021; Rigelman & Lewis, 2023), a need for valid measures is at the forefront. The goals of MCSs are to influence teacher practices and beliefs to improve student learning (e.g., AMTE, 2013; Campbell & Malkus, 2011). With the current measures available, however, there is fragmented evidence to make the connections among these goals. Without measures that accurately capture specific information pertaining to MCSs, there is a lack of empirical evidence about their work in schools and influence in the system of mathematics teaching and learning.

Purpose

The purpose of this systematic review is to understand the current instrumentation used in MCS research with the objective of identifying specific needs for validated instruments. This work was guided by the following research question: What are the current tools and instrumentation used for MCS research? For our theoretical framing, we draw on Gutiérrez's (2009) conceptualization of equity in mathematics education. Gutiérrez identifies four equity dimensions: (1) access; (2) achievement; (3) identity; and (4) power for which we will organize the MCS instrumentation.

Design Process

We draw on Cooper et al.'s (2019) comprehensive steps to achieve a high-quality literature synthesis (Sandelowski & Barroso, 2007) to inform both research and practice. In 2020, we analyzed a subset of our data corpus (n=130) that were tagged with a mathematics specialist code. We applied an open coding process to attend to how the mathematics specialist was presented within research. Our primary code identified the role or position of the mathematics specialist (e.g., coach, teacher leader) and our secondary code indicated the context (e.g., school, district). Last, we took this data set and identified the tools and instruments used in order to highlight the need for validated instruments for MSC research.

Implications

The implications for this work include stronger methodological practices for MCS research, in addition to using validated instruments to support MCSs in their practice.

COMPLEXITY, TEACHER AGENCY, AND THE FUTURE OF RESEARCH ON MATHEMATICS TEACHER LEARNING

Reanders6@ncsu.edu

Extensive research has been conducted on the characteristics of effective professional learning (PL); with many scholars asserting a consensus has been reached. However, empirical studies into the outcomes of PL initiatives do not consistently align with this consensus. In this paper it is suggested that a key element, namely teacher agency, has been overlooked. We advocate for the use of new conceptual frameworks that contextualize teacher learning as occurring within a complex learning system. This allows for the investigation of processes and interactions between parts of the system that support the emergence of learning. Our findings highlight the essential mechanisms that emerge from these systems when mathematics teachers are positioned as active participants in the design and facilitation of their own learning.

Keywords: Professional Development

Perspective of the Study

The characteristics of effective professional learning (PL) have been well documented, with some arguing that a consensus has been reached (e.g., Darling-Hammond et al., 2017; Desimone, 2009). An examination of literature spanning several decades indicates that the essential attributes for successful teacher PL include: a focus on subject matter content and pedagogy, collaboration and interaction with colleagues, engagement in active learning tasks for teachers, coherence with existing curricula and policies, and extended duration of PD programs (Desimone, 2009). What research has found however, is that even when PL programs for teachers are designed using these features they often produce conflicting results (Goldsmith et al., 2014). In fact, more recent critiques make note of the absence of teacher choice within discussion of PL models (see Boylan, 2021; Boylan et al., 2018). Without teacher involvement in designing and directing these learning experiences, PL programs may perpetuate the deficit view of teacher learning in which teachers are seen as passive receivers of knowledge (Davis & Renert, 2014; Bruce et al., 2010). To move away from the deficit view of teacher learning, researchers have begun to consider the role that shared leadership, time and space for PL, and high levels of teacher agency play in effective PL (Day, 2017; Hauge & Wan, 2019).

Building from the assumption that teachers are professionals with the ability to seek out, develop, and lead their own PL experiences, Sachs (2003; 2016) encourages the field to design and study PL experiences that position teachers as professionals. In fact, studies of PL models that sustain teacher learning found that high levels of teacher agency are required (Campbell et al., 2016; Day, 2017; Hauge & Wan, 2019). Therefore, a design and study of PL should go beyond the consideration of widely adopted key features (Biesta et al., 2015; Calvert, 2016) and investigate when teachers have agency, what emerges as explanatory mechanisms that support learning in these communities. By mechanisms we are referring to the processes and interactions between these key features that support learning.

To this end, this report investigates the following research question within a regional university-supported, multi-site PL initiative: When mathematics teachers are positioned as active participants in the design and facilitation of their own learning, what emerges as essential mechanisms of the PL initiatives that support this learning?

Theoretical Framework

As discussed, the consensus on key features of PL have provided the field with standards for how teachers should be supported in their learning. Missing from these features is the role that teacher agency plays in the design and implementation of PL for teachers.

Teacher Agency

Teacher agency is enacted when teachers "exert influence, make choices, and take stances on their work and/or professional identities" (Eteläpelto et al., 2013, as cited in Day, 2017, p. 37). When teachers possess agency, they can exert control and determine the actions they will undertake. Teacher agency, therefore, plays a crucial role in what is learned through engaging in PL of any type. Teachers bring their own experiences and expertise to the practice of teaching, and this is a valuable resource that should be part of any model of teacher PL (Guskey, 1986). Campbell et al. (2016) suggest that teachers are and should be leaders in their own PL and that a priority in designing and supporting teacher learning is the inclusion of teachers' voice in influencing the methods, goals, and content of that learning (Campbell et al., 2016).

Looking Beyond Individual Features of Teacher Professional Learning

We align with other researcher who view education as a complex learning system from which learning emerges (e.g., Cochran-Smith et al., 2014, Jacobsen et al., 2019; Opfer & Pedder, 2011). Research in teacher learning has often focused on specific features of PL rather than considering its complex nature and the ways that learning is socially constructed (Cochrane-Smith et al., 2014). Considering these features separately does not allow for an understanding of how the pieces interact and influence one another (Opfer & Pedder, 2011). Some wonder why some initiatives, designed using these effective strategies, are unsuccessful while others, with none of the characteristics of effective PL, are more successful (Opfer & Pedder, 2011). The issue may lie in the framework used to analyze these studies as current theoretical models of teachers' PL tend towards a linear and reductionist perspective (e.g., Cochran-Smith et al., 2014; Strom & Viesca, 2020).

Complexity Theory

Current research on mathematics teacher PL has begun to consider its complex nature and how the use of complexity science can help the field gain a deeper understanding of ways to support and possibly trigger this learning. (e.g. Cochran-Smith et al., 2014; Strom & Viesca, 2021). Complex systems are open, non-linear, not predictable, and not defined only by the sum of their parts but also by the ways that these parts interact with, and influence, each other and the environment (McMurtry, 2008). Complex systems are defined by key characteristics including self-organization, adaptation, nestedness, and emergence (Cilliers, 1998; Davis & Simmt, 2003). Self-organization suggests that there is no hierarchical authority imposing instructions on the system and is achieved through the non-linear interactions within the system and between the system and its environment (Strom & Viesca, 2021). Adaptation means that a system can change its structure, but involves more than a predictable, linear response to a system's environment (Davis & Simmt, 2003). Complex systems often involve systems nested within self-similar systems, with smaller components of a system resembling the system as a whole (Suurtamm,

2020). Emergence refers to the ongoing evolution of a system that arises through the interaction, self-organization, and adaptation of the nested systems (Davis & Sengupta, 2018).
Emergence also relies on a set of conditions which provide a framework to study what and how systems learn (Cochran-Smith et al., 2014; Davis et al., 2012). These different conditions include specialization and trans level learning. Specialization creates a constant tension between redundancy and diversity. In a professional learning community (PLC), redundancy is represented by the shared practices, assumptions, and expectations of mathematics teaching. Diversity manifests in the different beliefs, attitudes, experiences, and knowledge each teacher brings to teaching mathematics. Trans-level learning involves neighbor interactions in a system with decentralized control (Davis & Sumara, 2006). Neighbor interactions in a complex system involve individuals' "ideas, hunches, queries, and other manners of representation" (Davis & Sumara, 2006, p. 142) bumping up against and colliding with one another. In a PLC, these interactions could include sharing solutions to problems, co-planning lessons, discussing student and student thinking, or engaging in a pedagogical book study. Decentralized control suggests that these interactions occur as individuals and groups find their own reasons to share and listen to each other. Moving forward these characteristics and conditions are referred to as mechanisms that interact to support teacher learning.

Methods

This study was a qualitative multiple-case study (Creswell & Poth, 2018; Yin, 2016) combined with a complexity science framework. This research design was influenced by Anderson et al. (2005) who suggested combining the case study approach with complexity science as a way to gain insight into systems of learning. They argue that analyzing a system by simply breaking it into parts does not provide an adequate description of the mechanisms at play within that system (Anderson et al., 2005). This study moved beyond simply describing key features of PL and towards understanding the mechanisms that support educators, with high levels of teacher agency, as they work in a collaborative system.

Context and Participants

This study was part of a larger study that focused on the Ontario Association for Mathematics Educators Grade 9 Applied Math Inquiry Project (McKie, 2023; Suurtamm et al., 2017), from here referred to as the project. This project involved 10 high school PLCs from across the province. PLCs applied to participate in the project by submitting an application. The application needed to include a list of the PLC members and their roles, and a description of the PLCs self-defined problem of practice (McKie et al., 2017). This self-defined problem of practice highlights the way that teacher agency was purposefully integrated into the project design. The PLCs were supported to meet monthly within their own schools as well as multiple times each year at project wide meetings. The design of the project was influenced by the perspective that, similar to researchers, teachers assume an inquiry stance when examining their practice (Cochran-Smith & Lytle, 2009; Suurtamm & Koch, 2019). This inquiry stance involves the active, iterative process of engagement in, and reflection on, practice which results in the emergence of new ideas and actions (Suurtamm & Koch, 2019). The collaborative nature of the project, the high level of teacher agency, and the use of PLCs was informed by complexity theory (Suurtamm & Koch, 2019). This supported the focus on the role that nested systems, in this case the 10 PLCs in this project, played in influencing the emergence of learning. The condition of diversity was intentionally built into the project through the requirement that PLCs consist of individuals with varying roles such as administration, special education, and mathematics teachers (McKie et al., 2017). The 10 PLCs also represented a diversity of contexts and experiences. Some PLCs were situated in large urban settings and others in more remote settings or serving smaller populations. Some PLCs were established collaborative learning communities and others were newly formed.

Participants in this study were original project participants. Years of experience of these participants ranged from 12-32 years and different roles of the participants included principals, mathematics teachers, mathematics department heads, special education teachers, and research team members.

Data Collection and Analysis

Data for this study was collected in two phases, the first being a survey sent to all individuals who participated in the original project (N≈80). The survey served two purposes, the first to collect information related to the participant's position, role in the PLC formation, how the PLC operated, and the perceived influence the project had on the participant's learning. The second purpose was to identify, and recruit individuals for phase 2 of the study. The survey asked participants if they were interested in being contacted for further participation in this study. Those that indicated 'yes' were contacted to participate in semi-structured interviews during phase 2. These interviews (N=13) provided a deeper examination of the individuals' learning and the shared learning experiences within the nested systems of the PLCs and the project as a whole. Questions in each phase focused on teachers' experiences with the project, the influence the project had on the participant's learning, the collaborative nature of the project, and the sustainability of their learning. A theory-driven codebook (DeCuir-Gundy et al., 2011) was created using the mechanisms of complex learning systems described earlier, self-organization, adaptation, nestedness, diversity, redundancy, neighbor interactions, and decentralized control (Davis & Sumara, 2006). These codes were applied to survey and interview responses, next the results of this analysis are presented.

Results

Analysis of the data from the study revealed that four key mechanisms emerged that supported teacher learning. These include neighbor interactions, decentralized control, self-organization, and nestedness. These four mechanisms are not independent, rather they interact and influence each other.

Neighbor Interactions

Neighbor interactions in the project included time to interact with resources and other individuals and their ideas. At project-wide meetings the PLCs were introduced to different resources that the research team felt supported the identified issues and challenges. One particular resource, *5 Practices for Orchestrating Productive Mathematics Discussions* (Smith & Stein, 2015) was provided to each individual and multiple PLCs chose to incorporate this resource as part of their learning. Neighbor interactions with individuals and their ideas also were identified as an essential mechanism. These individuals included other educators, researchers, and students. Neighbor interactions included PLC members interacting with student thinking, PLCs discussing and negotiating new practices and ideas within their own context, and neighbor interactions across PLCs at the project-wide meetings. Responses to the Phase 1 survey overwhelmingly point to neighbor interactions as influencing teacher learning. 86% of survey respondents self-reported that interacting with resources and with others either from their own

PLC or across the project was either the most influential component on their learning or the highlight of the project for them. For example, one participant shared "the other teachers that we were able to network with and learn alongside with was amazing!! Really challenged our thinking on spiraling and rich tasks" (PLC 1, phase 1 survey) and from another participant, "a highlight of the project was meeting and sharing experiences, perspectives, and resources with colleagues all over the province" (PLC 7, phase 1 survey). Neighbor interactions were not a stand-alone feature, they were supported through the next key feature identified, decentralized control.

Decentralized Control

Although the project schedule of activities and overall goals were determined by project leaders, each PLC was in charge of determining their context specific goals, ways of working, and their focus throughout the project. In this way the project demonstrated decentralized control. At individual PLC meetings each PLC determined their schedule, focus, and activities. At project-wide meetings time for individual PLCs to work together was scheduled as was time for groups to collaborate across PLCs in ways that were meaningful to them. A PLC 1 participant commented that the "the teacher led approach to this was great!" suggesting that providing space for teacher voice and choice was a quality she identified as influential. Decentralized control supported neighbor interactions and created opportunities for individuals who may not have been supported in their own PLCs in ways that were meaningful to them. For example one participant shared how interacting with PLC 7 supported her own learning and that of her PLC:

> We learned about using rich tasks to drive instruction from William [PLC 7] and [the PI] suggested a Jo Boaler book for our group to read… our group continued to learn about Thinking Classrooms and spiraling curriculum mostly being influenced by the group from PLC 7. (PLC 1, Phase 1 survey)

Decentralized control supported neighbor interactions, these two mechanisms interacted to influence and support how the individuals and PLCs self-organized, the third essential mechanism that emerged from analysis of the data.

Self-organization

Self-organization was apparent at multiple levels in the project. This self-organization was not pre-determined at the beginning of the project but rather it was based on needs that arose through the neighbor interactions that were enabled in a network with decentralized control. The research team members from different PLCs were interacting, sharing information and experiences, and adopting different strategies to share with their assigned PLCs. Other ways the project demonstrated self-organization was PLCs seeking out, and making connections with, one another. Different PLCs created shared document folders online for sharing resources and also planned visits to each other's schools to collaborate. This self-organization came from neighbor interactions at the project-wide meetings and the PLCs sharing with one another. One participant explained that as the project progressed more opportunities to connect with other schools were created and the participants self-organized visits with at other school sites:

> Every time [the project] extended I seemed to be connected with new people along the way and that led to all kinds of exchanges with other teachers and other schools. It also led to some dates where we…went to the [other] school and we had [other PLCs in the project] coming to our school as well. (PLC 7, phase 2 interview)

During project-wide meetings different PLCs would seek out connections with people and resources that they felt could support their work and their learning. During the final project-wide meeting at the end of Year 2 different PLCs self-organized into working groups to develop presentations for the project's annual conference as well as for the Grade 9 project conferences that were organized to share the learning from the project with educators across the province. Self-organization, which was supported by neighbor interactions in a system with decentralized control was also made possible by the fourth essential mechanism, nestedness.

Nestedness

The nestedness of the project provided opportunities for individuals and PLCs to connect with others both within their own school and with others beyond their own PLCs. Several individuals commented on the fact that the project allowed them to get to better understand their colleagues professionally. Teachers being nested within PLCs in their own school provided opportunities for neighbor interactions:

> It was an interesting thing because working with [teacher], she and I have been friends for a million years right? And like we fished together, and we hang out together as much as we can right? But I think [the project] made me realize how she thought too, like it not only helped me identify the strengths of myself but of the people that were working with me in the project (PLC 4, phase 2 interview)

Nestedness at the project level introduced new, diverse perspectives and experiences as well. Individuals who were seeking new ideas beyond their own PLC were buoyed by the opportunity to learn with others across the province. One participant shared:

> I got a lot of energy from people from other schools that had the same kind of excitement about things as I did, but within my own board I don't know whether I felt that same level of excitement by others…I really enjoyed being able to get that perspective, like I really enjoyed meeting people from other schools and thought about "wow everybody should, we all should know what's going on out in all of [the province]" so we do have a better perspective [about] where we are at compared to them and where we should be at or what we should be, you know, aiming to be at. (PLC 10, phase 2 interview)

The nestedness of the project enabled the other essential mechanisms that emerged and together these four mechanisms; neighbor interactions, decentralized control, self-organization, and nestedness influenced teacher learning. Next, a discussion is presented on how these essential mechanisms of complex learning systems connect to the research on the key features of effective PL. Through this discussion we argue that the mechanisms of complexity offer insight into how and why these characteristics can support learning and why teacher agency is essential in PL.

Discussion

This study aimed to explore the mechanisms facilitating the emergence of learning in a PL experience where teachers actively participated in designing and directing their own learning. Within this study the emergence of teacher PL was considered using complexity theory. The findings suggest the importance of neighbor interactions, decentralized control, self-organization, and nestedness within PL experiences. These identified mechanisms connect to previous literature on key features of PL and also spotlight the importance of teacher agency to promote

PL. In what follows, we first make connections to previous literature on PL and then highlight mechanisms within PL experiences that promote teacher agency.

Connections to Literature: Neighbor Interactions

Participants in this study overwhelmingly stated that interacting with colleagues in their PLC and with others across the project had the biggest influence on their learning. This is in line with numerous researchers who have reported on the crucial role that teacher collaboration plays in supporting teacher PL (e.g., Borko & Potari, 2019; Schleicher, 2015; Stigler et al., 1999; Vescio et al., 2008). Collaboration has been previously identified as a key feature to PL experiences for teachers.

Neighbor interactions with resources such as rich tasks and the curriculum were also mentioned as key to teacher learning. This aligns with researchers who suggest that a key feature of effective PL should focus on content and be aligned with the curriculum (e.g., Ball et al., 2005; Cohen & Hill, 1998; CPRE, 1998; Darling-Hammond et al., 2017; Loucks-Horsley & Matsumoto; 1999). When teachers engage with content and curricula, specifically mathematical content, they are provided opportunities to develop a deeper understanding of concepts and even to change their own identities as learners of mathematics (Anderson et al., 2018).

Lastly, interacting with student thinking and student work emerged in this study as a widely adopted activity. Several researchers have identified a focus on student thinking as an effective strategy for teacher PL (Darling-Hammond et al., 2017; Roth et al., 2011; Smith & Stein, 2015). Focusing on student thinking can provide teachers opportunities to better understand student ideas in order to better anticipate and plan responses and prompts to students questions or misunderstanding (Roth et al., 2011; Smith & Stein, 2015). This study found that neighbor interactions promoted the emergence of learning within a PL experience as a mechanism that is essential to support the previously identified key features of professional development: collaboration, and a focus on content and pedagogy.

Mechanisms of Professional Learning that Support Teacher Agency

While neighbor interactions connect to previous literature on key features of PL (Darling-Hammond et al., 2017), decentralized control, self-organization, and nestedness highlight the importance of teacher agency, an emerging key feature of PL (Biesta et al., 2015; Calvert, 2016).

Decentralized control. Decentralized control implies a shared leadership where no individual makes decisions and controls the system. Davis and Sumara (2006) go so far as to say that a single leader choosing the direction in a system could eliminate the potential for learning to emerge from a system. Similarly, research suggests that for collaborative PL to be effective a PLC requires a shared leadership approach (Hipp et al., 2008; Leithwood & Riehl, 2005). Shared leadership implies that teachers participate in determining the focus and direction of PL activities (Calvert, 2016). Shared leadership aligns with teacher agency, an important characteristic of effective PL cited in the research literature (e.g., Biesta et al., 2015; Day, 2017; Hauge & Wan, 2019; Sachs, 2016). The mechanism of decentralized control is critical within the PL experience to allow for shared leadership to promote teacher agency.

Self-organization. Self-organization manifested across different levels of the project, including ways the project self-organized in response to PLC's needs and the ways that different individuals adapted their practices in response to neighbor interactions across the nested systems of the project. These examples of self-organization are similar to a claim by Davis and Simmt (2003) that systems in education are adaptive self-organizing systems. Self-organization is an ongoing phenomenon that arises from the interactions of parts of a system with decentralized control and the "process of self-organization changes the relationships among the elements of the system as new relationships emerge" (Cochran-Smith et al., 2014, p. 8). These new relationships were apparent in the ways the different PLCs established connections with others within, and beyond their own PLCs. Teachers choosing the tasks to engage with, the content to focus on, the models of PL to employ, and the learning experiences they chose to share with others in the project all influenced the self-organization of the learning systems involved in the project. All of these actions were determined and negotiated by the participants in the project rather than through top-down instruction. Through self-organization, teachers had the agency to influence their learning opportunities on multiple levels.

Nestedness. The nestedness of the project supported important neighbor interactions between individuals and PLCs. The opportunities for individuals in PLCs that lacked the necessary balance between conditions such as diversity and redundancy to find this balance with others across the nested system supported teacher agency and the emergence of learning. Studies that focused on collaboration and supporting communities of practice (Wenger, 1998) generally focused on what an individual learned through their involvement in a project rather than how the project influenced their learning, and the learning of a larger system (e.g., Zehetmeier, 2015). Through this study nestedness emerged as an essential mechanism of complex learning systems as it was critical to support teacher agency by allowing teachers, and PLCs, to seek out learning opportunities across PLCs in the project.

Conclusion

Supporting and establishing the essential mechanisms of complex learning systems aligns with much of the research on the characteristics of effective PL (e.g., Anderson et al., 2018; Hord, 2008; Liljedahl, 2018, & Loucks-Horsley & Matsumoto, 1999). Yet, establishing the key features of PL is not sufficient to support teachers in their learning (Day, 2017; Hauge & Wan, 2019). Understanding how mechanisms of complex systems interact and align with the features of PL provides insight into how and why these features support teacher learning. This study demonstrates that considering the ways to establish a balance of essential mechanisms necessary to support learning is crucial. Thus, whether designing PL explicitly or considering how to establish environments conducive to teacher learning, the field should consider, and strive to put in place, the mechanisms of complex learning systems. Particularly, those in positions to influence learning systems should be conscious of the ways that decentralized control, self-organization, and nestedness are manifested in their context and strive to support these factors in order to support neighbor interactions.

It is important to note that when a learning system is unable to achieve a balance of these mechanisms, teacher agency becomes critical to make connections across the larger educational system to support a balance. Thus, organizing teacher learning within a nested complex learning system can provide opportunities for teacher agency across levels within the system to support the emergence of learning. We recommended that teachers are provided opportunities to meet and interact with others beyond a teacher's own context. This can provide the necessary perturbations to encourage teachers to continually push their thinking and respond in novel ways to new ideas, leading to the emergence of learning.

Teacher agency has emerged as an important area of focus in research and centering the voice of the teacher was an important component of this study. This study highlights the importance of conducting research that centers teachers' voices because teachers' perspectives, expertise, and experience are valuable assets that enrich the research process and contribute to more meaningful understanding of the complexity of mathematics teachers' collaborative PL. As the world continually changes, for both students and educators, research must move beyond the linear models used to study teacher learning. Teaching and learning mathematics has always been a complex endeavor and in order to better support mathematics teacher learning the field must look beyond individual key features towards essential mechanisms that support learning in complex systems.

Facilitating classroom discussion is complex work, especially for elementary classroom teachers who must make sense of classroom discussion practices across content areas. We examined two teams of elementary teachers and teacher educators as they engaged in professional learning to understand what connections among classroom discussion practices across content areas emerged from their conversations and how these connections were leveraged to support mathematics classroom discussions. We elaborate on two key ways that cross-content practices were leveraged: student participation and teacher facilitation moves.

Keywords: Teacher Educators; Classroom Discourse; Elementary School Education

Mathematics classroom discussions can support students' deep mathematical learning and provide opportunities to make sense of new content (Kazemi & Stipek, 2001; O'Connor & Snow, 2017). However, literature concerned with supporting mathematics discussion tends to be siloed to practices intended only for mathematics content (e.g., Bishop et al., 2020; Webb et al., 2014). Classroom discussion is a valued dimension of instruction across content areas starting in early elementary grade levels (Fitzgerald & Palincsar, 2019). Elementary classroom teachers are uniquely tasked with facilitating classroom discussion across multiple content areas. As such, elementary teachers are expected to draw on a vast range of practices to balance social and content goals which vary by content area (Rainey & Moje, 2012).

In this study, we look specifically at how teachers consider the similarities of classroom discussion across content areas. We hypothesize that the similarities in elementary discussion practices across content areas can be leveraged by educators to create richer discussion in mathematics lessons. As such, we ask: what and how do teachers and teacher educators identify connections within classroom discussion practices across content areas?

Theoretical Framework

We are interested in examining how educators leverage their experience and expertise to support classroom discussion practices across content areas and make sense of high-quality instructional practices. As a theoretical framework, teachers' collective sense-making frames how educators collaborate to make connections in their discussion facilitation practices in mathematics and ELA. Coburn (2001) argues that teachers' sensemaking is social, as it is "rooted in social interaction and negotiation [and]... is deeply situated in teachers' embedded contexts" (p. 147). Collective sensemaking involves the interactions and negotiations among individuals to establish meaning of particular events or shared experiences (Coburn, 2001; Kelly, 2006). In other words, it is the opportunities teachers have to interact with one another in communities of practice (Wenger, 1998) that allow space for their professional learning.

Elementary teachers are expected to engage in high-quality instruction in multiple content areas, and that instruction is often expected to include discussion. While attention to researching teachers' discussion practices has focused on content-specific analysis (e.g., Bishop et al., 2020), we see opportunities in a collective sensemaking framework to examine how teachers use their different levels of expertise to negotiate meaning of classroom discussion across content areas. Sensemaking can thus occur in the interaction of talk (Bakhtin, 1981) where teachers' shared engagement with ideas prompts new or refined interpretations of ideas.

Methods

We draw on data collected from a larger study of professional learning (PL) that focused on supporting elementary teachers' classroom discussion practices. Our analysis focused on a subset of educators in one district in the northeastern United States, from Parks and South Elementary Schools (pseudonyms). Teachers met in grade level bands for full day job-embedded PL with teacher educators, including instructional coaches and a facilitator from the research team. The PL followed the Learning Labs structure (see Kazemi et al., 2018) and focused on developing classroom discussion practices in mathematics and ELA. Learning Labs consist of a cycle of (1) introducing new ideas related to content and pedagogy, (2) co-planning an instructional routine, (3) enacting the routine in one of the teachers' classrooms, and (4) debriefing the experience to make plans for their future instruction.

Data Collection

We focus specifically on the PL sessions with the third (N=3) and fifth (N=5) grade teachers because they engaged with a wide range of ideas about leveraging the classroom discussion practices in one content area to support another. In the 2022-2023 school year, each grade level team participated in a total of four Learning Labs (two mathematics and two ELA) with a PL facilitator and their instructional coaches. Among these teams, the teachers and teacher educators are primarily white women and come from a wide range of teaching experience. Each PL session was video and audio recorded.

Data Analysis

We used the conversations of teachers as they participated in the series of Learning Labs as our primary data source. Analysis focused on understanding what teachers and teacher educators said about connecting discussions across content areas during the PL sessions. We reviewed the introduction and enactment debrief portions (phase 1 and phase 4) of each Learning Lab (mathematics or ELA, eight Labs total). Using an inductive coding process aligned with a grounded theory approach (Charmaz, 2000), we reviewed these portions of the Learning Labs for moments where teachers reflected on their classroom discussion practices. Ultimately, we documented moments where educators talk about discussions in mathematics compared to other content areas (63 instances total). Then, using a constant comparative method (Charmaz, 2014), we identified larger themes of how teachers leveraged their understanding of classroom discussions across content areas. For this paper, we focus on instances where educators leveraged non-math content thinking to make sense of mathematics discussions.

Results

In our analysis of the third and fifth grade teams' interactions during their respective PL sessions, we identified common ways that the educators leveraged discussion practices across content areas to develop rich mathematics discussions. These four cross-content connection types were (1) similarities in classroom discussion norms, (2) adapting tasks, (3) similarities in student participation, and (4) similarities in teacher facilitation moves (see Table 1). Below we detail two of these types of connections with examples from the teachers and teacher educators.

Table 1: Cross-Content Connections to Support Classroom Discussion

Theme	Description	Example
Classroom Norms	Recognizing ways to develop the norms of discussion for mathematics as a form of developing social skills	Esther: [After our last ELA LL] I've been really trying, across all areas, to get kids to explain other students' thinking. In math, [...] "Why did this person do what they did?," getting kids to repeat what others said… to see if there was active listening. [Grade 3, ELA LL2]
Adapting tasks	Recognizing a need to adapt the goals or structure of a task to be more like tasks from a different content area	Greer: ELA tends to be a little bit more open with our questions when we're asking them during the read aloud. Olivia: How do we then open up like, we have to think of open tasks for kids, right, in math? [Grade 3, MATH LL1]
Student participation	Understanding the ways that students can participate in a discussion that work to create a comfortable environment	Greer: Students are more confident in math than reading. In math, there is a right answer and you can come to it in many ways. Reading is vague and there are multiple answers. It's harder to make a safe space with text because there is more variation and vulnerability. [Grade 3, ELA LL1]
Teacher facilitation moves	Naming facilitation moves that support discussion across content	Elliott: I'll put sunglasses on and they know I'm not there. They can't ask questions, they've got to figure things out on their own. [Grade 5, MATH LL2]

Student Participation

Regardless of content area, the teams developed an understanding of the ways that students can participate in a classroom discussion that work to create a "comfortable" environment. Teachers emphasized the importance of student participation and discussed ways to support students to feel comfortable to share their ideas during discussions, noting differences in student participation across content areas. In one such example, Esther, a third-grade teacher, described her observations about student participation, "It shifts throughout the day if they are comfortable with the content." She explained that in science and social studies students feel more comfortable and excited to respond. The teachers extended this idea by sharing their own observations and collectively came to associate student participation with confidence. Another third-grade teacher, Winter connected this to mathematics and ELA as she described,

> It is important to look at who is participating and who is not participating in all discussions. In math, a student may have an answer but not feel confident sharing it. In reading, students don't know how to say a word, so [they] won't try.

Teachers recognized that student participation was important across content areas but named differences in the ways that students might hold back from participating. They leveraged characteristics of the spaces in which students are comfortable to participate as they talked about how to support student participation in mathematics classroom discussions.

Teacher Facilitation Moves

Teachers also considered the specific pedagogical moves they might make in one content area for discussion that could easily be used in another, not just mathematics teaching. The connections they made focused on patterns of participation that could support classroom discussion across content areas. For example, the PL facilitator in a fifth grade Learning Lab asked what feels similar or different between leading discussions in reading and mathematics. Cait and Janet brought up the desire to move away from the typical discussion structure of initiate, respond, evaluate as a goal in both mathematics and ELA discussions, drawing on their experiences facilitating mathematics classroom discussion. Cait added that she wanted to “shift to other ways to get student responses and student discussion” such as having the teacher stand back to let students collaborate. In this example, Cait and Janet co-developed a shared goal to use facilitation moves that increased student voice in classroom discussion, drawing on the prior success the 5th grade team had with this particular teacher move in an earlier mathematics Learning Lab. We hypothesize that connections among pedagogical moves allowed teachers to extend their experiences facilitating classroom discussion across content areas.

Discussion

In their conversations during PL, educators made connections among discussion practices across content areas to leverage support of mathematics classroom discussion. We primarily focused on how these PL discussions support mathematics and identified ways that the teachers leveraged successful mathematics practices to support other content area discussions.

Each theme emerged from the conversations among teachers and teacher educators through collective sense-making (Coburn, 2001) of classroom discussion practices in elementary classrooms, grounded in their own discussions and collaboration. Collective sensemaking was evident in how educators listened to the reflections of their peers to refine their thinking about discussion practices. This work highlights how teachers draw on their experiences and interactions with one another to make meaning of instructional practices within their own contexts (Kelly, 2006; Wenger, 1998). Although we investigated these ideas with a small sample, this study sets a foundation for future work to examine teachers’ reflections in different settings to support teacher learning in their unique contexts.

Elementary teachers, who teach across content areas, are being asked to incorporate classroom discussion, but often without support for how these practices may be similar. The changing landscape of education and uncertainty in children's mathematical learning indicates an urgent need to support teachers to leverage their expertise in other content areas to support mathematics instruction. Thus, we argue that leveraging teachers' experiences in the areas of classroom discussion norms, adapting tasks, student participation, and teacher facilitation moves provides an opportunity for enriching mathematical discussion practice in the classroom.

ENHANCING TEACHERS' MATHEMATICAL KNOWLEDGE FOR TEACHING PROBLEM SOLVING SKILLS THROUGH LESSON STUDY

Brian Odiwuor

In mathematics education, significant attention has been given to understanding the knowledge teachers need to effectively teach mathematics. While much research has focused on the knowledge of pre-service and beginning teachers in the context of classroom mathematical problem-solving, there is limited insight into the knowledge in-service secondary teachers use to develop and teach mathematics through problem-solving. This participatory action research via lesson study reports the knowledge nine secondary math teachers in sub-Saharan Africa used to craft problem-solving lessons. The data revealed a collective understanding of problem-solving as involving high level, open middle tasks grounded in students' everyday experiences.

Keywords: Mathematical Knowledge for Teaching, Professional Development, Teacher Knowledge, Problem-Solving.

Mathematics Problem-Solving Knowledge for Teaching

Teachers are essential components of the education system and are pivotal in achieving a nation's educational goals. In mathematics education research, significant attention has been given to understanding the knowledge teachers need to teach mathematics effectively. A key contribution to this discourse is the Mathematical Knowledge for Teaching (MKT) framework (Ball et al., 2008), built on Shulman's (1986, 1987) seminal work advocating for a professionally oriented knowledge for teaching mathematics. Ball et al. conceptualized MKT as "mathematical knowledge needed to carry out the work of teaching mathematics. . . [emphasizing] the tasks involved in teaching and the mathematical demands of these tasks" (p. 395).

Teaching Through Problem Solving

The MKT framework laid the foundation for a new line of research focusing on Mathematics Problem-Solving Knowledge for Teaching (MPSKT) (Chapman, 2015; Foster et al., 2014; Clivaz et al., 2023). The MPSKT framework (see Table 1) underscores the importance of problem-solving skills, as emphasized by the National Council of Teachers of Mathematics (NCTM, 2000).

MPSKT includes understanding the need for authentic, non-routine tasks that challenge students' existing knowledge and skills, encouraging them to develop deeper understanding and proficiency (Bailey, 2022; Lester, 1994; Masingila et al., 2018). Mathematical problem-solving tasks should be meaningful, stimulating, and aligned with students' abilities and interest to promote effective problem-solving. Students should engage in solving tasks for which they do not have an immediate or obvious solution (Schoenfeld, 1985).

However, teaching problem solving poses significant challenges such as finding and selecting appropriate tasks or overcoming the persistence of traditional teaching methods (Masingila et al., 2018). As Lester (1994) notes, problem solving is a complex human endeavor that involves more than recalling facts or following routine or memorized procedures. As

Henningsen and Stein (1997) assert, teaching through problem solving involves selecting and implementing high-level tasks (Stylianides & Stylianides, 2008) while maintaining the level of cognitive demand.

Table 1: Mathematics Problem-Solving Knowledge for Teaching (Clivaz et al., 2023, p. 23)

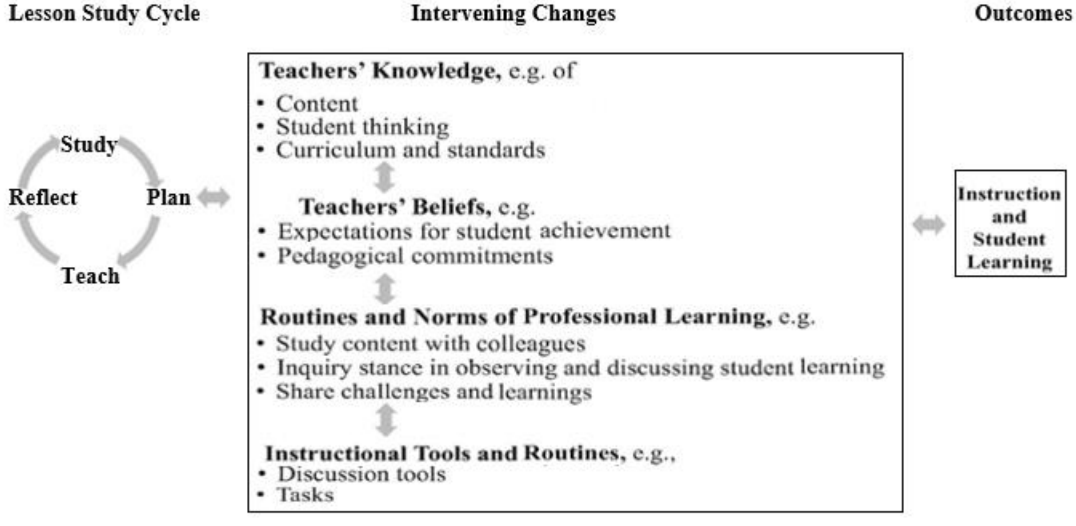
PS content knowledge	Knowledge of mathematical problems	Understanding of the nature of meaningful problems; structure and purpose of different types of problems; impact of problem characteristics on learners
	Knowledge of mathematical problem-solving (PS) *[do/meta]*	Being proficient in PS *[do]*. Understanding of mathematical PS as a way of thinking; PS models and the meaning and use of heuristics; how to interpret students' unusual solutions; implications of students' different approaches *[meta]*.
	Knowledge of problem posing	Understanding of problem posing before, during and after PS.
Pedagogical PS knowledge	Knowledge of students as mathematical problem solvers	Understanding what a student knows, can do and is disposed to do (e.g., students' difficulties with PS; characteristics of good problem solvers; students' PS thinking).
	Knowledge of instructional practices for PS	Understanding how and what it means to help students become better problem solvers (e.g., instructional techniques for heuristics/strategies, metacognition, use of technology and assessment of students' PS progress; when and how to intervene during students' PS).
	Knowledge of affective factors and beliefs *[teacher/student]*	Understanding the nature and impact of productive and unproductive affective factors and beliefs *[of the teachers/of the students]* on learning and teaching PS.

Overview of Study

Through a lesson study-based professional development program, this study examined how nine high school math teachers in sub-Saharan Africa comprehended and planned for teaching through problem-solving. This study addresses the question: How did nine high school math teachers in sub-Saharan Africa collectively comprehend problem-solving tasks and teaching through problem solving? The study contributes to our understanding of knowledge of mathematical problem-solving tasks, fostering a problem-solving-oriented classroom environment, and facilitating professional development on this approach.

The study employs Lewis et al. (2019) model of lesson study impact (see Figure 1), suggesting that "lesson study can influence instruction and student learning through intermediate changes in teachers' knowledge and beliefs, professional norms and routines, and instructional materials." (Lewis et al., 2019, p. 15). This model underscores the potential of lesson study to enhance teaching practices and student outcomes, supported by several other studies (Dotger et al, 2023; Lewis & Perry 2015, 2017; Pernilla & Henrik 2018). George Pólya's heuristic methods provided practical steps for problem-solving (Pólya, 1945), which were further reinforced by the National Council of Teachers of Mathematics (Cai & Lester, 2010; NCTM, 2000) standards emphasizing problem-solving as essential for mathematical understanding.

Figure 1: Theoretical model of lesson study impact (Lewis et al., 2019, p. 15)



Method

The study opted for participatory action research via lesson study to emphasize active participation and collaboration among all stakeholders involved (Lewis & Tshuchida, 1999; Stigler & Hiebert, 1999; Townsend & Taylor, 2022). The study took place within the Kenyan education system, with the goal of investigating the impact of lesson study on teachers' understanding of problem-solving tasks. Nine mathematics teachers from a Kenyan secondary school took part in a series of eight meetings, approximately 80 minutes each. The meetings focused on comprehending problem-solving teaching methods and planning and implementing lessons that followed this approach. Data sources included a pre-survey, recorded meetings, lesson plan, individual reflections from participants and researcher fieldnotes. The first author served as a knowledgeable other, offering support to participants throughout the process.

The first author conducted an initial focus group discussion with participants to identify a focal topic for lesson study. The cohort identified *similarity and enlargement* as a challenging yet essential topic for their curriculum. The cohort discussed what lesson study is and how it works, using resources from the Lesson Study Group at Mills College. The first author introduced participants to Polya's (1945) problem-solving framework: understanding the problem, devising a plan, carrying out the plan, and looking back. During discussion, the cohort considered reasons for teaching through problem solving, the role of teachers in problem-solving classrooms, the nature of problem-solving tasks, and how to orchestrate a problem-solving classroom.

Analysis, Results and Discussion

We used Reflexive Thematic Analysis (RTA), an analysis process that emphasizes active engagement and reflexivity of the researcher during analysis (Braun & Clarke, 2022). The unit of analysis was described as segments of communication reflecting participants' understanding of problem-solving tasks or pedagogy, which included individual sentences, detailed paragraphs, or group conversations. We generated initial codes that we merged into four major themes that describe how the cohort conceptualized problem-solving tasks and teaching through problem solving. We describe each theme and provide illustrative examples of the data that support each theme.

Open middle tasks. Teachers discussed creating tasks with multiple entry points, allowing students to approach problems in various ways and encouraging diverse problem-solving methods. This multidimensional approach ensures students can explore different solutions and deepen their understanding. For example:

> Mr. Mirumbe 24:59: The problems that we wish to have should be multi-dimensional. That a number of students should come with different ways that can be related to or not necessarily related, but they follow a certain rule that at the end of it, we can come up with a conclusion. (Day 3)
>
> Mr. Ambere 12:59: Whatever I highlighted from the lesson is that the students were using the various methods to solve the problem. . . . There are those who after being given the materials, they went directly by measurement and got the various dimensions. But there are those who didn't use the measurement, they just did the calculation to get the length and the width. (Day 6)

Challenge students' thinking. Teachers designed problems to challenge students' thinking and reasoning, avoiding tasks that they perceived as rote application of knowledge. Mr. Okello asked about the complexity of the questions, while Mr. Mirumbe emphasized the importance of problems that require deep thinking and decision-making. For example:

Mr. Okello 36:23: How about. . . if I may ask, the question, should it be complex or just a simple question? (Day 3)

Mirumbe 14:30: We give a problem, something that will require them to think and reason and solve the challenge that will be given to them. Not an exercise that they can copy the knowledge that they had learnt from the previous lesson to solve. Something that is quite challenging that can involve them using good decision. (Day 4)

Real-life relevance. Teachers emphasized the importance of connecting mathematical problems to real-life situations, such as measuring the height of a tree using shadows, as stated by Mr. Kasyoki. Md. Filomena noted that students often perform calculations without understanding the underlying concepts or real-life applications, which hinders the development of true problem-solving skills.

Mr. Kasyoki 30:20: Measuring the height of a tree using shadows. You see we cannot measure it directly. We cannot tell them to go and measure the height of a tall tree or a story building like our new academic block. Instead, they can find the height in terms of linear scale factor. They can measure their heights themselves by comparing [length of] shadows of the tree and a shorter object whose height they can obtain. (Day 4).

Md. Filomena 04:00: Like we said, most of the students can do the calculation of similarity and enlargement but they never think more about what they are doing. It's like they look for the formulas. When you are given this, you do this and leave but now they have never thought about it and the application. ...Are they[students] going to develop the problem-solving skills or it's just a matter of coming up with the formulae and using them in an exam. We talked about the application part of the similarity and also be able to relate in real life situation. (Day 5)

Students' ability. Teachers tailored tasks to match students' abilities, ensuring problems are challenging yet accessible. Mr. Kasyoki challenged his colleagues to consider the students' perspective and avoid overly complex tasks that might confuse them. The goal was to engage students meaningfully without causing frustration.

Mr. Kasyoki 53:15: So I think if we are the ones thinking this much, we have to ask ourselves how much our students will think about it. (Day 3)

Mr. Kasyoki 50:51: You may confuse our students if you give them money in fraction form. . . . how many times have you used currency in terms of fractions? How often? (Day 5)

Discussion

In a region where access to resources and opportunities is limited, a students' ability to think critically, creatively, and analytically can mean the difference between empowerment and disempowerment. Teaching through problem solving supports students to develop problem-solving skills. The MPSKT framework outlines knowledge that teachers need to effectively teach problem-solving skills. This study informs our understanding of how lesson study can support teachers to engage – and potentially develop -- their MPSKT, particularly in the areas of Knowledge of Mathematical Problems and Knowledge of Students as Mathematical Problem Solvers.

Engaging teachers in reflective practices is recognized as a crucial component of their adaptive expertise development. Drawing on this perspective of adaptive expertise development, we qualitatively examined how the design and structure of a Studio Day professional learning cycle afforded opportunities for reflective practice for secondary in-service mathematics teachers. We found that small group reflections, immediate reflections-on-action, and the use of videos afforded notable instances of reflective practices throughout the Studio Day Cycle that supported teachers' development of adaptive expertise of equity-based, language-responsive teaching. We suggest that Studio Day Cycles are one avenue to better support in-service teachers' development of adaptive expertise of mathematics language routines and multilingual learner core practices.

Keywords: Professional Development, Middle School Education, Equity, Inclusion, and Diversity

Supporting adaptive expertise development is one way the field can better prepare mathematic teachers to face the evolving challenges of teaching and attend to the diverse and emergent needs of students (Anthony et al., 2015). To effectively respond to the increasing linguistic diversity and growing proportion of multilingual learners in K-12 classrooms (Meyer et al., 2020), we contend that an adaptive expertise of equity-based, language-responsive pedagogy positions teachers to support all students in mathematics, especially multilingual learners (Roberts & Olarte, 2023). Despite the growing focus on equity-based pedagogies and curriculum for multilingual learners (e.g., de Araujo & Smith, 2021), the existing scholarship base on adaptive expertise has generally focused on pre-service teachers (e.g., Anthony et al., 2015). We argue that it is equally important to examine and identify best practices to support in-service teachers' development of adaptive expertise of mathematics instruction for multilingual learners. In the present work, we report on how teachers' participation in a professional learning cycle, Studio Days (Von Esch & Kavanagh, 2018), focused on mathematics language routines (Zwiers et al., 2017) and multilingual learner core practices (Roberts & Olarte, 2023) supported opportunities for the development of adaptive expertise of equity-based, language-responsive mathematics teaching.

Engaging teachers in reflective practices (e.g., Cavanagh & Prescott, 2010) – broadly referring to opportunities that teachers can be reflective and metacognitive about their teaching practices – is recognized as an integral dimension of adaptive expertise development (Anthony et al., 2015; Wetzel et al., 2015). Tsui (2009) asserted that "the process of reflection and conscious deliberation in which practical knowledge is theorized and theoretical knowledge is interpreted in practice" (p. 437), is how teachers develop adaptive expertise. Moreover, effective professional learning programs have been characterized as those that allow teachers to explore, inquire, experiment, and reflect (Wise et al., 1999). Although many scholars have reported on professional learning interventions that prompt mathematics teachers to engage in reflective practices and inquiry (e.g., Gningue et al., 2014), there is still limited research examining professional learning efforts that specifically encourage teachers to reflect on mathematics instruction for multilingual learners (de Araujo et al., 2018). The research question that guided this study was: How did opportunities for reflective practices within a Studio Day Cycle support mathematics teachers' development of adaptive expertise of mathematics instruction for multilingual learners?

Conceptual Framework

We draw on reflective practice (i.e., Muir & Beswick, 2007) and adaptive expertise (Yoon et al., 2015) to share how the design and structure of the Studio Day Cycle (Von Esch & Kavanagh, 2018) afforded teachers opportunities to engage in reflection that supported their adaptive expertise development.

Reflective Practice

Existing literature has widely emphasized the importance of teachers being metacognitive about their practice and how looking inward and reflecting on that practice is crucial to their development and change (Cavanagh & Prescott, 2010). Hayden et al. (2013) wrote, "Reflection on critical incidents in teaching and on feedback received can become the catalyst for transformative change in teaching practice" (p. 144), highlighting the salience of teachers both considering important events in their classrooms and receiving support to unpack those events. Encouraging teachers to reflect on their students' use of language in mathematics classrooms and their current language-responsive practices within a professional learning community can be conducive to developing their adaptive expertise. We align our work with Muir and Beswick (2007), who conceptualized reflective practice as "reflection that is deliberate and can be focused on events or incidents, and personal experiences" (p. 77). They offered a three-level model to examine in-service teachers' reflective practices: (1) *technical description,* or teachers recalling general accounts of classroom practices, focusing on technical aspects, and omitting value judgements to the experiences; (2) *deliberate reflection,* or teachers identifying 'critical incidents' and providing rationales for past and future actions; and (3) *critical reflection,* or teachers moving beyond identifying 'critical incidents' to consider others' perspectives and offer alternatives. We consider these forms of reflective practices to uniquely support teachers' development of dimensions of adaptive expertise.

Adaptive Expertise

Adaptive expertise broadly refers to the process of teachers' recognizing and identifying emergent needs, making sense of multiple perspectives, and orchestrating multiple teaching approaches to meet the demands of different situations (Hatano & Inagaki, 1984; Yoon et al., 2015). We utilize Yoon et al.'s (2015) characterization of three dimensions of adaptive expertise to describe teachers' mathematics instruction more explicitly for multilingual learners (See Table 1). Like other scholars who have brought the theories of reflective practice and adaptive expertise together (e.g., Anthony et al., 2015; Tsui, 2009), we consider opportunities of reflective practice as conduits of teachers' adaptive expertise development. With our goal of supporting the development of their adaptive expertise of mathematics instruction for multilingual learners, we aimed to engage in-service teachers in a myriad of reflective practices within a Studio Day Cycle.

Table 1: Adaptive Expertise of Mathematics Instruction for Multilingual Learners

Dimension	Description
Flexibility	Awareness of students and context, particularly multilingual learners. Ability to constantly adapt practice and respond to unexpected issues as related to students' needs, particularly multilingual learners.
Deeper Level of Understanding	Able to assimilate information and to implement or make connections that builds or addresses deeper level of knowledge. Able to bring in variations from outside the present system of activity as related to instruction for multilingual learners. Able to describe the affordances and constraints of mathematics language routines. Considers contexts in which to apply and integrate instructional practices for multilingual learners.
Deliberate Practice	Demonstrates an ability to show motivation, focus, and repeated effort to monitor their practice, and devises and subsequently attempts revamped attempts to improve implementation, as related to multilingual learners. Improves, assesses, and reflects on their own and others' implementation of language-responsive practices. Explicit evidence of reflecting on how to improve as related to mathematics language routines and other language-responsive practices. Describes how they are motivated to continue to develop their practice.

Method

Context

The present study is part of a large, multi-year funded project focused on supporting the development of mathematics teachers' adaptive expertise of mathematics language routines and data science instruction in a school district in the West Coast of the United States. We designed our professional development intervention around Studio Days (Von Esch & Kavanagh, 2018; See Figure 1 below). Adapted from Lesson Study, two teachers develop and study a single lesson (not necessarily the same lesson/content). However, their lessons are focused on the same focal mathematics language routine (MLR) paired with a multilingual learner core practice (Roberts & Olarte, 2023). Other teachers observe a live enactment of the lesson and reflect on the observed lesson. In the 2023-2024 academic year, we planned three Studio Day Cycles with participating teachers. Each Studio Day Cycle began with a Pre-Studio Day where the research team introduced the focal MLR and multilingual learner core practice. We outlined the stages of the routines, highlighted considerations for enacting the routines, and participating teachers experienced the routines as students. About one week after the Pre-Studio Day, two teachers volunteered to enact the focal routine in their classroom during the Studio Day, and the research team and other participating teachers observed these classroom enactments. The teachers then debriefed their enactment following their lesson, briefly sharing their experience, and receiving feedback from the observers. Then, about a week after the Studio Day, we reflected on that experience in a Post-Studio Day, where teachers reflected on video clips of the enactments, copies of student work from the Studio Day, and the MLR and multilingual learner core practice.

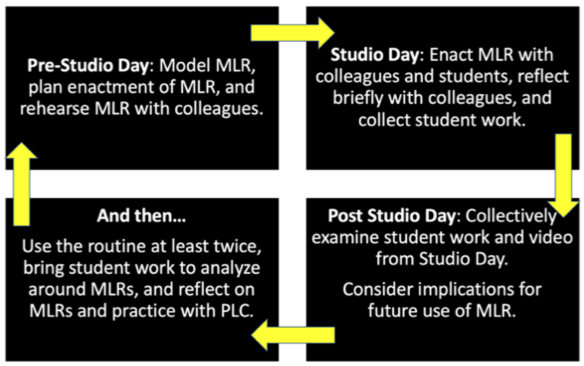

Figure 1: Studio Day Professional Learning Structure

Participants

The research team designed the Studio Day Cycle for the 2023-2024 academic year. Purposeful sampling (Miles et al., 2020) was used to recruit the district's mathematics instructional support specialist, three Math 7 teachers, and two Math 8 teachers from the three district junior high schools (See Table 2). For the present study, we report on the first Studio Day Cycle, where we focused on the mathematics language routine *Collect & Display,* paired with the multilingual learner core practice: *identifying disciplinary language demands and supports.* In Collect & Display, teachers capture students' oral words, ideas, phrases into a stable reference. The intent of the routine is to stabilize students' language in order to use their output as a reference for developing their mathematical language (Zwiers et al., 2017). The multilingual learner core practice of identifying disciplinary language demands and supports, refers to teachers employing or identifying language supports for students. They also adequately scaffold or produce language while attending to aspects of language that may be challenging for students (Aguirre & Bunch, 2012).

Table 2: Participant Profiles

Name (pseudonym)	Grade Level	Race/ Ethnicity (self-described)	Years Teaching Mathematics	Bilingual/ Multilingual (self-described)
Ms. Ruth	7th grade	White	26	–
Ms. Severn	7th grade	Caucasian	4	Semi Fluent in Spanish
Ms. Taylor	7th grade	White	34	–
Ms. Foster	8th grade	White	3	Russian
Ms. Penny	8th grade	White	2	–
Ms. Hope	Instructional Specialist	Caucasian	25	–

Data Collection and Analysis

We video- and audio-recorded each meeting of the Studio Day Cycle, and utilized the videos and transcriptions of each meeting to examine the types of reflective practices that teachers engaged in. First, we created content logs of the videos to identify notable instances of reflective practices. We then coded (Miles et al., 2020) the transcriptions for the type of reflective practice using Muir and Beswick's (2007) three-level model. This allowed us to describe how the participants reflected during the Studio Day Cycle. Next, we drew on Yoon et al.'s (2015) characterization of the three dimensions of adaptive expertise (again, see Table 1) to make sense of how the moments of reflective practice supported teachers' development of adaptive expertise. We met as a research team to discuss themes that we observed in the data and wrote analytic memos (Miles et al., 2020) to better understand how the opportunities of reflective practices within the Studio Day Cycle afforded or constrained teachers' adaptive expertise development.

Findings

To illustrate how the reflective practices within a Studio Day Cycle supported teachers' adaptive expertise development, we describe the structure of each day of the cycle and highlight the notable instances of reflective practices taken up by the participants.

Pre-Studio Day

Our goal for the Pre-Studio Day was to introduce teachers to the focal mathematics language routine Collect & Display, and to the multilingual learner core practice, identifying disciplinary language demands and supports. Although we observed instances of all three types of reflective practice during the Pre-Studio Day, we found that teachers primarily engaged in *technical descriptions*. This was expected given that this first day of the Studio Day Cycle was designed to introduce teachers to the core practice and MLR, as well as to get a sense of how teachers noticed their students' language use in the classroom and to discern what they already did to support students to read, write, and speak about mathematics. For example, Ms. Foster said,

> We've identified disciplinary language demands and supports, like making sure kids truly understand the words that we're saying mathematically. Like, just making sure if I'm saying "solve", what does that mean?...So, just making sure kids truly understand the words that we're saying and using their language to help bridge the gap [motions bringing hands together] between academic [language] and their every day [language].

This *technical description* of her students' language demands and her practice of building on students' language also revealed Ms. Foster's *flexibility,* or awareness of students' needs.

Reflective practices in small groups. One exemplar opportunity for reflective practice during the Pre-Studio Day was placing participants in small groups and having them reflect on the following questions: (1) Why do students use language in mathematics classrooms? (2) How do your students use language and communicate in the mathematics classroom? (3) What tools do your students use to use language and communicate in the mathematics classroom? The questions were purposefully posed to get a general sense of what teachers presently noticed and understood about their students' use of language. They were first given time to think individually, and this afforded opportunities to engage in *technical descriptions.* However, once the teachers were discussing in the small groups, we observed instances where teachers engaged in *deliberate reflection* as they identified critical incidents of students using language in the classroom, and *critical reflection* as they expanded beyond identifying critical incidents and considered the perspectives and experiences of the members of their small group. They used a Jamboard to record their ideas and display them to the whole group, where they shared such ideas as: "They use hands or drawings to clarify because they don't have formal language, so we try to get them to have language to explain" and "language is used to explain their thinking and to clarify their understanding." These ideas illustrated that the teachers were able to work in a group with each other to develop generalizable ideas in their *critical reflections*.

During the small group time, teachers went back and forth sharing their ideas, and it was in these rich discussions that we observed teachers engage in both *deliberate reflection* and *critical reflection.* For example, in one small group we observed teachers collectively reflecting on critical incidents of students' language use, such as students gesturing or asking each other questions in the classroom. Then, Ms. Hope demonstrated evidence of *critical reflection* as she considered the perspectives of the other members of the group, synthesized their group reflections, and articulated that students' language could be broadly categorized as "input and output." In these reflective practices, we again primarily saw evidence of *flexibility,* as evidenced by awareness of students' language in mathematics.

Studio Day

The Studio Day occurred one week after the Pre-Studio Day. On this day, Ms. Ruth and Ms. Taylor enacted the routine Collect & Display in one of their class periods. The other teacher participants took on participant-observer roles during the lessons, walking around, taking observation notes, and interacting with students. The Studio Day began with a pre-brief of Ms. Ruth's lesson, where she provided details of her lesson plan, her classroom, and her expectations of what the research team/other teachers should do during her lesson. After Ms. Ruth enacted the routine, the participants and the research team met to debrief Ms. Ruth's lesson. After this debrief, we held a similar pre-brief for Ms. Taylor's upcoming lesson. The other teachers took on similar participant-observer roles during Ms. Taylor's classroom enactment, and at the end of the day, we debriefed Ms. Taylor's enactment of Collect & Display. The reflective practices of the Studio Day privileged *deliberate reflection* and *critical reflection* because teachers observed actual classroom enactments through which they identified and reflected on critical incidents shortly after each teachers' enactment.

Immediate reflection-on-action. Key reflective features of the Studio Day were the pre-brief sessions that oriented teachers to details of the upcoming lesson, classroom dynamics, and student engagement prior to observing Ms. Ruth and Ms. Taylor enact the routine with their students, and the debriefs immediately after the lesson that engaged teachers in reflection-on-action (Manrique & Abchi, 2015). Reflection-on-action refers to teachers' purposeful reflection after their practice, and in our debriefs, we prompted teachers to reflect on Ms. Ruth's and Ms. Taylor's enactment of Collect & Display. For the enacting teachers, we asked them questions such as: (1) How did you feel about the lesson?; (2) Did you consider multilingual students during your lesson?; and (3) How did you adapt in real time? For the observing teachers, we asked them questions such as: (1) What did we see students doing during Collect & Display?; and (2) How did students engage with disciplinary language demands? The debriefs allowed the teacher who just enacted the routine to reflect on their teaching practices immediately after class, and provided the other participating teachers opportunities to share insights and feedback based on their observation notes. Moreover, we purposefully oriented teachers' reflections using the MLR and paired multilingual learner core practice.

Again, we observed that teachers were able to take up all three reflective practices during the debriefs. For example, Ms. Ruth engaged in *technical descriptions* and *deliberate reflection* within her own enactment of the routine and shared that the students were "very engaged and [for] kids who have difficulty accessing [the problem], it [Collect & Display] gives them opportunities to access, because there's no penalty for getting it wrong." During this moment of reflective practice, we found that Ms. Ruth exhibited the dimensions of adaptive expertise *flexibility* and *deeper level of understanding*, because she demonstrated an awareness of her students, and she articulated an affordance of Collect & Display – mainly that it was a routine that allowed students to access the mathematics content and language. The immediate reflections-on-action in the debriefs also afforded the observing teachers valuable reflective practices that developed their adaptive expertise. For example, Ms. Severn engaged in *technical descriptions* and *deliberate reflections* as she praised Ms. Ruth's ability to connect students' informal language with the formal mathematics language. She explained, "Highlighting the ways that informal and formal language related to each other was, I think, a good way to marry the different levels of language that the kids need." In this reflection, Ms. Severn exhibited *flexibility* because of her awareness of students' language use, and she also exhibited a *deeper level of understanding* of practice of identifying disciplinary language demands and supports. Through her reflection of Ms. Ruth's lesson, Ms. Severn shared those explicit connections between students' informal and formal language supported their language needs in mathematics.

Post-Studio Day

We held our Post-Studio Day one week after the Studio Day and in between this time, teachers were encouraged to continue to use the MLR in their classrooms. Additionally, to prepare for the Post-Studio Day, the research team purposefully selected video clips from Ms. Ruth's and Ms. Taylor's classroom enactments of Collect & Display. We selected clips from two types of videos: a video from an iPad turned towards the front of the classroom (i.e., focused on the teacher), and videos from Ordro headband cameras that students were wearing during class. We selected moments that would allow for broad reflection, as well as those that would allow for purposeful reflection on teachers' language-responsive mathematics instruction. We found that because a goal of the Post-Studio Day was to discuss how teachers can build on the enactments of the Studio Day and how they can implement the routine in their own classrooms, the moments of reflective practices on this last day primarily encompassed *deliberate reflections* and *critical* *reflections* and afforded development of the *deeper level of understanding* and *deliberate practice* dimensions of adaptive expertise. Participants were able to articulate how they might integrate the routine in their classroom and demonstrated motivation and desire to improve future implementations of the MLR.

Reflecting on videos enactments. The notable opportunity for reflective practice of the Post-Studio Day was when teachers were shown the video clips of Ms. Ruth's and Ms. Taylor's enactment of Collect & Display. Overall, the teachers reported that this was an extremely valuable opportunity not only to see themselves teach, but seeing the videos from the student headband cameras provided new insight into how the students worked with their peers, how they spoke about mathematics, and how they made sense of the task. Both Studio Day focal teachers had utilized the Desmos curriculum (Amplify Education, Inc., 2024) to enact Collect & Display, and the teachers demonstrated evidence of *technical descriptions* and *deliberate reflection* as they articulated details of their enactments and provided rationale for features of their Desmos activity. For example, Ms. Ruth explained, "I don't think I've ever gotten as, as rich variety… What's different? But it's really nice that we have a way for kids to share their thinking that's safe because you can anonymize it." In this moment, we also observed Ms. Ruth's development of a *deeper level of understanding* of the routine Collect & Display, because she described an affordance of facilitating the routine specifically through Desmos – integrating her understanding of the goals of the routine with what Desmos affords for the students. Mathematics language routines are flexible and adaptable, and we observed that teachers developed their adaptive expertise because they described the affordances and constraints of using technology to enact the routine instead of traditional paper/written work.

Discussion and Conclusion

We found that the Studio Day Cycle afforded valuable opportunities for reflective practices that supported teachers' development of adaptive expertise of language-responsive, mathematics pedagogy. Over the course of the cycle, we found notable instances of participants engaging in all three types of reflective practices that supported their development of adaptive expertise. For example, we found that participants most often engaged in *technical descriptions,* consistent with how this reflective practice is considered a lower-level reflection (Muir & Beswick, 2007). Additionally, in the moments of *technical descriptions,* we found teachers to most exhibit and develop *flexibility* as they demonstrated increasing awareness of students or adapted their practice in response to students' needs. Importantly, we found that design features of the Studio Day Cycle privileged specific types of reflective practices – such as viewing videos of classroom enactments encouraging *deliberate reflections*, because participants were oriented to specific critical incidents, and small group reflections encouraging *critical reflections* as teachers considered each other's perspectives and ideas. This is consistent with existing literature on the value of supporting teachers to engage in reflection-on-action (Manrique & Abchi, 2015) as well as the use of video in teachers' professional development (i.e., van Es & Sherin, 2010). The present work demonstrated that professional learning interventions can curate *catalysts of reflective practices* that can specifically support teachers' development of adaptive expertise of language-responsive mathematics instruction. With reflective practices a critical component of adaptive expertise development (Anthony et al., 2015), we suggest that Studio Day Cycles are flexible, adaptable models for interventions that can provide in-service mathematics valuable opportunities to develop their adaptive expertise of equity-based, language-responsive pedagogies for multilingual learners.

IN-SERVICE TEACHERS' PERFORMANCE ON FRACTION OPERATIONS

İbrahim Burak Ölmez
MEF University
olmezi@mef.edu.tr

This study explored 236 in-service elementary and middle grades mathematics teachers' knowledge on fraction operations across the U.S. The research questions were as follows:

1. To what extent do teachers solve problems that address fraction operations correctly?
2. What relationships exist among teachers' choices of fraction operations?

For each of the four problems, teachers were asked to select one of the following six choices:
i) $\frac{2}{3}$ x $\frac{4}{5}$ ii) $\frac{2}{3} + \frac{4}{5}$ iii) $\frac{4}{5} - \frac{2}{3}$ IV) $\frac{2}{3} \div \frac{4}{5}$ V) $\frac{4}{5} \div \frac{2}{3}$ VI) None of these

Table 1: Fraction Operations Problems

Key Concept	Problem
Fraction Partitive Division	**1)** A 4/5 of a package of butter weighs 1 pound. How much does a 2/3 of a package of butter of that same kind weigh?
Fraction Subtraction	**2)** Emily has a rope that is 4/5 meters long. However, she needs a rope that is exactly 2/3 meters long for a project. What part of her rope should Emily use for her project?
Fraction Multiplication	**3)** If 2/3 of a gallon of yogurt weighs 1 kilogram, then how many gallons are 4/5 of a kilogram of yogurt?
Fraction Measurement Division	**4)** You have 4/5 cups of honey. A batch of brittle calls for 2/3 cups of honey. How many batches of brittle can you make?

Results & Discussion

One main result was that only about a third of the sample of teachers responded to the fraction partitive division, fraction multiplication, and fraction subtraction problems correctly. On the other hand, teachers performed better on the fraction measurement division problem with about two-thirds of the sample's correct answer. Moreover, there was a statistically significant relationship between teachers' responses to each fraction operation and the remaining three operations (e.g., for fraction partitive division and multiplication; $\chi^2(25) = 108.6$, $p = .00$).

Table 2: Summary of the Results

	2/3 x 4/5	2/3 + 4/5	4/5 – 2/3	2/3 ÷ 4/5	4/5 ÷ 2/3	None
Problem 1 [2/3 ÷ 4/5]	66	3	9	75	25	58
Problem 2 [4/5 – 2/3]	38	3	89	28	16	62
Problem 3 [2/3 x 4/5]	91	1	6	48	41	49
Problem 4 [4/5 ÷ 2/3]	17	5	24	14	158	18

As consistent with prior research (e.g., Izsák et al., 2019; Ma, 2010), this study reveals that teachers had limited understanding of fraction operations. Contrary to the most findings in past research (e.g., Timmerman, 2014), teachers in the present study performed much better on the fraction measurement division problem than the fraction partitive division problem.

This paper explores the notion of teacher curiosity and connects it to the pedagogical work of K-5 mathematical inquiry. We explore teacher interviews from professional development (PD) designed to foster curiosity among elementary mathematics teachers to consider how teachers reflected on curiosity and the objects of their curiosity. Findings show that within the PD context, teachers: (a) expressed the importance of cultivating curiosity in their students, their colleagues, and themselves, and (b) expressed curiosity about: (1) children's mathematical thinking, (2) their own math instructional practices, and (3) their own affective state. We end with directions for future work.

Este artículo explora la noción de curiosidad docente y la conecta con el trabajo pedagógico de la investigación matemática K-5. Exploramos entrevistas con maestras participando en un desarrollo profesional (PD) diseñadas para fomentar la curiosidad para considerar cómo reflexionaron sobre la curiosidad y los objetos de su curiosidad. Encontramos que dentro del contexto del PD, los maestros: (a) expresaron la importancia de cultivar la curiosidad en sus estudiantes, sus colegas y en ellos mismos, y (b) expresaron curiosidad sobre: (1) el pensamiento matemático de los niños, (2) sus prácticas de instrucción, y (3) su propio estado afectivo. Terminamos con indicaciones para trabajos futuros.

Keywords: Professional development; Affect, emotion, beliefs, and attitudes; Elementary school education

A stance of curiosity is often assumed in teachers who center student thinking and inquiry in the mathematics classroom (e.g., Engle, 2013), though the field knows little about the construct of teacher curiosity or its cultivation. In the field of psychology, research has variously characterized curiosity as (a) a trait, with individuals being either more or less curious by nature, or (b) a state, a transient experience stimulated by the environment over which the individual has little control (Litman, 2005; Schmitt & Lahroodi, 2008). In either case, curiosity is viewed as a condition that fuels inquiry and, ultimately, learning. However, from a sociocultural perspective (Lave & Wenger, 1991), who we are in interaction with one another and our environment shapes and is shaped by the social world, rather than being purely internal or individual. In our work focusing on teacher curiosity, we frame curiosity as neither purely an individual trait or a state,

[2] All authors contributed equally to this paper.

but rather as a deliberate stance teachers can learn and then take on in their classrooms. Further, we differentiate teacher curiosity from related practices such as teacher noticing (Van Es, 2011) and inquiry, framing curiosity as a *stance* or *orientation* toward activity, others, and/or self that can make such connected practices more likely to occur. As such, we conceptualize and investigate teacher curiosity as a *learnable professional stance*, one that can be *fostered in communities of practice* by sharing in collective inquiry into and curiosity about the work of teaching and learning.

While the construct of teacher curiosity, in particular, has been underexplored, research into developing teachers' capacity to center, elicit, probe, and design instruction based on student thinking has shown that the most skilled teachers approach student thinking with curiosity (Franke et al., 2001). Indeed, Franke and colleagues (2001) described curiosity about students' mathematical thinking as one of the characteristics of teachers who were able to continue to learn from their daily practice after the end of formal professional development. Building on this work, Ananthanarajan (2020) recently operationalized teacher curiosity about student thinking in the context of mathematics teachers as an instance "where teachers recognize something as unknown, unfamiliar, puzzling, uncertain, or new in the context of teaching and learning, and feel motivated to initiate inquiry into that instance" (p. 31). She described how developing and making space for teachers' curiosity offers them the agency to follow their interests and ask questions that motivate inquiry in their own teaching practice. This operationalization focuses solely on teachers' curiosity about student's mathematical thinking, which we seek to broaden by more openly exploring the possible objects of teachers' curiosity when engaged in mathematics professional development (PD).

This paper explores the notion of teacher curiosity within the context of a PD program designed to cultivate curiosity as a component of inquiry-based mathematics teaching. The program took up the view that curiosity could both be learned by teachers and could in turn support their professional learning. In this context, we draw on interviews with participating teachers to explore the following question: When reflecting on PD and coaching designed to foster elementary mathematics teacher curiosity, to what degree did teachers express curiosity and what were the objects of that curiosity?

Methods

Professional Development Context

The PD explored here took place within a research-practice partnership (RPP) between university-based researchers and a small elementary school district in Northern California that serves a culturally and linguistically marginalized community. The district's mathematics coach, in collaboration with our research team, established a math teacher cohort of five teachers, all of whom volunteered to participate in two years of PD during the 2020-2021 and 2021-2022 school years. In the fall of 2020, the mathematics coach established a second math teacher cohort of four teachers, all of whom volunteered to participate in one year of PD during the 2021-2022 school year. This district PD built on previous work in the RPP (Osuna & Munson, 2023).

The PD, which was co-designed by the mathematics coach and the research team, included two-hour after-school meetings, twice per month, totaling 10 sessions each year. The PD program sought to support teachers in student-centered, responsive teaching in mathematical inquiry, along with one-on-one coaching sessions with the coach. With the onset of the COVID-19 pandemic in March 2020 and an abrupt shift to remote instruction, the need to support teachers and students in this context of incredible uncertainty came to the fore. With these shifts, curiosity became a prominent focus throughout the PD and coaching, as both a lens for considering student mathematical thinking and reflecting inward toward their own experiences and feelings.

PD activities and coaching sessions revolved around cultivating teachers' curiosity about mathematics and about students' mathematical thinking, such as analyzing students' mathematical work. Opportunities to reflect on and discuss their own affective states as it pertained to teaching during the pandemic were also regularly folded in. Table 1 summarizes the areas of focus and offers examples of PD activities within each area.

Data Sources

Several data sources were collected throughout the PD. The present analysis focuses on interviews with teacher participants. 15 semi-structured interviews were conducted on Zoom with six of the nine participating teachers, ranging from one to four interviews per teacher. Complications from the COVID-19 pandemic, including limited teacher bandwidth, impacted the number of interviews the research team was able to collect. Interviews were 30-60 minutes in length. Table 2 shows the timeline and distribution of interviews across teachers. All names are pseudonyms.

Table 1: Overview of PD areas of focus

Area of Focus	Description and Examples of Activities
Cultivating an inward-focused curiosity	Sessions included activities, discussions and reflection questions that prompted teachers to turn their curiosity inwards. The first session began with sharing what brings one joy, followed by an activity where they wrote their mathography. All sessions ended with individual reflection time, where teachers were prompted to articulate their lingering curiosities about themselves and their students, parts of their math instruction they're most proud of, or applying a curiosity lens to their own mathographies.
Cultivating curiosity about children's mathematical thinking and experiences	Sessions included activities and discussions looking at student math work or watching videos of students doing math engaging a curiosity lens. One such discussion began with the prompt of asking teachers to identify what they had found fascinating about a piece of student work. This was followed by sessions analyzing student work with a curiosity lens then reflecting on the experience.
Doing mathematical activities	Most sessions included an inquiry-based, open-ended math activity, such as Notice and Wonder, Which one doesn't belong?, or the Paper Folding task. These activities often culminated with a debrief discussion about how to adapt the activity for their students.

Learning and practicing teacher talk moves to elicit student thinking	Sessions included exploration of teacher talk moves, in particular moves to elicit student thinking. This was followed by watching videos of two teachers eliciting student thinking and discussing what was noticed in the videos, ending with a reflection.
Discussing readings	Discussions were primarily based on the book, *Becoming the math teacher you wish you'd had* by Tracy Zager, which offers ideas and strategies for teaching student-centered mathematics.

Data Analysis

Teacher interviews (n=15) were transcribed for analysis and used to inductively develop a definition of curiosity in the context of our data. We operationalized curiosity as: "Expressing an orientation of openness, inquiry, seeking learning, wonder, perplexity, and marvel, discussing trying to cultivate such an orientation, or naming curiosity as a goal or experience; promoting curiosity among colleagues or students; reflecting on being the object of another person's curiosity; or expressing the desire to seek information." This definition was refined through discussion and then applied to the interview and reflection data. Using our operationalized definition, we identified all instances of curiosity across the interviews.

We then coded across all the instances of curiosity (n = 63) and inductively classified the objects of teachers' curiosity. This approach revealed three distinct objects of teachers' curiosity, as well as expressions of the importance of cultivating curiosity among others. These 4 codes were then applied across the dataset. We then returned to the coded data and explored themes within the two most frequent codes: expressing curiosity about one's instructional practice and expressing curiosity about children's mathematical thinking. Below, we describe the overall findings and zoom into the themes within these two most frequent expressions of curiosity.

Table 2: Timeline and distribution of interviews across teachers

	Math Leads	Interview #1: Teacher Story	Interview #2: End of Year 1	Interview #3: Start of Year 2	Interview #4: End of Year 2
First Cohort	Alejandra	x	x	x	x
	Adeline	x	x		
	Ashley				x
	Roya	x	x	x	x
	Eujin				
Second	Nina	x	x	Teachers in the second cohort	

Cohort	Dolores	x	x	participated in the PD for one year.
	Soyoung			
	Nadia			

Findings

Across 15 interviews with six teachers, we recorded 63 instances of curiosity across all teachers as it related to their participation in the PD. As they reflected upon their learnings from PD and coaching, teachers: (a) expressed the importance of cultivating curiosity in their students, their colleagues, and themselves; and (b) expressed curiosity about various domains, in particular: (1) children's mathematical thinking, (2) their own math instructional practices, and (3) their own affective state.

Teachers expressed the importance of cultivating curiosity in others

Teachers expressed the importance of cultivating curiosity in others, in particular their own students' mathematical curiosity, their colleagues' curiosity about student thinking, and their own curiosity. For one, teachers expressed the importance of cultivating students' own curiosity about mathematics and each other's thinking. For example, Alejandra reflected on the importance of inspiring students to be curious about their own mathematical processes and thinking and being excited about mathematical possibilities:

> And what I have learned from this math cohort is that the most important thing is not that the students get the right answer, but the process behind… getting to the answer, even if their answer is right or wrong, is not as important as understanding their process and making them feel excited about math, helping them get excited and curious about math. (Alejandra)

Another teacher discussed connections between student curiosity and learning, noting how an orientation of curiosity supports sense-making and building mathematical understanding:

> 'Cause that's what their brains are trying to, like, make connections about, you know, that's what they're trying to understand. So like, uh, letting them guide that make sense 'cause then they're- they're already curious about it. They're already trying to understand it. So we just need to help kind of guide them and give them more tools and resources to build that understanding. (Ashley)

Teachers also expressed value in cultivating curiosity among their colleagues and themselves. For example, one teacher noticed the ways in which the PD coach fostered curiosity among teachers and remarked on its importance as "a really good approach" that ought to continue with more teachers in continuing years:

> [Coach], really, she, even when she comes to do like a math talk at a staff meeting. She's really just like, 'Okay, I'm showing you this and, hopefully, you are curious. If you are, you contact me, and I can show you more.' You know, like, she's trying to bring that curiosity out of the teachers, so that more people are interested in this work. So thinking about our site, I think that's a really good approach, maybe next year, just continue this work." (Adeline)

Another teacher remarked on the importance of the emerging curiosity among the fourth grade teaching team, who were not part of the PD, but were showing signs of being "very fascinated" by students, noting that this spread of curiosity was the most noteworthy commentary:

> Fourth grade [teaching team] seems to be very interested in how we're doing math because our kids are going into fourth grade and they're seeing like the results of inquiry, and they're like very fascinated by the strategies that they're seeing. So, I would say the biggest like commentary around it has been between fourth grade third grade and like within third grade. (Roya)

Teachers expressed curiosity about various domains

Teachers expressed curiosity about various domains, in particular: (1) children's mathematical thinking, (2) their own math instructional practices, and (3) their own affective state. While it was the least frequent code, teachers expressed curiosity about their affective state. Teachers at times expressed how curiosity generated feelings of excitement, vulnerability, and even hopefulness. Additionally, while the PD was explicitly structured to cultivate teachers' curiosity about students' mathematical thinking, teachers' curiosity about their own math instructional practices was the most frequent code across the data set. Below we focus on these two types of expressions of curiosity, in particular, illustrating how this lens of cultivating teachers' curiosity about students' mathematical thinking seemed to also promote curiosity about their own practice.

Teachers expressed curiosity about children's mathematical thinking. There were 16 instances of curiosity about students' mathematical thinking across the data set, and every teacher interviewed expressed this form of curiosity. As prioritized in the learning goals of professional development, teachers reflected on the importance and practice of being curious about children's mathematical thinking, shifting away from an evaluative stance. For example, Adeline described working to understand, rather than judge, her students' work:

> The biggest thing is really just be curious about student work and be curious about their thinking before you judge them—[laughs] I used the word judge—before you make assumptions, that's the biggest thing I think I learned from this work is you try to understand them. (Adeline)

Here Adeline reflected on the importance of trying to understand, rather than make assumptions about, her students' thinking. In addition to describing this shift from an evaluative stance to a curious one, teachers discussed what it looked like for them to enact this curiosity lens in their classrooms. Adeline elaborated in a later interview on how she worked to put this curiosity lens into practice when conferring with her students about their thinking:

> [In the past] I was kind of listening for their mistakes and then try to like help them to fix it [laughs]. So it's like kind of a different perspective…like, are you making sense of the problem? Does this student have a plan? And then, does this student know like -- like 'the plan' meaning like what kind of strategy to use--and then, does this student know how to pick the right tool? (Adeline)

In this quote, Adeline contrasted her past tendency of listening for mistakes in order to "fix them" with her curiosity lens of trying to understand students' sense-making. Similarly, Alejandra connected curiosity about what students are saying to staying present in conversations with students in-the-moment, stating:

> It is important that, first we need to have some questions in mind, some basic questions, and then from the students' responses build upon that and then ask them more questions that are just based in the present moment. We need to be 100% present, listening to our students and then being able to question them more, no? So that's how curiosity looks like to me, lots of questioning (Alejandra)

In these quotes, Alejandra and Adeline discussed the ways in which being curious when engaging with students supported them to be responsive to students' mathematical thinking. Although teachers acknowledged the challenges of staying curious about students' thinking in their classrooms, they also marveled at the joy that it brought them, as Ashley reflected:

> I wanted to enjoy math time more and like have more like fun with it and have it be more interesting and like not just like worksheets and be, uh, uh, like really curious and like thoughtful about what students were doing and like really like allow myself to-to be like that curious (Ashley)

Teachers expressed curiosity about their own mathematical instructional practices. There were 32 instances of curiosity about teachers' own mathematical instructional practices across the data set, and every teacher interviewed expressed this form of curiosity three or more times. In particular, teachers expressed curiosity about (a) a different way of teaching, (b) specific pedagogical approaches, and (c) their own professional growth journey.

Across interviews, teachers expressed curiosity about teaching mathematics in a different way than they currently were or had experienced as a student. For example, Ashley noticed the way she was teaching math was not working for her students and wanted to learn about how to shift her math instruction to better support her students. She stated:

> Um, so I think at that point I was looking for that because I could see students struggling with math and I was like, okay, this is not-- Like I know this is not the best way to teach them. So I was looking for other-other ways to teach it. (Ashley)

In addition to this general curiosity about changing math instructional practices, teachers also expressed curiosity about specific pedagogical approaches to teaching mathematics, including the role of students within those practices. In describing a learning experience in coaching, Alejandra talked about how she had specific questions about and then received support in implementing a conferring practice, explaining:

> If I had questions about like," Oh, am I doing the launch? Okay. Like, how am I doing conferring or how should I do?" So she helped me with conferring, with the launch, with the solving math problems and with the debrief. (Alejandra)

Roya also reflected on the particular pedagogical approach of re-engagement lessons and her curiosity and excitement about trying it with her students:

> I'm excited, I think I'm, I want to learn more about how to use student work more effectively in my classroom. Like one thing that I learned through the PDs last year were to try reengagement lessons and that was like, 'Wow I need to get on that level, but like I'm not

> there yet.' So I think learning how to use student work for the entire class to reengage them in like some big ideas. (Roya)

Finally, teachers described across interviews how their curiosity about the processes for their own learning or improving practice drove their learning in professional development and their work in coaching. Adeline gave multiple examples of how her curiosity lead the focus of her learning with her coach, and how powerful those learning and coaching experiences were. She elaborated:

> I could always talk to [coach] this year, just like you know, like, 'I'm really confused about this hundreds chart, because it's kind of, you know, like, there's 15 and then there's 25, kids are, you know like, could be a little confusing.' Like I always have questions about that, and then I just go to [coach], and we talk about it, and we sometimes we, just you know, we search, you know, we do some research together and just like a lot of, it's really helpful. That's one and second is kind of, I think it was helpful like for her to come and model for me like how to do certain routines and observe me. She was observing my, you know, conferring sessions and then we'll like—I'll confer with one student and then we go back to the main room, talk about it, and then go to the next group. We only tried that for two times, but that was very powerful too. We also tried, you know, recording lessons, so like I'll just record my lesson and then we kind of really think about like, what did I say and what did the students say? And then I realized, 'Oh I talk a lot' [laughs]. Just kind of, you know, that are, just really based on like my own practice and reflection was really helpful, I think. (Adeline)

Conclusion

In this analysis of a PD designed to cultivate teacher curiosity, teachers expressed curiosity about their students, their practice, and their own affective state while teaching student-centered mathematical inquiry, as well as expressed value in cultivating curiosity in others. While teachers described the act of being curious as complex and at times challenging, being curious and cultivating curiosity among students was also described in relation to feelings of joy and excitement. Curiosity also seemed to motivate teachers to get to learn more about a student and their mathematical thinking and wonderings, as well as to dig into their own teaching and its evolution toward more student-centered pedagogies. Our findings build on Anantharajan (2020), whose work focused specifically on teacher curiosity of students' mathematical thinking, to show that cultivating such curiosity (a) can occur collectively in a teacher professional learning community and (b) can lead to other forms of curiosity, including curiosity about instructional practice and even one's own affective experience teaching.

All in all, curiosity seems to hold strong potential as a lever toward ambitious, reflective, and even joyful instruction. A key implication is that efforts to stimulate curiosity may be an essential feature of high quality PD not yet referenced in commonly cited frameworks, such as Desimone (2009). New work is needed to explore the pedagogical, humanizing, and even wellbeing possibilities of cultivating curiosity among teachers and, in turn, students. Our exploratory work is limited by the exclusive focus on teacher interviews, rather than curiosity in-situ or other contexts. We see this small study as a jumping off point for further theorizing.

Factors Contributing to Instructional Shifts at the College Level

Priya V. Prasad
University of Texas at San Antonio
priya.prasad@utsa.edu

Jessica Gehrtz
University of Texas at San Antonio
jessica.gehrtz@utsa.edu

Despite copious evidence of the effectiveness of inquiry-oriented and student-centered instructional practices, many college instructors do not implement these instructional strategies. We report on a three-year project aimed at shifting instruction in College Algebra at one institution. This project established a professional learning community (PLC) of instructors around an incremental instructional improvement framework to guarantee instructor buy-in and increase the practicality of the development materials for use in the classroom. Preliminary results indicate that structural factors such as course coordination, dedicated PLC time, a lesson-study-like framework for improving course curricula and materials, and video clubs contributed to changes in both instructors' thinking and practice of inquiry-oriented teaching.

Keywords: Professional Development, Undergraduate Education, Instructional Activities and Practices

Inquiry-oriented mathematics instruction can lead to increased student learning and conceptual understandings (Freeman et al., 2014; Deslauriers et al., 2011; Kogan & Laursen, 2014). Additionally, there is evidence that students who report experiencing more student-centered techniques in their classes are less likely to switch out of a STEM degree (Ellis et al., 2014), and some studies suggesting that the benefits for underrepresented students in STEM are even higher (Kogan & Laursen, 2014). However, didactic lecture remains the most common form of instruction in STEM courses across the United States (Stains et al., 2018). Reasons for this include instructors' lack of personal experience with student-centered instructional practices (e.g., Andrews et al., 2015), fear of losing control of their classroom (e.g., Hayward et al., 2015), and particular beliefs about teaching and learning (e.g., Aragón et al., 2018). Further, mathematics instructors at the college level may have had few opportunities to participate in focused professional development around teaching. As such, it is challenging for many instructors to make lasting instructional changes that focus teaching on student-centered practices and leverage inquiry-based materials. Although instructional change can be difficult to catalyze, professional development through professional learning communities (PLCs) can be one way to support instructors through this process (Hayward et al., 2015; Lee & Lee, 2018; Tam, 2015). Specifically, PLCs create opportunities for instructors to reflect on and refine their practice and to generate new knowledge (Harris & Jones, 2010). This can result in transformational change when the PLCs possess high levels of professional capital, which refers to "the capacity to transform existing resources and constraints into opportunities through collective action" (Lee & Lee, 2018, p. 466), as well as when they focus on student learning (Bolam et al., 2005).

Description of Professional Learning Community

The goal of the federally-funded project described in this report was to empower College Algebra instructors at a large, Hispanic-serving southwestern university to improve instruction. The Practicality Ethic framework proposed by Doyle and Ponder (1977) helped us (the investigators) to structure the project, as it was originally designed to describe factors teachers consider when deciding whether or not innovative curricula was practical or deemed realistic for implementation in the context of an actual classroom. These factors are: 1) congruence: how compatible the change is with the instructor's classroom, setting, and instructional goals, 2) cost: if the potential benefits (e.g., student outcomes, student attitudes) that outweigh the effort and other costs of implementation, and 3) instrumentality: if the changes consist of clearly articulated procedures for ease of implementation in the instructor's classroom. Informed by the Practicality Ethic, we prioritized instructors' agency in choosing the content and and form of their curriculum (re)development project. In order to encourage instructors to think carefully in advance of their facilitation of lessons about students' opportunities to actively participate in the class, we leveraged the Continuous Improvement (CI) cycle (Berk & Hiebert, 2009), the incremental lesson improvement strategy informed by lesson study.

Continuous Improvement Framework

For each of the five "active" semesters of the project, during the time protected for PLC meetings, instructors chose specific focus lessons from the curriculum and implemented the CI cycle: (1) design a task that targets a particular student misconception or deepens understanding of a particular mathematical idea; (2) develop hypotheses about anticipated student responses; (3) collect data and analyze in the form of student work and classroom recordings; and (4) revise the task for use in subsequent iterations of the course. Our choice to use CI to guide course improvement was to seed gradual transformation made with smaller changes over time for sustained instructional improvement (Hiebert & Stigler, 2004), while also leveraging the knowledge, experience and priorities of instructors to guide these changes. We collected data in the form of instructor interviews, video-recorded class observations, recordings of PLC meetings (including each step of the CI cycle and video club meetings), and participant lesson plans.

Structural Factors Contributing to Instructional Change

We posit that the following structural factors contributed to meaningful instructional change in our context:

1. Course coordination and vertical alignment of curriculum: two years before the start of this project, the department embarked on a concerted effort to coordinate large multi-section courses. Instructors teaching the same course were strongly encouraged to meet regularly, align assessment across sections, and develop a list of student learning outcomes (SLOs) for their course. Course coordinators were similarly encouraged to meet with each other and discuss the progression of SLOs across subsequent courses.
2. Dedicated PLC time: this project provided each College Algebra instructor (all of whom were instructional faculty with 100% teaching loads) with a course release in order to participate in the PLC. Instead of teaching four courses each semester, participating instructors only taught three. Additionally, after the first semester of the project, which was utilized as an establishing and planning semester, all instructors of College Algebra participated in the PLC.

3. Continuous Improvement framework: Using the CI framework allowed us as facilitators to provide a structure for discussions about student thinking and developing active learning materials while still allowing the instructors' own priorities and ideas to guide the instructional improvement process.
4. Video club: embedded into the PLC and as part of the CI cycle, instructors participated in a video club where they observed each other's facilitation of the focus lessons for the semester. This gave instructors the opportunity to open up their practice to each other in a safe and structured way. As advocated by Berk and Hiebert (2009), we encouraged instructors during these video clubs to focus on *instruction* in their observations, not on the personal styles or quirks of the *instructors*.

We report below on preliminary findings that support the importance of each of these factors in catalyzing instructional change.

Preliminary Results

As a result, we have multiple sources of evidence of instructional change on a number of levels. We summarize the results of three preliminary studies below.

Study 1

We investigated the instructors' perceived barriers and drivers for implementing evidence-based instructional practices, drawing on the work of Shadle, et al. (2019). A thematic analysis of the interviews with instructors revealed that most of the barriers to implementing evidence based instructional practices (EBIPs) identified by Shadle et al. (2019) did not resonate with this group of instructors. Specifically, we found that certain departmental policies (e.g., course coordination) mitigated some of the barriers and that the experience of teaching online during the COVID-19 pandemic resulted in the creation of video resources. These resources alleviated the time pressure to "cover" all the required material, making instructors more open to trying out EBIPs. Additionally, we found that the PLC central to this project served as a driver, enabling instructors to implement more EBIPs. For example, the PLC included opportunities for instructors to observe their peers, which provided some accountability and helped instructors to identify and (continue to) implement more innovative strategies in their teaching (Gehrtz et al., 2022).

Study 2.

Next, we looked at instructors' attention during the PLC meetings when each instructor showed video-clips from an observation video of another participant teaching one of the lessons collaboratively developed as part of this project (i.e., video club meetings). Informed by the work of Kelley & Johnson (2022), we used the Instructional Triangle (Cohen & Ball, 2001) as an analytic tool to characterize each instructors' foci during the discussion. Preliminary analysis suggests that each instructor had a component of the instructional triangle that they tended to focus on for the initial observation, but then after participating in multiple video-club meetings and seeing what other instructors focused on in their presentations, the discussions tended to shift to focus more on teacher moves. We also noticed a shift from focusing on explanations of the content at the beginning of the semester to showcasing more clips that highlighted teacher actions to engage and support student learning at the end of the semester (Jones et al., 2023).

Study 3.

Then, we looked at what was happening in each instructor's class by using the Classroom Observation Protocol for Undergraduate STEM (COPUS; Smith et al., 2013) to analyze class video data, documenting what instructors were doing and what students were doing throughout the class period. We then grouped related codes and created radar plots with the percentage of class time spent with: Students Talking, Students Working, Students Receiving, Instructor Guiding, Instructor Presenting, and Instructor Guiding (Smith et al., 2014). This analysis revealed distinct changes within and across semesters with respect to how class time was spent. Specifically, we saw instructors spend less time lecturing while students were listening and taking notes. We also saw more opportunities in class for students to work individually or in groups and for students to talk in class. Additionally, this analysis allowed us to triangulate what was happening in class to what instructors were describing during interviews about their efforts to implement changes to their teaching by incorporating more evidence-based instructional practices (Gehrtz et al., 2024).

Discussion

Put together, these three studies show clear evidence of instructional change, at least during the period of the project. Moreover, interviews with instructors after they had been reassigned to other mathematics courses and were no longer participating in the PLC suggest that they wish to implement some of the lessons learned in the PLC with other courses. However, the dedicated collaboration time that was protected by the project is not available to instructional teams in other courses and instructor buy-in for implementing EBIPs varies across the department, making it difficult for the former College Algebra instructors to overcome the systemic barriers for inquiry-oriented learning that the structure of the PLC and the College Algebra course temporarily eradicated.

However, instructors in the PLC are themselves thinking about the sustainability of the instructional improvements. At the end of the project, the College Algebra curriculum will have been completely revamped based on instructors' interpretation of the evidence-based instructional practices. Additionally, College Algebra course coordinators have started to use the video club recordings of classes in the pre-course orientation meeting for new instructors. The current PLC members are also working on an instructor's guide to the course that can preserve their accumulated knowledge and disseminate it to subsequent course team members. These actions speak to the dedication of these instructors to preserve and sustain the work of the project.

Further Questions

We are currently pursuing a number of other research questions and logistical considerations based on this project:

1. What is the effect (if any) of these instructional shifts on student outcomes?
2. Has participation in this project shifted instructors' beliefs about or use of EBIPs? Is it possible to track these shifts by referencing their interviews, the PLC meeting recordings, or other sources of data that we have collected?
3. How do we preserve the progress made during the project and sustain the work going forward, given the importance of the dedicated PLC time in shifting instructional practices?

Although the evidence of structural factors that influence instructional change may be of use to other investigators and facilitators of professional development for college mathematics faculty, the question of the lasting impact of this project remains open.

DEMONSTRATING ADAPTIVE EXPERTISE ACROSS A COLLECT AND DISPLAY STUDIO DAY CYCLE

Sarah A. Roberts
University of California, Santa Barbara
sroberts@education.ucsb.edu

Marcela Alvarez
University of California, Santa Barbara
marcelaalvarez@ucsb.edu

We examined three elementary teachers' participation in a mathematics language routine (MLR) Collect and Display Studio Day, a modification of Japanese Lesson Study. Our study was guided by a theoretical framework of adaptive expertise. We collected video data from a Studio Day to understand the following: How did elementary teachers demonstrate adaptive expertise of the Collect and Display MLR within their participation during a Studio Day? We analyzed the data using three dimensions of adaptive expertise: flexibility, deeper level of understanding, and deliberative practice. We found that teachers demonstrated dimensions of adaptive expertise during the Studio Day Cycle and we share implications for practice and research.

Keywords: professional development; equity, inclusion, and diversity; elementary school education

Few mathematics teachers have had professional learning experiences that bridge both multilingual learners and mathematics (Ballantyne et al., 2008). This paper focuses on a professional learning experience that use Studio Days (Von Esch & Kavanagh, 2018), a modified version of lesson study, which allowed teachers to focus on language and mathematics simultaneously through the use of mathematics language routines (MLRs; Zwiers et al., 2017). These routines are meant to engage multilingual learners in rich instruction and curriculum; they allow students to access mathematics texts and to communicate mathematical reasoning. MLRs are scaffolded routines intended to lead to students' independent participation in the mathematics classroom through supporting sense-making, optimizing output, cultivating conversation, and maximizing linguistic and cognitive meta-awareness (Zwiers et al., 2017). For example, students might engage in the MLR Collect and Display, the focus of this paper, in which teachers capture students' oral words, ideas, phrases into a stable reference. The purpose of the routine is to stabilize students' language in order to use their output as a reference for developing their mathematical language (Zwiers et al., 2017). While MLRs are becoming more ubiquitous in curricular materials (i.e., Illustrative Mathematics, 2019), the field's understanding of how teachers make sense of these materials and use them with their students, such as within the Studio Day professional learning experience, is still unclear. As teachers make instructional decisions about how to teach MLRs, we should understand how they are making sense of this work. This paper seeks to describe how teachers made sense of how to work with a MLR, including how they made sense of how to work with the content they were teaching their students and how they made sense of how to attend to language they were working with within their classroom to engage in content simultaneously while working on that MLR. Our research question was: How did elementary teachers demonstrate adaptive expertise of the Collect and Display MLR during their participation within a Studio Day?

Adaptive Expertise

Our theoretical framework uses the construct adaptive expertise (Hatano & Inagaki, 1984). We defined adaptive expertise as the ability to implement MLRs, with the flexibility to navigate a localized context without sacrificing ambition or complexity (Hatano & Inagaki, 1984). Hatano and Inagaki found that adaptive experts differed from routine experts in that that were: able to adapt to a desired outcome; able to demonstrate the usefulness of their skill, displaying the context in which the skill was used; and able to find value by the group members. Others have continued to build on this fundamental theory regarding adaptive expertise, in education and beyond. Von Esch and Kavanagh (2018) noted that adaptive expertise is being able to draw on and retrieve relevant existing knowledge. For example, citing Bransford et al. (2007), Von Esch and Kavanagh explained that "adaptive experts organize their knowledge within a conceptual framework of key concepts that guide that their thinking and facilitate use of that knowledge" (p. 241). In this way, adaptive experts are able to flexibly use knowledge that they have developed around a framework they have developed. Additionally, Schwartz noted that people who are adaptive experts are able to rearrange their environments and their thinking, allowing them to acquire and access skills and knowledge. Notably, Schwartz et al. (2005) also explained the importance of being able to move away from efficiency (i.e., learning a single routine, to learn multiple routines and be flexible with them—this takes time and effort).

Teachers with adaptive expertise are able to use their knowledge of their students as they adapt their practices and curriculum (Beltramo, 2017). Teachers who possess adaptive expertise are able to scaffold students' mathematical development through the use of effective instruction and appropriate assessment tools, based on the content they are learning and the context of the students and school environment (Heinze et al., 2009). In this study, we are particularly interested in teachers' development of adaptive expertise as related to MLRs, so as to better attend to multilingual learners. To operationalize our definition of adaptive expertise, we drew from Yoon et al. (2019), who identified three dimensions of adaptive expertise: flexibility, deeper understanding, and deliberate practice. These categories of adaptive expertise will be used for understanding how elementary teachers demonstrated adaptive expertise of the Collect and Display MLR within their participation during a Studio Day.

Method

Our study was situated in a school district in California that included a substantial number of multilingual learners. Teachers from a single elementary school, Alhambra Elementary School (pseudonyms are used for all proper names), participated in a single-year professional learning program organized around multilingual learner mathematics Studio Days (Von Esch & Kavanagh, 2018)—we focus on a single cycle for this paper, organized around the MLR Collect and Display, described above, examining just the Studio Day aspect of this cycle. A third grade teacher and two fifth grade teachers participated in the study, all self-identified as female, and two identified as white and one as Hispanic. This paper is a descriptive case study (Merriam, 1998) of one Studio Day, and we examine the two teachers who conducted Studio Day lessons: two fifth grade teachers: Ms. Moreno and Ms. Butler.

Data Collection and Analysis

The larger project collected multiple sources of data; because of the brevity of this report, we focused on videotaped meetings with teachers, as well as videotaped classroom enactments of the Studio Day. We transcribed these videos using Otter.ai and then cleaned the transcriptions. To analyze our data, we first coded data for instances of MLRs. We then coded these instances of MLRs using a priori codes of Yoon et al.'s (2019) three dimensions of adaptive expertise: flexibility, deeper understanding, and deliberate practice to code our multiple data sources. We then examined each occurrence within the Studio Day, as well as each adaptive expertise dimension to make sense of how elementary teachers demonstrated adaptive expertise of the Collect and Display MLR within their participation during a Studio Day.

Findings

We share key findings of the dimensions of adaptive expertise from the Studio Day. Our Studio Day model is organized around a common MLR. On this particular day, the teachers also planned to teach the same lesson. Following the first lesson, the second teacher, Ms. Butler, changed her lesson based on the observations of Ms. Moreno's lesson. We found that the teachers' lessons tended to include more instances of flexibility and deeper level of understanding. Opportunities to reflect on improving practice were present in the debriefs following the lesson included more instances of deliberate practice, which, we do not describe in this paper.

Lesson 1 – Ms. Moreno

Ms. Moreno's enactment in the classroom of her Collect and Display MLR included evidence of the adaptive expertise dimensions of (a) flexibility because of her awareness to students, particularly multilingual learners, and her attending to students' needs in real-time; as well as (b) deeper level of understanding because of her bringing in variations to the MLR. Ms. Moreno's flexibility occurred as she engaged with the MLR and noted aloud to students what she was doing, such as, "So, I heard a couple of you say that you were multiplying," she was aware of her students through her revoicing of students' ideas (Moschkovich, 1999). With regards to a deeper level of understanding, Ms. Moreno explained to the students regarding the Collect and Display, "Remember, this was just a little refresher." In this way, Ms. Moreno made the MLR a review for students and decided how she would implement the MLR with her students, bringing in a variation for how it would be used in her class. This illustrated a variation from how the MLR was originally shared in the Pre-Studio Day.

Lesson 2 – Ms. Butler

Ms. Butler similarly demonstrated the two dimensions Ms. Moreno exhibited in her lesson: (a) flexibility and (b) deeper level of understanding during her enactment of Collect and Display. Ms. Moreno and Ms. Butler had planned their lessons together, as noted above, and had originally planned to teach the same lesson. Additionally, because Ms. Butler made changes in the moment, her practice demonstrated (c) deliberate practice. with instances of revamping her practice in the moment. Students had difficulties with some of the unit fraction concepts in Ms. Moreno's class, which were meant to be a review for students (the content had been taught earlier in the year). Ms. Butler's changes illustrated her deeper level of understanding of the MLR because was able to assimilate information from an outside source (her observation of Ms. Moreno's class) and make connections that built a deeper level of understanding (change the lesson to better meet the needs of her students). Ms. Butler, instead of teaching the second lesson in the unit, as Ms. Moreno had, taught the first lesson in the unit as a refresher for students.

Ms. Butler's attention to Ms. Moreno's lesson also changed the mathematical terms that Ms. Butler highlighted in her Collect and Display. For example, within her Studio Day lesson, Ms. Butler shared the following with her students:

> I was noticing some different words that you were saying. And, we were talking about the area of these fractions…But, I'm going to write on there the formula for area, because that's really important…We were also talking about shaded. I heard that word a lot.

Ms. Butler made sense of Ms. Moreno's lesson and adapted her Collect and Display and highlighted being able to draw on applicable knowledge during the use of the MLR (Von Esch & Kavanagh, 2018). She also demonstrated flexibility in this instance through valuing students' contributions, noticing what they said and writing those ideas up for other students to see that they were valued.

In another instance, Ms. Butler shared her flexibility with her students, explaining,

> As you guys were working, I was listening to what you were talking about, and I was writing them down. And, so now, we have this ongoing, and this is going to be an ongoing chart of vocabulary that we're going to use as we continue learning about fractions.

She illustrated that she was listening and had an awareness of her students while they were working, which demonstrated her flexibility during the MLR. Her flexibility was illustrated through noting that she was "listing to what you were talking about."

Discussion

We found that elementary teachers who participated in a Collect and Display MLR Studio Day demonstrated two of Yoon et al.'s (2019) dimensions of adaptive expertise—flexibility and deeper level of understanding. The Studio Day provided space for teachers to demonstrate these dimensions of adaptive expertise within the context of their classrooms. For example, Ms. Moreno and Ms. Butler were able to demonstrate flexibility and deeper level of understanding while highlighting particular terms on their Collect and Display MLR. These MLRs provided a context through which teachers could attend to the needs of their multilingual learners in real-time, such as by revoicing their students' ideas and by valuing their students' contributions. Working with other teachers allowed the teachers to consider these future pedagogical practices, highlighting the value of working in the Studio Day space. For instance, Ms. Butler was able to make changes to her practice in real-time (deliberate practice). These examples of adaptive expertise highlight the value of the Studio Day as a supportive environment for teachers to demonstrate adaptive expertise of Collect and Display and to attend to and consider the needs of their multilingual learners.

Implications

This study provides both theoretical and practical implications to our understanding of adaptive expertise, MLRs, and Studio Days. We provided an application Yoon et al. (2019) to MLRs within a Studio Day context, bringing these three constructs together to help add to the limited research on multilingual learners, mathematics education, and professional learning research (de Araujo et al., 2018) while also helping the field understand how teachers make sense of MLRs, through the use of a frame of adaptive expertise. Research on MLRs is still quite scant even if they are becoming more visible in practice, and this research helps to add to the field's understanding of their use. Practically, this research provides information about MLRs in practice in elementary schools. Currently, research (i.e., Zahner, 2021) has focused on the use of this pedagogy at the secondary level. This research provides a practical image of elementary teachers using MLRs, especially as they become ubiquitous in curricular materials. Additionally, the Studio Day Cycle becomes a potential space for developing the adaptive expertise of MLRs, as seen with Collect and Display and other MLRs, with this study providing a practical image for doing so.

USING GALLERY WALKS FOR COMPARE AND CONNECT: DEVELOPING ADAPTIVE EXPERTISE OF MATHEMATICS LANGUAGE ROUTINES

Sarah A. Roberts

We examined teachers' development of adaptive expertise of mathematics language routines (MLRs) as they engaged in Studio Day professional learning focused on the MLR Compare and Connect. We collected video data from pre- and post-Studio Day meetings, as well as debriefs and their lesson enactments. We analyzed the data using three dimensions of adaptive expertise: flexibility, deeper level of understanding, and deliberate practice. We share a case study of a teacher exhibiting dimensions of adaptive expertise during the Studio Day Cycle through the use of a gallery walk. The teacher's enactment of the MLR Compare and Connect provides an image of a teacher's adaptive expertise of this MLR and helps us understand these MLRs and how teachers use and make sense of them in their instruction.

Keywords: Professional development; equity, inclusion, and diversity

This paper focuses on a professional learning experience for secondary mathematics teachers that used Studio Days model of professional learning (Von Esch & Kavanagh, 2018), which is a modified version of Japanese Lesson Study. Our Studio Day experience for teachers was focused on language and mathematics simultaneously through the use of mathematics language routines (MLRs; Zwiers et al., 2017), a unique experience for most mathematics teachers, as few mathematics teachers have had professional learning experiences that bridge both multilingual learners and mathematics teaching (Ballantyne et al., 2008). MLRs are scaffolded routines intended to lead to students' independent participation in the mathematics classroom through supporting sense-making, optimizing output, cultivating conversation, and maximizing linguistic and cognitive meta-awareness (Zwiers et al., 2017). In this Studio Day Cycle, teachers learned about the MLR Compare and Connect, which engages students in comparing and contrasting different mathematical approaches through examining different mathematical representations, approaches, examples, or language (Zwiers et al., 2017). Students are meant to develop meta-cognitive and meta-linguistic through their conversations with peers (Zwiers et al., 2017). Teachers need more than a cursory understanding of these MLRs to help their students to use and make sense of these routines in their classrooms (i.e., more than reading directions of how to use them off a page). Additionally, as a field, we need to understand how teachers use and make sense of these routines. Therefore, we saw Studio Day professional learning experiences as a space for teachers to develop adaptive expertise with MLRs. We define adaptive expertise as the ability to implement MLRs with the flexibility to navigate a localized context without sacrificing ambition or complexity (Hatano & Inagaki, 1984). Our research question was: How did a teacher make sense of the MLR Compare and Connect during a Studio Day Cycle in ways that demonstrated their adaptive expertise?

Adaptive Expertise

Our theoretical framework uses the construct adaptive expertise (Hatano & Inagaki, 1984), as defined above. Adaptive experts differed from routine experts because they were able (a) to adapt to a desired outcome; (b) to demonstrate the usefulness of their skill; and (c) to find value in their work from their group members. Schwartz et al. (2005) explained the importance of being able to move away from efficiency. For example, it takes time and effort to move from learning a single routine to learning multiple routines and being flexible with them. Von Esch and Kavanagh (2018) also developed on Hatano and Inagaki's concept of expertise and noted that adaptive expertise is being able to draw on and retrieve relevant existing knowledge. For example, adaptive experts are able to flexibly use knowledge that they have developed around a framework they have developed.

Teachers who possess adaptive expertise are use their knowledge of their students as they adapt their practices, curriculum, and instruction (Beltramo, 2017), scaffolding students' mathematical development through the use of effective instruction and appropriate assessment tools (Heinze et al., 2009). In this study, we were particularly interested in teachers' development of adaptive expertise as related to MLRs, so as to better attend to multilingual learners. We operationalize our definition of adaptive expertise, drawing from Yoon et al. (2019), who identified three dimensions of adaptive expertise—flexibility: exhibits an awareness of students, particularly multilingual learners and context, as related to MLRs; deeper understanding: brings in variations related to the MLRs and considers affordances and constraints of the MLRs; and deliberate practice: demonstrates motivation, focus, and repeated effort to monitor their practice and devises and subsequently attempts improved implementation. These categories of adaptive expertise will be used for understanding how the secondary teachers demonstrated adaptive expertise of the Compare and Connect MLR within their participation during a Studio Day Cycle.

Method

Our study was situated in a school district on the West Coast that included a substantial number of multilingual learners. This paper focuses on the second of three Studio Day Cycles during the 2023-24 school year.

Context: Studio Days Enactment of Multilingual Learner Principles and MLRs

Each Studio Day Cycle involved three professional development meetings and targeted a single MLR, with this cycle attending to the MLR Compare and Connect, described in the introduction. During the pre-Studio Day, teachers learned about the MLR and prepared to implement a lesson that included this MLR. Teachers then enacted this lesson at their school during the Studio Day, with teachers observing each other's implementation. During the final day of the cycle, the post-Studio Day, teachers examined and analyzed student work and video clips from the implementation, shared challenges and successes, and considered implications for their future practice.

Participants

Four junior high school teachers from the three junior high schools in the district participated in the study. This paper is a descriptive case study (Merriam, 1998) of one of these teachers, Ms. Severn.

Data Collection and Data Analysis

The larger project collected multiple sources of data; because of the brevity of this report, we focused on videotaped pre-, post-, and Studio Day meetings with teachers, as well as videotaped classroom enactments. We transcribed these videos using Otter.ai and then cleaned the transcriptions. We examined the transcripts, and first coded for instances when there were instances of MLRs occurring within the data. Next, we coded these MLR instances for adaptive expertise related to the MLR within each aspect of the Studio Day Cycle transcripts. We used a priori codes of Yoon et al.'s (2019) three dimensions of adaptive expertise: flexibility, deeper understanding, and deliberate practice to code our multiple data sources. We then examined each occurrence within a single Studio Day component (i.e., only pre-Studio Day), as well as examined each adaptive expertise dimension (i.e., only flexibility) to make sense of how participants demonstrated adaptive expertise of the Compare and Connect MLR within their participation during a Studio Day Cycle. We looked for themes within the Studio Day components and the adaptive expertise dimensions and share these themes within our findings.

Findings

We found that one teacher, Ms. Severn, used a gallery walk (e.g., sharing student work) to make sense of and enact the Compare and Connect MLR with their students, thereby making the MLR their own and exhibiting their adaptive expertise of the MLR. We share key dimensions of their adaptive expertise from aspects of the Studio Day Cycle to illustrate the teachers' process for this work.

Pre-Studio Day

Part of the initial work during the pre-Studio Day is to provide teachers an overview of the MLR. During this initial overview, the first author shared that there were multiple ways for teachers to "Compare" work during the Compare and Connect MLR. The author noted, "You could do a gallery walk and just have students put up work." A few minutes later, Ms. Severn asked, "How would a gallery walk work in our classroom with filming students?" Because this is a research study, there are considerations regarding moving non-consented students out of sight during lessons. However, we were very mindful of keeping lessons flowing as normally as possible and let Ms. Severn know this. We highlight that Ms. Severn was already considering how to enact Compare and Connect before she had experienced the routine—simply after a brief overview of the routine. This is the beginnings of Ms. Severn's deeper level of understanding, as she considered contexts in which to apply the MLR within her own classroom. Ms. Severn was using knowledge of her own students to begin to make the lesson her own (Beltramo, 2017).

Studio Day – Ms. Severn's Gallery Walk

Ms. Severn taught the first lesson during the Studio Day. She provided an overview of her lesson during the pre-brief, then taught her lesson, and then had a debrief of her lesson.

Pre-brief of Ms. Severn's enactment. The group began the day with an overview of Ms. Severn's lesson. Ms. Severn explained that the lesson would be focused on a proportional relationship, with each group solving with a specific representation. She explained: "So, I'll assign them to use an equation and a unit rate, a table, or a graph…Then we'll have them look at each other's representations and compare how they solved the problem against each representation." This task considered how Ms. Severn brought the MLR into her own classroom practice, within a specific mathematics task, illustrating a deeper level of understanding. Further, Ms. Severn shared that the MLR was meant to get the students talking to each other about mathematics, because the class was "really hesitant to talk at all." Enacting the MLR as she did employed Ms. Severn's flexibility, or her awareness of her students, particularly her multilingual learners, as she worked to adapt to their needs, particularly getting them to talk about the mathematics in her class.

Ms. Severn's enactment of the gallery walk. Ms. Severn introduced the task and reminded them of the work they had already done related to the content:

> We've talked about tables this unit. We've talked about equations this unit. We've talked about graphs this unit. Each of your table groups is going to get randomly assigned one of those representations and then you're only going to be able to solve the problem with that representation.

She then told the students that "each group needs a poster." Students then knew what was required of them within the task but notifying students of the work they would be doing also illustrated, as noted above, how she had made the MLR her own, highlighting her deeper level of understanding of the MLR. The structure of the MLR as enacted went beyond the first author suggesting, "You could do a gallery walk."

Approximately 22 minutes into the class, Ms. Severn further explained the class' work to complete within the MLR, noting,

> We're doing to do what's called a 'gallery walk'….I'm going to give you this graphic organizer here, and it says 'ratio,' 'table of values,' 'graph,' and 'equation.'…And you are going to have four minutes to walk around the classroom and look at how other people solved this problem and write in the box describing how groups solved the problem.

Ms. Severn, in providing students with a graphic organizer, attended to students' linguistic and mathematical needs during the Compare and Connect MLR, highlighting her flexibility. A graphic organizer, such as this, provided a scaffold for multilingual learners, which allowed access to the content for multilingual learners (Echevarria et al., 2006). Further, Ms. Severn made the gallery walk her own, providing guidelines to students, moving from the broad strokes provided in the pre-Studio Day to fine-tuned details needed for enactment with students, exemplifying a deeper level of understanding. She further provided students with sentence frames and direction for how to engage in their discussions in pairs, for example, "If you're the partner that's sitting closer to the back wall…you are the partner that's going to speak first." These language supports provided ways for multilingual learners to engage in the discussions that she had wanted to support and had noted in the pre-brief, marking, again, her flexibility, particularly related to her multilingual learners.

Discussion

We found that a teacher made sense of the MLR Compare and Connect during a Studio Day Cycle in ways that demonstrated their adaptive expertise through the use of a gallery walk, exhibiting both her deeper level of understanding and her flexibility (Yoon et al., 2019). Ms. Severn was able to use this MLR to engage students in mathematical conversations around proportional reasoning through the gallery walk and more specifically through her graphic organizer—supporting students both mathematically and linguistically (Zwiers et al., 2017). Her flexibility illuminated her attention to multilingual learners. Ms. Severn's enactment of the MLR Compare and Connect provides the field an image of a teacher's adaptive expertise of this MLR. Such an imagine helps us understand these MLRs and how teachers use and make sense of them in their instruction. Future research can then examine how students, particularly multilingual learners, use and make sense of these MLRs in their learning.

BUILDING A TEACHER COMMUNITY OF PRACTICE THROUGH STUDIO DAYS

Margarita A. Rodriguez
University of California
Santa Barbara
margarita_rodriguez@ucsb.edu

Sarah A. Roberts
University of California
Santa Barbara
sarahann_roberts@ucsb.edu

T. Royce Olarte
University of California
Santa Barbara
tolarte@ucsb.edu

Keywords: Professional Development; Equity, Inclusion and Diversity

Our work uses Studio Day Cycles (Von Esch & Kavanagh, 2018) focused on the integration and development of mathematics language routines (MLRs; Zweirs et al., 2017). Our conceptual framework draws on two key ideas: communities of practice (Lave & Wenger, 1991) and teacher communities (CoP; Grossman et al., 2001). We discuss each and how they interact with each other. Therefore, our research question was: How, if at all, did a Studio Day Cycle establish a teacher learning community to support teachers to engage in reflection around use of the MLRs?

Method

Our study was situated in a school district on the West Coast that included a substantial number of multilingual learners as part of a larger, multi-year study focused on Studio Day Cycles. We focused on a single cycle that occurred during Fall 2023. We worked with five junior high school teachers and qualitatively analyzed their Google Form reflections using the dimensions of CoP: mutuality, joint enterprise, and shared repertoire.

Findings

Our study found evidence of all three dimensions of CoP. First, Ms. Ruth felt very supported by the "team of teachers" and welcomed their questions, evidencing mutuality. Second, teacher participants considered each other's practice, thought about, and made plans to take what they had learned into their instruction (moving from the mutuality to considering their joint enterprise). Finally, established a shared repertoire around the MLRs by providing examples of what the MLRs looked like in practice and developing joint definitions and understandings of the MLRs that could be used for further reflection.

Discussion and Conclusion

The Studio Day Cycle supported the development of a teacher community of practice by supporting teachers to reflect on their use of the MLRs. As we seek to continue supporting teachers in their work of considering the needs of multilingual learners, it is important to establish spaces and communities where teachers are able to rely on and learn from each other.

CONNECTING VISIONS OF EQUITABLE MATHEMATICS INSTRUCTION TO PRACTICE: A FIRST-YEAR TEACHERS' COMMUNITY OF PRACTICE

Kathryn M. Rupe
Western Washington University
rupek@wwu.edu

Dawn M. Woods
Oakland University
dawnwoods@oakland.edu

Keywords: Instructional vision; professional development; equity, inclusion, and diversity

One way to support first-year teachers (FYTs) to navigate tensions between their instructional visions and the realities of school culture while developing as critical educators is through a community of practice (CoP), which serves as the theoretical framework for this study. A thriving CoP can be a space for FYTs to reflect upon and share their experiences as they work to create elementary mathematics classrooms that honor all students' mathematical thinking and strive to center equity and justice (Woods & Rupe, 2024). Through shared curiosity FYTs can think critically about their students as mathematical doers within the daily realities of teaching. Yet, we wondered how do FYTs' visions of equitable and high-quality mathematics instruction serve as filters for the equity-based instruction they enact during their first year of teaching?

Methods

There are three CoPs in this study, with a total of 15 elementary FYTs. Two cohorts of FYTs graduated from the same Pacific Northwest university in 2022 or 2023. One cohort of five FYTs graduated in 2023 from the same university in the Midwest. Each FYT was individually interviewed before the CoP began and at the end of their first year teaching. They described their visions of high-quality and equitable mathematics instruction using the VHQMI and VEMI interview protocols (Munter, 2014; Haines et al., in preparation). Other data sources included transcripts of monthly CoP meetings and individual reflective journals. Thematic analysis was used to identify patterns in the data (Braun & Clarke, 2006). We began analysis by coding interviews and monthly CoP transcripts for semantic themes and then through a recursive process, moved to the latent level of analysis and identified (or examined) the underlying ideas, assumptions, and conceptualizations (Saldaña, 2021).

Summary of Results

Initial findings have shown numerous examples of FYTs grappling with and expanding on ideas from their interviews throughout the school year. For example, Halley shared in August,

> At the beginning of a lesson, I would look for ways the teacher is making the math lesson accessible for all students to start. Are there multiple entry points into the task or different ways for students to access the same idea? Are there places students know they can look for help, like across the room or among peers? I'd also look for a lot of sense making conversations and talk. Including the children's voices a lot, not just the teacher talking…

These ideas of accessibility, emphasizing sense-making, and including students' voices were revisited often by Halley in meetings, journals and other artifacts. This is only one example of how FYTs' instructional visions acted as filters for enacted equity-based instruction. Analysis across the three cohorts is ongoing, yet the implications highlight the tensions FYTs faced (and the supports that they need during their coursework and in the first year of teaching) so that they continue to critically think about their students as mathematical doers within the daily realities of classroom teaching.

AN INDUCTIVE EXPLORATION OF TEACHER MOTIVATION AND PERCEIVED LEARNING IN THE COACHING PARTNERSHIP

Evthokia Stephanie Saclarides
University of Cincinnati
saclares@ucmail.uc.edu

Ryan Gillespie
University of Idaho
rgillespie@uidaho.edu

We partnered with nine elementary teachers who were engaged in coaching cycles with their school-based coach to improve their mathematics instruction. We conducted 16 semi-structured interviews to better understand why they were motivated to engage in coaching, what they reported learning from the experience, and the extent to which there was parity between teachers' motivating reasons to engage in coaching and their perceived learning. Qualitative analyses indicated that teachers frequently reported improved understanding of mathematics content and pedagogy as both the motivation to engage in coaching and their perceived learning. Furthermore, analyses showed five overarching trends when exploring motivation and perceived learning parity. Implications for practice and future research are discussed.

Keywords: Instructional Leadership, Professional Development, Teacher Educators

Since its inception in the US in the 1980s (e.g., Joyce & Showers, 1981), coaching has become a widespread mechanism to support improvements to mathematics teaching. We define a coach as someone who works directly with a teacher, or group of teachers, on instructional improvement issues in service of improving student learning (Baker et al., 2022a). The proliferation of coaching within mathematics education has spurred a body of research focused on understanding how coaches and teachers work together (e.g., Gillespie et al., 2024) and the outcomes of these interactions (e.g., Kraft et al., 2018).

Existing research has tended to center on coaching outcomes such as enhanced student achievement (e.g., Campbell & Malkus, 2011), instead of teachers' learning interests who initiate coaching interactions. As coaching is a responsive professional learning method, it is critical to understand what motivates teachers to engage in coaching and their desired growth. Furthermore, a teacher's practice is a complex interaction of knowledge, skills, identities, and beliefs (Grossman et al., 2009). Coaching holds the potential to develop mathematics teachers' instructional practice in unique and nuanced ways since a coach can engage a teacher in customizable interactions involving collaborative planning, teaching, and reflecting. Thus, coaches can support teachers in ways that extend beyond student achievement measures and deductive evaluation of pre-determined teaching practices which have been the focus of existing coaching studies.

To this point, there has been no systematic analysis exploring (a) teachers' motivation to engage in coaching to improve their mathematics teaching and (b) teacher's perceptions of how they benefited from engaging with a coach. Furthermore, the field knows little about how teachers' motivation to engage in coaching aligns with their perceptions about what they learned. In response, we designed an exploratory study in a context in which teachers had open access to one-on-one coaching cycles with school-based coaches to improve their teaching of mathematics. We pursued answers to the following research questions: (a) What motivates teachers to engage in coaching?, (b) What do teachers perceive they learn from their engagement in coaching?, and (c) To what degree is there parity between teachers' motivation to engage in coaching and what they perceive they learn?

Method

Context and Participants

This study took place in Midtown and Southampton school districts, which had instructional and content-focused coaching programs (respectively). Across these two school districts, we partnered with nine elementary teachers who were currently engaged in one-on-one coaching cycles with their school-based coach. In both contexts, a coaching cycle was a three-part activity in which the teacher and coach collaboratively planned, taught, and reflected upon a mathematics lesson. All teachers identify as White females, and had 1-23 years of teaching experience across grades pre-kindergarten through 5^{th}.

Data Source

This analysis rests upon 16 semi-structured interviews that were conducted one-on-one with each participant before and after their coaching cycle. In the interview before the coaching cycle, we asked participants questions to gauge their motivation to engage in coaching. In the interview after the coaching cycle had ended, we first asked our participants to remind us what motivated them to engage in coaching. Next, participants were asked questions to better understand what they perceived they learned. All interviews were audio recorded and transcribed.

Analytic Technique

Motivation and Perceived Learning

All 16 interview transcripts were read multiple times to support the researchers in developing a holistic understanding of the teacher participants' emic perspectives regarding their motivation to engage in coaching, as well as what they perceived they learned. Next, the broad codes of *motivation* and *perceived learning* were applied to interview excerpts to identify instances in which the participants discussed what motivated them to engage in coaching or what they reported learning. Then, all interview excerpts that had previously been coded with the broad codes of *motivation* or *perceived learning* were read again, and a sub-code was added through an open coding process to capture the specific motivating factor or learning that teachers noted (e.g., differentiation). Then, these sub-codes were inductively clustered into broader categories (e.g., pedagogy) based on their relationships with one another, until all sub-codes could be accounted for. Last, matrices with counts based on the total number of teachers who reported a particular motivation or perceived learning were generated to facilitate pattern detection.

Parity

Parity refers to the extent to which there was congruence between a teacher's motivation to engage in coaching with what that teacher perceived they learned. We began by creating individual teacher profiles using a template. In the template, we recorded the specific motivation and perceived learning sub-codes (e.g., differentiation), as well as the broad category (e.g., pedagogy) under which each sub-code was nested, for each teacher. Next, we coded for parity, or congruence, and assigned one of two codes to each motivating and perceived learning sub-code: (a) paired, and (b) unpaired. Paired was assigned when a motivation sub-code reappeared as a perceived learning sub-code for an individual teacher. Unpaired was assigned when a motivation sub-code did not reappear as a perceived learning sub-code (Unpaired-M), or when a perceived learning sub-code did not appear as a motivation sub-code for an individual teacher (Unpaired-PL). Hence, we assigned the codes paired and unpaired to each motivating and perceived learning sub-code for each teacher and recorded these codes in the templates for each teacher profile. After this round of coding, we looked across all teacher profiles to develop generalizable cases of teacher parity to understand how teachers' motivation to engage in coaching aligned with their perceptions of their learning.

Findings

Teachers' Motivation and Perceived Learning

Teachers described eight different topics when discussing what motivated them to engage in coaching (RQ1), as well as what they perceived they learned (RQ2). In Table 1, we report the number of teachers who mentioned these topics and highlight that the most common topics for both motivation and perceived learning were mathematics content and pedagogy.

Table 1: Overall Teacher Motivation and Perceived Learning

Topic	Definition	Motivation	Perceived Learning
Content	Teachers were motivated to engage in coaching and/or reported learning about math content, which included deepening their own and/or students' understanding of math, enhancing their own and/or students' beliefs and attitudes towards math, changing their own beliefs about students' math capabilities, and/or anticipating students' thinking and/or misconceptions about math.	6	7
Pedagogy	Teachers were motivated to engage in coaching and/or reported learning about pedagogical tools, including: strategies for differentiation, questioning, formative assessment, engagement and incorporating kinesthetic movement; new learning routines; and pacing issues.	5	7
Curriculum	Teachers were motivated to engage in coaching and/or reported learning about curricular issues, including deepening their understanding of the district-provided curriculum, or finding high-quality curricular resources.	3	3
Behavior Management	Teachers were motivated to engage in coaching and/or reported learning about how to improve student behaviors in their classroom.	3	1
Professional Development Opportunity	Teachers were motivated to engage in coaching and/or reported learning about professional development opportunities, in particular coaching, they could pursue to improve themselves as educators.	2	1
Policy	Teachers were motivated to engage in coaching because of policy-related reasons, such as being on an improvement plan and/or wanting to improve their evaluation scores.	2	0
Coaching Knowledge	Teachers were motivated to engage in coaching because they perceived it would enable coaches to deepen their coaching knowledge by interacting with different teachers, thereby becoming more effective coaches.	1	0

Relationship Building	Teachers were motivated to engage in coaching because they wanted to strengthen their relationship with their coach.	1	0

Parity Between Teachers' Motivation and Perceived Learning

For third research question, we explored the extent to which there was parity between teachers' motivation to engage in coaching and what they reported learning. We conceptualized five potential configurations relating the parity of motivation to perceived learning and then located each teacher profile within one of these five configurations (see Figure 2). The most common configuration involved partial parity (n = 5) in which (a) certain aspects of teachers' motivations were also highlighted in their perceived learning and (b) teachers reported perceived learning beyond what initially motivated them to engage in coaching. For example, Barbara described improved questioning in both her motivation for coaching and her perceived learning. Barbara also reported learning about differentiation and anticipating students' mathematical thinking which was not mentioned as a motivation prior to her interactions with her coach.

	Teachers	Definition	Motivation	Perceived Learning
Complete Parity	None	Only paired motivation and perceived learning	X	X
Lack of Parity	Lindsey Michelle	Only unpaired motivation and perceived learning	X	Y
Partial Parity	Mackenzie	Paired motivation and perceived learning AND unpaired motivation	X and Y	Y
Partial Parity	Brianna	Paired motivation and perceived learning AND unpaired learning	X	X and Y
Partial Parity	Barbara Caroline Cathy Cecilia Jennifer	Paired motivation and perceived learning AND unpaired motivation AND unpaired perceived learning	X and Y	X and Z

Figure 2: Parity Trends

Discussion and Implications

One overarching contribution of this study is that it centers teachers' voices in the coaching partnership. Given calls to dignify teachers as professionals by providing them with choice and agency regarding their own professional learning needs (Lieberman & Pointer Mace, 2008), we contend that coaching research must examine teachers' voices, wants, needs, and perspectives. This exploratory, relatively small-scale interview study takes an important first step in that direction as we focus on teachers' motivation to engage in coaching, as well as what teachers report they learn through. Through this work, we hope to pave the way for future coaching research to similarly center teachers' voices in the coaching partnership.

Overall, we found that mathematics content and pedagogy were prevalent motivating factors and perceived learnings for teacher participants. The prevalence of these categories highlight the importance of providing coaches with ongoing professional learning opportunities that will enable them to deepen their content knowledge as well as equip them with rich pedagogical tools to engage diverse student learners. Oftentimes, coaches' professional learning needs are overlooked once they assume their new positions as they are "anointed and/or appointed without the proper background related to their content, pedagogical, and leadership knowledge and skills" (Fennell, 2017, p. 9). Hence, school districts must consider how they are providing job-embedded support for coaches so they have opportunities for professional growth. Findings regarding partial parity between motivation and perceived learning provide new insights about the responsive nature of coaching as a professional learning activity. Mainly, coaches were able help teachers grow towards outcomes named at the outset of coaching interactions while also supporting professional development beyond these predetermined outcomes.

Keywords: Professional Development, Instructional Activities and Practices

Teachers often have discretion in how they format their lessons (e.g., whole-class, groups), even if they are required to use specific textbooks, technology, or common assessments. Additionally, teachers have a choice in using combinations of whole-class discourse, independent, or group work time to engage students in mathematics (Otten et al., 2022). We hypothesize professional developers need to be cognizant of teachers' lesson formats when offering instructional suggestions. For example, if a teacher does not use group work regularly, they may be hesitant to implement interventions designed for group work. These suggestions should be close to teachers' current practices, small in grain size, and be something a teacher could easily take up (Litke, 2020; Star, 2016). We asked, how do teachers' lesson formats impact how they take up instructional nudges provided in a professional development setting?

We observed seven Algebra I teachers' lesson formats as part of a larger study (Candela et al., 2024). We utilized Year 1 observations to identify the percent of time dedicated to whole-class discourse, independent work, and group work. In Year 2 we deployed 16 instructional nudges that are small instructional suggestions, closely aligned to teachers' practices, and have potential to be high uptake (Authors). We aligned the design of the instructional nudges with different lesson formats. For example, One Paper is an instructional nudge that encourages a teacher to use group work and Rate and Review is designed for independent work time where students rate responses to worked problems, much like they would reviewing a product. Teachers selected instructional nudges and we used observations and interviews to capture which one's teachers enacted.

We identified relationships between the time spent in each lesson format and the instructional nudges enacted. One teachers' instruction was typically whole-class discourse, short independent work time, more whole-class discourse, and finally independent work time. This teacher only implemented instructional nudges that fit in during whole-class discourse, and as the teacher spent most of their class time in this format, it follows they would take up nudges that fit in this format. This finding was similar across teachers. We will share visual displays of our results for all teachers and discuss the instructional nudges with the most uptake in relation to format. Implications suggest teachers are more likely to take up practices that are more closely aligned with their current practices and suggest those providing professional development should keep this in mind when planning interventions.

Keywords: Mathematical Knowledge for Teaching, Professional Development, Referent Unit

Referent units in fractions are often overlooked by elementary and secondary math teachers. Research highlights the challenges teachers face in presenting fractions effectively (Copur-Gencturk & Ölmez, 2022; Izsák et al., 2019; Wang et al., 2023). This study, grounded in Knowledge in Pieces (KiP) (diSessa, 2016, 2018), aims to provide insights into PD initiatives designed to enhance teachers' attending of referent units, crucial for future fraction teaching.

This intrinsic case study (Stake, 1995) focuses on Marcus, a middle school teacher with six years of experience. He participated in a weeklong PD including solving fraction problems and discussing referent units. Analysis centered on Marcus's intuitive (pre-PD interview data) and developed understanding of referent units (post-PD reflection data).

Before the PD, Marcus intuitively partition a garden to rows and did not realize he used a row as his referent unit. Post-PD, he began connecting these intuitive methods with a clearer understanding of the referent unit. For example, in the Mathtopia problem, Marcus initially misinterpreted the referent unit (e.g., "Okra of 3/16"), but adjusted his thinking with facilitator guidance, leading to a better attending of the where the whole appears (e.g., "Okra is 3/64").

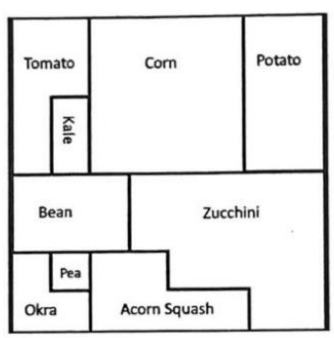

Figure: Mathtopia problem used in PD

Our study aligns with existing research, revealing a notable issue among teachers struggling to keep track of referent units in fraction operations. This highlights the necessity for targeted support to help teachers like Marcus establish stronger connections between partitioning strategies and a consistent awareness of the referent unit.

EMBEDDING TEACHER LEARNING OPPORTUNITIES IN UNIT ASSESSMENTS

Corey Webel	Eric Partridge	Salima Karim

webelcm@missouri.edu	egpbk6@missouri.edu	s.karim@missouri.edu

Keywords: Professional Development, Systemic Change, Teacher Knowledge

One empirically supported way of improving elementary mathematics teaching is engaging teachers in developing and using knowledge of student thinking in their instruction (Carpenter et al., 2000). A significant challenge, however, is embedding these kinds of learning experiences in the day-to-day work of teaching, especially given the many constraints and pressures elementary teachers must navigate. In this project, we sought to understand how unit assessments might function as a site for such learning experiences, and how facilitated grade level team meetings might support teachers in developing and using knowledge about student thinking in their planning and teaching.

The study was guided by a theory that acknowledges both individual and situated aspects of knowledge (Cobb & Bowers, 1999); in particular, we are interested in how knowledge development occurs within a group when the object of learning—knowledge of student thinking—is situated in an artifact of instruction—the unit assessment—that has substantial salience for elementary teachers. The study was conducted in a school district that had adopted commercially published textbook with seven to nine units in each grade level. A team of teachers and leaders worked to adapt the unit assessments so that they would be open to a variety of strategies and created strategy rubrics based on the Cognitively Guided Instruction research project (e.g., Carpenter et al., 2014). Four schools were selected to participate in the study over the course of a school year. The grade level teams for third, fourth, and fifth grade engaged in a series of meetings facilitated by an instructional coach in which they discussed the strategies students used on the assessments when given prior to the start of a unit (pre-test) and at the end of a unit (post-test). Between these two meetings, there was a third meeting in which the group collectively planned a lesson, with the intention to use information about student thinking to guide their planning. Finally, the district also had purchased an online assessment program that ranked students in terms of their grade level (e.g., two grade levels behind). These were used to identify students, and eventually teachers, for interventions. We created charts showing the distribution of student strategies (Kazemi et al., 2016) on the unit tests and juxtaposed these with results from the district assessment program and shared these with teachers between meetings.

We recorded all teacher meetings and analyzed them in terms of "teacher talk paths" (Murata et al., 2012). Specifically, we attended to how participants incorporated the information about student thinking embedded in the assessment materials into their conversations about students and about teaching. We also recorded meetings between the team facilitators.

Early results show that teacher teams spent a substantial portion of their time in initial meetings discussing their students' work on the assessments—determining what counted as evidence of which strategies, etc. Facilitators played a key role in connecting these conversations to information about student thinking more generally (sometimes in response to teachers' statements about student deficiencies) and also prompting teachers to connect information from the assessments to their planning/teaching practices. In addition, the charts with the distribution of student strategies provided a context for discussing differences in the how the unit assessments and the online assessment program supported instructional decisions.

Keywords: Professional Development, Research Methods, Instructional Activities and Practices

The idea that professional development should be done with teachers, rather than to them, means professional developers should account for teachers' perspectives as they design professional development (Desimone, 2009; Feiman-Nemser, 2001). Drawing on this, we know mathematics teachers have aspects of their instruction they are and are not pleased with. For example, a teacher may be pleased with how they go over homework, or they may not be pleased with how group work is facilitated in the classroom. It made us wonder, do teachers take up ideas from professional development based on self-identified areas of their teaching strengths, areas for growth, or somewhere in between? This study is set within the context of a professional development focused on teachers' uptake of instructional nudges (de Araujo et al., 2022), where teachers were given choice as to what they engage with. Instructional nudges are small suggestions closely aligned with teachers' practice that we hypothesize will have high uptake (de Araujo et al., 2022). In order to determine which of these nudges the teachers are taking up, we investigated the question of what instructional nudges do mathematics teachers select (or not select) and how do their choices relate to their identified areas of strength and growth?

We surveyed 7 Algebra teachers to identify aspects of their instruction they were pleased with or not, from a list of 15 (e.g., going over homework, facilitating discussion, group work). During the school year, we provided a set of 16 instructional nudges aligned to various aspects of teachers' instruction and provided choice as to which one(s) teachers might engage with. At the end of the school year, we interviewed each teacher about which instructional nudges they enacted in their classroom and the extent to which they loved or hated each instructional nudge. Preliminary findings suggest teachers were more apt to implement instructional nudges which aligned with aspects of their instruction they were pleased with. On the other hand, aspects of teachers' instruction they were not pleased with had more in common with nudges that were only implemented once. During our poster presentation, we will share visual displays of our results and discuss the types of instructional nudges that had the most uptake in relation to aspects of teachers' self-identified areas of strength and areas of growth in their classrooms. Discussion is welcome as we envision a future for mathematics professional learning opportunities for teachers and professional developers.

Numeracy has played an increasingly important role in schooling in recent years, with the recognition that individuals need to be numerate in order to cope with the mathematical demands of everyday life. One societal issue involving a great deal of mathematical information is climate change. We conducted a study to understand the Australian general public's (n = 144) climate change views, practices, and numeracy capabilities. Based on our analysis of questionnaire data, we found that many participants lacked understanding of climate change information presented in stacked bar graphs. Furthermore, several participants seemed unable to focus on the mathematical content of the numeracy questions; instead, they responded in emotional, non-mathematical ways. Consequently, we argue that numeracy education needs to include a focus on the dispositional aspects of numeracy, per the Goos et al. (2014) model.

Keywords: data analysis and statistics; mathematical representations

It has long been argued that one of the purposes of mathematics education should be to prepare individuals to cope with the mathematical demands of everyday life (Paulos, 1988). In the past decade, increasing emphasis has been placed on the role of numeracy, or mathematical literacy (See Forgasz et al., 2017, for a discussion of terminology), in schooling. For instance, in Australia, numeracy is one of seven general capabilities that must be incorporated across the curriculum, in order to "equip young Australians with the knowledge, skills, behaviours and dispositions to live and work successfully" (Australian Curriculum, Assessment and Reporting Authority, 2023, para. 1). One key aspect of being a numerate citizen is the ability to understand data that are presented in popular media and other contexts. These data pertain to a variety of aspects of everyday life, such as health (e.g., COVID-19 data) and politics (e.g., polling data).

Climate change is another topic for which data are presented using a variety of mathematical models and representations. The role of numeracy in the general public's understanding of and responses to climate change issues is complex and often has implications for climate change-related communication, governance, policy, and community education (Kahan et al., 2012). Numerate individuals can typically interpret and transform data into informed decisions and responses, aligning their perceptions with scientific concepts (Nurse & Grant, 2019). This capability, however, notably deviates in the context of climate change-related data, where individuals frequently resort to preferred interpretations that align with their ideological predispositions (Gilden & Peters, 2017; Nurse & Grant, 2019). Therefore, effective climate change education strategies need to focus not only on enhancing numeracy and scientific literacy but also on addressing the motivated reasoning influenced by psychological and ideological factors (van der Linden, 2021).

Recognising the significance of these climate change challenges, Monash University has identified climate change as a major focus area and has provided funding for research projects on this topic, such as our project. Given the limited research concerning the general public's numeracy capabilities in the context of climate change, we focused on the Australian general public's climate change views, practices, and numeracy capabilities. Here, we focus on our participants' numeracy capabilities, sharing findings from our analysis of questionnaire data.

Objectives

As mentioned, the purpose of our study was to understand the Australian general public's climate change views, practices, and numeracy capabilities. We also sought to understand participants' views of climate change and education, as well as whether there were any differences between non-teacher and teacher participants' responses. The research question that will be addressed in this paper is "What numeracy capabilities does the Australian general public demonstrate when interacting with climate change data?"

Theoretical Framework

We view numeracy in accordance with Goos et al.'s (2014) 21st Century Numeracy Model. Namely, context is central to numeracy: That is, numeracy involves mathematics being applied to a context, such as citizenship, work, and personal and social situations. However, numeracy is more than simply the application of mathematics to a real-world context: To be numerate, people need to have mathematical knowledge (e.g., problem-solving, estimation), positive dispositions toward the use of mathematics (e.g., flexibility, confidence), and the capabilities to use tools (e.g., representational tools like graphs, physical tools like rulers). The final aspect underpinning the model is critical orientation, which refers to the ability to consider the veracity of mathematical information, use mathematics to make decisions and support arguments, and question whether answers/outcomes make sense, particularly given the context. We used this model in the design of our numeracy questions, as well as our analysis methods.

Research Design

In the following sections, we describe the data collection instrument and issues encountered during data collection, share researcher positionality statements, provide participant information, and discuss our analysis process.

Data Collection Instrument

Our questionnaire, which contained both closed and open-ended questions, was posted on Qualtrics. There were approximately 20 questions (There were a few questions that were only asked of teacher participants), and the questionnaire took 10 to 15 minutes to complete.

In the first section, Demographic Information, participants were asked to indicate their state/territory, age range (Note: Participants had to be 18 years of age or older), gender, and highest level of education completed (multiple-choice questions). The gender question also had a textbox where participants could enter their gender if the options provided (i.e., woman, man, non-binary, and prefer not to say) were not suitable. In the second section, Climate Change and Education, participants were asked about their views regarding teaching climate change generally, as well as about their own experiences as students. Teacher participants were asked about their experiences teaching about the topic. In the third section, Climate Change Views and Practices, participants were asked more general questions regarding their views (e.g., re:

government policies) and practices (e.g., re: information sources).

The final section, Climate Change and Numeracy, is the focus of this paper. Participants were asked three levelled questions about a stacked bar graph (Figure 1) regarding youths' views of the severity of climate change compared to 12 other global concerns (Kessler, 2019).

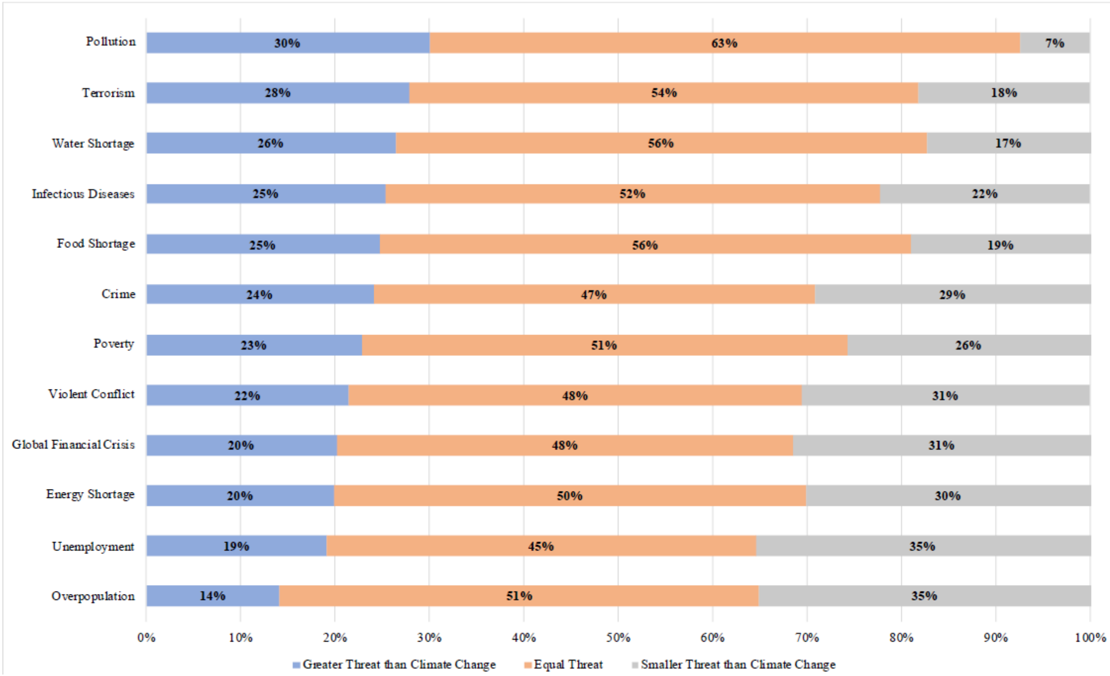

Figure 1: Comparison of Global Threat Severity and Climate Change (Kessler, 2019)

All three questions had multiple-choice response options, and the 'medium' question also had a text box where participants were asked to explain their answer.

Data Collection Issues

We advertised the study on Monash University's Faculty of Education Facebook page. Soon after the advertisement was posted, climate change deniers bombarded the post with negative comments, expletives, and calls for their contacts to complete the survey and skew our dataset. We held an emergency meeting within a day of these issues arising, during which our faculty media contact was notified by Facebook that the advertisement was being taken down due to complaints that it was 'political.'

Researcher Positionality

Our research team comprises academics with expertise in mathematics and numeracy education (Hall), environmental education (Almeida and Arachchige), and STEM education (Kidman). We combined our knowledge and experience to design this multifaceted project. Hall and Almeida led the data collection phase, and thus faced the reactions from the climate change deniers firsthand. We reacted very differently to the trolling, based on our relationships to climate change. Namely, Hall had a generalized reaction of anger and frustration, whereas Almeida felt personally attacked, given her experience working in environmental education.

Participants

In total, 144 participants completed the questionnaire. As hoped by the climate change deniers, the data were indeed very skewed: Most participants were older men (74.3% men; 67.4% over the age of 60). Fewer than 10% of participants were under the age of 50. Despite the skewed age and gender profiles of the participants, the educational qualifications of the participants were broadly nationally representative (Australian Bureau of Statistics, 2023).

Data Analysis

The multiple-choice questions were analyzed via descriptive statistics (counts, percentages). More complex statistical analyses could not be completed due to the skew in the dataset. Responses to the open-ended question were analyzed through via emergent coding (Creswell, 2014). That is, the responses were read several times to get a sense of the dataset. Initial codes were then created and applied. Following this process, codes were combined and refined.

Results

In the following sections, we discuss the findings for the three numeracy questions. Although 144 participants completed the questionnaire, far fewer people responded to the multiple-choice numeracy questions, which may be indicative of people's discomfort with mathematical content, or response fatigue, as the numeracy questions were near the end of the questionnaire.

'Easy' Question (*n* = 78)

The 'easy' question involved participants selecting which of four provided options had the lowest percentage of respondents (from Kessler, 2021) who selected 'equal threat'; hence, only one piece of data from each bar on the graph was required to answer the question. Approximately two thirds of participants (65.4%) responded correctly.

'Medium' Question (*n* = 76)

The 'medium' question involved participants indicating which of the 12 threats was viewed most similarly to climate change (by the participants in Kessler's study). Not only were there more response options than there were for the 'easy' question; the question's wording was less direct. Consequently, a lower proportion of respondents (47.4%) selected the correct response. Participants were provided with a text box in which to explain their multiple-choice selection. Several participants took this opportunity to make non-mathematical comments, such as "STOP SCARING AND DEMORALISING OUR YOUTH WITH THIS RUBBISH!!" (P91). Notably, 14 participants who had not responded to the multiple-choice question still wrote something in the textbox. Of the participants who answered the multiple-choice question correctly, half provided a mathematical explanation in the text box, compared to only 20% of the participants who answered the multiple-choice question incorrectly.

'Hard' Question (*n* = 75)

The 'hard' question was "Which of the following global threats has the **most similar** percentages of respondents who answered **greater threat than climate change** OR **smaller threat than climate change**?" An example of the percentages for these two categories was then provided for Overpopulation. As with the 'easy' question, participants had to select from four options; however, they had to utilize two pieces of information from each bar to respond to the 'hard' question. Participants struggled with this question, with only 42.7% responding correctly.

Discussion and Conclusions

Numeracy is a crucial capability for adults to possess and develop, particularly as society becomes more data-drenched. In our study, we sought to understand adults' capacity to analyze graphs involving climate change data. Despite the questions being at an elementary school level, fewer than half of the participants were able to correctly identify the correct response to the 'medium' and 'hard' questions. Concerningly, many participants seemed unable to focus on the mathematical concepts at hand due to their emotional responses to the topic. At the conference, we plan to share additional findings by participant group.

Acknowledgements

We wish to acknowledge the financial support provided for this research project by the Impact 2030 research grant program from the Faculty of Education at Monash University.

Data literacy promotes understanding of statistics about society (Engel, 2022) and as educators, we should arm students with data tools to form their opinions about phenomena in the world (Gal, 2002, 2023). An NSF project, Data Science Infused for Undergraduate STEM Education (DIFUSE), seeks to integrate data science into college introductory courses and develop modules that provide students with visualization tools that offload timely computation. These modules allow students to apply mathematics and statistics concepts to gain an understanding of data. A module was adapted for use with high school students. Our study investigates students' interests, experiences, and resources related to data science.

Keywords: Data Analysis and Statistics; High School Education; Instructional Activities and Practices; Affect, Emotion, Beliefs, and Attitudes

The 21st-century workforce is increasingly data-centric, emphasizing the importance of exposing students to data science, ideally starting from K-12 education (Franklin & Bargagliotti, 2020). In an era dominated by data, the modern student needs education to focus on being both a producer and a consumer of statistics (Gould, 2017). Researchers suggest that media reports can motivate students and visualizations coupled with proper scaffolding aid conceptual understanding (Budgett & Rose, 2017). To address this imperative, we adapted a data science module developed in a college environmental studies class for use in high school classrooms. This original module was to cultivate students' interest in data science, by showing practical applications of data science across various fields. We intentionally selected a module that did not require mathematics and statistics content beyond the high school level.

Objectives

We enacted a lesson with a module (DIFUSE Team, 2023) in high school classes to evaluate its use in high school and students' responses. Our research question is how are high school students' interests, experience, and resources related to data science impacted through their work with a data science module? The module uses Louisiana COVID data with a focus on death rates and includes demographic, geographic, and environmental data such as air quality. It provides students with three visualizations (interactive map, correlation matrix, and regression) to aid their understanding. We made modifications to the lesson as appropriate for high school students. Recognizing that many students struggle with mastering key mathematical concepts such as proportional reasoning and geometry, we started the lesson with an activity aimed at clarifying the difference between the number of deaths and the death rate. We used CDC's Data Visualization which allows worldwide analysis of COVID deaths and death rates. We discussed adding a third quantitative variable to a scatterplot by using a bubble chart. We used The Learning Network's [What's Going on in this Graph: Earthquakes] to evaluate whether bubbles should be scaled by area or diameter. Given that Data Scientists vary in technical expertise and most high school students are not proficient in computer programming, we gave them the option to either review and modify the Python code or create a change request form to scale the bubbles correctly. Although lesson modifications were made for high school students, the data and visualization tools used remained the same.

Framework

As we designed the lesson, we used the DIFUSE framework to provide coherence throughout the data investigation (see Figure 1). Like many other data science frameworks, this simply granularizes some of the broader categories of the GAISE II statistical problem-solving process (SPSP) of (1) Formulate Statistical Questions, (2) Consider/Collect Data, (3) Analyze the Data, and (4) Interpret the Results (Bargagliotti et al, 2020).

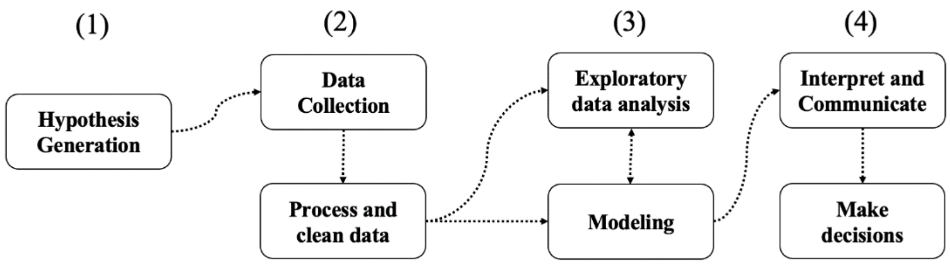

Figure 1: [Report] and [Project] Framework relationship

SPSP was initially developed as part of the original GAISE Pre-K–12 guidelines (Franklin et al., 2007) to infuse statistics in Pre-K–12 education. These efforts to create data-literate high school students were used as a basis for probability and statistics within the Common Core math standards. The SPSP is not necessarily a linear process and curiosity should remain throughout. Analyzing data might prompt new questions that require additional data to be collected or considered. With the increased availability of data, one of the changes to the original GAISE SPSP was the addition of "consider" data, allowing an investigation to start with reviewing data before formulating a statistical investigative question.

This data investigation allowed the students to start with the data and use some visualization tools to analyze data, continually question, and formulate a statistical investigative question. We scaffolded their work to encourage them to think more deeply and communicate the data in a way that answers the statistical investigating question they created. To complete the SPSP and communicate their results, the final product for each group was to complete a poster and submit it to [ASA's high school data visualization contest].

Methods

We utilized a mixed methods approach, blending qualitative and quantitative research techniques. This approach enabled us to thoroughly comprehend the research subject by incorporating diverse data types and viewpoints (Creswell & Creswell, 2017). This study focuses on an AP statistics class of 23 students in the southeast where students used the modified environmental studies module to understand relationships of quantitative variables. They had prior instruction on analyzing one quantitative variable and used CODAP, calculators, spreadsheets, and some applets to visualize data.

To assess students' interests, experiences, and resources and how they were impacted by this lesson, we created an adapted version of the DIFUSE Survey of Attitudes toward Data Science (SADS, Li et al, 2018). This included 14 items, both qualitative and quantitative questions (e.g., "I feel capable when measuring the relationship between two quantitative variables" and "Explain what you would consider when looking at the relationship between two quantitative variables"). Survey data were gathered as pre- and post-module deployment and the initial survey was given prior to any instruction on two quantitative variables, but after the students had worked with one quantitative variable (e.g., center, variation, distribution, z-scores). In the post-surveys, students reflected on their experiences and responded whether they were interested in participating in an interview. We selected students based on their work and classroom discussions within their groups. We interviewed three students using a semi-structured approach, creating recordings and transcripts. Interviews included open-ended questions (e.g. "How was the process of working with the data science module?"). We employed emergent coding due to the broad and exploratory nature of our research question (Blair, 2015).

Results

The students held positive views regarding their attitudes and beliefs about data science both before and after the module. Most consistently valued data science, displaying interest in working with data and recognizing the importance of data science skills for their future. Most students report not getting too frustrated when working with data. An interesting shift from pre- to post-surveys was related to components of the SPSP: (3) Analyze Data and (4) Communicate Results. Although the students' strong desires to communicate with data increased substantially (by roughly 80%), their inclination to analyze the data decreased (see Table 1).

Table 1: Pre- and Post-Survey Results for (3) Analyze Data and (4) Communicate Results

	Pre-Survey	Post-Survey	Percent Increase (Percent Decrease)
Strong desire to communicate with data	31%	56%	81%
Inclination to analyze data (likely)	40%	54%	35%
(very likely)	44%	31%	30%

This was a similar finding to what had been witnessed in DIFUSE modules at the college level. They appreciated having the computation offloaded and using the results of the visualization tools to gain insights and communicate findings.

Our survey also included some open-ended questions and from a qualitative perspective, students were glad to have multivariate datasets and work through the entire statistical problem-solving process. They specifically mentioned that it was "interesting" and "enjoyable" to analyze complex, multivariate data with visualization tools to complete an in-depth investigation. The frustration that students felt arose from not understanding certain aspects, making errors, or experiencing difficulties with tools and resources. There was a shift towards a more positive attitude and increased confidence in working through the statistical investigative process with a large multivariate dataset. From a skills perspective, students noticed an improvement where they no longer conflated analyzing one quantitative variable with analyzing more than one quantitative variable. Additionally, their descriptions of relationships were more refined, for example including strength, direction, and form.

Our interviews confirmed the survey findings and provided some interesting feedback about their interests, resources, and experiences which students were asked to self-rate on a scale of 1-10. Interest increased by 78% on average and was driven by the novelty of the interactive map and correlation matrix, working with multiple variables, and having to communicate results formally. One student stated, "I felt like a real data scientist". Experiences increased on average by 133% and can be attributed to grappling with the new visualizations, seeing actual computer code, and completing an entire investigation (SPSP) using real data. Resources showed the largest increase of 162% on average. This was due to students continually questioning and iterating to include more variables in the explanation of the real-world phenomenon and gaining a better understanding of r-squared and p-values and how they connect to a graph. One student commented on his opportunity to (4) Interpret the Results:

"…this project helped me to better communicate a couple of different statistics like the p-value. I learned how to interpret and communicate the data better".

Based on the findings of the analysis, it is evident that the data science module had a significant positive impact on students' interests, experiences, and resources related to data science. The majority of students valued data science, showing increased interest in working with data and recognizing its importance for their future. Overall, the data supports the effectiveness of the data science module in enhancing students' interests, experiences, and resources related to data science.

Discussion and Conclusions

Overall, high school students were able to work with a modified DIFUSE module which not only deepened their understanding of the content but increased their engagement and made them feel like real data scientists when completing an investigation. The positive shift in students' attitudes and beliefs towards data science highlights the importance of incorporating practical, hands-on experiences in data science education. By engaging students in real-world data analysis projects using the SPSP, educators can not only increase students' interest in the subject but also enhance their skills in data analysis (Hicks & Irizarry, 2018). By exposing students to a variety of data visualizations and analysis techniques, educators can help them develop a more comprehensive understanding of data science concepts and improve their analytical skills

(Bargagliotti, 2020; Keller et al., 2020). This study highlights the importance of incorporating practical, hands-on experiences in data science education to enhance students' interests, experiences, and resources in data analysis. By doing so, educators can better prepare students for careers in data science and related fields. Modules that provide students with data alongside tools that offer visualizations and offload computation might help students. This could aid their conceptual understanding and allow them to navigate throughout the SPSP asking more questions to tell more intricate stories. Future work might consider studying students' conceptual change, implementing this module in other classes, and developing different modules for high school classes based on teacher and student interests.

DEDUCTION, INDUCTION, AND ABDUCTION: STUDENTS' WAYS OF REASONING ABOUT SAMPLING DISTRIBUTIONS

Claire Miller
University of Georgia
clairemiller@uga.edu

Statistical reasoning is inherently different from mathematical reasoning because reasoning about data involves reasoning with uncertainty. In mathematics, deduction and induction are privileged, but abductive reasoning can be powerful when reasoning about data, especially when making inferences from sample data. This study examines three classic forms of inferential reasoning—deduction, induction, and abduction—novice statistics students employed during two task-based clinical interviews. All three forms of reasoning were evident, though not all were productive. Findings suggest that inductive reasoning is productive when estimating sampling variability and abductive reasoning is useful when estimating an unknown population parameter.

Keywords: cognition, data analysis and statistics

Understanding ideas of sampling, sampling distributions, and statistical inference are important for improving students' statistical literacy and productive citizenship. Data are everywhere. Data collected from samples are often reported in the form of polls, medical studies, and advertisement information and an understanding of sampling distributions and statistical inference is important for evaluating data-based claims (Bargagliotti et al., 2020; Ben-Zvi & Garfield, 2004; Garfield et al., 2015; Saldanha & Thompson, 2007). Consistent with the conference theme of "envisioning the future of mathematics education," it is important to acknowledge the growing prevalence of conflicting reports in the media and support students in becoming "critical consumers" of these statistically-based results (GAISE College Report ASA Revision Committee, 2016, p. 8).

The concept of sampling distribution is a foundational concept in statistical inference, which is the main focus of introductory statistics courses, whether at the secondary, undergraduate, or graduate level (Ben-Zvi et al., 2015; Lipson, 2003). Despite the importance of understanding statistical inference and sampling distributions, research suggests that students struggle with these ideas (Saldanha & Thompson, 2002, 2014; Sotos et al., 2007). Although many students can carry out the calculations involved in formal inference procedures, such as confidence intervals and hypothesis tests, they often struggle to understand the underlying process and logic behind statistical inference (Chance et al., 2004). One reason for this difficulty stems from the complex and abstract concept of sampling distribution, which requires students to coordinate multiple ideas such as sample, population, distribution, variability, and repeated sampling (Noll & Shaughnessy, 2012). I argue that another source of difficulty is that the forms of reasoning that are expected and highlighted in statistics differ from those that are standard in mathematics.

Theoretical Framework

Statistical reasoning is inherently different from mathematical reasoning. Mathematical reasoning is often deterministic, emphasizing deductive reasoning and proof. In contrast, statistical reasoning *lacks* definitiveness and includes probability, randomness, and uncertainty (Groth, 2015). Reasoning is typically defined as a process of transforming given information to develop a conclusion or make an inference (e.g., Galotti, 1989; National Council of Teachers of Mathematics, 2009). Deduction, induction, and abduction are three classic forms of inferential reasoning and can be modeled with a triadic structure involving a case, rule, and result that are linked in a particular order (Peirce, 1878; Reid & Knipping, 2010). A *case* is a specific observation that a condition holds. A condition describes an attribute of something, or a relation between things. A *rule* is a general proposition that states that if one condition occurs then another one will also occur. A *result* is a specific observation, similar to a case, but referring to a condition that depends on another one linked to it by a rule. The order in which one links a case, rule, and result determines the kind of inference—deduction, induction, or abduction—needed to make a conclusion. In deductive reasoning, a rule and a case conclude a result. In inductive reasoning, a case and a result (or often, many cases and many results) lead to a rule. In abductive reasoning, a result and a rule infer a case. Consider the different ways case, rule, and result can be linked in Peirce's (1878) original example about a pile of beans found on a table: (1) If I know that all of the beans in the bag on the floor are white (the rule) and that a pile of beans on the table is from the bag on the floor (the case), then I can *deduce* (with certainty) that all of the beans in the pile on the table are white (the result); (2) If I know that a pile of beans on the table is from the bag of beans on the floor (case) and that all of the beans in the pile on the table are white (result), then I can *induce* that (probably) all of the beans in the bag on the floor are white (rule); and (3) If I know that all of the beans in the pile on the table are white (result) and all of the beans in the bag on the floor are white (rule), then I may *abduce* that (possibly) the pile of beans on the table is from the bag of beans on the floor (case).

Although mathematics and statistics can share similar forms of reasoning, the emphases in each field differ. In mathematics there is an emphasis on deduction and proof, arriving at conclusions with certainty, and establishing truth. Although deduction can occur in statistics with the application of general rules to particular sets of data, such as using a rule to determine outliers in a set of data, the emphasis in statistics is not on deduction. Instead, it is on reasoning with uncertainty, a feature of both inductive and abductive reasoning. Thus, it is productive to examine how students reason about foundational statistical ideas, such as sampling distributions, from this lens.

Methods

Participants for this study were eleven undergraduate students who recently completed an introductory statistics course. The data come from two clinical interviews, each 60-75 minutes in length, in which participants worked through a series of statistical tasks related to sampling distributions. I investigated the question: What forms of reasoning do novice statistics students employ when reasoning about sampling distributions?

In the first interview, I gave participants information about students at a large university with a known parameter of interest (20% of the undergraduates are business majors). I asked them to do each of the following: provide an interval estimate for the outcome of any single random sample, predict the sample proportion for many hypothetical random samples of size 100, physically drew many samples from a large box of beads with proportions corresponding to the population, examine the collection of sample outcomes, and compare their predictions to their actual sample outcomes. Participants then used a web-based applet to simulate taking 500 random samples of size 100 and provided an updated interval estimate for the outcome of any one single random sample. In the second interview, participants drew one sample from a second box of beads, simulating all students at a second large university with some unknown parameter of interest (the box was covered so the contents were hidden from the participants). Based on one sample outcome, participants made an initial prediction for the unknown population parameter, tested and refined their prediction using the web-based applet, and ultimately provided a range of plausible values they believed captured the true population proportion.

After checking and timestamping interview transcripts against the video recordings of the interviews, I identified reasoning excerpts—instances in which participants provided justification or explanation for a claim. For each reasoning excerpt, I identified case, rule, and result, then examined how the participant linked them to infer the form of reasoning they employed. At this time, I have analyzed interview data for nine participants. This paper reports preliminary results from my analysis for this subset of participants.

Results

When giving a range of percentages they would expect to get in any one single random sample of 100 drawn from a large university with 20% business majors, participants reasoned deductively *prior* to drawing any physical or simulated samples and inductively *after* drawing many physical and simulated samples. Prior to drawing any samples, six participants gave an interval estimate with a margin of error between 5% and 10% and provided various justifications for their choice of margin of error. Tami explained that "5 is a good number," whereas Eric drew on his previous experience in chemistry: "If you're assigned a study and they have this number as the assumed...like when you cook this compound it should weigh about this…as long as you're within 5% of that, then you're not wildly off." Although their reason for choosing 5% as their margin of error differed, both Tami and Eric applied their rule (random sampling produces outcomes that vary from the population parameter by about 5%) to a case (a random sample of 100 was drawn from a large university with 20% business majors) to *deduce* a result (the sample outcome should be between 15% and 25%). After drawing many physical and simulated samples, all but one participant updated their interval estimate based on similarities they observed in the samples they had drawn. For example, Jess updated her initial range (11% to 29%) to 15% to 25% and referenced both the physical and simulated samples she drew: "I'm going off of the curve here and kind of off of the samples that I did…[there are] a lot of dots gathered around 15 and then around 25 and after that it kind of drops pretty dramatically." Similarly, Lyla justified her range of 10% to 30% based on similarities she observed in the physical and simulated samples she had drawn: "From the samples we've taken so far…we've taken a lot…but I don't think we've gone above 30 and we haven't really gone below 10." Although participants provided different ranges, they used multiple cases (all of these random samples were drawn from a population of undergraduates with 20% business majors) and multiple results (most of these samples produced outcomes between [lower bound] and [upper bound]) to *induce* a rule (I expect that any one single random sample of 100 drawn from this population to produce a sample outcome between [lower bound] and [upper bound]).

In the second interview, participants made a prediction for the unknown population parameter based on their one sample outcome from the second box of beads. When asked how they could test their prediction, six participants reasoned inductively when they proposed drawing more samples from the box of beads to look for a pattern. However, when asked how they could use the web-based applet to test their prediction, all but one participant reasoned abductively to hypothesize and evaluate multiple populations (with different parameters) from which their single sample could have been taken. Initially, Lorraine said, “Take a ton of samples to see what the actual proportion is. [Look for] the center of [the distribution], so the mean or the median, so we could see where the true proportion is.” Tyra also wanted to collect more samples from the box of beads to see “where they group up…where the center is.” Lorraine, Tyra, and others proposed using multiple cases (multiple random samples drawn from the population with an unknown parameter) and multiple results (observing where the sample outcomes are centered) to *induce* a rule (the true population proportion). Later, Lorraine tested 60% by constructing a simulated sampling distribution using the web-based applet, ultimately deciding it was a plausible value for the unknown population parameter: “It looks like [my sample outcome of] 52 would be reasonable [because] there's a pretty significant number of results that are 52. And then past that is where [the distribution] tends to kind of taper out.” Lorraine used a result (one random sample of 100 produced a sample outcome of 52 business majors) and a rule (a population with 60% business majors produces several sample outcomes of 52) to *abduce* a case (the sample I drew could have come from a population with 60% business majors). Lyla reasoned similarly to decide that 30% was *not* a plausible value for the unknown population parameter based on her sample outcome of 46%: “Looking at this [dot plot], 46 doesn't seem very likely to occur…that probability is looking very low. I would expect a number not to exceed 42. Based from this, I would say 0.3 isn't a good prediction.” Both Lorraine and Lyla continued to test multiple values, ultimately abducing a range of plausible values for the unknown parameter. Lyla’s abduction was particularly powerful for her, enabling her to make sense of the process and logic behind constructing an interval estimate for the unknown parameter:

> That was just really cool to go backward. When you take stat, it’s like oh, we have this confidence that this number is going to fall in blah, blah, blah, blah. But working backwards shows the logic behind it even more. I thought it make sense to me before…our rationale for drawing these conclusions. But going backwards, it’s another level of understanding.

Discussion

This study provides insight into novice statistics students’ existing ways of reasoning about sampling distributions. As reported in the results, each form of reasoning was evident in at least one participant’s thinking about sampling distributions. However, not all three are productive ways of reasoning. Inducing an interval estimate for a single random sample was productive because participants were able to estimate how far a sample statistic varies from the population parameter. In addition, participants later used their interval estimate to determine whether particular sample outcomes were surprising. Although productive in such cases, inductive reasoning may not be productive when making inferences from sample data to an unknown population of interest. Lorraine and others proposed drawing multiple samples from the population with the unknown parameter, and observing where the sample outcomes clustered to determine the true population parameter. Reasoning inductively in this way is productive if the population of interest is a box of beads from which samples are easy to collect. However, the box of beads represented students at a large university; it is not feasible to draw multiple random samples of students from a large university. Instead, reasoning abductively is productive in this scenario. Participants who reasoned abductively to hypothesize and evaluate multiple values for the unknown population proportion were successful in making an inference from one sample to the larger population from which it was drawn by estimating the unknown parameter.

Supporting students in reasoning abductively is especially important because this kind of reasoning differs greatly from the forms of reasoning students have experienced in their K-12 years in mathematics classes that privilege deduction. Providing students with opportunities to make and test multiple predictions when drawing conclusions from data is one way to support students in reasoning abductively. Thus, this study has the potential to inform task development, specifically designing tasks that promote abductive reasoning. Supporting students to reason in this way can help them develop strong statistical reasoning skills to critically evaluate evidence and claims based on data, a crucial skill needed for living in a data-driven society.

REFUTATION TEXT OFFERS MIXED EFFECTS ON NIGERIAN PRE-SERVICE TEACHERS' USE OF THE REPRESENTATIVENESS HEURISTIC

Modiu Olaguro
Virginia Tech
olaguro@vt.edu

This study enlisted a refutation text to foster conceptual change among 71 preservice teachers of mathematics education in situations that might elicit the use of the representativeness heuristic. Statistically significant differences were found between respondents' pre- and post-tests, with more than half exhibiting normative reasoning after prior use of the heuristic. Analysis of their written explanations revealed differential patterns in their reasoning across two effect categories. Implications for misconception research and practice are discussed.

Keywords: Conceptual Change, Probability, Refutation Text, Representativeness.

Probabilistic misconceptions have been documented to differ in the extent to which they are amenable to change (Jones et al., 1997), with the representativeness heuristic being a prominent one. As the name suggests, it involves quantifying the occurrence of a random phenomenon "by the degree to which it: (i) is similar in essential characteristics to its parent population; and (ii) reflects the salient features of the process by which it is generated." (Kahneman & Tversky, 1972, p. 430). A variety of studies have been conducted to ascertain the prevalence of the heuristic among different populations, especially preservice teachers (PST). In Wilkins (2007), 11 out of 15 PSTs relied on it. The rate was 17.5% in Kustos and Zelkowski (2013).

Several efforts have been made for the jettisoning of misconceptions for normative ideas. They have mostly included programs involving predictions and data analyses through engaging in experiments and simulations (Fischbein & Gazit, 1984; Jones et al., 1997). Although these interventions have returned modest gains, the fruitfulness of conceptual change (CC) strategies in overcoming mathematical misconceptions (Lem et al., 2017) may offer a commensurate path to forging acceptable conceptions of probability. Consequently, this study adopts one CC approach—refutation text—as a probable mechanism to overcome the misconception involving the use of the representativeness heuristic among PSTs.

Theoretical Framework

Refutation texts: offering a switch from S1 to S2

Misconceptions are known to be resistant to change because they portray beliefs about chance phenomena. And since beliefs are personal, subjective truths, the feeling of agency conditions the holder to stick to them irrespective of their source. With an alternative conception offering valid explanations in certain contexts (Savard, 2014), the automaticity and effortlessness (see properties of S1, Kahneman, 2003) characterizing alternative conceptions purports to be valid across contexts. Consequently, getting the holder toward CC will involve a radical shift from existing to new conceptions, abled due to at least three reasons: dissatisfaction, intelligibility, and plausibility (Posner et al., 1982).

A refutation text (RT) offers an avenue for enabling this switch. By exposing the misconception, a cognitive conflict is created that might cause a person to attend to salient aspects of the problem they would otherwise not have. Based on the strengths of the belief, this encounter with such explicit information prepares the ground for alternative explanations that might help resolve the conflict, setting the stage for an activation of a cognitive ecology that decontextualizes the problem, a feature of S2 thinking (Kahneman, 2003).

Commonly used RTs are characterized by three properties: (1) description of a misconception, (2) refutation of the misconception, and (3) subsequent provision of a normative conception (Chi, 2008). Refuting a misconception comes with reasons why such beliefs are not viable, generalizable, or consistent, to—as Leron and Hazzan argue—bring "S2 to intervene in its role as critic of S1" (2006, p. 109). Consequently, it may be valuable to enlist a RT to answer the following questions: (1) What are the effects of a RT on PSTs' use of the representativeness heuristic? (2) What qualitative affordances exist within and across the pattern of effects?

Methods

The study involved 71 PSTs of mathematics education at a university in south-western Nigeria. Following informed consent, they were issued a pre-test containing a question to elicit their use of the representativeness heuristic which was immediately followed with an issuance of the RT (without being told about a post-test which was administered after 2 hours).

Table 1: Pre-test and Post-test on the Representativeness Heuristic

Pre-test	Post-test
An experiment requires you to flip a penny 100 times and record whether the penny comes up <u>heads</u> or <u>tails</u>. On the first 10 flips the penny comes up <u>heads.</u> After flipping the penny 90 more times, how many <u>heads</u> would you expect to get out of the total 100 flips? Answer………..… (Please explain your answer below).	Suppose you toss a fair coin six times, recording the result of each toss. For instance, if you toss a <u>head</u> and then five <u>tails</u> in a row, you would write H T T T T T. Which is the *least likely* result? (a) H T H T H T (b) H H T H T T (c) H H H T T T (d) T T T H T T (e) All are equally likely. (Please explain your answer below).

Following the plurality of indicators of the representativeness heuristic (see Tversky & Kahneman, 1974), I adopted the hermeneutical position of content analysis (Mayring, 2015) to develop a RT—that largely attended to the misconception of chance indicator of the heuristic typified by less runs and more switches—with a goal of influencing S1 thinkers to interrogate their reasoning to fit into S2. The RT was content-validated by a professor of mathematics education who teaches a graduate-level probability methods' course. The content of the RT is as shown in Table 2.

Table 2: Refutation Text on the Representativeness Heuristic

Refutation Text

In a game of Ludo[3] between Ghufran and Imran, Ghufran threw three double sixes and a 3,4 (i.e., 6-6, 6-6, 6-6, 3-4). When it was Imran's turn, he threw a 4-5. After counting his scores, Ghufran again threw almost the exact same sequence (i.e., 6-6, 6-6, 6-6, 1-5). In protest, Imran said the game was rigged, threatening to opt out of it. While it may be difficult to convince him otherwise, the scenario does not in any way suggest cheating but a valid random process. Specifically, underlying such thinking is a misconception called *representativeness*. Because the throw of the pair of dice represents a random process, individuals often expect the outcomes to appear in a strictly random manner however short or long the sequence. Had Ghufran thrown a sequence like 6-6, 5-4, 3,2, 1-3, 4-4, 1-6, 1-1, 4-2 rather than 6-6, 6-6, 6-6, 3-4 and 6-6, 6-6, 6-6, 1-5 on his first eight throws, Imran might not have alleged rigging. But both sets of outcomes represent valid random processes. As such, they have the same chance of occurring.

To analyze the data, I coded the keys 1—for both pre- (*55*) and posttests (option *e*)—and other options 0, making the data suitable for analysis using the McNemar (Binomial) Test. To answer RQ1, the test was used to determine if an intervention effect existed as measured by changes either in the positive or negative direction. To answer RQ2, two respondents' written explanations were described across positive and negative effects.

Results and Discussion

Quantitative

The RT had a major influence on 48 PSTs (see Table 3). Specifically, 40 respondents switched from the heuristic use to normative conception. In contrast, a fifth of those that were positively influenced were impacted negatively by the intervention. The RT also had no effect on 18 respondents. 5 respondents were consistent in their exhibition of the normative conception at the pre and posttests (reinforcing effect). Collapsing the rows (pretest) and columns (posttest) shows the prevalence of this misconception before (81.7%) and after (36.6%) the intervention. Similarly, 18.3% and 63.4% were without the misconception before and after. Overall, I documented a statistically significant change in PSTs' responses (N=71, p<.001) associated with pre and post-test, suggesting that the RT had an effect in getting PSTs to undergo CC.

Table 3: Prevalence and Changes in the use of the Representativeness Heuristic Before and After Intervention

	All		
	0	1	T
0	18	40	58
1	8	5	13
T	26	45	71

[3] Ludo is a boardgame played by 2 or 4 people. A turn is initiated when an opponent fails to throw a double six on a pair of dice.

Qualitative Differences

In this section I provide excerpts from two respondents who made switches between S1 and S2 thinking as inferred from results of the quantitative analysis.

Table 4: Excerpts Across Positive and Negative Effects

Effects	Excerpts	
	Pre	Post
Positive	Since each flip of a fair coin is independent, the probability of getting heads remains 0.5. Therefore, you would expect to get heads approximately 50 times out of 100 flips, regardless of the outcomes of the first 10 flips.	They are equally likely to have the same result because the probability of getting head or tail in each outcome is equal.
Negative	The chances of getting heads and tails are equal because you cannot determine how many heads will come up after the total experiment but since we have 10 flips already and the chances of the remaining 90 times flipping is equal, you can say 10+½(90) = 55.	The least likely result of the tossing of a fair coin six times is getting three heads and three tails in a row as a possible outcome of an event.

The explanations from the respondent (Opebe) who made a positive switch show an understanding of randomness at the pre and post-tests. Therefore, evidence for the influence of the RT in causing Opebe to engage in the slow, systematic thinking of S2 at the posttest lies in his jettisoning of the need to balance out the outcome, causing him to conceive of all the options as equally likely. In contrast, a scrutiny of Moladun's excerpt presents unclear results even as I classified its effect negative. While she avoided the heuristic at the pretest by applying the base-rate frequency, she initially claimed that the probability was indeterminate. It is possible her answer at the post test was more of an outcome approach (see Konold, 1989) than a desire to map the sample to population. For this reason, it is not clear if the RT really had a negative effect on her because a similar reasoning that masks misconception of chance (see Tversky & Kahneman, 1974) undergirds her explanations both before and after she engaged with the RT.

Conclusions

This study set out to ascertain the effects of a RT on PSTs use of the representativeness heuristic. Based on quantitative analysis, the intervention promoted CC although posing differential effects on the respondents. Qualitative analysis showed that the intervention was mostly effective when the RT matched with the specific representativeness indicator. Owing to the demonstrated potential of the intervention, it may be valuable to enlist CC strategies into the design of instructional programs for fostering normative probabilistic ideas. Therefore, textbook authors may find the structure of RTs useful as a complement, or alternative to the existing writing style that largely involves mere presentation of normative ideas. Overall, this study offers preliminary evidence for an approach other than experiments and simulations in building probabilistic conceptions, one that may especially be worthwhile in countries where students have little access to materials to conduct such experiments.

Limitation and Future Research

Restricting the RT to a single indicator of representativeness (misconception of chance) is a major limitation of the study. For this reason, the RT better attends to the post test than the pretest whose normative reasoning owes to attending to the base-rate frequency. Future research might incorporate more indicators that would lend the RT to a broad array of chance situations.

Acknowledgments

This brief report was built on the readings and ideas from the probability course I took from my doctoral advisor, Dr. Jesse Wilkins, which underwent more thought in courses with Dr. Estrella Johnson and Dr. Marcus Johnson. Dr. Marcus Johnson particularly introduced me to CC and suggested that I look beyond describing misconceptions to fostering CC. I'd like to thank them, and Dr. Adeneye Awofala and Mahmud Olaguro for helping with the data collection.

En esta investigación se analiza cómo estudiantes de bachillerato avanzan en la conceptualización de la recta de mejor ajuste usando tecnología. Veintidós estudiantes participaron en parejas en un taller con tres actividades centradas en la relación entre dos variables. Las tareas incluyeron construir y analizar diagramas de dispersión, interpolar y ajustar una recta, y manipular una recta en GeoGebra para minimizar la distancia a los puntos. Los resultados se agruparon según similitudes en las respuestas, destacando el desarrollo de una comprensión global de los datos. Se identificaron tres fases clave en la conceptualización de la recta de mejor ajuste: usar el diagrama de dispersión, interpolar una recta en la nube de puntos, y entender los residuos y minimizar la distancia entre la recta y los puntos. Se concluye que el uso de dispositivos tecnológicos permite a los estudiantes formar conceptos para concebir la recta de mejor ajuste como un agregado.

Palabras clave: Informal Education; Data Analysis and Statistics; Technology.

Introducción

La enseñanza de la estadística es crucial en la sociedad actual, donde la abundancia de datos requiere ciudadanos capaces de analizarlos y tomar decisiones informadas. La correlación y regresión son tópicos fundamentales de la estadística, y presentan desafíos educativos debido a la necesidad de articular aspectos matemáticos y estadísticos. Aunque se desarrollan en cursos universitarios, también se abordan en niveles educativos básicos y medios, con enfoques diferentes. En el nivel bachillerato, la correlación y regresión aun requiere enseñarse desde un enfoque informal por la carencia por parte de los estudiantes de las herramientas matemáticas necesarias. Para un enfoque informal los recursos tecnológicos, como CODAP y GeoGebra, ofrecen la oportunidad de apoyar a los estudiantes en dichas circunstancias para que adquieran las ideas centrales del tema.

La idea de "agregado" es muy útil en la educación estadística para interpretar el nivel de comprensión de los estudiantes de conceptos estadísticos, pero también para señalar un objetivo de aprendizaje. Algunas investigaciones revelan que los estudiantes tienden a enfocarse en detalles individuales de los datos en lugar de considerar propiedades del conjunto completo de datos (Bakker y Gravemeijer, 2004; Konold y Higgins, 2002). Esta tendencia se observa en varios conceptos estadísticos, entre ellos, el de la recta de mejor ajuste, donde al trazarla con sus recursos intuitivos los estudiantes suelen centrarse en algunos datos específicos en lugar de buscar combinar todos los datos para que estén representados por la recta resultante. Las actividades propuestas en este estudio utilizan la tecnología para propiciar que los estudiantes formen conceptos que les permitan entender como combinar los datos para dar lugar a la recta de mejor ajuste. El artículo propone actividades con CODAP y GeoGebra para responder la pregunta ¿cómo los estudiantes de bachillerato conceptualizan la recta de mejor ajuste con ayuda de la tecnología?

Antecedentes

Los estudios con estudiantes universitarios revelan interpretaciones erróneas del coeficiente de correlación (Truran, 1995) y una mejor capacidad para estimar la correlación a través de diagramas de dispersión (Sánchez-Cobo et al., 2000). Sorto et al. (2011) identifican tres estrategias intuitivas que utilizan los estudiantes universitarios (tecnología industrial) y futuros profesores para trazar la recta de mejor ajuste: 1) una que divide los puntos de datos por la mitad, 2) una que pasa por puntos medios, 3) una que une el primer y el último punto. Tales estrategias muestran que el criterio de minimizar las distancias de los puntos a la recta para obtener la recta de mejor ajuste no es intuitivo. En niveles de secundaria y bachillerato, Hourigan y Leavy (2021) hallaron que estudiantes de sexto grado a menudo tienen una comprensión local de la asociación estadística y enfrentan dificultades al crear gráficos de covariación, mientras Moritz (2004) y Watson y Moritz (2007) identifican distintos niveles de razonamiento en la interpretación de estos gráficos. En cuanto a la concepción de la correlación, Estepa y Batanero (1996) identifican visiones variadas, incluyendo visiones deterministas, locales y causales. Casey (2014, 2015) y Nagle et al. (2017) observan estrategias similares a las de Sorto et al. (2011) con estudiantes de nivel medio básico. Varios estudios utilizan tecnología para enseñar estos conceptos (Medina et al., 2019; Gil y Gibbs, 2017). Biehler et al. (2018) proponen dimensiones para diseñar entornos de aprendizaje estadístico, enfatizando el uso de datos reales y herramientas tecnológicas. Este estudio retoma la centralidad del papel del software que enfatizan dichas investigaciones para apoyar la comprensión de la recta de mejor ajuste.

Marco Conceptual

El *razonamiento covariacional estadístico* aborda la relación entre dos variables estadísticas e incluye conceptos como datos bivariados, diagramas de dispersión y correlación y la recta de mejor ajuste (Zieffler y Garfield, 2009). Este estudio se centra en la recta de mejor ajuste y otros conceptos relacionados. Los datos bivariados son pares de observaciones de dos variables numéricas diferentes (cada pareja de datos corresponde a medidas tomadas sobre una misma unidad de análisis), mientras que un diagrama de dispersión es la representación de los datos bivariados en un plano cartesiano. La covariación estadística describe cómo varían conjuntamente dos variables, con el diagrama de dispersión proporcionando una visión general. La correlación mide la relación lineal entre dos variables, mientras que la recta de regresión de mínimos cuadrados es un modelo de cómo cambia una variable de respuesta en función de una variable explicativa (Moore, 2000).

Un *enfoque informal del razonamiento covariacional* busca introducir los conceptos asociados a la regresión y correlación a un nivel de elaboración simbólica y matemática accesible para los alumnos. Se propone como una estrategia para introducir los conceptos desde niveles básicos y medios como antecedente para un tratamiento más formal en niveles universitarios. Makar y Rubin (2009) delinearon un marco para la inferencia estadística informal (IEI), que se puede aplicar de manera análoga al razonamiento covariacional informal. Este último implica juicios, razonamientos y procedimientos basados en los datos bivariados a la mano, pero con generalizaciones (ir más allá de los datos) y reconocimiento de la incertidumbre involucrada en tales generalizaciones. La evaluación de actividades se guía por esta caracterización, distinguiendo entre enfoque intuitivo e informal; el primero es espontáneo mientras que el segundo es resultado de un aprendizaje e implica procesamiento de datos para la resolución de problemas (Rossman, 2008).

La *agregación* es el proceso de combinar múltiples observaciones o medidas individuales para formar un objeto estadístico que los asimila y engloba; el objeto así obtenido es un agregado (Stigler, 2016). Aunque implica simplificación y generalización, la agregación revela tendencias y patrones generales en los datos, permitiendo hacer inferencias y afirmaciones sobre variables complejas. Desarrollar una "vista agregada" implica comprender y analizar los datos como un todo colectivo, pero esta perspectiva depende del tipo de agregado utilizado. La construcción de un agregado específico es crucial para obtener una visión global de los datos, ya que diferentes agregados revelan distintas propiedades globales del conjunto de datos.

La revolución *tecnológica* ha transformado la educación estadística, proporcionando recursos para fortalecer el razonamiento de los estudiantes en el análisis de datos (Biehler, et al. 2013). La representación dinámica de datos bivariados en diagramas de dispersión y sus medidas estadísticas facilitan el desarrollo del razonamiento covariacional informal en las aulas. La tecnología permite explorar la relación entre la forma de una nube de puntos y su coeficiente de correlación, además de investigar el efecto de variar un punto en el conjunto de datos. También permite introducir conceptos como residuos y minimización de la distancia entre una nube de puntos y una recta de ajuste de manera comprensible para los estudiantes. Plataformas como CODAP y software como GeoGebra se utilizan para crear dispositivos educativos que promueven la comprensión sin requerir a los estudiantes habilidades matemáticas avanzadas, haciendo el tema accesible y dinámico para el aprendizaje estadístico

Metodología

El presente estudio empleó un método cualitativo y exploratorio que fomenta la resolución colaborativa de problemas con tecnología y guía del profesor. El análisis de relaciones entre variables con datos bivariados es un desafío para los estudiantes al carecer de un procedimiento establecido. Optamos por datos de nutrición, relevantes para la salud y la alimentación, lo que puede aumentar la motivación y la comprensión (Garfield y Ben-Zvi, 2008; Neumann et al., 2013). La resolución colaborativa de problemas en parejas potencia el proceso, permitiendo el intercambio de ideas, negociación y expresión conjunta (Yackel et al., 1991; Webb y Mastergeorge, 2003), reflejando la dinámica del aula (Cobb et al., 2003). La tecnología, como CODAP y GeoGebra, ofrece nuevas oportunidades de aprendizaje, permitiendo manipular datos y visualizar conceptos en tiempo real (Biehler, et al. 2013). Esto facilita la comprensión de la relación entre variables y la construcción de la recta de mejor ajuste. Las actividades están diseñadas para que las parejas de estudiantes dejen evidencia de su razonamiento sobre la correlación y la recta de ajuste, con intervenciones del profesor para explicar el funcionamiento del software y aclarar la intención de la actividad, pero mínimas con respecto a la solución del problema en turno.

El estudio involucró a 22 estudiantes de bachillerato, con edades entre 16 y 18 años, dirigidos por la autora y la profesora titular. Aunque no tenían conocimientos previos sobre correlación y regresión, contaban con experiencia en el plano cartesiano y funciones lineales y cuadráticas, proporcionando una base útil para el enfoque informal del tema. Se diseñaron e implementaron dos actividades.

Los datos se recopilaron de las hojas de trabajo de los estudiantes en parejas, con la autora como administradora de los instrumentos. La primera actividad utilizó datos nutricionales de productos de McDonald's y Burger King, obtenidos de las páginas web oficiales (https://www.mcdonalds.com, https://www.bk.com/menu/search-by-nutrition). La segunda actividad se basó en un escenario del libro de texto *The Practice of Statistics* de Starnes et al. (2010), con un applet digital de GeoGebra diseñado para su aplicación. A continuación, se describe cada actividad y el análisis previo de los elementos que las componen.

La actividad 1 presenta una situación y preguntas diseñadas para explorar el razonamiento de los estudiantes sobre la relación entre variables (consulte la Figura 1). Destaca por su contexto familiar, preguntas abiertas y fomento del uso de tecnología. Los estudiantes enfrentan la tensión entre sus creencias previas y la información del diagrama de dispersión, lo que dificulta observar los datos de forma puramente cuantitativa. Se busca comprender los juicios que los estudiantes establecen sobre la relación entre variables en un contexto específico. La herramienta CODAP facilita la creación y visualización de la nube de datos bivariados.

Actividad 1: *Situación:* Quizás, oyes o creas que las grasas y las calorías son dañinas para tu salud. Es verdad, que algunas personas ingieren más grasas y más calorías de las que necesitan, pero sin ellas no tendrían suficiente energía para realizar sus actividades y crecer. ¿Qué has escuchado sobre las grasas y las calorías que contiene un alimento? Muchos alimentos contienen grasas y calorías, mucha gente cree que la grasa influye notablemente en la cantidad de calorías totales que contiene ¿Tú qué opinas? ¿Cómo podrías saber si la cantidad de grasa influye en la cantidad de calorías? A continuación, los datos de la tabla 1 muestran la cantidad de grasa en gramos y el número de calorías en algunos productos de McDonald's y Burger King.

Tabla 1. Grasa y Calorías de algunos productos de McDonalds y Burger King

	Producto	Grasa(g)	Calorías (Kcal)
McDonald' s	Big Mac	27	540
	Cheeseburger	12	300
	Quarter Pounder with Cheese	26	510
	McDouble	18	390
	Double Quarter Pounder with Cheese	45	780
	Bacon Ranch Grilled Chicken Salad	13	300
Burger King	Hamburger	10	240
	Cheeseburger	16	320
	Bacon y Cheese WHOPPER	51	790
	DOUBLE WHOPPER	58	900
	Double Pretzel Bacon King	60	920
	Chicken Club Salad-Grilled	41	610

a) Observa los datos de la tabla 1 ¿Cuál crees que es la relación entre los gramos de grasa y las calorías? Explica tu respuesta.

Utilizando tecnología digital: Abrir la plataforma digital *CODAP* y crear el diagrama de dispersión de los datos bivariados (grasa, calorías) presentados en la tabla 1. Sigue las indicaciones del profesor.

b) ¿Qué características se podrían tener en cuenta al interpretar un diagrama de dispersión?
c) ¿Qué puedes decir de la relación entre los gramos de grasa y el número de calorías?

Figura 1: Actividad 1

La actividad 2 presenta una situación y preguntas centradas en el razonamiento sobre la recta de mejor ajuste en un contexto de nutrición (consulte la Figura 2). Las primeras preguntas de la actividad 2 buscan que los estudiantes establezcan la idea de informar que una relación se dice que es lineal si los datos en la nube de puntos se conglomeran formando una línea. Se utiliza un applet de GeoGebra para que los estudiantes comprendan las ideas detrás de la regresión lineal, enfocándose en la optimización de distancias.

Actividad 2: *Situación.* Un estudio investigó por qué algunas personas no aumentan de peso incluso cuando comen en exceso. Los investigadores se preguntaron lo siguiente: ¿los cambios en la inquietud y otras actividades no relacionadas con el ejercicio explican el aumento o disminución de peso en las personas que comen en exceso? Deliberadamente sobrealimentaron a 12 adultos jóvenes sanos durante 8 semanas y midieron el aumento de grasa y el cambio en el uso de energía a partir de actividades no relacionadas con el ejercicio (ANE). Midieron el aumento de grasa (en kilogramos) y el cambio en el uso de energía (en calorías) a partir de otra actividad no relacionada con el ejercicio ya sea inquietud, vida diaria y cosas por el estilo (tabla 2).

Tabla 2. Medidas de Cambio en ANE y Aumento de Grasa en los 12 Adultos Jóvenes

Cambio ANE (cal)	-94	-57	-29	135	143	245	355	486	535	571	620	690
Aumento de Grasa (Kg)	4.2	3	3.7	2.7	3.2	2.4	1.3	1.6	2.2	1	2.3	1.1

a) Discute con tu compañero y describe la relación entre el cambio ANE y el aumento de grasa.
b) Realiza el diagrama de dispersión en CODAP y describe el comportamiento de la nube de puntos.

Abre el archivo de GeoGebra (el estudiante visualiza la figura B). Lee cuidadosamente lo siguiente: El archivo muestra el diagrama de dispersión de los datos (puntos azules) de la tabla 2 junto con una línea verde la cual puedes mover con los símbolos en rojo ◆ . El segmento punteado de color rojo muestra la distancia que va desde el punto azul a la recta verde, su valor corresponde a la diferencia entre la ordenada del punto azul (y) y la ordenada del punto que pertenece a la recta verde (ŷ), a este valor lo llamaremos residual, y la "Distancia de los puntos a la recta" es la suma de todos los residuales.

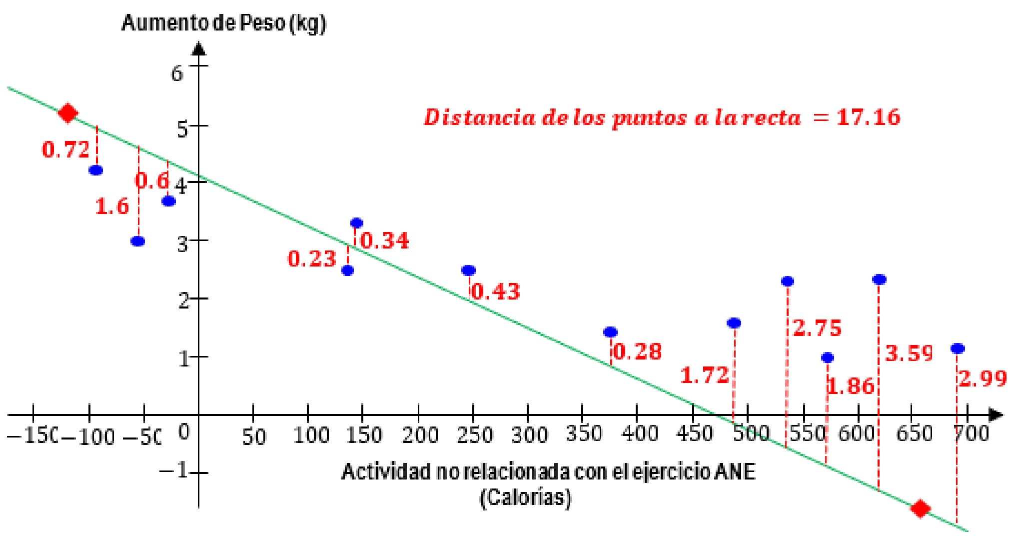

Figura B. Captura de Pantalla de la Vista Gráfica de la Tarea en GeoGebra

Mueve la línea verde, explora lo que ocurre con el valor de cada residual y responde:

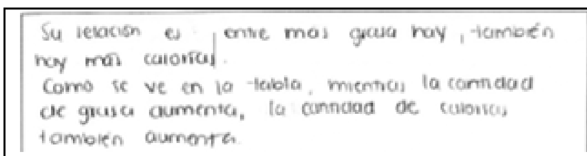
c) ¿Dónde colocarías una recta para que corresponda a la recta que mejor se ajuste a los puntos? Explica el criterio que utilizaste.
d) ¿Qué ocurre con el valor de cada residual si mueves la recta cerca o lejos de la nube de puntos?
e) ¿La manera como ubicaste la recta movible es igual a la recta arrojada por GeoGebra? ¿Sí? ¿No? ¿En qué se diferencian? ¿Cuál crees es el criterio que utiliza GeoGebra para determinar la recta de mejor ajuste?

Figura 2: Actividad 2

Conviene notar que se evita el uso del concepto de distancia cuadrática para no complicar la construcción de la medida de distancia de un conjunto de datos a una recta. El applet de GeoGebra permite visualizar una recta movible y calcular automáticamente la distancia de la nube de puntos a la recta. La función definida muestra el error o residual de un punto como la distancia vertical entre el punto y la recta, se define la distancia de la nube de puntos a la recta como la suma de los residuales. Se compararon las respuestas de parejas de estudiantes para identificar patrones de respuesta, destacando los rasgos comunes en los procedimientos o razonamientos similares. La codificación de estos patrones simplifica la descripción y análisis de las respuestas.

Resultados y Discusión

Este análisis ofrece una visión general de las respuestas grupales y analiza sus procesos de razonamiento, complementándolos con comentarios analíticos para una mejor comprensión. En la actividad 1, los estudiantes abordan la relación entre gramos de grasa y calorías en dos enfoques: *global-cualitativo* y *particular-cuantitativo*. El primero evalúa la tendencia general de los datos y su descripción cualitativa (ver Figura 3-a); el segundo busca expresar los cambios específicos en cada dato a través de secuencias numéricas o funciones, aunque sin éxito (ver Figura 3-b). Ocho parejas ofrecen una valoración cualitativa, mientras que tres intentan un análisis cuantitativo.



"su relación es que entre más grasa hay también más calorías. Como se ve en la tabla mientras la cantidad de grasa aumenta la cantidad de calorías también aumenta"

(a)

"…en 5 productos calculamos la pendiente de las calorías respecto a las grasas y llegamos a la conclusión que por [cada] 1 g de grasa hay 20.7 Kcal.

$$m = \frac{x}{y} = \frac{540}{57} = 20$$

$$m = \frac{y}{x} = \frac{300}{12} = 25"$$

(b)

Figura 3: Ejemplo de respuestas que involucra juzgar la relación entre las dos variables en la actividad 1

Utilizando CODAP, las respuestas se dividen en *casi-linealidad* e *irregularidad* en la distribución de datos (ver Figura 4). El uso del diagrama de dispersión facilita la percepción de una tendencia general y la irregularidad. Aunque los estudiantes prefiguran el agregado, no saben cómo combinar los datos para construirlo. En resumen, el diagrama de dispersión y la tarea de ajustar una recta permiten a los estudiantes pensar en combinaciones de puntos para construir un agregado, aunque requieren un método más preciso.

En la Actividad 2, se repiten preguntas similares a la relación entre las variables como en la Actividad 1. Cinco parejas describen una tendencia global entre cambio ANE (actividades no relacionadas con el ejercicio) y grasa, mientras tres reconocen una dependencia sin establecer una regla definida y tres basan sus respuestas en un modelo contextual sin obtener conclusiones de los datos. En la pregunta (b), ocho parejas identifican una relación inversa entre cambio ANE y grasa, mientras tres se centran en el contexto sin datos concretos.

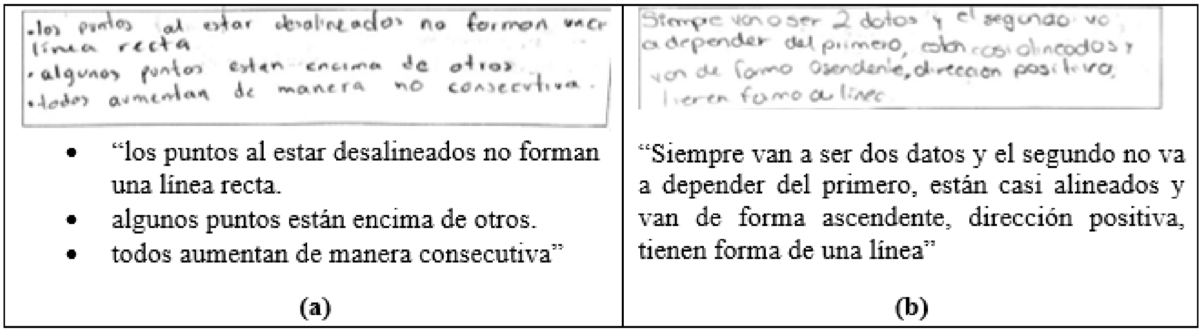


Figura 4: Ejemplo de respuestas al analizar la relación en el diagrama de dispersión en la actividad 1

La diferencia con la actividad 1 es que ahora la tendencia es negativa y la variable cambio ANE es menos familiar para los estudiantes. Probablemente por esto, los resultados no son mejores que en la actividad 1, además de que hubo respuestas basadas en creencias previas sobre el contexto. El objetivo de esta parte es introducir a los estudiantes al problema y proponerles utilizar GeoGebra para centrarse en la idea de distancia de un conjunto de puntos a una recta y minimizarla. Por lo tanto, se presenta la actividad donde los estudiantes utilizan el programa GeoGebra para representar los datos del problema y una recta móvil que permite observar los residuos y su suma. La pregunta (a) es similar a la actividad anterior, pero ahora los estudiantes pueden mover la recta preconstruida en la pantalla y observar las distancias verticales de cada punto a la recta, así como la suma de estos residuos. Las respuestas de los estudiantes se clasifican en tres categorías: "Puntos en la recta", "Cercanía" y "Minimización de residuos". Las respuestas varían desde asociar la recta de mejor ajuste a la minimización de la distancia entre la recta y los puntos hasta simplemente medir la cercanía visualmente sin usar los recursos del software (ver Figura 5-a). Algunos estudiantes basan sus respuestas en la minimización de los residuos, relacionándola con la distancia de los puntos a la recta de ajuste (ver Figura 5-b).

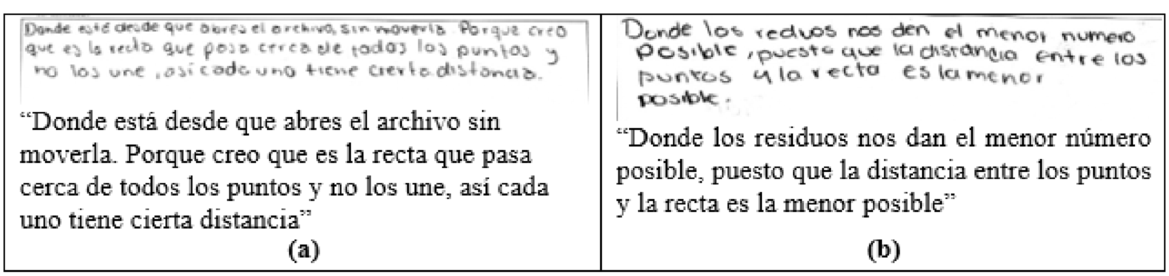

Figura 5: Ejemplos de respuestas del criterio para la recta de mejor ajuste en la actividad 2

Varios estudiantes muestran dificultad para entender la construcción del agregado al buscar minimizar cada residuo de manera particular y asumir que esto resulta en la distancia mínima de los puntos a la recta; esto no funciona, pues cuando un residuo se reduce otro aumenta. Es significativo que no encuentren natural minimizar la distancia (total) y entender que esto produce una distribución óptima de residuos. Ellos pretenden controlar los residuos particulares para minimizar la distancia global, pero no comprenden que este proceso funciona en sentido inverso. No obstante, más tarde, con la intervención oportuna del profesor conseguirán comprenderlo mediante preguntas que los invitan al descubrimiento y reflexión cómo: ¿Qué pasaría si hacemos que un residuo sea cero? ¿Creen que la distancia global sería mínima? Por favor, hagan que un residuo sea cero ¿Qué pasa? Una vez que se dan cuenta que no se logra minimizar ¿Qué pasa si la suma global de los residuos es mínima?

En la pregunta (b), se busca que los estudiantes reflexionen sobre la relación entre la distancia de la recta a los puntos y el valor de cada residuo. Las respuestas se dividen en tres grupos: descriptivo, enfoque en lo particular y la recta centrada. Algunos estudiantes comprenden que al minimizar los residuos se minimiza la distancia de la nube de puntos a la recta, mientras que otros consideran que la posición central de la recta resulta en una menor suma de residuos. En la pregunta final, los estudiantes comparan la recta móvil con la recta de regresión obtenida por GeoGebra, destacando diferencias en la posición relativa de las rectas y en las distancias a los puntos. Se observa que las respuestas demuestran una comprensión de las propiedades generales de las rectas de mejor ajuste y muestran un avance hacia una vista agregada de las mismas. Sin embargo, no se aborda el criterio específico que utiliza GeoGebra para determinar la recta de mejor ajuste, es decir, el método de mínimos cuadrados. La actividad resulta difícil para los estudiantes porque deben coordinar dos variables para obtener la recta que minimiza la distancia. Las operaciones realizadas en GeoGebra corresponden formalmente a la optimización de una función de dos variables, lo cual se logra con precisión mediante técnicas de derivadas parciales. Es importante que el profesor comprenda la relación entre el enfoque informal con GeoGebra y el enfoque formal para abordar las dificultades de los estudiantes.

Conclusiones

La pregunta que impulsó esta investigación fue ¿cómo conceptualizan los estudiantes de bachillerato la recta de mejor ajuste con ayuda de la tecnología? Nuestra respuesta es que el uso de dispositivos tecnológicos permite a los estudiantes formar conceptos para concebir la recta de mejor ajuste como un agregado. El uso del diagrama de dispersión, a diferencia de la simple presentación de datos en una tabla, les permitió percibir tanto la tendencia general de los datos como la irregularidad entre los puntos. La tarea de interpolar una recta enfrenta a los estudiantes a estrategias diferentes para fijar una recta representativa, aunque estas siguen siendo intuitivas y visuales. La introducción de los conceptos de residuo y distancia de una recta a la nube de puntos, mediante el programa GeoGebra, permitió a los estudiantes operacionalizar su idea intuitiva de cercanía de una recta a los puntos y entender cómo se combinan los datos para dar lugar a la recta de mejor ajuste.

En resumen, los estudiantes conceptualizan transitando por experiencias que incluyen nociones de irregularidad, tendencia de la nube de puntos, residuos, distancia de una recta a un conjunto de puntos y minimización de dicha distancia, facilitadas por el uso de la tecnología. Aunque responden a diferentes niveles, la tendencia es captar la recta de mejor ajuste como un agregado. Además, este trabajo propone una trayectoria que ayuda a los estudiantes a comprender los conceptos que les permiten construir la recta de mejor ajuste, especialmente la idea de distancia basada en el concepto de residuo, facilitando así una vista agregada del conjunto de datos en relación con la recta de mejor ajuste. Queda pendiente desarrollar las componentes de variabilidad e inferencia en relación con la recta de mejor ajuste y explorar en futuras investigaciones una actividad similar, pero con distancias cuadráticas en lugar de lineales.

TEACHERS' KNOWLEDGE OF STUDENTS' REASONING: THE CASE OF SIMULATED SAMPLING DISTRIBUTIONS

Francisco Sepúlveda Vega
Cinvestav, México
francisco.sepulveda@cinvestav.mx

Ernesto Sánchez Sánchez

esanchez0155@gmail.com

Keywords: Data Analysis and Statistics, Professional Development, Teacher Knowledge.

Short-term professional development courses with specific domain learning outcomes are useful to revise concepts that have changed and inform in-service teachers how they can exploit the affordances of technology to enhance their classroom practices (Ling, 2014). We investigate how teachers develop knowledge of students' reasoning about sampling distributions within a 20-hour on-line course. Our research question is: how teachers' understanding of student reasoning through simulated sampling distributions emerges?

Conceptual framework

Informal Approach to Significance Tests for Proportions

We utilize simulated sampling distributions (SSD) to model scenarios assuming the null hypothesis is true, thereby estimating p-values without complex formulas. This approach is feasible for high school students without advanced mathematical tools (Case & Jacobbe, 2018).

Students' Understanding of SSD

High school students' conceptions evolve from interpreting SSD as real samples to viewing SSD as a pattern of variation. This is an abstraction process (Sepúlveda & Sánchez, 2023).

Methodology and Results

The research was conducted with 16 experienced high school teachers during a 20-hour on-line professional development course. Teachers analyzed typical student responses to significance testing problems to interpret their reasoning. Here we compare two activities, both designed to improve teachers' ability to understand student reasoning in the context of SSD.

Problem 1: Teachers analyzed a student response where students misinterpreted SSD as representing real samples and based their conclusions on frequency without considering uncertainty. The analysis revealed that teachers' initial responses were mostly descriptive and evaluative, lacking deeper inference into students' reasoning.

Problem 3: Teachers assessed a response where students correctly used SSD to estimate the p-value but made an incorrect decision about repairing a machine. Here, teachers showed progress by making more detailed inferences about student reasoning, though still struggled to fully explain students' incorrect decisions.

Discussion and Conclusions

The study shows that teachers' ability to interpret students' reasoning improves through targeted professional development. Initially, teachers focused on what was absent in student answers. However, with guided activities, they began to attend more to students' reasoning. This progress is attributed to the design of the course, which emphasized interpreting students' implicit judgments (Brandom, 2000). Two main lessons emerged: a) Interpreting students' reasoning with SSD is challenging for teachers due to a tendency to prioritize their own content knowledge because of their lack of experience with this approach. b) Teachers can improve their ability to interpret student reasoning, but more extensive effort is needed to develop this habit.

DIRT DON'T HURT: HOW RELEVANT SOIL DATA CAN SUPPORT LEARNING AND MOTIVATION AT A HISPANIC SERVING INSTITUTION

Ian Thacker, Ph.D.	Rebecca Schroeder, Ph.D.	Sara Shields-Menard, Ph.D.
UT San Antonio	UT San Antonio	UT San Antonio
ian.thacker@utsa.edu	rebecca.schroeder@utsa.edu	sara.shields-menard@utsa.edu

To create opportunities for meaningful applications of data-science for diverse students, we developed and implemented an online learning module focused on engaging students at a Hispanic Serving Institution (HSI) in an analysis of authentic soil data. Development of the module occurred over three design iterations involving interviews with 10 undergraduate STEM students. We then implemented the finalized module in three undergraduate microbiology classrooms (N=118) using a pretest, posttest, comparison group quasi-experimental study design. Findings revealed that, after adjusting for key variables, the intervention group demonstrated significantly greater microbiology knowledge than the comparison group. Path analyses revealed indirect effects of the intervention through value and interest in STEM.

In today's world, data is ubiquitous and data literacy is essential across industries (Börner et al., 2019). However, traditional data science courses are not meeting students' needs (Baumer, 2015), and racial diversity in STEM is lacking (Cruz et al., 2018; Fry et al., 2021; NSF, 2015). This project aimed to enhance STEM learning among Hispanic students by leveraging their cultural resources (Gonzalez et al., 1995; Wilson-Lopez et al., 2016). We developed an online module on soil microbiology, utilizing data science tools to engage students at a Hispanic Serving Institution (HSI) and assess their impact on STEM learning and motivation.

Theoretical Framework

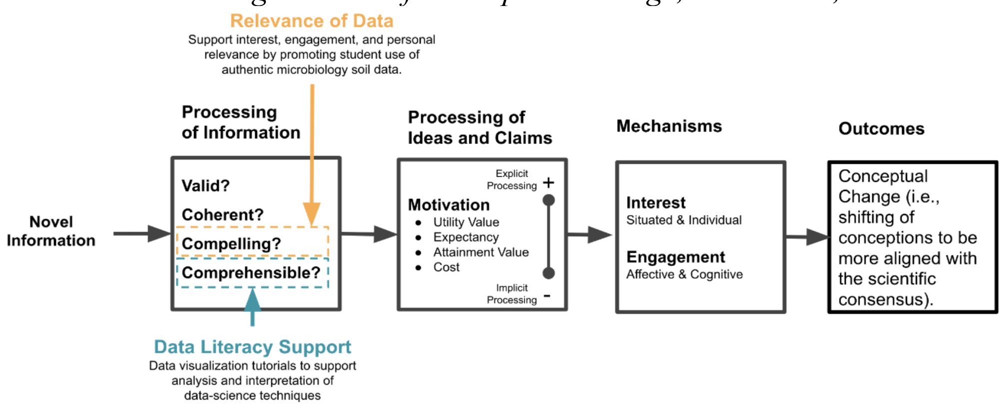
To frame how data visualizations can support science learning for Hispanic students, we integrate theories of Conceptual Change, Data Visualization Literacy, and Expectancy Value. *Conceptual change* theory posits that presenting people with novel information can shift their conceptions about science topics to be more aligned with the scientific consensus (Dole & Sinatra, 1998). For example, the Plausibility Judgments for Conceptual Change model (PJCC; Lombardi et al., 2016) suggests that people process information better if it is *comprehensible*, *coherent* with prior experiences, *compelling*, *relevant*, and stems from *credible* sources. People then judge the plausibility of associated claims and restructure knowledge as a result. Plausibility judgments involve more explicit processing depending on learners' motivation, engagement, and emotion, which then predicts the likelihood that conceptual change will occur.

The *Expectancy Value Theory* (EVT) helps frame motivational factors, and proposes that it is driven by learners' expectancy for success and task value (Eccles et al., 1983; Wigfield et al., 2017). According to EVT, there are four different types of task value: *intrinsic value* is when a learner values a task because they find the activity enjoyable for its own sake, *attainment value* is perceived personal importance of a task as it relates to one's identity, *utility value* refers to perceptions that a task may be useful to a learner to achieve their present or future goals, and *cost* is the extent of time and effort that is perceived to complete a task. Utility value interventions—especially those that are personal and relevant to students—can significantly enhance value, interest, and learning, particularly for underrepresented students (Harackiewicz et al., 2016).

The *Data Visualization Literacy framework* (DVL-FW; Börner et al., 2019) suggests that data visualizations can help ground abstract concepts. Accordingly, a central process required to interpret data from visualizations is *translating* relevant problems of interest into problems of data. As such, our project aimed to leverage students' knowledge to contextualize data.

We synthesized these theories in a process model (see Figure 1) to inform our intervention development and that we also tested using path model analyses. The model predicts that an intervention intended to expose students to compelling and comprehensible microbiology data would trigger motivational processes (i.e., improve utility value, expectancy, attainment value, and reduced cost), which would activate mechanism variables (student interest and engagement), which would predict increased learning outcomes (i.e., microbiology knowledge). Furthermore, we sought to facilitate change by centering learning around compelling topics that students found relevant, and supporting data literacy to improve data comprehensibility.

Figure 1. *Intervention Logic Model of Conceptual Change, Motivation, and Data Literacy*



To test this theoretical model, we designed and tested an interdisciplinary learning experience for undergraduate students at an HSI. We addressed the following research questions:

- **RQ1.** How can a learning intervention be developed to leverage undergraduate students' motivation for the learning of soil microbiology and data literacy skills?
- **RQ2.** To what extent will such an intervention support students' microbiology knowledge, data literacy skills, engagement, interest, and task value in STEM?
- **RQ3.** Will the hypothesized relationships between task value processes and achievement outcomes be mediated by mechanisms of interest and engagement? (See Figure 1)

This project addressed these research questions through two studies. The first was a formative study focused on creating an online module and the second was a comparative study testing the effectiveness of this intervention using quasi-experimental research.

Study 1: A Design-Based Research Study

To answer the first research question, we used a design-based research (DBR) approach to guide the development and revision of an interactive online intervention (Hoadley & Campos, 2022) on soil microbiology. The re-design, implementation, and revisions occurred over several iterations, resulting in an open-source module for undergraduate microbiology students. The module introduces students to the Tiny Earth Initiative (Hurley et al., 2021), which focuses on identifying new antibiotics in soil. It includes information on the antibiotic resistance crisis, microbial ecology, data visualization tools, and interpretation of soil data visualizations.

We conducted 10 recorded cognitive interviews (Desimone & Le Floch, 2004) via Zoom with a convenience sample of undergraduate students at an HSI in Summer and Fall 2023. Students self-identified as Female (70%), Male (20%), Nonbinary (10%), Hispanic (50%), White (40%), Black (10%), Asian (20%), and English Learners (30%). Interviews focused on student feedback to guide revisions of the module and surveys. Zoom recordings were transcribed and open-coded (Corbin & Strauss, 1990) to examine student engagement and learning.

RQ1 Results: A Module for Soil Microbiology Data Exploration. Revisions focused on improving interactivity, engagement, visual appeal, and ease of data and text interpretation, especially for English learners. The finalized intervention and surveys can be accessed using this link: https://www.softchalkcloud.com/lesson/serve/34E2zGcmQxaWZl/html. Ultimately, this version of the module was used in the second phase of the study.

Study 2: A Quasi-Experimental Study Testing Effects of the Design

To answer the second research question, we recruited 118 undergraduate students from an HSI in a southern U.S. state. Students reported their year of study (1% first year, 13% second year, 38% third year, 38% fourth year, 10% other), gender (76% Female, 21% Male, 1.7% Nonbinary, 1.7% prefer not to say), ethnicity (56% Hispanic), race (1% American Indian/Alaska Native, 13% Asian, 6% Black/African-American, 10% Two or more races, 58% White/Caucasian, 11% Other race), and whether they were enrolled in a STEM major (78% STEM major, 15% not STEM, 3% plan to enroll in a STEM major, 4% Other).

The intervention group consisted of 101 students from two undergraduate microbiology courses and the comparison group consisted of 17 students from a separate course. All participants first completed a 12-item pretest questionnaire on microbiology knowledge and an item that captured students' perceptions of the relevance of data science.

After the pretest, learners either completed the module (treatment group) or continued with "business as usual" (comparison group). All participants then completed an identical post-test of microbiology knowledge and data literacy. Participants also completed a microbiology-specific interest scale (adapted from Hulleman et al., 2010), a Data-Science-specific interest scale (adapted from Hulleman et al., 2010), the Cognitive Engagement scale (Greene, 2015), and a Task Value scale (Kossovich et al., 2015). Internal reliability for all scales at pretest and posttest were judged using Cronbach's alpha, and are reported in Table 1.

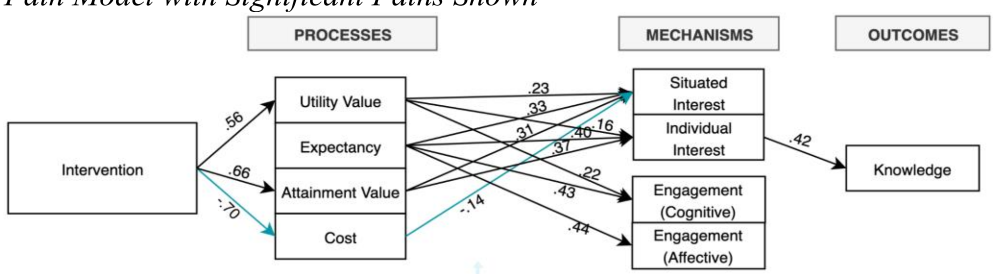
Note: *$p < .05$; **$p < .01$; ***$p < .001$

We assessed if baseline measures differed by condition. Chi-Squared analyses showed gender, ethnicity, race, English speaking status, and STEM status were independent of condition (all $p > .117$). However, year of study ($p < .001$) and pretest knowledge ($p < .001$) were significantly lower in the control group. Thus, we included these as covariates in all analyses. Raw means, standard deviations by condition, and intercorrelations are in Table 1.

RQ2 Results: Module Effects on Learning & Motivation. To assess the module's effects on knowledge, data literacy, engagement, interest, and value in STEM, we used multiple regression with robust standard errors. Predictors included the treatment condition, pre-test scores, and covariates. We predicted the module would improve outcomes due to greater comprehensibility, compellingness, and engaging information (Dole & Sinatra, 1998; Lombardi et al., 2016). Findings showed significant effects on posttest knowledge ($\beta = 1.67$, $p < .001$) and data science relevance before adjusting for pretest knowledge and year ($\beta = .66$, $p = .012$). The intervention promoted situated interest ($\beta = 0.73$, $p = .014$), value of science ($\beta = 0.66$, $p = .029$), and reduced perceptions of cost ($\beta = -0.70$, $p = .013$), but effects on initial interest and utility value were marginal. No significant moderation effects of gender or ethnicity interactions were found. A summary of the standardized regression coefficients, standard errors, and p-values for analyses can be found in the Supplemental Materials, Table S1 and Table S2.

RQ3 Results: Path Analysis. We tested a model predicting process variables (utility value, expectancy, attainment value, cost), followed by mechanism variables (STEM interest), engagement (cognitive, affective), and academic outcomes (microbiology knowledge). Pretest knowledge and year of study were covariates. The model had satisfactory fit (RMSEA=.081, SRMR=.073, CFI=.982, TLI=.943, AIC=2209, Chi-Square=35, df=20; Hu & Bentler, 1999).

Figure 3. *Path Model with Significant Paths Shown*



Note. Only paths that are significant at the .05 level are shown, blue paths are used when coefficients are negative. All variables shown represent values at posttest. All coefficients represent standardized βs.

Figure 3 shows the full path model with all coefficients. The intervention influenced motivation processes, significantly affecting reported utility value, attainment value, and cost. These motivational process variables were associated with mechanism variables: utility value was positively associated with situated interest, individual interest, and cognitive engagement; expectancy positively predicted situated interest, initial interest, cognitive and affective engagement; attainment value positively predicted situated and initial interest; cost negatively predicted situated interest. Of the mechanism variables only individual interest significantly predicted microbiology knowledge.

Significance

We aimed to develop and test an online learning module for microbiology students at an HSI to enhance STEM learning and motivation. Students using the module had greater posttest knowledge, perceived data-science relevance, science interest, situated interest, utility value, decreased perceptions of cost compared with a comparison group. Findings support prior research showing that interventions supporting perceptions of utility can enhance motivation and achievement in STEM. We also tested predictions by Hulleman and Harackiewicz (2021), finding that value perceptions significantly predicted psychological mechanisms, which predicted achievement outcomes. The intervention had marginally significant indirect effects on achievement through attainment value and individual interest, indicating that interest and engagement may be important mechanisms for expectancy and value.

In summary, this study supports a long-term agenda focused on interdisciplinary STEM applications for Hispanic students, contributing to theory and practice by testing conceptual change models, exploring mathematical reasoning in science learning, and producing a shareable intervention for science instructors and the public.

STATISTICAL LITERACY OF UNDERGRADUATE STUDENTS IN MEDIA CONTEXTS

Samuel Waters
University of Northern Colorado
samuel.waters@unco.edu

Statistical and mathematical products in the news take on many forms, requiring inter-related skills to appropriately comprehend and evaluate (Gal & Geiger, 2022). This study used task-based interviews to investigate how students in an introductory statistics course utilizing a simulation-based curriculum apply statistical concepts when critiquing statistics in the news media. Analysis identified students wanting more information, using intuition over statistical thinking, and challenges in connecting statistical ideas to critical questioning. Findings support the inclusion of media items in discussions and activities in introductory statistics courses.

Keywords: Data Analysis and Statistics, Undergraduate Education

With the pervasiveness of data in everyday life and ongoing uncertainties about the quality of information found in the media, statistics educators are concerned about how to prepare students to engage with data in meaningful ways (Burrill & Pfannkuch, 2023). Simulation-based curricula (SBC) have grown in popularity in introductory statistics courses (Tintle et al., 2015). Example applications in an introductory course include generating confidence intervals from bootstrap distributions and simulating null distributions to calculate p-values for hypothesis tests instead of using theoretical distributions (Lock et al., 2021). Advocates of simulation-based methods assert the methods allow students to see the logic and power of statistical interference (Tintle et al., 2015). Researchers identified consistent improvements in students' statistical literacy when they engage with SBC compared to engaging in more theory-based curricula (e.g. Chance et al, 2022; Maurer & Lock, 2016).

While research calls for increased use of SBC in introductory statistics courses (Tintle et al., 2015), research is less clear about how simulation-based methods help prepare students to engage with statistics in the increasingly complex media environment. This study brings together research on statistical literacy, SBC, and statistics in media to understand how students in introductory statistics courses engage with statistical information in media settings. Specifically, this study addresses the research question: *what statistical topics do students in an introductory statistics course utilizing a simulation-based curriculum apply when critiquing statistics in the news media and at what level of statistical literacy?*

Methods

This study adopted Watson and Callingham's (2003) construct of statistical literacy, grounding statistical literacy in the need for understanding, interpreting, and communicating in real-word contexts such as the news media. Watson and Callingham developed a six-level statistical literacy construct. Each level is characterized by the types of task steps students take while engaging with statistical tasks. Progressing to higher levels requires more detailed use of statistical terminology and topics in connection with deeper engagement with the task's context. Levels 1 and 2 involve mostly non-statistical thinking, instead relying on personal experiences and intuition. Levels 3 and 4 utilize statistical terminology and arguments with increasing amounts of justification and connections to the task's context. Level 5 and 6 incorporate critical questioning and engagement concerning the data and conclusions.

Five undergraduate students (one male, four female), representing diverse academic programs, participated in one, 25 to 45-minute task-based interview. Participants were enrolled in an introductory statistics course utilizing materials which incorporated simulation-based methods (Lock et al., 2021). Each participant completed three tasks; each task had two parts. First, participants received a mock news headline and were prompted to consider how someone might arrive at the stated conclusion and discuss any questions or concerns. Headlines were provided separately because previous research suggested headlines are particularly important in communicating news and can influence the reading of an article (Adams et al., 2017). Following discussion of the headline, participants received a short article containing information about the statistics and evidence behind the claim made in the headline. Participants evaluated the statistics presented and considered questions or concerns they had.

Designed tasks focused on statistical topics prevalent in the news (e.g., sampling and data collection) and topics related to simulation-based methods (e.g., variation, p-values, and hypothesis tests) (Chance et al., 2022). Each task incorporated multiple categories of statistical and mathematical products (StaMPs) in the news identified by Gal and Geiger (2022) to ensure tasks represented a range of statistical demands present in the media. Tasks incorporated five of the nine categories of StaMPs: (a) descriptive quantitative information; (b) models, predications, causality, and risk; (c) data quality and strength of evidence; (d) demographics and comparative thinking; and (e) critical demands.

All interviews were transcribed and coded by the researcher. First-cycle coding involved a combination of descriptive coding to identify statistical topics, In Vivo coding to highlight participant thinking, and magnitude coding to assign a level on Watson and Callingham's (2003) construct of statistical literacy. Second-cycle coding first identified ideas for each participant and then used pattern coding for cross-case analysis to develop major themes.

Findings

Participants (all names pseudonyms) mentioned the statistical topics of sampling, study design, and hypothesis testing at various levels of statistical literacy across the three tasks. Within the topics, additional themes included: wanting more information, relying on non-statistical arguments, and struggling to connect statistical ideas to critical questions. Assigned statistical literacy levels are included in parentheses following any quotes.

Participants frequently noted the lack of data, details, and numbers in the headlines and articles. For example, in the Blue Light task, which described two experiments with conflicting results, students had trouble evaluating the article's claim with limited information. Requests for more details often focused on a lack of specific numbers, such as when Erich stated, "because the only statistic here is 'over 200 participants,' they've come to no conclusion" (1). Participants did not always recognize or acknowledge non-numerical information about study design and data collection as relevant to evaluating the statistical claims. Furthermore, participants rarely indicated the information they wanted. For example, in the Birth Rates task, Violet noted "I think they just have lack of data" (2). When asked about what additional data would be helpful, Violet responded "I think… probably more specificities like… I don't know" (2).

Participants' initial reactions to the headlines often drew on intuition and personal experience. For example, Emma said "I wear blue light glasses when I'm studying" (1) before sharing she thought they helped her. In most instances, these initial statements about the headline aligned with participants' subsequent task responses after reading the article. For the GPA task, several participants were willing to accept the results being reported without engaging in statistical thinking. All participants demonstrated higher levels of statistical literacy when prompted by task questions and/or researcher but connections to initial reactions continued.

Participants relied on their intuition more than statistical reasoning when evaluating the difference in GPAs between the two groups reported in the GPA task. Many quickly wrote off this difference as not significant without statistical justification (3), such as when Alex said, "point two is like one better exam basically" (3). Other participants used the word *significant* more colloquially as opposed to in a statistical way, even after being asked what significance meant to them. No participants questioned how much variation existed in the measures or connected significance to other conversations around hypothesis tests. Since participants did not find the difference to be meaningful to them, they appeared less critical of the results.

While participants rarely used explicit statistical terminology, each participant touched on the topics of causation and confounding variables by offering alternative explanations for the reported relationships. For example, in response to the GPA task's claim that breakfast improves student GPA, Claire pondered "does this have to do with when people actually wake up? Does this have to do with the nutritional aspect of actually eating breakfast… or just the internal factor of having the motivation to do things" (3). Alex (5) and Erich (5) demonstrated higher levels of statistical literacy on this topic by connecting their concerns about causation to the design of the study. Although participants appropriately questioned the causal claim made in the GPA task, participants used similar strategies for the Birth Rates and Blue Light tasks even when no causal claims were made or the study utilized a randomized controlled design.

Without prompting, participants rarely commented on specific methods of statistical analysis such as conducting a hypothesis test. When asked how the conclusions in the headlines could be determined, participants offered comments about data collection such as "take a regular person without blue light glasses, and then take someone that uses blue light glasses and determine the effects" (Violet, 4) but comparison groups were not always discussed when prompted about hypothesis tests. Emma, Erich, and Alex described an appropriate null and alternative hypothesis when prompted, with Erich also connecting their hypothesis tests to the idea of a p-value, describing "when you really look at how big that difference is, it seems like it would really fall well within a standard of error of just an average null hypothesis" (5).

Participants rarely mentioned ideas of simulation. One notable instance occurred with Violet's work on the GPA task. After the researcher asked Violet about assessing the difference in GPAs from a statistical approach, Violet mentioned statistical significance, sketched a bell-curve, and marked an area that could represent a p-value. However, Violet was unable to connect her statistical knowledge to the context, stating, "it's different because it's on a graph and everything though" (3). Alex was the only participant to fully utilize ideas of simulation when during the Blue Light task, she explained a randomization distribution "accounts for all of the statistics that appear by random chance or coincidence if the null hypothesis is true….and if it's outside the certain area, then it would be unlikely that is due to coincidence" (5).

All five participants consistently implemented critical questioning when addressing sampling but not always backed by statistical reasoning. Many remarks addressed sample size, such as Claire noting "so you have 200 participants. That seems like a pretty good number" (3). While most participants stated larger samples were better, not all could articulate why. For example, Erich explained, “it’s just a good rule to go with. When you can, always have more data to help support the evidence” (3). Alex responded at Level 6 regarding sampling, using it during the Blue Light Task as a possible explanation for the different findings, stating “so if [researchers] previously used less participants, then they had less data and the data that they received was probably more coincidental.” Alex did not utilize this reasoning during the birth rates tasks while Emma and Claire both explained how a smaller number of births could explain the difference in birth rates. Other comments on the sample related to how representative or generalizable the sample was, such as Emma stating, “because it’s at one college, it’s kind of dependent on just students at that college” (4). However, none of the participants mentioned the randomization of a sample in relation to representativeness.

Table 1: Range of Statistical Literacy Levels by Task

	Alex	Claire	Emma	Erich	Violet
Birth Rates Task	2-6 (3)	2-6 (4)	3-6 (5)	2-5 (3)	2-4 (2)
Blue Light Task	1-6 (5)	2-4 (4)	2-5 (4)	1-4 (4)	1-4 (2)
GPA Task	1-6 (4)	1-5 (3)	1-5 (3)	1-5 (4)	1-4 (3)

Table 1 identifies the range in the levels of statistical literacy for each participant’s task steps for each task. The number in parentheses following the range represents an overall level for the task determined by considering the levels of all the task steps across statistical topics.

Discussion and Conclusion

The study found students in an introductory statistics course demonstrated varying levels of statistical literacy across multiple statistical topics when engaging in critiquing statistics in the news media. Participants consistently demonstrated higher levels of statistical literacy regarding sampling. However, participants were far less consistent in connecting their understanding of study design, hypothesis tests, and causation to the context for critical questioning. Instead, participants frequently relied on intuitive, non-statistical thinking. Additional statistical reasoning was often made after specific prompting, suggesting participants had understandings of relevant statistical topics that were not initially applied. This finding aligns with previous research identifying that students demonstrate lower statistical literacy on assessment items that heavily incorporate relevant contexts (Phadke et al., 2022).

Notable aspects of the media-based tasks contributed to participants’ display of statistical literacy during the interviews. Participants’ views about a headline frequently carried over into the critiquing of the article, sometimes including participants being less critical of information that aligned with their initial ideas. Adams et al. (2017) similarly noted how headlines can have an ongoing influence on readers. Participants identified the lack of details and specific numbers as a challenge to evaluating the statistical evidence behind the articles’ claims. Dealing with the uncertainty resulting from missing or vague information highlights the critical demands of statistical and mathematical products in the news (Gal & Geiger, 2022).

The results have implications for future research and instruction. Researchers could consider adjustments to media-based tasks for richer discussion of statistical topics. Larger differences between groups may elicit richer discussions since participants will not immediately dismiss results. Task development should consider balancing the amount of numerical information and vagueness so that tasks allow for application of statistical thinking while still representing realistic media contexts. Instructors and course developers of introductory statistics courses should consider incorporating media-based tasks into class activities and assessments. Doing so can highlight the use of statistics in real-world environments and provide opportunities to critically question claims using statistical thinking. Developing statistical literacy in media contexts is crucial to preparing an informed, critical citizenry ready to tackle a data-filled future.

SUPPORTING TEACHERS’ CRITICAL READING OF A RELEVANT DATA VISUALIZATION

APOYAR LA LECTURA CRÍTICA DE LOS DOCENTES DE VISUALIZACIONES DE DATOS RELEVANTES

Travis Weiland	Laura Shelton	Mandana Delavari

In this paper we present findings from a design research study of an activity designed to engage teachers in critically reading a relevant data visualization. To help us capture the ways that the teachers were reading the data visualization we created a new framework for reading data visualizations from a critical statistical literacy perspective building from prior research. The two-dimensional framework is designed to capture types of reading (i.e. reading the data, reading between the data, reading beyond the data, and reading behind the data) intersected with layers of reading the word and the world with data (i.e. reading the word, reading the world personally and culturally, and reading the world socio-politically). We found participants engaging in every type and layer of reading data visualizations from our framework. However, they most frequently engaged in reading at the sociopolitical layer.

Keywords: Data Analysis and Statistics, Teacher Educators, Design Experiments.

Choice of Problem

The reading of graphs of data has been often associated with statistical literacy (Gal, 2002), which has been included in the school mathematics curriculum of the U.S. over the past several decades (Scheaffer & Jacobbe, 2014). Past scholarship (i.e., Curcio, 1987; Friel et al., 2001; Shaughnessy, 2007) synthesized different ways that people engage in reading graphs and also shaped curriculum and guided scholarship on people’s understanding of reading graphs. However, the ways data is visualized has changed significantly over the past few decades due to technological advances and new forms of media. Wilkerson and Laina (2018) describe data visualizations as those that “use context rich and interactive methods to create narratives and allow users to explore data for themselves” (p. 1). This definition expands beyond traditional graphs to include new forms of data visualization, such as dynamic and interactive spatial displays of data or scrolly-telling, where data visualizations change as a person scrolls down an article on a device. With such advances in how data is visualized and presented to the public, we see a need to revisit old frameworks with new data and lenses to consider the realities of how people encounter data in the world today.

Teachers, who are entrusted to enact the mathematics curriculum that students experience directly (Remillard & Heck, 2014), are at the forefront of curricular shifts such as updating how we teach and learn about data visualizations. As a result, in this study, we focus on a design research study of supporting mathematics teachers’ in critically reading data visualizations. Studying mathematics teachers reading of data visualizations is particularly important not just because they can shift the types of experiences students have with statistics, but because they themselves have often had few if any prior experiences learning statistics themselves (Shaughnessy, 2007). Additionally, past work has found that mathematics teachers are not confident in their ability to teach the statistics concepts required in their state standards (Lovett & Lee, 2017, 2019). The emergence of data science entering the K-12 curriculum in many states (Drozda et al., 2022) has only increased the demand on mathematics teachers to incorporate data visualization into their curriculum.

In this paper, we study the research question: How do mathematics teachers read a relevant data visualization? To help us capture the ways that the teachers were reading the data visualization, we created a new framework for reading data visualizations from a critical statistical literacy perspective (Author, 2017) building from prior research. We discuss implications for the design of data visualization activities for teacher education. This study addresses the theme of the conference, envisioning the future of mathematics education in times of uncertainty, by considering new ways of engaging in the reading of data visualizations, which is increasingly a crucial practice as a member of democratic societies that have become increasingly dominated by data in our current information age.

Theoretical Framework

Our framework is composed of two dimensions. One dimension is types of reading (i.e. reading, reading between, reading beyond, and reading behind), drawing from past scholarship that focused on people's reading of graphs and supporting graph comprehension (Curcio, 1987; Friel et al., 2001; Shaughnessy, 2007). We found this dimension alone was insufficient to capture the different ways people read data visualizations, as past scholarship only took a disciplinary and objective look at graphs. From our critical statistical literacy perspective, what was missing was a critical epistemological perspective, which more recent literature has considered. Drawing from Lee et al.'s (2021) Call for a Humanistic Stance in Data Science Education, where they put forth three layers of such an education including personal, cultural, and sociopolitical layers, we added a second dimension of layers of reading practices where one layer captures the more technical disciplinary practices that we refer to as reading the word drawing from Paulo Freire's (1970) literacy work and then two more layers that center on reading the world with one layer focusing on personal/community practices and the other is focused on sociopolitical factors. We also liken this perspective to the key aspects of culturally relevant pedagogy, where academic excellence maps to reading the word, cultural competence maps to reading the world with personal/cultural practices, and sociopolitical consciousness maps to reading the world sociopolitical practices (Ladson-Billings, 1995).

To unpack the specific practices of our two-dimensional framework we first drew upon past scholarship on reading graphs (Curcio, 1987; Friel et al., 2001; Shaughnessy, 2007). Curcio (1987) created three types of reading graphs for educators to consider as they formulate tasks and questions aimed at improving students' graph comprehension – reading the data, reading between the data, and reading beyond the data. The descriptions of these can be found in Table 1. Shaughnessy (2007) extended these reading levels to incorporate a fourth level – reading behind the data – to highlight the causes for variation in data represented in graphs and to make connections between the context of the data and the graph. Since then, numerous studies have used the reading levels framework to analyze news stories and student work with graphs, statistical tables, and maps (da Silva et al., 2021; Rubel et al., 2016). There is also important work from statistical literacy on reading in statistics such as considering how data is collected to determine what type of claims are warranted, when common forms of bias are present in the methods and other common methodological issue such as sample size (Bailey & McCulloch, 2023; Gal, 2002; Utts, 2003). These practices focus on disciplinary practices which we mapped to the reading the word layer of the framework.

Reading the world facilitates an individual's understanding of themselves, their culture, and their community (personal/cultural layer) as well as analyses of power, oppression, and structural inequities (sociopolitical layer; Freire, 1970; Gutstein, 2006). For example, Rubel et al. (2016) discuss how students often try to locate themselves in the data they are investigating. Rubel et al. (2021) extends their previous work by further considering the practices of narrating, formatting, and framing involved in taking critical reads of data visualizations. These practices describe considering the author's message in a data visualization and how they have highlighted certain aspects of the visualization to convey a message. Bailey and McCulloch (2023) also discuss practices such as acknowledging alternate explanations of the data and recognizing gaps in one's knowledge of the context being explored that is needed to interpret the statistical message. Kahn et al., 2022) also went beyond previous work and additionally included the consideration of feeling and emotions in the reading of data visualizations. It is important to note that though we developed categories in our framework that we differentiate we see them as deeply interrelated where expertise consists of coordinating between different types of reading of data visualizations to read the word and the world.

Table 1: Framework for Critically Reading Data Visualizations

Reading Types	Reading the Word Practices	Reading the World Personal/Community Practices	Reading the World Sociopolitical Practices
Reading the data **Extract information from the data (Friel et al., 2001)**	To recognize the components of graphs, the interrelationships among these components, and the effect of these components on the presentation of information in graphs (Friel et al., 2001) To speak the language of specific graphs when reasoning about information displayed in graphical form (Friel et al., 2001)	Looking for oneself in the data (Rubel et al., 2016)	Look for source of data Look for author/affiliation of visualization Questioning why an author has highlighted particular aspects of a graph or left them absent
Reading between the data **Find relationships in the data (Friel et al., 2001)**	To understand the relationships among a table, a graph, and the data being analyzed (Friel et al., 2001). Finding relationships or trends in the data visualized Recognizing the types of relationships (correlational or causal) can be claimed based on the data collection methods (Utts, 2003)	Making sense of the data visualization in relation to one's own personal experiences	Questioning how and why the author has highlighted particular relationships in the graph (Rubel et al. 2021)

	Identifying the relationships highlighted in the graph (Framing; Rubel et al. 2021)		
Reading beyond the data **Move beyond the data (Friel et al., 2001) to consider interpretations, inferences, and predictions/ extrapolations**	Interpreting information in a graph and answering questions about it (Shaughnessy, 2007) Predicting outcomes based on reasonable claims made from the graph (Shaughnessy, 2007) Making claims/inferences based on patterns and trends in the data to a population beyond what is represented in the data	Making predictions/ claims/ inferences from the data visualizations by drawing upon one's own personal experiences Recognition of one's bias and its impact on interpreting data (Bailey & McCulloch, 2023; Author, 2017) Acknowledging possible Alternate Explanations (Bailey & McCulloch, 2023) Drawing upon personal experiences facing inequities in the interpretation of the data visualization (Bailey & McCulloch, 2023) Connecting to one's feelings/emotions related to the data visualization (Kahn et al. 2022)	Making connections to alternate explanations of others (Bailey & McCulloch, 2023) Recognizing the story, the author is trying to tell with this data (Rubel, 2021) Questioning the author's motives for telling this story (Rubel et al., 2021) Identifying structural inequities at play in the interpretation of the data visualization (Bailey & McCulloch, 2023)
Reading behind the data **Making connections between the context and the data (Shaughnessy, 2007)**	Looking for possible causes of variation (Shaughnessy, 2007), based on the context being measured and the way the data was collected Looking for relationships between variables based on the context Recognizing appropriate graphs for a given data set and its context (Shaughnessy, 2007) Recognizing Appropriate Statistics & Appropriate Representations (Bailey & McCulloch, in 2023)	Using your knowledge of the context of the data to interpret why particular patterns exist in data as well as data generation process Using knowledge of one's community to interpret why particular patterns exist in the data to question aspects of the data generations process Questioning the investigative process undertaken based on personal experiences/identity Recognition of the gaps in one's knowledge of the context needed to interpret the statistical message. (Bailey & McCulloch, 2023)	Questioning sample size and methods (Bailey & McCulloch, 2023) and their impacts on inferences (i.e. practical significance vs. statistical significant; effect vs. no effect) (Utts, 2003) Recognizing when common sources of bias are present in the data collection (Utts, 2003) Recognizing and questioning the source of the data including what is quantified and how it was measured (Rubel et al., 2021; Author, 2017)

Mode of Inquiry

Research Design

This qualitative study is part of a larger design-based research project (Bakker, 2018; Cobb et al., 2003) studying mathematics teacher's development of critical statistical literacies for doing and teaching statistics. The work reported here is our fourth iteration of this framework. The seven participants in our study are high school math teachers recruited from a school district in the southeastern U.S. One of our participants was a district administrator. Six participants identified as a woman, and one identified as a man. Five participants identified as Black or African American, and two identified as white. The teachers' years of experience include: two people with 4-7 years of experience; one person with 8-10 years of experience; and four people with 16+ years of experience.

Design Activity

The activity the participants engaged in was a modified notice and wonder activity on a data visualization that was published by the North Carolina Department of Public Instruction (see Figure 1).

Figure 1: Data visualization published by the North Carolina Department of Public Instruction.

Data Collection and Procedure

Data sources included video recordings of the professional development session, daily written reflections by participants, and ongoing work samples. This comprehensive approach allowed us to capture the nuances and variations in how teachers engage with and interpret data visualizations. The data was collected over a two-week period of the professional development during the summer of 2023. This pilot study focuses on the first 15 minutes of a single introductory activity where the participants are given three questions to consider about a data visualization (see Figure 1): What do you notice? What do you wonder? How does this impact your community? Three members of the research team were present and helped facilitate the professional development and took on a researcher/participant role during the activity.

Analysis

Participant and researcher utterances during the session were coded based on the critical reading data visualizations framework outlined in Table 1.. Three of the authors independently coded the responses, and a comparison was conducted. Differences in coding were discussed until the coders reached 100% agreement. This rigorous coding process enhances the trustworthiness and dependability of our analysis, providing a solid foundation for understanding the diverse ways in which teachers read and interpret data visualizations (Lincoln & Guba, 1985). After coding, we then looked at the frequency of each reading type and layer represented in the data. We identified the patterns in the frequencies for further exploration. We arrived at our findings by looking at themes in the data analysis across reading type, layer, and participant. Once we identified patterns across the themes to develop our findings, described in further detail below.

Findings

We identified two main findings that answer our research question: How do mathematics teachers read a relevant data visualization? In our first finding, we discovered that teachers exhibited engagement across all reading types, with a noticeable emphasis on reading behind the data. Additionally, our analysis revealed that teachers engaged with all three layers of reading, with a predominant focus on the sociopolitical layer. For our second finding, we noticed that different participants engaged in different frequencies.

Table 2 demonstrates the ways teachers engaged with the reading types and layers. Some reading types were taken up less often. For example, reading between the data was underrepresented at the word and personal layers, and no teachers engaged in the reading beyond the data at the word layer.

Table 2: Counts and Precents of Code Occurrences for Each Dimension of the Framework for Reading Data Visualization

	Reading The data	Reading Between the Data	Reading Beyond the Data	Reading Behind the Data	Row Total
Word	9 (16%)	1 (2%)	0 (0%)	3 (5%)	13 (23%)
Personal	1 (2%)	1 (2%)	5 (9%)	5 (9%)	12 (21%)
Sociopolitical	3 (5%)	9 (16%)	10 (18%)	10 (18%)	32 (56%)
Column Total	13 (23%)	11 (19%)	15 (26%)	18 (32%)	57 (100%)

Note: *Percentage values have been rounded to the nearest whole number for clarity and ease of interpretation. The values in parentheses are the counts of each code's occurrence. All percentages are out of the total of 57 occurrences.*

In analyzing the various reading types, regardless of the layer (considering one dimension of our framework), we observed that teachers notably engaged in reading behind the data (18/57; 32%), surpassing the percentages of other reading types such as reading the data (13/57; 23%), reading between the data (11/57; 19%), and reading beyond the data (15/57; 26%). For example, Leona's statement, "you see that important. It's also the vocabulary of median and average because if the community doesn't understand the differences," serves as one instance of reading behind data (from sociopolitical perspective) and that reflects her acknowledgment of the significance of statistical terminology and the importance of understanding small differences in data analysis. By emphasizing the need for clarity and comprehension among community, she is making a connection between the data and its relevance to the community's knowledge and understanding in a way that it is important for everyone in the community to understand the numbers, so they know how that affects them.

In examining the different layers, irrespective of the reading types (considering the alternate dimension of our framework), we found that teachers engaged in reading the data visualization in sociopolitical ways more than any other layer (32/57; 56% overall), compared to the personal layer (12/57; 21%) and the word layer (13/57; 23%). The reading practices in the sociopolitical layer focus on considering the sociocultural context of the data visualization, which the teachers have firsthand experience and background knowledge of. To illustrate this, consider the following statement from Nancy where she questions the relationships the author of the data visualization is highlight, “But glossing over the fact that we have the small print that says average and then, yeah, median and you're wanting me to compare those two.” Nancy goes on to read the data in a sociopolitical way combining her knowledge of the content with her knowledge of her community to point out that this approach is taking advantage of a common misunderstanding of the differences of means and medians and how the shape of a distribution impacts them, “they say the middle income the middle of this and they don't realize that, that middle is usually the median because we know the distribution is not going to be a symmetric or roughly symmetric right.” Teachers also read beyond the data unpacking the story they thought the author of the data visualization was trying to make and questioning the authors motives. For example, Anna stated, “I think this is designed to show that teachers are making more than most North Carolina incomes.” Some participants also began to make connections between the data visualization they were reading and how they could use it in their own teaching. For example, Melody said, "So I would have used this as a perfect example to my students of how we can make statistics say anything we want," where she is connecting issues of the story being presented how she could use this in her teaching.

We also found that the teachers engaged in reading the data visualization in different ways. Three of the teachers did not engage in verbally describing their reading of the data visualization throughout the fifteen-minute activity. Interestingly, these were the teachers with the least prior teaching experience in the group, though all three had at least four years of prior experience so they were by no means novices. Of the five teachers that did verbalize their reading of the data visualization, three out of the five used sociopolitical more than any other reading type. Table 3 provides a breakdown of each participant’s reading type and layer.

Table 3 Instances of teacher engagement with data visualization activity

		Nancy	Anna	Leona	Natalie	Melody
Reading the Word	Reading the data	2	3	2	2	0
	Reading Between the data	1	0	0	0	0
	Reading Beyond the data	0	0	0	0	0
	Reading Behind the Data	1	0	0	1	1
	Reading the data	1	0	0	0	0
	Reading Between the data	1	0	0	0	0

Kosko, K. W., Caniglia, J., Courtney, S., Zolfaghari, M., & Morris, G. A., (2024). *Proceedings of the forty-sixth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Kent State University.

Reading the World Personal	Reading Beyond the data	2	0	1	1	1
	Reading Behind the Data	3	0	0	1	1
Reading the World Sociopolitical	Reading the data	1	1	0	1	0
	Reading Between the data	3	4	0	2	0
	Reading Beyond the data	2	3	1	2	2
	Reading Behind the data	0	0	3	2	5

Note. *The columns in this table exclusively represent data for teachers who actively engaged in verbal communication during the activity. There were also three teachers who did not engage in verbal discourse during the specified period.*

Out of all the participants, Nancy used the most variety of reading types throughout the entire activity. Nancy’s engagement is significant because she engaged in almost every type of reading at every layer, which was not typically as evidenced in Table 2. For example, she was the only participant that engaged in reading the data and reading between the data at the personal layer evidenced in her statement:

> That's the question, does the data represent you? So you subscribe to an identity or something of that nature and but when you look for the data on that identity or whatever it is that are you representing it in that, like does it represent you, It's supposed to represent population or something like that.

Nancy’s ability to clearly verbalize her reading of the data visualization was found across the activity and contributed to why so many of her utterances were coded from our framework. This also points to a limitation of our study in that we don’t know how the participants who were not as good at communicating their reading of the graph or chose not to communicate at all were engaged in reading the data visualization. This has implications for our design and pedagogy, which we discuss in the next section.

Conclusions and Implications

In this study we sought to explore how mathematics teachers read a relevant data visualization. Drawing from data collected from a larger design research project, we were able to begin to investigate our question and further refine a framework for reading data visualizations. Our framework allowed us to find interesting patterns in the video data we analyzed from the first 15 minutes of a design activity where teachers were engaged in a modified notice and wonder activity with a data visualization we specifically selected because it’s sociopolitical relevance to the teachers in our study. One finding was that the teachers engaged in reading both the word and the world in many different ways and in particular heavily engaged in sociopolitical readings of the world through the data visualization. This finding has implications for future design in that we hypothesize the reason for the participants’ reading predominantly through the sociopolitical layer was because of the relevance of the data visualization itself. The teachers demonstrated a desire to critically examine data beyond its surface level and show interest in uncovering underlying patterns, causes of variation, identifying biases in data collection methods, and understanding contextual factors.

Another finding from this study was that the teachers engaged in reading the data visualization in different ways. Of particular concern for us was that three participants did not engage in verbalizing their reading of the data visualization. As a contextual note this activity did occur early on in our larger study while we were working on building community amongst the participants and the participants that did not engage in this activity did so in future activities. However, moving forward, we see it as important to consider how to engage more of the participants in the discussion. We also noticed related to this that finding that of the five teachers engaged in the activity – four had 16+ years of experience. The people with the least experience engaged the least. This points to possible power dynamics that might be at play in the discourse, which was beyond the scope of our analysis, but we believe should be considered in future work.

As data visualizations have become increasingly common in the media today, we see an increased need for teachers to engage in such data visualization activities and to translate them into meaningful experiences for their students as well. Furthermore, we believe our framework can be useful in helping research not only design activities in the future but to analyze the ways in which people engage in reading data visualizations.

Embodied learning pedagogy emerges as a promising approach in STEM education, but there remains a gap between experiments in the lab and practices in real classrooms. In particular, when learners come into the class for an embodied learning experience, their understanding of the concepts differs. We posit the Perform First Hypothesis, suggesting that performing physical activities benefits learners with less prior knowledge more than those with more knowledge. Results from a longitudinal classroom experiment that compares the effects of observing versus performing embodied learning activities in students with different levels of prior knowledge supports this hypothesis. We found a significant interaction between the levels of embodiment and learners' prior knowledge. The findings shed light on the design of embodied learning experiences for learners with different levels of prior knowledge in real classrooms.

Keywords: Curriculum Development, Embodied Learning, Statistics and Data Science Education

Objectives of the Study

Embodied learning pedagogies has emerged as a promising approach to fostering transferable knowledge. Yet, questions remain about the practical application of embodied learning in real-world classroom settings. First, even if there is laboratory evidence that embodied pedagogy facilitates better learning of a single construct, what is its applicability and impact in a longitudinal course, encompassing a multitude of concepts? Second, with an increasing number of students traditionally outside the STEM sphere enrolling in STEM-related courses, could embodied learning be an effective strategy to help students with low prior knowledge?

To begin answering these questions, we build up a theoretical framework based on current literature looking for clues about how embodied pedagogy might impact long-term learning of diverse learners. Then we detail the results of an in-class intervention experiment that exposed students to embodied learning activities for nine weeks.

Theoretical Framework

Embodied cognition frameworks assume that concepts are grounded in action and perception (Barsalou, 1999; Borghi & Pecher, 2011; Clark, 2008; Golonka & Wilson, 2012). Physical actions observed and performed during learning and encoding influence our mental representations as well as subsequent retrieval, reasoning, and problem-solving (Barsalou, 2008; Fu & Franz, 2014). Thus, it is crucial for classroom instruction to consider embodied pedagogies.

Although past research has demonstrated that an embodied pedagogy (e.g. gesture) is more effective than a non-embodied one (e.g. no gesture), we are early in our understanding of how and when embodied pedagogies influence learning (Goldin-Meadow & Wagner, 2005; Johnson-Glenberg & Megowan-Romanowicz, 2017; Zhang et al., 2021, 2022). One important element is the treatment of prior knowledge, which is often controlled by random assignment or treated as a covariate in the lab. However, when learners come into a class, their understanding differs. This raises a critical question: How do interventions with different levels of embodiment impact learners with different levels of prior knowledge and experiences in the domain?

To answer this question, we posit the Perform First Hypothesis: performing bodily actions will benefit learners with no or low prior knowledge in the domain more than learners with high prior knowledge. In other words, whereas traditionally in educational interventions, students' prior knowledge of the concepts positively correlates with their performance after the intervention, performing embodied activities might mitigate or even eliminate this correlation.

Our hypothesis is grounded in the perceptual symbols system theory: when people first have a perceptual experience, it activates neurons that are mentally stored as multimodal frames of perceptual symbols (Barsalou, 2008). Later, these frames can be activated and function as simulators that enable people to reactivate the same neural connections and simulate the original experience without bodily actions (Glenberg, 1997; Pezzulo & Calvi, 2011). However, if learners lack the prior experience to develop the simulator, they need to first perform the actions to gain the perceptual experience necessary for the multimodal representations to develop.

Although how prior knowledge and the type of embodied intervention interact over time has not been directly examined for performing versus observing actions, past research has shown that low-prior-knowledge learners benefited more (1) from physical than virtual manipulation (Zacharia et al., 2012); (2) from concrete than abstract gesture (Congdon & Goldin-Meadow, 2021); (3) from object manipulation than gesture (Congdon et al., 2018). In all cases, the more embodied pedagogy seemed to be more contributive for learners with low prior knowledge. However, those are highly controlled lab experiments. Because developing expertise in STEM domains is a prolonged process, a single intervention may not fully elucidate this interaction.

The Current Study

In the current study, we use embodied pedagogies to develop a lab curriculum of a college-level introductory statistics course. Participants were randomly assigned to a partner. Within each dyad, one was randomly assigned to be a performer, who would perform hands-on activities, and another was assigned to be a recorder, who would observe and record their partner. We hypothesized an interaction between the types of embodied intervention (i.e. condition) and participants' prior knowledge such that low-prior-knowledge performers would outperform low-prior-knowledge recorders, but high-prior-knowledge performers would not.

Methods

Participants

Participants were students enrolled at a large public research university, taking an introductory psychological statistics course. The course taught statistics from a textbook employing a modeling approach with R programming (Son & Stigler, 2023), delivered through a technology platform called CourseKata.org. The class was structured as two weekly lectures and a lab session. The experimental interventions took place during the 50-minute lab sessions for nine weeks. Students were allowed to miss one session without losing participation points.

Among the final sample size of 227, 171 students self-identified as female (75%), 49 as male (22%), and 7 as non-binary (3%). The self-reported race and ethnicity were as follows: 100 Asian or Asian American (44%), 8 Black or African American (4%), 47 Hispanic, Latino or Spanish origin (21%), 13 Middle Eastern or North African (6%), 46 White (20%), and 13 mixed/multi races (6%).

Design and Procedure

Each randomly assigned dyad were further randomly assigned to either the perform condition (n = 113) or the observe/record condition (n = 114). The performers were expected to perform embodied instructional actions designed to enhance learning. The observers observed and recorded these actions using their phone or tablet. Their role and partner stayed the same for the entire course. If a student's partner could not make it to a lab, the student would be temporarily paired with another student while maintaining their role. Using a cover story, students were informed that we wanted to use their hand movement video to design a pedagogical agent.

Starting Week 2, each lab starts with a set of "practice questions." Students were given 6-10 minutes to complete the questions through a Qualtrics survey. Half questions functioned as a delayed posttest, to measure what students have learned from the previous week. The other half functioned as a pretest to assess what students might already know about the to be taught concepts. Week 2 only had pretest questions, because Week 1 was a general introduction to the lab without embodied activities. After taking the survey, students engaged in a lesson that incorporated embodied activities consisted of object manipulation, gesture, and drawing. One activity example is cutting out a piece of paper with a dataset and used the pieces to perform "shuffling" and "resampling" (i.e. sampling with replacement). Based on assigned condition, they either performed or observed and recorded their partner performing these activities.

Materials

Each week, students received a paper worksheet and a Jupiter Notebook with coding activities. A description of the lab schedule and activities is available through Open Science Framework: https://osf.io/ntsr2/?view_only=ce650267f407451a9ea26abcb428d8f7.

Measures

Pretest performance / Prior knowledge. Participants' pretest performance was measured using half of the practice questions administered to students at the beginning of each lab. There were four trained coders, and every question was coded by two coders to ensure inter-rater reliability. The rubric was jointly determined with the four coders and the lead researcher. Each question was worth one point, with half points given to correct but incomplete answers or those with minor misunderstandings. All coding was conducted blind to condition.

Delayed post-test performance. Participants' delayed post-test performance was measured using the other half of the practice questions. It was coded the same way as the pretest.

Results

Transparency in Data, Analysis, and Materials

The deidentified data and analytic syntax are available through the Open Science Framework. The study design, hypotheses, and analytic plan were not pre-registered.

Missing Data Handling

When students did not come to a lab, or if their partner was switched during a lab, their data for that week was treated as missing. We imputed the missing data using the Markov Chain Monte Carlo (MCMC) algorithm as implemented in the Blimp application (Enders, 2017).

Three-Level Multilevel Modeling (MLM)

We specified a three-level MLM. Level-1 was the repeated measures (the intraclass correlation coefficient (ICC) for the post-test performance = 68.8%). Level-2 was the students (ICC = 23.8%), who are nested in partners/dyads (i.e. Level-3, ICC = 7%). Below, we show the equation for the overall model (Raudenbush & Bryk, 2002):

$$Posttest_{ijk} = \gamma_{000} + \gamma_{010}Condition_{jk} + \gamma_{020}\,Pretest_{jk}^{b.cgm} + \gamma_{030}Condition_{jk} * \,Pretest_{jk}^{b.cgm} + \gamma_{100}\,Pretest_{ijk}^{w} + \gamma_{110}\,Pretest_{ijk}^{w} * Condition_{jk} + \;\gamma_{200}Time_{ijk} + \gamma_{210}Condition_{jk} * Time_{ijk} + u_{00k} + r_{0jk} + e_{ijk}$$

In above, $Pretest_{jk}^{b.cgm}$ is the variation between each student's average pretest performance, and $Pretest_{ijk}^{w}$ is the variation within each students' pretest performance. Because the variation in pretest has both level-1 and -2 variation, the interaction between pretest performance and the condition was partitioned into the interaction between condition and each student's average pretest performance (i.e. γ_{030}), which we will refer to as the level-2 interaction, and the interaction between condition and the variation within each individual's pretest performance (i.e. γ_{110}), which we will refer to as the cross-level interaction.

We used maximum likelihood estimation and fit the model using Blimp 3. There was no significant level-2 interaction between condition and pretest performance (median = 0.09, 95% credible interval = [-0.15, 0.34], yet there was a significant cross-level interaction between condition and pretest (median = -0.12, 95% credible interval = [-0.22, -0.01]).

We next probed the significant cross-level interaction at each condition. For observers, the correlation between pretest performance and delayed posttest performance was statistically significant (median = 0.11, 95% credible interval = [0.03, 0.18]). However, for performers, the correlation was not (median = -0.01, 95% credible interval = [-0.08, 0.07]).

Discussion

In the current project, we designed and implemented an embodied lab curriculum in a college-level introductory statistics course, testing how different embodied interventions impact learners with different levels of prior knowledge. We put forward the Perform First Hypothesis, which posits that learners who had low prior knowledge need to perform the activities to reap the most benefit out of the hands-on instruction whereas high prior knowledge learners can benefit similarly from observing a hands-on demonstration. The results supported our hypothesis: there was a significant correlation between prior knowledge and posttest performance in the Observe condition, but this correlation was not significant in the Perform condition.

The findings also suggest a new research direction for the field of embodied learning. Beyond investigating merely the efficacy of embodied interventions, the current study informs the field to ask nuanced questions of what and when - what type of embodied pedagogies are the most effective, and are they the most effective?

The contrast between performing and observing hands-on activities is not the only important comparison. We started with this distinction because they are both commonly seen in research and practice. The idea that "performing" is unique and foundational is not new. Piaget argued that the sensorimotor stage of development is foundational to later higher-order thinking with abstract concepts (Piaget, 1983; Piaget & Inhelder, 1969). However, embodiment came likely through a continuum from purely abstract to highly embodied instead of distinct categories. We urge future studies to investigate other forms of embodied pedagogies to fully elucidate the question of "what" and "when."

Lastly, our findings have crucial implications for instructional design. Although teacher demonstrations are easier to implement in class, novices seem benefit more from performing physical activities. After giving students meaningful hands-on experience, teachers can then give demonstration or even more abstract instructions. Future research should continue exploring the nuanced ways in which different embodied pedagogies impact learners at different time points of their knowledge development, catering to the diverse needs of learners in in STEM domains.

CONNECTING DATA SCIENCE AND ARTS: EXPLORING DATA-ART INTEGRATION IN A DATA-ART INQUIRY PROGRAM

Yilang Zhao
University of Tennessee, Knoxville
yzhao97@utk.edu

Keywords: informal education, integrated STEAM

In this era of big data, data science education involves immersing students in the context where data originates, profoundly influencing their interaction with data (Wilkerson & Polman, 2020). As students encounter data not only within the confines of the classroom but also in the real world, this contextual immersion renders data science education inherently interdisciplinary.

One way to explore this interdisciplinarity is to integrate data science education with the arts. Previous research has shown the potential enhancement of students' data science learning through the integration of arts (Bhargava et al., 2016; Matuk et al., 2022). Despite this, the specific intersection of data and arts remains underexplored. Our research seeks to address this gap by investigating how students connect data and arts when creating artistic data visualizations.

In light of the promising intersection of data science education and arts education, we designed a 14-week data-art inquiry program in an afterschool setting. 23 middle and high students, referred to as "data artists" (DAs), participated in this program. The program was structured in three phases: weeks 1 to 3 involved DAs reimagining and reinterpreting existing data visualizations to learn fundamental data science concepts; weeks 4 to 7 saw DAs creating their initial artistic data visualizations using data from local agencies; in the last segment of this program, DAs selected their topic, collected data, and created their own unique data visualizations.

To answer our research question, we interviewed six groups of DAs to investigate how they incorporated data into their art creation after the program ended. Using an inductive coding method (Saldaña, 2009), we analyzed the interview transcripts to gain insights into their methods of integrating data and art. Our preliminary findings revealed three key insights. Firstly, DAs employed color coding to represent their data in their data visualizations, such as the left picture of Figure 1, where a group of DAs investigated people's preferences for school lunch items, calculated preference scores, and used different colors for each item. Secondly, the sizes of artistic elements were used to signify differences in data sets, as seen in the middle picture of Figure 1, where a group of DAs explored the salary disparities between baseball coaches of two local universities and used logos with different sizes to show the difference. Lastly, the format of source data influenced the format of their artistic data visualization, exemplified in the right picture of Figure 1, where a group of DAs transformed qualitative data on text messages during an active shooting into a visualization format that resonated with its source.

Figure 1: School lunch, college coach pay, and gun violence

CONCEPTUAL ACCOMMODATION AND EXPERIENCING COGNITIVE DISEQUILIBRIUM: MAGIC OR MATHEMATICS?

Elahe Allahyari
Western Illinois University
E-allahyari@wiu.edu

This paper explores how two undergraduate students come to the existential moment of expressing mathematics as magic. The "Experience" of a mathematical transitional moment might include feelings; however, our experience is normally considerably richer in content than simple feeling. This study investigates how undergraduate students face disequilibrium when they are involved in problem solving situations that call for exponential modeling. Further, it explores whether there is an alignment between experiencing disequilibrium and a conceptual accommodation to a new contextual situation. The analysis is guided by a concept projection perspective (diSessa & Wagner 2005; Wagner 2010). The results suggest that there is alignment between experiencing a cognitive disequilibrium and the process of conceptual accommodation as a form of learning.

Keywords: Phenomenology, Knowledge Elements, Cognitive State, Concept Projection

Introduction

"What is mathematics?" This is a deceptively simple question that does not have a simple answer. To understand the philosophy of mathematics, we need to dig into the philosophy of the mind and the philosophy of language. The main goal of this research is to explore the epistemological foundations of the understanding of mathematics within a specific mathematical topic, focusing on individuals' internal mathematical and linguistic reasoning processes. In this study, I aim to observe the moments in which individuals make sense of their activity and come to understand mathematical ideas. By understanding these moments, we might comprehend the epistemic forms of knowledge that learners activate and perceive through specific linguistic cues embedded in the context.

The impetus for my dissertation study originated in my experience over six semesters of teaching *Algebra II* at a mid-western university. I observed that students were struggling to model exponentially in half-life type problems. However, I observed that in some problems that required a deeper conceptual understanding of the problem, there appeared to be a greater possibility that students would appropriately model exponentially. For example, students appeared more open to appropriately using exponential modeling in situations that involved interest rates or population growth/decay. These observations made me interested in studying how contextual variation can influence learners' understanding of exponential modeling.

Background

Exponential functions are a difficult, yet essential, mathematical concept that play an important role in the study of advanced mathematics (Ellis et al. 2016; Weber 2002). Weber (2002) focused on students' initial understandings of exponential functions. Weber's main result from the work was that, although all students in their study could compute exponents in simple questions, only few students could reason about the process of exponentiation as a pattern of change. Confrey and Smith (1994, 1995) introduced the idea of "*splitting*" structure as a multiplicative pattern, which opened an avenue for its application as a rate-of-change perspective and "*covariation*". Building upon the notion of "covariational" thinking, Ellis et al. (2016) introduced an Exponential Growth Learning Trajectory (EGLT), which identified three stages of students' conceptual development: pre-functional reasoning, the covariation view, and the correspondence view.

Recognizing covariational thinking, which originated from the idea of *split,* is important for designing tasks to explore students' understanding of exponential functions. However, a major gap in the study of exponential functions concerns how we can develop an understanding of exponential growth specified through contexts that are *only* associated with exponentiation. For example, as it is explained above, Ellis' stages of developing an understanding of exponential growth lacks specificity with respect to the type of function. Covariational thinking is important for the learning of any function, not just exponential functions, and thus the question is: What features of a context can provoke *exponential modeling*?

The results of Weber's (2002), Confery and Smith (1994, 1995), and Ellis et al.'s (2016) work creates some essential questions in understanding exponential functions: Why do students encounter difficulty with reasoning about the process of exponentiation? Can contextual variations steer learners' thinking specifically towards understanding the use of exponential models? How does students' thinking in this domain confront cognitive conflicts (disequilibrium)? How do they move through the disequilibrium and equilibration of a new understanding? And how do learners experience these transitional moments?

In this study, I attempt to investigate the moment at which students perceive *mathematics as magic* as a phenomenological experience. Phenomenology, not as a method but as a theory of studying experience in the stage of consciousness, is the study of phenomena as they appear in our experience of things and thoughts. Phenomenology studies the structure of various types of experiences, including embodied actions and linguistic activity, as different forms of social activities (Smith & Thomasson, 2005). For exploring students' experiences of special transitional moments, we need to explore the appearance of knowledge resources as learners activate them. We need to investigate moments at which learners find mathematical validation for their reasoning, as well as identify and investigate different forms of embodied cognition to explain how students reach mathematics as magic.

In the field of mathematics education, the epistemological descriptions of moments of disequilibrium, resolution, and satisfaction after a conceptual accommodation and new equilibration should be mathematical. Studying how students activate the knowledge resource of exponential modeling helped me to observe some moments in which, I believe, students experienced a certain type of cognitive disequilibrium and conceptual accommodation. Wondering about the following two questions led me to perform this study:

1. How do students react to a possible disequilibrium between prior experience with linear modeling and their new understanding of exponential modeling?
2. How do students undergo a process of conceptual accommodation when they are establishing or modifying a new existing scheme? What is the role of cognitive disequilibrium in the process of conceptual accommodation?

Theoretical Perspective and Conceptual Framing

I sought a modern theory of learning that fits in with my overarching constructivist perspective, in which individuals' internal process of actively constructing knowledge is foregrounded. In addition, I attempted to cover a phenomenological perspective to capture the whole mathematical experience resulting in the experience of cognitive disequilibrium and conceptual accommodation. Knowledge in Pieces (KiP) is a heuristic epistemological framework that is informed by Piagetian constructivism and cognitive modeling (diSessa, 1993; 2018). Moreover, knowledge activation and use in the KiP perspective is *highly contextual*, based on students' perceptions of features of contexts.

In further development of the KiP perspective, diSessa and Wagner (2005) describe the knowledge as a construct of *concept projection.* Wagner (2010) provided an extension of the theory of concept projection, which demonstrated Piagetian processes of *assimilation* and *accommodation* as compositional stages of concept projection. "Concept projections are collections of assimilatory and interpretive knowledge elements associated with some concept, and the construction of new concept projections reflects a process of conceptual accommodation to new contextual situations" (Wagner, 2010, p.451). I used this conceptual frame to investigate how students activate different resources of knowledge, especially when they attempt to reflect on a process of conceptual accommodation. In exploring how students come to model exponentially, it appeared that learners could build new knowledge elements—exponential understanding—which was the result of passing through multiple disequilibrium and accommodating the knowledge elements to particular contexts (Allahyari, 2023).

Specifically, in this study, I analyze different cognitive states that include several transitional moments as well as show how context variation can influence learners' knowledge activation. The unit of analysis in the current study are moments at which learners perceived context as an external cue and experienced different cognitive states, which are the collection of assimilatory and interpretative knowledge elements and a process of conceptual accommodation to new contextual situations. In other words, the core of my conceptual framework is to observe students' mathematical experience through specific types of knowledge activation that might pass through disequilibrium and new concept projections that reflect a process of conceptual accommodation.

Method

This study is part of a larger study in which 14 students participated in at least one round of interviews. They participated in a problem-solving situation with four problems in the first round, which was the main problem-solving session. Data for this research was collected through the first rounds of interviews (45-100 minutes of problem solving). The interviews included screen sharing a specially designed set of slides I created through Desmos Activity Builder (DAB). Participants were undergraduate students who enrolled in an Algebra II at a large public midwestern university. I recorded with audio and video while they worked in DAB or a paper-pencil situation in which they described their thoughts aloud as they worked on contextual problems involving exponential modeling.

I observed and analyzed moment-by-moment thinking and reasoning processes in order to see fine-grained ideas of how students moved through experiencing a certain type of cognitive harmony, from experiencing a possible disequilibrium, to the possible process of conceptual accommodation. There was special attention paid to capturing the moments in which learners' patterns of knowledge activation were changed, the type of knowledge resource, the observation of confronting possible disequilibrium, a moment-by-moment report of facial expressions during the process of concept projection, and the recording of gesture expression.

I asked participants to solve the problems in Table 1 and to explain their reasoning aloud. An analysis of explanatory language used during the interviews enabled me to recognize the pattern of reasoning and how learners experienced assimilatory cognizing moments or conceptual accommodation of different knowledge resources. I recognized a possible alignment between experiencing disequilibrium and new concept projections in context that call for exponential modeling.

Table 1. Exponential Problems That Participants Worked on During the Interviews

Title of Tasks	Description of Contextual Tasks
Baseline problem	What does the function $f(x) = b^x$ mean to you? What do you think of when you see this function?
People Diagnosed with Covid-19 in City A	In City A the number of people who have Covid-19 increases by 11% every 10 days. The initial population of people who are diagnosed with Covid-19 in City A is 1500. Create an equation that models this situation.
People Diagnosed with Covid-19 in City B	In City B the number of people who have Covid-19 decreases by 11% every 10 days. The initial population of people who are diagnosed with Covid-19 in City B is 1500. Create an equation that models this situation.

Analysis

Coming to solve the problem of City A is the heart of this study, where we can see how students face multiple disequilibrium, attempt to find a local resolution through returning to the context and genuinely playing with the linguistic cues of the mathematical context, then accommodating a new understanding of the context. Out of fourteen participants of the larger study, three students stuck with linear modeling in all problems and did not experience any disequilibrium. Three other students already knew the exponential model (without deep reasoning, they modeled the problem as an exponential model, more like memorizing the exponential model for the specific population growth context). Eight students experienced some transitional moments, including a certain type of disequilibrium, when they ended up modeling exponentially in City A and City B problems. I observed that the first reaction to the City A and City B problem was expecting a linear model:

Ken: After 10 days the population is 1500 times 0.11 plus 1500 which is 1665
Interviewer: Great! How about after 20 days?

Ken: It should be the same, but 2 times zero point 11; like this $1500 + 2 \times 0.11 \times 1500$

She continued to do the problem the same after 30 days before making a linear model. Before I felt that she was completely satisfied with the model, I asked her a question: "I just have one question, I can see that in each step you are going back to the original population (1500), but is it like 11 percent of the new population or the original one?" After she received the question, she stopped, looked around, then started to read the problem one more time, crossed out whatever she wrote, and then started from a new page, rewriting the information of the problem from the beginning and whispering important information as she was writing. As she was finding the new pattern for calculating the population growth, she was talking with me (or it was a laud self-talk):

I can see that it should be the 11 percent of the new population…because it is increasing every 10 days, **it** means it should increase on an already increased population, not the original one. For example, the new increase for 20 days should happen on an already increased population.

She eventually found the base of 1.11 by doing some mathematical procedures; eventually, she could generalize to an exponential model of $f(x) = 1500 \times (1.11)^x$. In the City B problem, I did not create a contradictory question to see if she could figure out the exponentiation process more independently. I could see that she was facing multiple disequilibrium when it was a declining situation. I believe she was experiencing two different cognitive state simultaneously. She was recognizing the similarities between the City A and City B problems. She knows that for 20 days she should start from 1335—recursive dependency knowledge elements (Allahyari, 2023); however, a declining situation as multiplicative/exponential process was violating her expectation. It seems that there is expectation of growth for a multiplicative situation for her. From one side she was activating assimilatory and interpretative knowledge elements (recognition of recursive dependency), form the other side she was experiencing a new disequilibrium:

I know the population after 20 days should be 1335- 0.11 times 1335 which is 1188…I'm lost a little bit! I am not sure I am right, are we multiplying? Can we multiply, then it decreases? But the pattern should be multiplying by 0.89; there is no other way! It is 0.89 square times 1500, so it is like the inverse of the City A problem, but a square is increasing or decreasing? I do not know! I think my brain is processing still!

She was simultaneously reacting differently; like experiencing different feeling at the same time: Happy to recognize the similarity that has been explored enough in the previous context, while, not expecting multiplicative situation in a declining process. For a moment she closed her eyes and she said, "I am totally lost!". I could not let her to stay in the very contradictory cognitive states. I realized that she needs a reliance point, a form of confirmation from the similarities she is recognizing.

Interviewer: So how is that multiplying after 20 days?

Ken:	It is another 0.89 times the new population (1335)
Interviewer:	And what is that?
Ken:	It is 1188
Interviewer:	Do you want to check your model for 20 days?
Ken:	You mean $(0.89)^2 \times 1500$?
Interviewer:	That's the model you found, isn't it?
Ken:	Yes! Let's see! It is 1188! Oh Gosh! **It feels like magic!** Learning math is so interesting, why is it like this? For a moment I feel completely lost, but in a moment one thing makes sense then everything makes perfect sense and proves each other. I am serious! This is a major breakthrough. (Covering her eyes with both her hands, then whole her face).

I have observed that sometimes it is hard for students to expect a declining population to be modeled exponentially. Not only should they conquer their linear expectation, but they need to overcome expecting an exponential model that cannot show a declining situation. That is why I call this situation facing multiple disequilibrium. As I observed and watched students' videos over and over, I realized experiencing disequilibrium is actually experiencing a "violation of expectation" that is usually experienced when learners attempt to accommodate a new concept projection. Here, the already settled expectation is a linear expectation, yet it is not satisfied by the linguistic cues of the contexts–City A and City B problems that should be modeled exponentially. I called this violation of expectation, when the context does not fit, experiencing a cognitive disequilibrium.

Tom was a student who showed the *manifestation of experiencing disequilibrium***.** When he was very close to seeing the exponential model in the City A problem, he instead strongly expressed his proportional expectation. In the middle of making sense of the structure, he left all his findings and faced a huge *disequilibrium* with satisfying a systematic and already established proportional scheme. He even saw 1.11 times 1.11 times 1500, but then instead of seeing 1.11 squared times 1500 he stopped and said wait a minute and started to work on his paper:

Tom:	Am I doing so wrong? (very sad and disappointed)
Interviewer:	Why? What did you find?
Tom:	I found 1.321 when I divided 1848 by 1500
Interviewer:	What about the first 10 days
Tom:	That works well. $\frac{1665}{1500}$ is 1.11 which makes a lot of sense.
Interviewer:	What did you expect?
Tom:	I thought $\frac{1848.15}{1500}$ should be 1.22 because it increases 11% each time

I asked him to believe in himself because he was going to be surprised how smart he was. He found the population after 30 days and he multiplied 1.11 three times; then he could see the exponential model. "The *Multiplicative Recursive Dependency* well-imbedded in the context task appeared to help Tom to prefer working with his understanding of context rather than sticking with his proportional expectation" (Allahyari, 2023). He eventually could coordinate his perception of the situation with his strategy for calculating an increasing Covid19 population in each step and to resolve an apparent contradiction in his thinking. He was so happy after seeing the model; it was like a cry of joy, but I went even further! I needed him to find a way to compare the exponential process with his expectation.

Tom:	So! f (x) would be: $f(x) = (1.1)^x \times 1500$ Right? Cool.
Interviewer:	Wonderful! Now, do you want to calculate what you find for 1.11 square?
Tom:	Sure! It is 1.321! What? What is that? ***Is it magic****?*

He saw 1.321 again, but instead of being devastated like the first time, he was joyfully asking if it was magic! This time, 1.321 was affirmation that his understanding of the context fit very well with the model that he created. When he found the exponential model, he stood up, and then sat; he shook his head three times and said: "Oh - that is so cool! I made it - I found it!"; then, seeing 1.321 completed his joy. He was laughing loudly, asking, "Is it magic?" I call this moment an *existential moment* resulting from a mathematical change. He eagerly got validation for what "he found" from the second problem, City B.

For the City B problem, it seems to me that Tom was in an assimilatory situation in which he needed to assimilate the situation to his vision about exponentiation. He did not experience any major disequilibrium; he was productively struggling to find 0.89 as the base, but that struggle was not like an "earthquake" to violate his expectation. He was expecting an exponential situation, but it was challenging to find the base. Eventually, he could find the model in this problem too, but there was not a cry of joy after he modeled exponentially. He was clearly happy, his eyes were shining, but he did not ask about any magic; it was more an assimilation of a projected concept.

Discussion

This study is part of a larger study in which eight undergraduate students came to experience productive disequilibrium, accommodate new understandings of the situation, and generalize problems to make abstract models. Among all eight undergraduate students, Tom and Ken stated a specific form of expression in the final steps of modeling situations: *"Is it magic?"* They both showed specific types of cries of joy and happiness in their facial and body gestures. I believe they were experiencing the moment of mathematical eureka through coming to understand and activate knowledge resources of exponential modeling. Tom participated in one round of interviews, while Ken participated in two rounds of interviews.

Tom was the first student in whom I observed a special *harmony* in his resistance to the population growth problem (Table 1). For the City A problem, Tom experienced a disequilibrium (expecting a linear proportion), resolved the disequilibrium by genuinely working with context and refining the linguistic cues, accommodated a new understanding of the situation, and finally generalized the problem to make the abstract models. Ken was one of six students who went through problem solving with seven problems and two rounds of interviews. There is enough evidence that she experienced cognitive states that resulted in expressing mathematics as magic, including conceptual accommodation of a new concept projection at the end of the City B problem. After facing multiple disequilibrium, she said the same as Tom: "Is it magic or something? It seems I am doing magic, and you just light up to show me how I did it."

When the concept projection and the interpretative knowledge element are more in the construct of new reflection as a process of conceptual accommodation, there is more possibility for a learners' cognitive pathway that include facing cognitive disequilibrium. In other words, there is strong *alignment* between experiencing disequilibrium and a new concept projection. I believe we need to further explore what makes mathematics so interesting that students might joyfully express, "Is it magic?" One thing that this study proves is that passing through a cognitive disequilibrium seems a necessary step before a conceptual accommodation to the new contextual situation and realizing the beauty of mathematics.

All eight students of the larger study who could model exponentially at the end of the City A or City B problems (in the first interview) first expected a linear model, but the linear model did not fit well with the context they were understanding. This was the moment at which they experienced disequilibrium, and it was manifested in Tom's interviews very transparently: He was devastated when he divided 1843 by 1500. He needed to accommodate the new concept projection (exponential model); and a well-embedded Multiplicative Recursive Dependency (Allahyari, 2023) helped him to resolve the disequilibrium locally. Tom played genuinely with the context until he could model in a way that was confirmed with the context (conceptual accommodating to new contextual situations).

Implication

In the mathematics education field, such revelations about the interplay between context and students' experience of context (the whole experience, which involves the knowledge resources participants activate and not just students' feelings) is an important line of work that has practical significance with respect to teaching and learning. Besides exploring a dialectical movement between the epistemological investigation of learners' cognitive development and the ontological exploration of specific features of linguistic contexts, this type of study can underscore the need for more epistemological investigations across disciplinary topics that may lend insight into the organization of learners' perceptions and inferences.

A NARRATIVE INQUIRY ACROSS RACE/ETHNIC GROUPS: PARENTS' MATHEMATICS LEARNING EXPERIENCES AND KINDERGARTENERS' MATHEMATICS INTEREST

Kudirat Alli-Balogun
University at Buffalo
kudiratt@aol.com

Ji-Won Son

jiwonson@buffalo.edu

Learning and teaching mathematics are crucial yet challenging, with racial and ethnic disparities persisting in academic success. White and Asian-American children often outperform minorities. Early math education is vital for national development, but many low-socioeconomic children lack numeracy skills. Framed by sociocultural theory, this study investigates parent-child math experiences across four ethnic groups. Interviews with 20 pairs reveal themes like parental support and communication impact on children's interests. Parental experiences profoundly shape children's math interests, passed down through generations. Diverse parental attitudes prompt efforts nurturing mathematical curiosity. Communication, beyond verbal, bridges linguistic barriers and enriches parent-child bonds. This study adds to literature on parental involvement in math education and emphasizes collaboration among parents, children, and schools. Insights offer a basis for future research, promoting effective communication and equitable math proficiency.

Keywords: Early Math Interest, Mathematics Learning Experiences, Parent Impact on Student Learning, Parent's Mathematics Learning Experience.

The foundation of a child's initial math experience and identity is established within the home (Gozel & Toptas, 2018). According to the report by the National Mathematics Advisory Panel (NMAP, 2008), mathematical abilities in children develops during their early years, even before they enter kindergarten. Notably, when cultural values and parental involvement are acknowledged and integrated into classroom teaching methods, students, particularly those from marginalized cultures, tend to perform better (Hill, 2018). Consequently, parental involvement is a variable, among others that have a positive impact on children's mathematics education (Dinkelmann & Buff, 2016; Kung & Lee, 2016; Temur et al., 2018). However, despite these factors, students in the United States continue to struggle with mathematics learning, as reported by the National Assessment of Educational Progress (NAEP, 2015). The strength of mathematics knowledge during kindergarten and a positive self-perception of mathematics serves as strong predictors of students' career choices in mathematics, science/math teaching, and STEM fields of study (Cribbs, 2012; Morgan-Smith, 2019). Understanding the variables that contribute to positive mathematics learning, particularly at a young age, remains crucial in fostering students' engagement in mathematics and related fields of study (Cribbs, 2012; Hren, 2015; Kiss, 2018). Thus, this study aimed to examine the role of parents' mathematics learning experiences in how they engage their young children in mathematics learning at home.

Theoretical Framework

Drawing from various theoretical perspectives, including Vygotsky's Sociocultural Perspective, Culturally Responsive Theory, and the Concept of Interest and Learning, this study aimed to explore how parental discussions about mathematics shape young children's mathematical interests (Bikner-Ahsbahs & Presmeg, 2015). Research suggests that parental attitudes and past experiences with mathematics significantly influence children's engagement with the subject, with memories and feelings about mathematics learning dictating parental views of themselves as mathematics learners (Antolin Drešar & Lipovec, 2017). Moreover, children's interest in learning mathematics is influenced by the opinions conveyed by their parents, highlighting the importance of parental communication in fostering a positive learning environment (Hand, 2003; Franke et al., 2007). Through a qualitative design, this study sought to delve deeper into what parents are saying about mathematics and how these messages are interpreted by young students, particularly in light of parents' past mathematics learning experiences. Furthermore, this study assumed that young children's interest in mathematics can be influenced by their perception of their parents' attitudes toward the subject.

Grounded in Vygotsky's sociocultural perspective, the Concept of Interest and Learning, and culturally responsive theory, the research aimed to uncover the dynamics of parent-child interactions regarding mathematics (Rosa & Tudge, 2013; Eccles, 2014; Gay, 2018), these theories acceded to the crucial and significant role the home environment plays in a child's early life development and learning (John-Steiner & Mahn, 1996; Rosa & Tudge, 2013; Vygotsky, 1978); supporting the trajectory that human development, growth, and learning are 'formally and informally' impacted by their environment (Artigue et al., 2007, as cited in Lester, 2007, p. 1025). Within these structures, social and cultural practices and identities are formed. Knowledge of mathematics that gradually crystalize in human/cultural practices and interactions as they occur in homes, (Artigue et al., 2007, as cited in Lester, 2007, p. 1025) give credence to how mathematics understanding is shaped during early life and development (Mohr-Schroeder et al., 2017). Mathematics educators have the responsibility therefore, of understanding parents' mathematics learning experience, how this experience is communicated, and its impact on young students' mathematics interest; creating a deeper enabling environment for young students' mathematics learning (Hand, 2003, as cited in Franke et al., 2007).

However, despite the existence of the abundance of empirical studies on parental involvement of different constructs, little to no study exists in the body of literature on the construct of parental mathematics learning experience. The broad spectrum of the pedagogy on parental involvement captures the "home-based and school-based activities through which parents transmit their own skills, knowledge, attitudes, and values to their children. As a result of the complexity and multidimensional nature of the concept of parental involvement, parental experience appears absorbed in this construct. These constructs in research can be fully understood and captured with narrative (in-depth semi-structured or structured) interviews (Antolin Drešar & Lipovec, 2017). By understanding the role of parental communication in shaping children's mathematical interests, the study sought to contribute to the existing literature on mathematics education and inform strategies for promoting positive attitudes towards mathematics among young learners (Krapp, 1999; Renninger & Hidi, 2017).

Methods

Narrative inquiry allows for a nuanced exploration of parent-child interactions within the familial context (Bates, 2004; McMullen & de Abreu, 2011; Mruk, 2006; Mueller, 2019). Adopting a qualitative narrative design approach, drawing from a socio-cultural perspective and employing narrative inquiry methodology, this study sought to examine how individuals construct meaning from events in their lives, through meticulous examination of parents' stories about their experiences with mathematics. The use of episodic interviewing techniques enables participants to recount specific events and experiences, providing detailed insights into the dynamics of parent-child discourse regarding mathematics. Narrative inquiry offers a comprehensive exploration of parent-child interactions within the family microsystem. Additionally, narrative inquiry addresses gaps in prior studies by offering a qualitative exploration of parent-child discourse, which quantitative measures alone cannot capture (Mohr-Schroeder, 2017). Grounded in theoretical frameworks such as Bronfenbrenner's Ecological Systems Theory and Vygotsky's socio-cultural perspective (John-Steiner & Mahn, 1996; Rosa & Tudge, 2013; Vygotsky, 1978), and by analyzing narratives, this research aimed to deepen the understanding of the factors that shape young children's interest in mathematics, thereby contributing to the literature on mathematics education.

Building on a previous pilot study, this research employs both deductive and inductive approaches to understand the relationship between parents' mathematics learning experiences and their children's interest in mathematics (Alli-Balogun, 2022; Bates, 2004). The pilot study identified key themes, providing a framework for the analysis in the present investigation. By addressing limitations identified in the pilot study and deepening our understanding of parent-child dynamics in mathematics education, this research also aimed to contribute to the existing literature and inform strategies for promoting positive attitudes towards mathematics among parents and young learners (Smith & Johnson, 2010).

Participants. Kindergarten experiences can shape future math attitudes, impacting career success in STEM fields. Early math interventions benefit all children, especially those from underrepresented minorities and low socioeconomic backgrounds. To ensure diversity, this study recruited kindergarten children aged 4-6 and their parents. Participants included parents and children from African-American, White, Asian, and Hispanic/Latinx backgrounds. Forty participants, including 20 parents and 20 kindergarten children, participated in the study (see table 1).

Table 1: Gender Distribution by Race/Ethnicity

	Parents		Children	
Race/Ethnicity	Female	Male	Female	Male
Asian/Pacific Islander	2 (5.0%)	3 (7.5%)	3 (7.5%)	2 (5.0%)
Black or African American	4 (10.0%)	1 (2.5%)	4 (10.0%)	1 (2.5%)
Hispanic/Latinx	5 (12.5%)	0 (0%)	1 (2.5%)	4 (10.0%)
White	3 (7.5%)	2 (5.0%)	5 (12.5%)	0 (0%)

Data Collection. This qualitative study employed narrative data collection methods to delve into the complex dynamics of parental experiences and children's perceptions of mathematics. The research methodology centered on semi-structured interviews, strategically designed to elicit rich narratives from participants. To ensure diverse representation, a stratified purposeful sampling approach was adopted, targeting participants from four racial and ethnic backgrounds. Efforts to recruit participants involved both word-of-mouth referrals and targeted outreach in public spaces frequented by families, such as parks and eateries. Interview sessions, conducted either in-person or over the phone, were tailored to accommodate the attention span and comprehension level of both parents and children. Children's interviews were relatively brief, lasting approximately 10-15 minutes, while parents engaged in more extensive discussions lasting around 30 minutes. Throughout the interview process, meticulous attention was paid to maintaining participants' comfort and confidentiality. Audio recordings were used to capture participants' responses verbatim, allowing for thorough analysis. Additionally, follow-up prompts and post-interview communications were employed to clarify any ambiguities and ensure the accurate representation of participants' perspectives. Anonymity was preserved through coded identification numbers assigned to each participant, safeguarding their privacy throughout the research process.

Instruments The interview protocol employed in this study adhered to established qualitative research methodologies, drawing on semi-structured questioning to facilitate in-depth exploration of participants' experiences and perspectives. A primary instrument utilized is the episodic narrative interview technique, comprising six steps outlined by Mueller (2019), which guides researchers in eliciting detailed narratives. This protocol, validated through a process involving parents and kindergartners not included in the study, enabled the collection of nuanced accounts regarding parental experiences with mathematics learning and children's interpretations of these experiences. The interviews are carefully designed to ensure clarity and depth, incorporating prompts and questions adapted from previous research studies and validated instruments such as the Mathematics Interest Inventory (MII) by Stevens and Olivárez (2005). Interviews with parents and children are conducted with sensitivity to their comfort and engagement, with children's interviews deliberately kept shorter to accommodate their attention spans. Thematic analysis, conducted using NVivo coding software, facilitated the identification and exploration of patterns and themes within the collected data, contributing to a comprehensive understanding of the research questions at hand.

Data Analysis The analytical framework of this study was anchored in thematic analytical techniques developed by Braun and Clarke (2006), emphasizing the generation of in-depth data to foster a deeper understanding of early childhood mathematics learning. Through semi-structured interviews and meticulous transcription processes aided by Wreally transcription services and Nvivo coding software, each interview was thoroughly analyzed to identify emerging patterns and themes. The study's objective was to amplify the voices of both young learners (kindergarteners) and their parents, exploring the impact of parents' mathematics learning experiences and discussions on their children's interpretation and development of an interest in mathematics. Thematic analysis, following Braun and Clarke's phases, allowed for the identification and exploration of significant themes within the collected data, offering insights into parental roles, children's interpretations, and the dynamics of math-related conversations within families. By engaging in this comprehensive analysis, the study sought to address overarching research questions regarding parental experiences, intergenerational transmission of attitudes towards math, and its implications for children's attitudes and interests in the subject. During the coding phase, meaningful patterns emerged, such as the importance of math education, the use of manipulatives, and parental involvement in understanding math concepts. Table 2 provides an excerpt of some of these codes generated from the data.

Table 2: Sample Codes

Codes	Quotes
Math was taught as important	"I think my parents teach me that [math] is very important."
Using toys as manipulatives	"Counting blocks, toys sometimes."
Nurturing children's strengths and working on weaknesses	"My parents were very supportive and nurtured us where our strong suits are, [and] recognized where maybe we were weaker."
Parents helped in understanding math	"My dad would help me. He would help me try to figure out the equation."

These codes were clustered based on similarities, leading to the identification of initial themes. An example of an initial theme is shown in Figure 1.

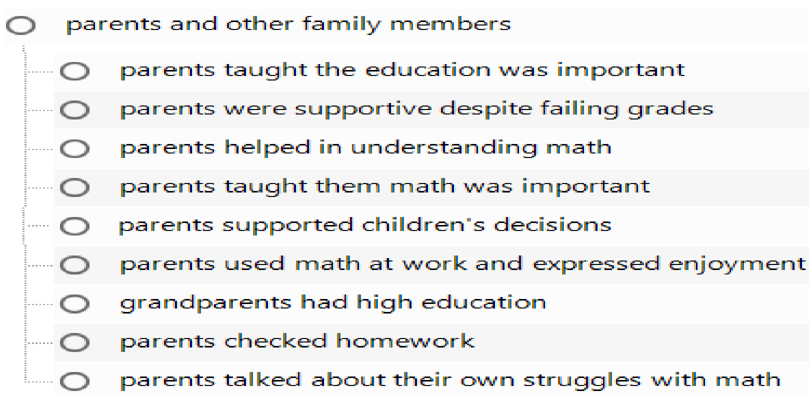

Figure 1: Sample Cluster

Subsequently, the initial themes underwent a higher level of abstraction, forming broader categories of meanings reflective of common experiences among participants. The hierarchical organization of codes facilitated by NVivo software enabled the formation and management of initial themes. Thematic maps were created to visually represent the relationships among identified themes, contributing to a cohesive narrative of participants' experiences. Through this rigorous coding and thematic analysis process, the study aimed to provide clarity and precision in understanding the complexities of parent-child interactions regarding mathematics learning, shedding light on the factors shaping children's attitudes and interests in mathematics.

Summary of Findings

An analysis of the data after repeated reading emerged seven themes. Through semi-structured interviews, participants shared their personal narratives with mathematics learning. Braun and Clarke's (2006) phases of thematic analysis were used on the interview data, from which the themes emerged. The first research question resulted in three themes: (a) Supportive Environment, (b) Own Math Ability, and (c) Perceived Usefulness. The second research question revealed two themes: (a) Indirect Conversations through Parental Motivation and (b) Indirect Conversations through Parental Support. The third research question resulted in two themes: (a)

Parental Influence and (b) School Environment Influence. The themes and their definitions are presented in table 3 below.

Table 3: Themes and Definitions

Themes	Definition
Supportive Environment: Having support contributed to parents' experiences in learning math	Parents who received support from parents, teachers, tutors, other family members and peers while learning math typically enjoyed the learning experience, while parents who did not receive or lacked support typically did not enjoy learning math
Own Math Ability: Math ability contributed to parents' experiences in learning math	Parents who perceived themselves to be good in math generally enjoyed learning math as a student, while parents who perceived themselves to lack analytical skills generally expressed disliking math when they were students
Perceived Usefulness: Perceived usefulness of math contributed to parents' experiences in enjoying math	Parents who perceived math was useful for their future careers and continued to apply math in their current careers generally liked math, while parents who did not find math useful generally disliked math
Parental Motivation: Parents motivate their children to learn math	Regardless of racial and cultural backgrounds, parents typically wanted their children to do well in math and help them become encouraged to learn math
Parental Support: Parents support their children's math learning	Regardless of racial and cultural backgrounds, parents generally provided the same or more support for their children while learning math than they received when they were students
Parental Influence: Children's interest in math is influenced by parents	Children typically expressed feeling good about math when their parents helped them with homework and integrated math activities in their everyday lives, and when they perceived that their parents liked math
School Environment Influence: Children's interest in math is influenced by their experiences at school	Teachers' support for children in understanding math while at school influenced the students' drive to remain engaged in learning math

Discussion and Implications

It is widely understood that decisions, policies, curriculum are designed and developed in response to research findings and the significance of parents' own mathematics learning experience on students' mathematics learning and identity is not an exception which hitherto has little to no evidence in literature. The thematic findings of this study supported the theoretical notions of Vygotsky and Bronfenbrenner on human development, sociocultural perspective and learning (Bronfenbrenner, 1992; Vygotsky, 1978; 1995), and Epstein's theoretical Model of School-Family-Community Partnership (Epstein, 1995). Vygotsky's theory stipulated that, though a child can be "spontaneous", meaning to understand or learn something on their own, there are other learnings a child gets only within an instruction, also known as "nonspontaneous" (Clarà, 2017, p. 55). Vygotsky described this type of child-adult collaboration as 'Intellectual Imitation', in which the adult forms a meaning, new for the child, and the child imitates that meaning (Clarà, 2017, p.55; Vygotsky, 1987, p. 210). Inferring to the type of parental involvement in kindergarteners' mathematics learning as suggested by the thematic findings, this study draws attention to how teachers and the mathematics community can be guided in support of parents in advancing mathematics learning of young scholars.

Further, the themes that emerged revealed that parent's mathematics learning experience influenced their role in their young children's development of mathematics interest. Parents' own positive experiences of learning mathematics in school and their own parents' influence on their mathematics learning impacted their perceptions of the need to develop their children's mathematics skills. Intellectual imitation does not always result in the formation of non-spontaneous meaning (p.55). Subsequently, in this study, when the parent participants acknowledged that their role in encouraging and supporting mathematics learning of their child originated from their own positive mathematics learning experiences, influenced by their own parents, it could be identified as intellectual imitation. Further, it was stipulated by Vygotsky (Clarà, 2017) that a child attains a higher level of development when a series of spontaneous meaning is formed by the child from a non-spontaneous meaning that the child gathered from an intellectual imitation of adult-child instruction. This higher level of development is referred to in Vygotsky's theory as the Zone of Proximal Development (ZPD) (Clarà, 2017) within which lives the possibility of the child attaining a higher level of development from a non-spontaneous encounter.

The parents in this study generally perceived that their children needed to learn mathematics and that mathematics was an important life skill. The themes generated from the data revealed that parents may not necessarily orally communicate their mathematics learning experiences to their kindergarten children, however parents often helped their children become familiar, interested, and comfortable with mathematics.

Limitations and Areas for Future Study

The investigation into parents' discussions about math with their kindergarteners was framed within a socio-cultural lens, drawing on key theoretical perspectives such as Vygotsky's sociocultural theory and Bronfenbrenner's ecological systems theory. These frameworks provided a rich foundation for comprehending the dynamic interactions between parents, children, and their socio-cultural contexts. However, the generalizability of the research findings is inherently constrained by several factors, including geographical location, sample size, and the subjective nature of participants' responses, which may be susceptible to bias. While the study's sampling strategy was purposive and incorporated a stratified random selection method to ensure representation of the socio-economic and ethnic diversity within the target population, its scope is inherently delimited to the specific context of kindergartners and their parents, rendering expansion of the results to broader populations questionable. Future research endeavors of this nature should consider designs integrating parent-child observations to mitigate the impact of subjective bias arising from self-reported accounts.

The implications of this study extend to various stakeholders, including parents, educators, policymakers, and researchers. For parents and educators, fostering engagement in math learning through collaborative efforts and culturally responsive approaches is essential. Parental attitudes, both conscious and subconscious, are undeniably shaped by their historical encounters with learning mathematics, and enhancing parental involvement in their children's mathematical education could be achieved through rudimentary training programs. Additionally, educators should develop and implement culturally responsive mathematics curricula that recognize the impact of socio-economic disparities on students' math interest and integrate diverse cultural perspectives to create an inclusive learning environment. Policymakers should support the establishment of parent engagement programs and allocate resources for comprehensive professional development programs for teachers to address the diverse needs of students within a math classroom. Furthermore, future research directions should focus on promoting mathematical literacy, incorporating diverse math role models, and developing early intervention initiatives to nurture math interest among young children from various socio-economic backgrounds. Through collaborative efforts, stakeholders can create a supportive ecosystem that nurtures mathematical curiosity and enthusiasm, ultimately creating a more inclusive and equitable mathematics education environment.

Conclusion

This narrative inquiry, rooted in Vygotsky's sociocultural perspective, culturally responsive theory, and the nexus of interest and learning, delved into the intricate dynamics shaping kindergarteners' mathematical trajectories. Conducted with 20 parent-child pairs from diverse ethnic backgrounds, the study explored parental discussions about mathematics and their impact on children's perceptions and interests. It sought to bridge racial and ethnic disparities in these conversations, aiming to nurture curiosity and reverse declining minority participation in STEM fields. Key themes emerged, highlighting the profound influence of supportive environments, intergenerational transfer of mathematical skills, and the perceived usefulness of mathematics. These insights emphasized the critical role of parental engagement in fostering robust educational foundations and equal opportunities, illuminating pathways for collaborative synergy between parents, children, and schools to shape effective learning experiences and scholarly achievement. Moreover, the study revealed how parents creatively communicated their mathematical experiences to their children, surpassing verbal exchanges and embedding a legacy of positive mathematical attitudes for future generations.

FRUSTRATION AND POTENTIAL: EARLY ELEMENTARY SCHOOL STUDENTS' FEELINGS TOWARDS MATH ERRORS

Mari Altshuler
University of Illinois Urbana-Champaign
mshuler@illinois.edu

Christopher Leatherwood
University of Pittsburgh
chrisleatherwood@pitt.edu

Keywords: Affect, Emotion, Beliefs, and Attitudes; Elementary School Education; Early Childhood Education

"Sometimes I feel disappointed in myself, but I know I can always try again and get better." Here, third grader Torrin described contradictory feelings about making mistakes in math; he felt disappointed and saw potential for improvement. His nuanced take reflects a dichotomy not often seen in adolescents' relationships with mathematical mistakes (Bray, 2013; Cohen, 1990; Radatz, 1980; Santagata, 2004). Teachers' perceptions and use of errors in math class often lead middle and upper grade students to internalize errors as reflective of their capabilities (Son & Sinclair, 2010). In turn, mistakes become detrimental to students' mathematics identities (Martin, 2006; Steele, 1997) instead of being opportunities to learn. Research shows that when teachers do leverage mistakes as valuable sources for inquiry (Borasi, 1987; Kramarski & Zoldan, 2008), adolescent students are more willing to engage with difficult problems and explore their own errors publicly (Leatherwood, 2022). However, teachers often shy away from this model and instead avoid error exploration in fear of damaging students' self-esteem or encouraging the reproduction of incorrect computations (Bray, 2013; Ma, 1999; Schleppenbach et al., 2007). Though literature has explored how young children learn mathematics (e.g. Kilpatrick et al., 2001) and their dispositions towards mathematics (e.g. Beyers, 2011), young children's feelings towards errors have not been extensively studied. This led us to ask, "How do early elementary school students feel about making mathematical errors?"

The data for this study come from a dissertation project (Altshuler, 2022). Thirty 1st-3rd grade Chicagoland students participated in semi-structured interviews (Spradley, 1979) over Zoom in November 2020. As identified by their caregivers, 18 of the participants were female, and 12 were male. Five were African American/Black, 5 were Asian, 2 were Hispanic/Latinx, 15 were white, 2 were multiracial, and 1 self-identified as Middle Eastern. Our conversations addressed students' experiences with and feelings towards math; this study involved analysis of interview questions that focused specifically on students' responses to mistakes. Using the identify-and-eliminate (Radatz, 1980) and error-for-inquiry (Borasi, 1987) theoretical frameworks, we engaged in qualitative analysis, which included line-by-line investigation of students' quotes, clustering of students' responses by theme, and identifying patterns across the data set.

Aligned with an identify-and-eliminate model, preliminary findings show that early elementary school students often experience negative emotions when they make mathematical mistakes. These negative sentiments are commonly directed at themselves–for not understanding the material, not completing the work accurately, or for facing consequences like receiving a low grade–and are similar to what is seen in the literature on adolescents' feelings towards errors. However, unlike adolescents, the young students in this study also acknowledged their potential to change and grow, often expressing that they had the opportunity to try again after making a mistake. These sentiments are more aligned with an error-for-inquiry model. If teachers leverage these sentiments and emphasize the opportunity to learn from mistakes, we can support students to build resilience, perseverance, and positive identities as mathematical sense-makers.

MATHEMATICS AND SCIENCE SENSEMAKING IN LEARNING THE NONLINEAR DYNAMICS OF CLIMATE MODELS

Amber Armstrong
University of Minnesota
armst417@umn.edu

Anita Schuchardt
University of Minnesota
aschucha@umn.edu

Keywords: Modeling; Sustainability; Undergraduate Education; Integrated STEM/STEAM

Global models of climate often consist of computer simulations that represent climate using mathematical equations carrying scientific meaning (Skovsmose, 2021). The mathematical and scientific foundations of climate models can provide opportunities to integrate mathematics and science instruction, fostering a deeper understanding of both subjects (Barwell, 2013). The North Atlantic circulation system, for example, has been modeled using systems of nonlinear differential equations, which are based on the salinity and temperature differences across the North Atlantic (e.g., Stommel, 1961). This model shows how ocean currents can slow due to rising temperatures and freshwater influxes from melting ice, limiting the flow of warmer water traveling to higher latitudes. With less warm water traveling to polar regions, equatorial regions remain warm as the polar regions become colder. To understand how students conceptualize such models, we examine undergraduate students' mathematics and science sensemaking processes while working on a model of the North Atlantic current.

We employ the *Sci-Math framework* (Zhao & Schuchardt, 2021) to understand how students engage in mathematical and scientific sensemaking during a climate modeling task. Scientific sensemaking can encompass how students interpret the meaning of variables and equations, as well as understanding the trends or patterns among such variables. Scientific sensemaking also includes how students point to mechanisms that explain how or why a scientific phenomenon occurs. Mathematics sensemaking can include how students complete mathematical procedures and identify mathematical rules to guide their calculations. It also includes how students make sense of the structure of an equation, the quantitative relationship between variables, as well as the underlying mathematical concepts behind an equation.

We examine how undergraduate students enrolled in a biology course make sense of a model of Earth's climate. During the climate model task, students adjust the initial values for temperature and salinity differences across the two regions of the North Atlantic, which affect the rate of ocean flow. Through discussing the stark contrast between initial conditions that create high and low water flow between two regions of the North Atlantic, students can make sense of the nonlinear behavior of climate systems by recognizing that the increasing global average annual temperatures do not always lead to higher temperatures everywhere on the planet.

We collected data from students working in small groups on the climate modeling task. Data include written student materials and video-recordings of their group work. To analyze the data, we use a priori coding schemes from the Sci-Math framework (Zhao & Schuchardt, 2021).

Preliminary results indicate that individuals notice patterns both qualitatively (i.e., general understanding of science concepts) and quantitatively (i.e., make sense of the rates of change and covarying variables). These results provide a springboard into understanding how the nonlinear dynamics of climate change can be taught in mathematics and science classrooms.

EFFECT OF IBL VS LECTURE-BASED INSTRUCTION ON CALCULUS I STUDENTS' MATH ANXIETY

Harman P. Aryal
Stockton University
harman.aryal@stockton.edu

Math-anxious students exhibit physical, mental, and emotional symptoms. These symptoms often have short-term and long-term impacts on students' mathematics learning. This research sought to understand the effect of inquiry-based learning versus lecture-based instruction on Calculus I students' math anxiety. Findings revealed that the activities, such as collaborative work, optional and ungraded work, and the instructor's caring nature decreased IBL students' anxiety, whereas the instructor's readiness to explain the material in class when students asked decreased lecture-based students' anxiety. However, the tests and exams and responding to the instructor's questions in front of their peer increased groups anxiety.

Keywords: Math anxiety, inquiry-based learning, collaboration.

Math anxiety significantly affects students' mathematics learning and academic performance. Students who are highly anxious exhibit physical, mental, and emotional symptoms. Physical symptoms include nausea, sweaty palms, and increased cardiovascular activity (Ashcraft, 2002; Chang & Beilock, 2016). Mental symptoms include an inability to concentrate and mind blanking (Plaisance, 2009; Ruffins, 2007). Emotional symptoms include extreme nervousness and apprehension (Mattarella-Micke et al., 2011). As a short-term consequence of these symptoms, students may dislike mathematics and take fewer mathematics courses, and in the long term, they tend to avoid mathematics and mathematics-related courses (Godbey, 1997; Hembree, 1990). Due to such impacts of math anxiety on students' mathematics learning and performance, this research investigated the root causes of math anxiety and explore the potential interventions to alleviate it. As such, this study explored students' perceptions and experiences of learning Calculus I via inquiry-based learning (IBL) versus lecture-based instruction and the impact of these instructional approaches on respective groups' math anxiety.

Literature Review

Math anxiety has been a part of the human experience for a long time. The verse, "Multiplication is vexation ... and practice drives me mad," can be traced back to at least the 16th century (Dowker et al., 2016). However, it wasn't until 1957, when Dreger and Aiken introduced the concept of "number anxiety," that math anxiety began to receive increased attention. Subsequently, Richardson and Suinn (1972) conducted the first formal study of math anxiety, defining it as "feelings of tension and anxiety that interfere with the manipulation of numbers and the solving of mathematical problems in a wide range of everyday life and academic situations" (p. 551). Since then, research on math anxiety has been extensively investigated.

Traditional lecturing, which is a predominant mode of instruction in college mathematics courses across the United States (Stains et. al., 2018) and is ineffective in helping students learn mathematics (Boaler, 2008), could be one of the possible reasons for evoking math anxiety among students. The lecture-based does not offer substantial opportunities for students to share each other's ideas and experiences with their teachers and peers. On the other hand, IBL, which is an active learning pedagogy, provides extensive opportunities for students where they can work in pairs or groups to make conjectures, gather information for problem-solving, and present their work to groups and to the whole class (Kogan & Laursen, 2014). Through a comparative study, Laursen et al. (2014) reported that students in IBL math-track courses achieved greater learning gains than their non-IBL peers in cognitive, affective, and collaborative areas. Similarly, Laursen et al. (2011) found that the IBL students were involved more in interacting with each other and with the instructor, and they were more involved in setting the course pace and direction. It is also reported that IBL enhances students' conceptual understanding (Jensen, 2006), communication skills, confidence, and self-efficacy (Laursen et al., 2011). Considering such benefits of IBL, this study examined the relative changes in the anxiety scores of Calculus I students' using an abbreviated version of the Mathematics Anxiety Rating Scale (MARS-S).

Methodology

Research Background and Participants

The sample of this study comprised of students who were enrolled in the Calculus I course and were taught using either IBL or lecture-based instruction during Spring 2021 at a university located in the Midwestern United States. Students who received IBL instruction were in the IBL group, and those who received lectures were in a lecture-based group.

The IBL instructor usually began the class by welcoming students and briefing them on the activities for the day. When he had to introduce a new lesson, he would begin the class with an interactive lecture; otherwise, he directed students to work collaboratively in Teams breakout rooms, where they usually shared each other's ideas and solved assigned problems. The instructor would visit each group and monitor their work. At the end, the students would return to the main room, where the instructor facilitated a whole class discussion.

On the other hand, the lecture-based instructor began the class by asking if the students had any questions from the previous class. If they had questions, the instructor explained the concepts as needed. Then, the instructor usually began the lecture by solving preselected examples using the Notability app from his iPad. Occasionally, the instructor paused during the lecture and asked some questions to the entire class. Students were never sent to breakout rooms and were never provided opportunities for group discussions.

Data Collection and Analysis

This study was conducted in two phases. First, data were collected from 15 students in the IBL group and 23 students in the lecture-based group using the MARS-S as a pre- and posttest. Based on the change in anxiety scores from pre to posttest, 9 students from the IBL group (3 greatly increased, 3 greatly decreased, and 3 did not change much) and 3 students from the lecture-based group (1 student from each category) were interviewed using semi-structured questions such as "Could you please describe your reactions when you felt anxious (e.g., sweaty palms, inability to concentrate, increased heartbeat)?" The data thus collected were transcribed using NVivo, a qualitative data analysis software, and several open codes were generated. Then, the codes were combined to identify various emergent themes. The results were then organized based on these themes.

Results

In the following sections, I present the major findings from the analysis of the data obtained from the class observations and student interviews. In so doing, I compare the results from the cross-analysis of the IBL and lecture-based group's data.

The in-class group work and lecturing reduced IBL students' anxiety; out-of-class group chats reduced lecture-based students' anxiety. IBL students experienced about 20% lecturing and 80% collaborative work in each class, while lecture-based students were fully lectured in each class, but some students managed to communicate via the GroupMe chat application. An IBL student said, "I think doing the task in a group reduced it for sure, and ... watching the videos in class, like that does not stress me out or anything." Because of the collaborative learning opportunities, IBL students became closer to each other and were comfortable asking questions, responding to groupmates' questions, proposing their solution strategies, and listening to their peers' different perspectives. Such activities made them feel relaxed and also helped to reduce their anxiety. On the other hand, lecture-based students initiated out-of-class collaboration via GroupMe. A lecture-based student said, "We all try to help each other out [on GroupMe] so I would say it's very collaborative." They maintained this throughout the semester, where they felt comfortable asking questions and responding to each other. The cooperation and mutual support received by these students during the chat reduced their anxieties and frustrations while learning Calculus I.

Instructors' readiness to meet and help students at any time decreased IBL students' anxiety; the long wait for the instructor's email replies increased lecture-based students' anxiety. The IBL instructor's readiness to meet with students at any time and discuss their questions, concerns, or problems in and out of class decreased IBL students' anxiety. IBL students felt comfortable asking questions to the instructor at any time—during class, at the end of class, right after class, or by scheduling a virtual meeting—and discussing their problems. They could approach the instructor at "eleven o'clock at night or 7:00 am that morning;" he was always ready to meet and talk with them. Students could also send their questions or concerns via email, to which he replied promptly. This kind of flexibility from the instructor made students calm down and reduced their anxiety. Alternatively, although the lecture-based instructor encouraged students to reach out to him with their questions, students had to wait for long hours for his email responses. Students were disappointed and frustrated by not receiving a response to their emails for several days. Liz, for example, mentioned, "We have an assignment that's due on Friday, and I need help. And I can't afford to wait three days for you [the instructor] to email me back because this piece of information is necessary for me to do 60 percent of the assignment."

Optional tasks and ungraded assignments decreased IBL students' anxiety, and the overwhelming number of online homework problems, especially at the beginning of the semester, increased lecture-based students' anxiety. In addition to the midterms, the IBL instructor engaged students in both optional and mandatory work, which was rarely graded. His pretasks were optional and ungraded but recommended for students to complete before each class. A student stated, "I know they're just used for practice and prep for the exams and for class. So, I don't feel as stressed about them." However, the tasks, mock exams, and group competitions were mandatory and required to be completed during class but were rarely graded. Students did not feel stressed working with the optional and ungraded tasks and activities because they did not impact their grades; rather, these activities reduced IBL students' anxiety by developing confidence and problem-solving ability.

Lecture-based students, on the other hand, experienced stress, frustration, and anxiety when they confronted so many online problems as homework assignments during the first week. A student stated, “He gave us homework assignments that had eighty-seven problems. ... But that was really the only thing that made me feel anxious about the assignments.” Students were anxious, thinking that they might continue receiving problems in the same manner. However, their anxiety reduced as the online homework problems decreased as the semester progressed.

Both IBL and lecture-based students felt anxious about being called on during the lectures and whole-class discussions. Students in both groups experienced anxiety, specifically during whole-class discussions, thinking that the instructor might randomly call on them for a response at. An IBL student, Camila, stated, “The rest of the time, I am comfortable until he directly calls on me.” These students were worried about their colleagues’ judgments when they could not respond to the instructor's questions correctly and instantly. Likewise, lecture-based students were worried about being called on during the lecture for similar reasons. Unlike the IBL students, lecture-based students were usually busy “trying to write everything down” that the instructor wrote, and they experienced nervousness when they did not respond quickly to the instructor’s abrupt questions. One of the lecture-based students, Liz, stated, “Occasionally he would … call on someone, and if they wouldn't know, he'd be like, you should know this. I would be, like, woo, I should know this by now, which would freak me out a little bit.”

Tests and quizzes, online learning, and proctored-track exams increased both IBL and lecture-based students’ anxiety. Both IBL and lecture-based students were anxious about learning online virtually and taking proctored-track exams. Although midterms and final exams were cumulative for IBL students, they were more anxious about taking the final exam than the midterms. “I was very confident going into it [exam]. And then, I started the test, and I felt like my mind just went blank, and I couldn't think.” Likewise, the lecture-based students were anxious about taking the tests and the final exams because they weighed the largest proportion of the overall grades. A lecture-based student reported, “I get anxious, especially when I'm taking a test; my heart races, and I feel like my throat sort of closes a little bit.” Also, lecture-based students were anxious to see a few questions on the exams because they would lose huge points if they did even a single problem incorrectly.

Online learning was another aspect that induced anxiety among both groups of students. IBL and lecture-based students occasionally missed part of or the entire class due to poor Wi-Fi connections, which added extra pressure on students. Moreover, proctored-track exams caused anxiety among both groups of students. They were anxious about being watched by someone remotely and hearing a loud noise when someone asked clarifying questions to the instructor.

Instructors’ questions increased both IBL and lecture-based students’ anxiety. Instructor questions—either during lectures or whole-class discussions—increased both IBL and lecture-based students’ anxiety. Three out of nine IBL students said that they feared the instructor’s questions, specifically when they were unsure of the answers and were still processing the information. Maria said she is terrified of instructor questions, thinking of giving an incorrect answer in front of her colleagues who were not from her small collaborative group. A lecture-based student said, “I was a little stressed out because he would call on people, and I was scared that he would call on me.” Although lecture-based students experienced similar types of anxiety in responding to instructor questions, they were also anxious about the instructor’s verbal pressures, such as, “There's been a couple of times when he [the instructor] said, you should know this, and I did not know it, and that made me very anxious," Liz from the lecture-based class said.

Discussion

Results show that factors such as the instructor's amicable and cordial nature, extended help for students at all times, in-class group work, and optional and ungraded homework decreased IBL students' anxiety. However, factors such as responding to the instructor's questions and asking questions in front of their peers increased these students' anxiety. On the other hand, activities such as an overwhelming number of online homework problems that were due every week, thinking of being called on for a response in class, responding to the instructor's questions, and fast-paced teaching increased lecture-based students' anxiety. However, the instructor's readiness to explain the materials in class reduced the lecture-based students' anxiety.

Based on the findings from the present study, I recommend that although some factors of the instructional environment, student behaviors, and instructor behaviors have been found to increase anxiety among both groups of students, many other factors have lessened their stress, frustration, and anxiety. It is suggested to the instructors of Calculus I and other similar mathematics courses to implement IBL in their classes or at least transition toward student-centered approaches to instruction because of the benefits of such instructional practices on students' critical thinking, reasoning, and problem-solving abilities. It is also suggested to avoid the instructional activities that have been found to increase students' anxiety.

Affective state may play a significant role in shaping what students value in mathematics. This study examines how high school students' attitudes, anxieties, and images of mathematics may affect their values toward mathematics. A quantitative survey was conducted with 208 grade ten students from 6 randomly selected high schools in Kathmandu, Nepal. The survey data was analyzed with factor analysis and structural equation modeling. The results revealed that students' overall attitudes toward mathematics significantly affected their perceived values of mathematics. Students' anxieties and images of mathematics did not significantly affect their values of mathematics. The pedagogical implications of the findings have been discussed.

Keywords: Images of mathematics, Math Anxiety, Attitude toward Mathematics, Values of Mathematics.

Introduction

There is a growing interest in the affective constructs of mathematics learning, such as images, anxieties, and attitudes toward mathematics. Several past studies focused on students' decisions to learn and use mathematics in everyday life (Wilkins, 2003), students' images of mathematics (Jankvist, 2015; Sam, 1999), mathematics anxieties (Ma & Kishor, 1997), attitudes toward mathematics (Niepel et al., 2018), and value of mathematics (Österling, 2013; Wakhata et al., 2022). Past studies interrelated students' anxieties and attitudes toward mathematics to their achievement (Ma & Kishor, 1997) or highlighted the importance of these affective variables in shaping students' interest, motivation, self-esteem, and perseverance to learn mathematics. However, most of these studies focused on images, anxieties, confidence, and attitudes toward mathematics and their relation to students' performance, but not in an integrated way to examine how they affect each other (Belbase, 2013). In this context, there are a few studies on the values of mathematics concerning students' images, anxieties, and attitudes toward mathematics (e.g., Lamichhane & Belbase, 2017; Paudel, 2019; Thapa & Paudel, 2020). Students' images, anxieties, attitudes, and values in mathematics have been a general concern in Nepal because many students either fail or perform poorly at the school level and national exams (Education Review Office, 2015 & 2020). It is the interest of teachers, students, and educators to know how these four constructs interact and influence each other. In this context, the research question for this study was: How do the affective constructs of mathematics anxiety, attitude, image, and value predict each other?

Images, Anxieties, Attitudes, and Values of Mathematics

The term image of mathematics has been studied from different perspectives, for example, teachers' images of mathematics (Mura, 1993), public images of mathematics (Sam, 1999), and students' images of mathematics (Jankvist, 2015; Lamichhane & Belbase, 2017). This perspective views mathematics differently, demonstrating different images of mathematics, for example, symbolic images, utilitarian images, and absolute images (Sam, 1999). Students' images of mathematics can be depicted with different metaphors as a useful tool to understand students' images of mathematics (Osman et al., 2010). These metaphors were solving riddles, using a calculator, considering bank manager as a profession, and mathematics as numbers. On the other hand, mathematics anxiety can be considered one of the negative factors that may cause "feelings of tension and anxiety that interfere with the manipulation of numbers and the solving of mathematical problems in a wide variety of ordinary life and academic situations" (Richardson & Suinn, 1972, p. 551). Therefore, mathematics anxiety may also cause them to realize that they are "powerless, out of control, lacking in self-esteem" (Zaslavsky, 1994, p. 19). The attitudes result from positive, neutral, or negative experiences developed over a long period, seemingly directed to act and behave differently upon any object, event, problem, or human being (Elci, 2017; Utsumi & Mendes, 2000). Students' attitudes toward mathematics are associated with value, self-confidence, enjoyment, and motivation (Primi et al., 2020; Tapia & Marsh, 2004). In this context, students' success or failure in mathematics may depend upon their attitudes and beliefs toward the importance, worth, and usefulness of mathematics (Elci, 2017; Kunwar, 2020). In contrast, students' values of mathematics focus on what they consider as a part of the subject matter and learning it in social, historical, cultural, and technological contexts (Baba et al., 2012; Tang et al., 2020). These values also connect with relationship, power, and identity (Guitérez, 2010; Österling, 2013; Skovsmose, 2009), and demonstrate one's normative and historical viewpoints about mathematics and its processes (Baba et al., 2012; Ernest, 1991). Therefore, students' value of mathematics may also relate to their mental, social, and cultural wellbeing (Clarkson et al., 2010; Bishop, 2012), which may provide them with confidence and positive thought about it.

Method

A quantitative cross-section survey design was used in this study to explore the high school students' affective states in terms of images, anxieties, and attitudes toward mathematics and how these states may influence students' values of mathematics. The study design was based on a Likert-scale questionnaire distributed to a sample of students studying at grade ten in public and private schools in Kathmandu. The tool was based on the theoretical construct of images, anxieties, and attitudes toward mathematics (Belbase, 2013; Fennema & Sherman,1976) and methodological assumptions of survey design (Cohen et al., 2018). The study site was Kathmandu, Nepal. A sample of 208 grade-ten students from six secondary (three private and three public) schools in Kathmandu was randomly selected for the study. A questionnaire was administered in the sample schools by visiting the schools by two researchers. Informed consent was obtained from the schools, mathematics teachers, and students in grade ten classrooms in the respective schools. The data were transformed into Statistical Package for Social Sciences (IBM SPSS 28) and AMOS 28 for analyses and interpretations. The overall reliability of the instrument was measured with a sample of 208 students, and Cronbach's alpha was found to be 0.932 for 41 items (Cohen et al., 2018). Confirmatory factor analysis was performed in IBM SPSS 28, and it was validated with a structural equation model in IBM AMOS 28 considering image, anxiety, attitude, and value toward mathematics as exogenous (independent) and endogenous (dependent) variables turn by turn to discover the best predictor model (Kline, 2005).

Results

A path analysis was performed in the structural equation modeling (SEM) to determine if students' affective constructs of anxieties, attitudes, images, and values of mathematics influence each other. The iterative processes of path analysis were performed for anxieties, attitudes, images, and values to validate the items in models 1 to 3. Fit indices of CMIN/DF, GFI, CFI, and RMSEA were used to validate the confirmatory factor analysis and the direct impact of independent variables on independent variables. The analysis of fit indices showed that the model fit was robust in the third iteration with CMIN/DF = 1.477, GFI = 0.861, CFI = 0.916, and RMSEA = 0.048. These results were acceptable (West et al., 2023). The structural equation models were fitted for each of these variables, considering them dependent variables one by one and others as independent variables in different models (Table 1, Figures 1- 4).

Results showed that mathematical attitude was a significant predictor of students' values of mathematics, but anxieties and images were not significant at 0.05 level of significance (Table 1 and Figure 1). Likewise, attitude significantly predicted students' mathematics anxiety at a 0.01 significance level (Table 1, Figure 2). Anxiety was also a significant predictor of students' attitudes toward mathematics (Table 1, Figure 3). None of the three variables, anxieties, attitudes, and values, were significant predictors of students' images of mathematics (Table 1, Figure 4). The model to predict attitude was the strongest among the four models, with the largest R-squared value. Results of Models 4-7 are presented in the Table 1 and Figures 1-4.

Table 1: Maximum Likelihood Estimates Standard Regression Weights (SRW) and R^2

Model 4		Model 5		Model 6		Model 7	
Variables	SRW	Variables	SRW	Variables	SRW	Variables	SRW

Discussion, Conclusion, and Implication

The four components of affective states in students' mathematics were—anxiety, image, attitude, and value. The structural equation models demonstrated an impact of students' attitudes toward mathematics on values. These values are associated with self-efficacy, mathematical tasks, and its application in life and career has been studied and used to predict such mathematical behavior of learners (Gjicali & Lipnevich, 2021). Students' attitude toward mathematics significantly predicts their intention to study mathematics, their behavioral engagement as mediated through intention, and their mathematics achievement when mediated with intention and behavior (Gjicali & Lipnevich, 2021; Wang et al., 2020 & 2022). These studies and others related students' attitudes toward their value of mathematics regarding their intention, role, and action to perform or improve in mathematics. However, students' mathematics anxiety and image of mathematics were not good predictors of value. School and classroom context may significantly shape and interact among these psychological and affective constructs (Akey, 2006). The students may feel that mathematics is easy or difficult and that high or low anxiety should not affect their value toward mathematics (Lamichhane, 2020; Sam, 1999). Likewise, anxieties and attitudes toward mathematics seem to be strong predictors of each other, which is also supported by literature (Elci, 2017; Primi et al., 2020; Zaslavsky, 1994).

In conclusion, the results of this study showed that four constructs- images, anxieties, attitudes, and values may interact and influence each other. Students' attitude toward mathematics can predict their value of the subject positively. Attitude and anxiety can predict each other. However, the image of mathematics is a general construct that may not be predicted by attitude, anxiety, and value of mathematics. Mathematics teachers and educators may use students' mathematics attitude as a predictor of what they value and what is their anxiety level that may influence the quality of their mathematics learning. These psychological constructs may promote better mathematics classroom learning experiences (Everingham et al., 2017). Therefore, mathematics teachers should consider them while teaching students so that they are interested and motivated. Hence, mathematics teachers may focus on students' wellbeing through positive psychological development with images, anxieties, and attitudes for a greater value of mathematics learning (Hill & Seah, 2023). The study had some limitations due to the sample size of 208 students, which may influence the findings' generalizability in the larger student population in Nepal and elsewhere. Future studies should be conducted with a larger sample size and more sophisticated analyses to generalize results at national and international levels.

Executive functions (EFs) are related to mathematics achievement, yet much is still unknown about how or why these relations exist. Improved measurement of EFs in students' math learning is needed to answer such questions equitably. Further, if research is conducted with the goal of informing teaching and learning, the EF assessments should focus on students' strengths and provide data that is useful and understandable to educators and students. In this paper, we explore how interdisciplinary teams of educators, developers, and researchers have assessed EFs in the mathematics context. We present strategies for assessing EFs more equitably and discuss implications for measuring EFs on various partners' activities within the research and development and implementation of mathematics curricula.

Keywords: Cognition; Equity, Inclusion, & Diversity; Assessment

Introduction

Executive functions (EFs) are a set of cognitive processes important for directing our thoughts and actions to what is necessary for achieving our goals. One popular model of EFs categorizes them as three separable, but overlapping functions known as working memory, inhibition, and cognitive flexibility (Miyake et al., 2000). Mathematics requires all three of these cognitive processes: thinking flexibly, holding and updating important information in working memory (e.g. Raghubar et al., 2010), and inhibiting misconceptions and irrelevant information or rules (e.g., Cragg et al., 2017). EFs are related to performance on mathematics tasks, and have been shown to predict mathematics achievement longitudinally (Cragg & Gilmore, 2014; Ribner, 2020). Teachers have also noticed that EFs are important for math learning based on their observations in the classroom (Gilmore & Cragg, 2014). However, there are few educationally-relevant causal studies of these relationships (Clements et al., 2016). We need better theory and measurement of executive functions in mathematics to understand why these relationships exist and whether executive functions should be intentionally targeted through math interventions (Medrano & Prather, 2023; Scerif et al., 2023; Wilkey, 2023; Younger et al., 2023).

EFs measured during a numerical task are more strongly related to math achievement than EFs measured during tasks that do not explicitly include math-related information (Gilmore et al., 2015; Wilkey & Price, 2019). This suggests that the mathematical learning context should be considered when investigating relationships between EFs and mathematics (Gilmore, 2023; Medrano & Prather, 2023; Niebaum & Munakata, 2023). Moreover, a more strengths-based approach to measuring executive functions is needed that reflects the diverse environments in which children are learning (Miller-Cotto et al., 2022). However, there is a large disconnect between research in math education and research in math cognition (Berch, 2016; Bruce et al., 2017). Math education researchers have long argued cognitive researchers should better consider the educational context in which math learning occurs (de Freitas & Sinclair, 2015; Verschaffel, Lehtinen, Van Dooren, 2016). Researchers in cognitive science and education often use different terminology to refer to similar constructs, which contributes to the divide across fields, and the gap between research and practice (Berch, 2016). For example, one study found that only 20% of teachers were familiar with the term executive functions (Cragg & Gilmore, 2014). EFs are typically assessed by having children complete cognitive behavioral tasks that measure accuracy and response time, or by having parents or teachers complete a rating scale of a child's everyday functioning, and these different measurement formats are not equivalent or interchangeable (Toplak et al., 2013). There is a building consensus that EF assessments need to account for individual differences and contexts; however, there is a dearth of practical solutions at this time. It therefore remains unclear exactly how or why teachers should assess and support executive functions in the mathematics classroom.

Context and Purpose of this Research

The EF + Math Program was developed to explore the core hypothesis that math intervention approaches which contain support for developing EFs can lead to improved mathematics achievement. EF + Math enlisted a portfolio approach, which entails multiple project teams designing and studying interventions which test this core hypothesis, along with other project teams focused on developing effective and equitable assessments and technologies to support measurement of EFs in mathematics. Each project team is interdisciplinary, with educators, researchers, and developers coming together to mitigate challenges that can arise in bridging research to practice (Uncapher, 2018).

The project teams established their approaches to answering the core hypothesis of the EF + Math Program through collaborative discussions, which allowed for the designed interventions and assessments, and their theories of action to be situated not only within the research base, but within the needs of real classroom contexts, educators, and diverse student populations. However, this inclusive approach to research and development raises tensions about the relationships between researchers' assessment of cognitive constructs and the ways that data informs educator practice and student learning (Uncapher, et al., 2022). We elevate one of those tensions in relation to our focus on executive functions in the mathematics contexts: to what extent is the assessment of EF in the mathematics contexts useful, and for which partners? Each project team encountered this tension in their work, and addressed it through different approaches, based on their conceptualizations of EFs in mathematics contexts and the ways that EF supports were incorporated into their interventions. In this paper, we ask, "how have project teams navigated the needs of researchers, developers, educators, and students in assessing EFs in math contexts? How can EFs be assessed in ways that inform both educational practice and mechanistic cognitive research questions?"

Conceptual Framework: Inclusive Research And Development

We examine this research question through the lens of inclusive research & development (iR&D; EF + Math, 2023). The IR&D model is part of the larger movement toward educational participatory research methodologies and partnerships (Amiel & Reeves, 2008; Vaugh & Jaquez, 2020). In these methodologies and partnership models, researchers, developers, and educators are positioned as collaborative partners and actively work to deconstruct hierarchies of power.

However, even in iR&D-driven projects, tensions can arise regarding the role and purpose of conducting research on interventions, especially given the relations different team members may have to the data. For example, researchers collect and analyze data to provide findings to developers and educators, as well as answering more generalizable research questions. Developers use data to inform future development of the interventions, including improving data collection mechanisms or structures to share data findings and implications with teachers and students within the intervention itself. Finally, teachers collect and use data to inform the supports they provide students, future adaptations of curricular materials, and other implications for practice; teachers also provide valuable context and interpretations of data to support researchers and developers in their work. Equity not only means that these different purposes and goals for engaging in research can cause project teams to take a particular approach to their assessment strategies, such as this paper's focus on EFs in math. Equitable approaches to assessment center the lived realities, needs, and assets of students, particularly students of color.

Data and Methods

The research questions and related findings presented in this paper are part of a set of larger, ongoing research studies. Each project team has conducted several cycles of inclusive R&D. Across these cycles, project teams created and updated study design documents, research plans, and measurement plans. For this analysis, our data sources included these documents, as well as notes taken during conversations about measurement and data collection with project teams throughout the inclusive R&D cycles. We have conducted initial analyses of the project team documents and conversation notes; as the teams' are actively engaged in inclusive R&D cycles, future analyses will include additional data sources and updated themes. To answer our research questions, we first identified sections of text that referred to the measurement or assessment of EFs. Within these sections, we coded for the "how" a project team assessed EFs and the "why" for their decisions. We looked for shifts across time for each project team to identify key moments for analysis. Finally, we looked to see how the methods for assessing or the justification for those methods were in response to researcher, teacher, or developer needs and uses of data. The themes presented in this paper represent two types of equitable EF assessments developed and refined through inclusive R&D.

Results: Equitable Approaches to Assessing EFs in Mathematics Contexts

Defining EFs within Mathematical Activity

Assessments do not always provide discipline-specific approaches to measuring EFs; given research on the role of context (Medrano & Prather, 2023; Niebaum & Munakata, 2023), it is essential for researchers to continue developing assessments that capture EFs in mathematics. Measuring EFs in the mathematics context can be approached by capturing in-the-moment data on student activity while actively doing mathematics. The Project teams worked to develop new assessments involving technological features and varied data sources to define EFs in the mathematical context more equitably and in ways that honor students' epistemic diversity.

One project team's intervention focused on the role of EFs in middle school students' collaborative problem solving practices (Kuchynka, et al., 2023). They developed a qualitative coding scheme that identifies what EFs look like in student talk or student actions during problem solving (Renninger, et al., 2023). This assessment strategy leverages qualitative data sources, such as transcripts or observations. Researchers are still able to conduct analyses on the relationships between EFs and math learning; such a coding scheme is also supportive of teacher use to develop an understanding of what EFs look like, noticing of when students are engaging their EFs, and cultivating awareness of how teaching practices or curricular materials can create opportunities for students to engage their EFs within a task.

Another team conceptualized EFs within the context of rational number learning, with an embodied cognition approach driving their intervention design and implementation. Their team developed a rational number knowledge assessment that requires students to engage their EFs to shift across strategies, filter information, and manipulate quantities flexibly. Administering this assessment allowed teachers to focus on assessing mathematical task performance and gathering rational number knowledge evidence, while still providing researchers with relevant and useful data on EFs.

Measuring EF Fluctuations and Communicating Findings Effectively

Traditional measures of EFs often provide static snapshots of student performance on EF tasks. In reality, students' engagement of EFs on a given day or within a task is dependent on a variety of factors, including social and cultural contexts, affective factors, and personal differences. Equitable assessments of EFs should be more flexible and dynamic to mirror this reality and disrupt static labeling practices common in schooling. Approaches to measuring student EFs can include more regular assessments, but also involve the communication of assessment data back to students and teachers to inform adaptations of teachers' practice, as well as supports for developing student agency.

One team has focused on the development and iteration of a machine-learning assessment tool that collects "in the moment" data on students' engagement of EFs and other metacognitive processes (Zhang, et al., 2022). This tool provides an asset-based approach to understanding the variability in students' EFs within problem solving tasks; the assessment aims to promote more accurate understandings of what students are able to do. This team's technology takes in large amounts of qualitative data and presents summaries of data trends to educators through a dashboard view. The teachers are able to view key information about students and classes, as well as implications for their pedagogy, use of particular materials, or scaffolds that may be high leverage supports for students based on their EFs needs that day.

Another project team is developing an app that can quickly and easily assess daily fluctuations in students' EFs (Ghil, et al., 2022). They are developing an adaptive technology that can optimize the EF assessment items students should complete each day; this capacity will allow researchers to model EF trends using minimal data and limiting teacher burden (Katsumba, et al., 2023). Additionally, this team has worked to develop a dashboard that displays these fluctuations to students and educators in positive, asset-based ways. The dashboard, which was co-designed with students themselves, presents data in understandable amounts, and includes recommendations for students to enact agency over their learning based on their data for the day.

Implications and Conclusions

The project teams have continued to iterate upon their approaches to assessing EFs as part of inclusive research and development processes. As the approaches are implemented in additional educational environments, new information is collected regarding their effectiveness and applicability. Further, researcher, educator, and developer goals for understanding EFs in math contexts will continue to evolve as part of the broader fields of math education and math cognition. The EF + MathProgram and its project teams will continue to explore the question, “to what extent is the assessment of EF in the mathematics context useful, and for whom?”

In collaborative partnerships, each party may require or prioritize different data sources or varied granularity to be able to achieve their own goals. Navigating these tensions and creating strategies for assessment in inclusive R&D cycles is non-trivial activities. By documenting the strategies developed by EF + Math’s project teams, we hope to encourage continued conversation and exploration of the role of assessment and measurement in iR&D activities. We envision a future for mathematics education where multiple partners are able to effectively collaborate to design and test solutions that address the challenges educators face in their mathematics classrooms in order to support all students in achieving their full potential as brilliant mathematicians.

USING LINES OF PRACTICE IN IDENTITY ANALYSIS

Katherine C. Chapman
Vanderbilt University
k.chapman@vanderbilt.edu

Melissa S. Gresalfi
Vanderbilt University
melissa.gresalfi@vanderbilt.edu

The literature using psychological constructs like "interest" has rarely been brought together with the robust and developing literature of sociocultural perspectives on math identity in K-12 classrooms. Similarly, work on hobbyist communities and other non-academic pursuits has yet to make consistent contact with the literature on developing STEM identities in school. In this study, we look at retrospective interviews following women who consider themselves lifelong knitters, and compare the processes of identification in both knitting and mathematics through the lens of lines of practice *as developed by Azevedo (2011). We find that while women describe consistent and flexible preferences across both domains, they are often met with two limiting factors that impede identification: binary thinking about math ability, and a highly circumscribed participation structure.*

Keywords: Gender, Informal Education, Integrated STEM / STEAM, Ethnomathematics

Objectives and Purpose of the study

While research on mathematics identity has been located almost exclusively in schools, clearly not all mathematics learning experiences are the same, and there is reason to question whether school is anywhere close to ideal. Ethnographic research on student learning has demonstrated that the practices of mathematics are locally constituted, and can transform the nature of mathematical activity. Early work conducted by anthropologists and cultural psychologists (Saxe, 1988; Lave, Murtaugh, & de la Rocha, 1984), enhanced our understanding of mathematical activity as a socially mediated process that connects to history, tools, and other people. This work demonstrated that school mathematics is a peculiar enterprise that has a profound influence on what people ultimately think about mathematics (Boaler & Greeno, 2000; Nasir, 2002; Schoenfeld, 1989). Other versions of mathematics could potentially transform the kinds of relationships to the discipline that we generally observe in school (Taylor 2009; Gonzalez et al 2001). The goal of this paper is to build on this literature in order to explore how identities are tied to local practices in different domains.

In this study, we use an interactionist perspective to explore the question of how school mathematics might be productively reorganized to invite broader participation among a more diverse group of students, particularly women and girls. In order to investigate what kinds of experiences might promote lifelong engagement with STEM, we look to textile crafting, which is a hobby often pursued by women across the lifespan, and which is frequently said to involve elements of mathematics. Our work builds on Azevedo's *lines of practice* (2011), combining psychological accounts of interest development with interactionist ideas about the inextricability of individual identities and the opportunities they have to develop in social practice.

Methods of inquiry

Participants were identified through participation in an online survey about mathematics in textile crafting. From over 1,500 responses, we interviewed roughly 40 participants. We conducted semi-structured, retrospective interviews to explore the connections and contrast between women's experiences with knitting and their experiences with K–12 mathematics. From those interviews, we chose eight women who represented an even balance across two categories—four who rejected a math identity in relation to school (though they considered themselves knitters, and agreed that knitting involves mathematics), and four who said that they enjoyed math in school and generally considered themselves "math people." These interviews were chosen for the depth of their answers to our questions.

Using a grounded theory approach, we build from data toward a theory of how long-term engagement is built and sustained that pulls together previous work using the constructs of interest and identity (e.g. Ames & Archer, 1988; Anderman et al., 2001; Gee, 2000; Hand & Gresalfi, 2015; Holland et al., 2001; Meece, Anderman, & Anderman, 2006; Murayama & Elliot, 2009; Wenger, 1998; Wigfield & Eccles, 2000). After our initial rounds of theory development, we consulted the relevant literature and found that our emerging theory fit well with Azevedo's observations of hobbyist communities. Thus, this preliminary analysis attempts to situate our grounded theory in relation to that framework.

Briefly, Azevedo's "lines of practice" framework describes how individual "preferences" and broader "conditions of practice" weave together to create "lines of practice" that support and sustain participation in a broader social practice over time. Any given individual may have one or many different lines of practice that constitute their participation in a community of practice, and two participants may have lines of practices that are similar or different from one another's. Thus, lines of practice are constitutive of broader social practices, but not wholly determinant of, or determined by, other definitions of those social practices.

Preliminary results

Reject Math Group

Although the knitters who shared a dislike of school math described a range of preferences for what they liked about knitting, they collectively described overlapping conditions of practice that nevertheless supported their ultimate identification with the craft. Rather than seeing knitting as a set of practices that are interesting only for some people, instead they described how practices were inviting and supportive of a range of ways of engaging. Indeed, most knitters identified more than one line of practice that supported their continued engagement. In contrast, the practices of school math, as described by the knitters, failed to support those very same preferences. Overall, what is most clear is that having access to assistance and an understanding of the "discipline," that is, why things work as they do, was widely supportive of a range of preferences for knitting. This same lack of access to understanding was uniformly what turned these women off to mathematics, even though for some of them, understanding mathematics was something that became more common and accessible for them later in life.

Identify with Math

Knitters in our sample who identified with math described very similar lines of practices to those who did not identify with math. These knitters widely had a preference for being able to figure things out for themselves, a preference that was met by conditions of practice that supported such independence, either through the fabric that knitters create or through the myriad resources available. These knitters also expressed preferences in mathematics that were consistent with their stated preferences in knitting, but here very different lines of practice emerged, which, for these women, ultimately led to identification. This largely appeared to be due to finding a different set of conditions of practice in their mathematics classes, either in the form of supportive or innovative teachers, support from home, or just a tendency to find that mathematics makes sense. Thus the difference between those who identified with math and those who did not identify with math did not seem to be based on a difference in preference, but rather based on a difference in conditions, with those who ultimately identified with math finding that the conditions of practice they encountered supported their preferences for engaging.

Participants express consistent preferences across domains

One possible explanation for the difference in identification between math and craft is that people who like both disciplines are simply more flexible, or that there are other factors that mediate their enjoyment, such as self-efficacy or confidence. Perhaps what people get from crafting is different from what they get from mathematics, and people who identify with math simply have a more favorable attitude toward what they are offered in that domain than others.

In contrast to this theory, we find remarkable consistency in the preferences people express in each domain. This finding suggests that people know what works for them—at least in retrospect—and that failing to provide opportunities to engage in their preferred way can lead to disidentification. Refusing to guide someone who prefers to defer to a trusted other is potentially just as damaging as telling someone who prefers to be her own locus of authority to memorize an algorithm for the sake of time. Just as importantly, however, when offered choices, people are often not limited to a single mode of engagement.

Across all eight interviews, while there was a fair amount of diversity in stated preferences throughout the group, we saw remarkable consistency within each interview across the two domains. In other words, we saw some people who preferred to be the locus of authority, and others who preferred to trust an expert, but anyone who stated a clear preference had the same preference in both knitting and math.

Rather than people being more flexible, our findings suggest that it is the disciplines themselves that appear to offer more or less flexibility to participants. This finding suggests that while people may have a primary preference, they are nevertheless willing to engage differently if the circumstances call for it. This observation also anticipates objections to the implications of our finding that there are "better" ways to engage in mathematics and people should be pushed to adopt these, despite their underlying preferences. Though it is beyond the scope of this paper to either agree or disagree with such a normative statement, other findings suggest that supporting people in their preferred method of engagement does not lock them into only that method, but rather supports a more diverse set of engagement patterns.

Stated preferences do not alone explain identification with a domain

Given that math was described by most participants as being relatively monolithic, one possible explanation for the diverging identification patterns is simply that while math and craft have some overlapping content, that overlap has little to do with the aspects of each practice that draw people to the disciplines. Were this the case, we might expect to see a profile of preferences that leads to identification in each discipline, or at least a subset that is required for liking math. Instead, we find multiple different "kinds of people" who found their way into each discipline. Thus, as many scholars have noted, the identification process must be a more complex interplay between individual preferences and the environment.

Of the four people who said they liked math in school, one said she preferred to focus on the experience, and on learning; one said she preferred to focus on learning, and preferred a different locus of authority depending on the task; one said she wanted to be the locus of authority and to focus on learning; and one said she preferred to trust either an expert or the discipline more generally. Of the four who said they did not like math in school, one said she preferred to be the locus of authority, but focused on either the experience or the outcome, depending on the project (Alicia); one said she preferred to be the locus of authority and focused on outcome or learning depending on the project (Carol); one said she preferred to trust an expert, and to focus on either the experience or the outcome, depending on the circumstances; and one said she preferred to be the locus of authority, though she never got that chance in math. In other words, there is no profile of preferences that would predict whether a person might come to love math or to hate it.

Identifying narratives on a longer timescale explains identification across lines of practice.

We found, to our surprise, that there were some people for whom the same conditions of practice in math and knitting seemed to elicit different interpretations of themselves, and ultimately, led to different patterns of identification. In looking more closely, it appeared not that our interviewees had different preferences in relation to these conditions, but rather, different interpretations of these conditions, which seemed to be attributable to a set of different cultural narratives about math and knitting. These included several well-known ideas, such as: math is an innate talent (that you either have or you don't have); speed is indicative of skill, and math involves creativity, but only once you've mastered the building blocks. Some of these narratives had parallels in knitting, though with noticeable amendments: crafters come in all types (and they're all valid); what is satisfying about knitting is open to personal judgement; crafting experience is learned/earned; and crafting is a learnable talent, but artistry is innate.

Discussion and Conclusions

Narratives about domains are hugely influential in how interactions are made meaningful in identity development. For example, struggle alone (either a lack of it, or some individual preference for it) does not explain how people come to view mathematics. Whether a person struggles or not interacts with prevailing cultural narratives about what that struggle means. In knitting, throughout our sample we hear reference to the idea that crafting expertise is learned/earned and that what is satisfying about knitting is open to personal interpretation. In math, however, the dominant cultural narrative is that math ability is a thing you either have or you don’t, though occasionally this is mediated or replaced by the idea that academic achievement takes effort. It is in the context of these narratives that personal struggle in math classes is seen as either evidence that you don’t belong, or a challenge that can be overcome with hard work.

As Azevdeo (2011) has observed, identity development in hobbyist communities often relies on a collection of lines of practice that sometimes overlap and occasionally conflict, rather than a single unifying experience. For our participants, this finding holds true in knitting, and appears to allow individuals to carve out an idiosyncratic path through the identification process that actually binds them to the community rather than splintering. In school math, however, binary thinking pervades—students are often told you’re either a math person or you aren’t—innately smart and talented, or not—and they are not given alternative ways to engage with the discipline that still “count” as math. The exception that proves the rule is often women who come to like math after they’ve left school, when they are afforded new and different opportunities to reclaim a math identity in a more flexible narrative environment.

UNPACKING FRACTION UNDERSTANDING OF A NEURODIVERGENT STUDENT: CONNECTING AND QUESTIONING ACROSS FRAMEWORKS

Angela R. Crawford
Boise State University
angelacrawford1@boisestate.edu

Ramey Uriarte
Boise State University
rameyuriarte@boisestate.edu

We unpack the fraction understanding of a neurodivergent student in the context of equal sharing tasks by considering three frameworks: equipartitioning (Confrey et al., 2009), mental actions in fraction schemes (Steffe & Olive, 2010), and persistent understandings (Lewis, 2014). During a teaching experiment guided by the equipartitioning learning trajectory (Confrey et al., 2014), the student, Macey, evidenced unanticipated fraction understandings across fraction representations (symbolic, discrete contexts, single and multiple continuous wholes). Each framework offers implications for Macey's thinking. We discuss how applying the frameworks to these data surfaces connections across them and numerous questions with implications for future research.

Keywords: Students with Disabilities, Cognition, Rational Numbers, Learning Trajectories and Progressions

The complexity of fraction understanding is evident in the numerous frameworks used to study it. It is also evident in the extensive literature describing challenges students face in developing rich conceptual understanding in this area. To date, a limited number of studies have investigated the conceptual understandings that neurodivergent students construct around meanings for fractions (e.g., Crawford, 2022; Hunt & Empson, 2015; Lewis, 2014). In the spirit of the theoretical and methodological shifts recognized by PME-NA 2024 conference organizers and expressed in the theme, "Envisioning the future of mathematics education in uncertain times," we center a neurodivergent student's thinking about fractions. We unpack this student's thinking by applying multiple conceptual frameworks, aiming to profit from the complexity and uncertainty that emerges. We claim that by embracing the potential of difference in centering neurodiversity and in interpretations across frameworks, we can move the field forward toward richer, deeper knowledge of student learning. Our goal is to engage in dialogue with the mathematics education community, bringing multiple perspectives together to collectively enrich understanding of the learning of fractions.

Conceptual Frameworks

We identified three frameworks which potentially provide insights into how a neurodivergent student, Macey, has constructed understandings of fractions: equipartitioning (Confrey et al., 2009), mental actions that make up fraction schemes (Steffe & Olive, 2010), and persistent understandings of fractions (Lewis, 2014).

The first framework we consider is equipartitioning. Equipartitioning is the foundational concept in a learning trajectory for developing understanding of fractions as ratios (Confrey et al., 2014). Equipartitioning combines the ideas of equivalence and partitioning in the creation of equal-sized groups through splitting, a cognitive operation grounded in awareness of the multiplicative relationship between partitions and the whole (e.g., given a ¼ share, the whole is four times larger; Confrey et al., 2009). The fraction meaning associated with splitting and equipartitioning is many-to-one, that is, understanding of fraction as ratio (Confrey, 1994). The idea of many-to-one is a relational idea applied to fractional shares of collections of discrete objects, single continuous wholes, and multiple continuous wholes (Confrey et al., 2014). Macey's development of relational thinking and multiplicative reasoning in the equipartitioning learning trajectory is described in depth in a previous publication (Crawford, 2022).

The second framework is mental actions within fraction schemes. This framework uses similar terms as the equipartitioning framework but there are subtle differences in meanings for fractions. This framework takes a contrasting many-as-one approach by focusing on partitioning and iterating a continuous whole unit, often represented as a bar model (Steffe & Olive, 2010). Attention is given to iterating and counting the shares that are part of a whole (e.g., a ¼ share would be iterated four times to create a one). The fractions schemes are cognitive structures used for operating with parts and wholes (Steffe & Olive, 2010), and there are hypothesized progressions in which these schemes are constructed (Hackenberg, 2007; Steffe & Olive, 2010; Wilkins & Norton, 2018). The schemes coordinate mental actions recognized by the student as operations for completing the mathematical task. These mental actions are: partitioning (creating equal-sized parts), iterating (repeating a unit of length to produce a connected whole), disembedding (taking out parts while maintaining awareness of the relationship to the whole), splitting (combining partitioning and iterating as inverse actions), and units coordination (maintaining relationships among levels of units). These mental actions can be applied in part-whole contexts (Olive & Vomvoridi, 2006; Steffe & Olive, 2010) or in measurement contexts (Wilkins & Norton, 2018).

The third framework we include is Lewis's (2014) "persistent understandings" of fractions. This framework attends explicitly to difference across individuals as they construct fraction understanding. Persistent understandings are theorized to have been constructed by neurodivergent individuals within socio-cultural interactions, recognizing the diverse ways learners interpret and construct meaning around representations (Lewis, 2014). Persistent understandings are those that are: a) likely qualitatively different from their peers, b) present challenges to the individual's ability to make sense of more complex fraction concepts, and c) not easily resolved through intervention. Some persistent understandings Lewis identified were: viewing fractions as "taking" the shaded part away (and attending to the fraction complement); applying a discrete set model to continuous models; viewing fraction representations as comprising two parts rather than part of a whole; understanding fractions as the number of pieces rather than the size of the piece; and comparing fractions based on the number of pieces. Lewis describes these understandings in symbolic representations and part-whole contexts.

Purpose

The goal of this analysis was to carefully examine Macey's fraction naming to characterize understandings that she had constructed. We present Macey's thinking for consideration in light of the three frameworks for describing fraction understanding: equipartitioning, mental actions in fraction schemes, and persistent understandings. We bring these frameworks into conversation with one another, and consider how, in combination, they might help to further our knowledge regarding the ways in which fraction understandings develop.

Method

Participant

At the time of this study Macey was in the summer between Grade 5 and 6 and was 11 years old. Macey attended a public school in the United States and received special education services in a pull-out program ("resource room") and private tutoring. Cognitive testing indicated Macey had strengths in visual-spatial, fluid, and deductive reasoning. She had difficulty with language processing, integrating information, abstract reasoning, and executive functions. All sessions took place at Macey's home with one of Macey's parents present.

Context

After two diagnostic meetings, a teaching experiment with Macey comprised 11 sessions, each ranging from 35–50 minutes. The teaching experiment was guided by the equipartitioning learning trajectory (Confrey et al., 2014). The first author, Angie, conducted all of the teaching experiment sessions. Angie has 18 years of experience teaching math in grades 1—8, including working in whole class, small group, and one-to-one settings with neurodiverse students. Angie designed a planning protocol with goals and tasks based on the learning trajectory, anticipated thinking and strategies that would emerge, and scripted teacher questions. Angie implemented tasks as described in research literature with supports planned to be enacted as needed. Angie also used a reflection protocol with prompts for summarizing Macey's activities, teacher responses, adjustments made to plans and rationale for these adjustments.

Data Sources and Analysis

Data sources were videos, transcripts, and Macey's written work from four tasks. The tasks elicited Macey's fraction understandings using different representations: symbolic only (i.e., ¾), fractional share of a collection (discrete representation), fractional share of a single whole (continuous representation), and fractional share of multiple continuous wholes (continuous representation).

Retrospective analysis of these data was completed using a three-level analysis (Simon, 2019). The first level of analysis remained close to the data, by descriptively coding student activity, representations used, features attended to, language used, etc. The second level of analysis involved making inferences across tasks. Codes across tasks were compared to look for patterns in fraction naming (including correctness of response) across forms of representation. The third level of analysis involved broad inferences to describe patterns not directly visible in the data (Simon, 2019). These are abductive inferences which, if true, can explain the data and speak generally to the topic under investigation. Thus, claims about Macey's understanding are abductive inferences supported by the patterns identified in the second level of analysis. These inferences led us to ask questions pertaining to the three frameworks.

Findings

We present Macey's responses to a series of tasks and provide our interpretations of her activity for each. In each of the tasks, Macey's strategy of distributing shares demonstrates the fundamental requirements of equipartitioning: creating a correct number of shares, ensuring shares are of equal size, and exhausting the whole. This leads her to creating "fair shares." As we progress across examples, we draw attention to aspects of her responses which are indicative of difference in her thinking. Finally, we offer the abductive inferences we make about Macey's understanding of fractions. Because Angie was the teacher-researcher in the interactions with Macey, Angie is referred to as "I" or by name in the findings.

Task 1: Meaning for a Symbolic Fraction

During our first meeting, I gave Macey an index card with ¾ written on it, and I asked, "What do you think of when you see this fraction?" Macey's response was, "I think like…I think like…three rows of four [draws a 3 x 4 array of dots]," (see Figure 1). I asked her what makes her think of four rows. She replied, "Like, say you have umm…13 cookies and they're in three rows of four. And you have three friends. And you give four cookies to each friend. And then you would have zero left over. So, three rows of four…would each…three rows… Yeah. Three rows of four makes… It's like 3 [gesturing over the rows] plus 4."

Macey represented the fraction with discrete objects within a collection. We note that Macey viewed the fraction as a sharing situation, in this case sharing cookies among friends, which is consistent with equipartitioning and mental actions within fraction schemes. Disregarding her statement of 13 cookies as a counting error, we note that shares were equally divided. The numerator was a count of the number of rows, or the number of sharers. The denominator was the number of items in the row, that is, the number of cookies. The fraction was not described as part in relation to a larger whole. Thus, Macey did not demonstrate many-to-one or many-as-one thinking. Rather, the fraction was two numeric and separate values in a multiplication context.

Figure 1. The image on the left shows Macey's drawing of three rows of four to illustrate the fraction ¾. The image on the right shows Macey's partitioning of 20 gold coins among five pirates.

Task 2: Fractional Shares of Collections

I presented Macey with the task of using 20 connecting cubes that represented gold coins in a treasure chest and asked her to share the coins evenly among five pirates. Macey distributed the cubes one by one into five piles (see Figure 1). I asked her how much each pirate received, and she answered, "Four." Then I asked what fraction of the whole treasure that was, and she replied, "1/4." I asked her to count out the fractional shares, and she counted "¼, 2/4, ¾, 4/4, 5/4."

Like the symbolic task, Macey appeared to have identified the numerator as the count of the shares (corresponding in total to the number of sharers). Also like the symbolic task, the denominator was not determined based on a referent whole. Instead the denominator reflected the size of the individual share, its quantity. This might be explained by the previous question directing her attention to how many each received or by the discrete nature of the cubes. However, in light of her response to the symbolic task, another interpretation of her thinking is that she understood the denominator as the quantity in the share (similar to the number of cookies in each row). That is, she may have been seeing five groups, each the "size" of four. This again indicates she may not be viewing the part in relation to the whole as is the focus of equipartitioning and or as disembedded from a whole as in the mental actions framework. We also note that her final count resulted in an improper fraction which did not seem problematic for Macey. If this fractions as counts is a persistent understanding similar to Lewis's (2014) fraction quantities as counts of partitions, it is not constrained to unit fractions or by the number of partitions in a whole.

Task 3: Fractional Shares of a Continuous Whole

I gave Macey a long strip of yellow construction paper and told her it was a giant french fry that friends could share (see Figure 2). Each time I asked her to create shares for a number of friends, she used her fingers to estimate a piece of the fry and iterated across the strip. When it was too big, she went back and made the distance between her fingers smaller and iterated again. Once she verified the size she was estimating would fit within the whole, she repeated the process again, marking the strip and then cutting it into parts. I asked her to name the unit fractions and to count the fractional amounts. She named and counted the partitions correctly (e.g., "⅓, ⅔, 3/3").

Macey demonstrated awareness that the number of pieces create a connected whole, an idea that is part of the mental action of iteration. As evidenced previously, Macey identified the numerator as counts of the shares. Unlike the cookies in an array and the pirates' treasure contexts, the value Macey identified for the denominator was based on the number of partitions to the whole, mapping to the number of sharers. In this context, of equipartitioning a single, continuous whole, Macey was able to give the mathematically correct answers.

We also worked with Cuisenaire rods and bar models without context. Told that a rod represented ¼, Macey iterated and traced each iteration, counting with fractions as she went. She continued beyond the whole, counting "5/4, 6/4" before stopping. I asked her if she could keep going, and she said, "Yes, but I will run out of paper."

Based on this activity, we infer Macey understood the numerator not just as a counting number but also as the number of iterations. This activity also indicates she had little trouble with the idea that one can iterate a partition beyond a whole. Considering this in light of the evidence that she was not attending to the referent whole with discrete representations, we suggest Macey was not disembedding the ¼ rod or viewing the rod as ¼ the size of the whole. Rather she may have considered this as a new quantity emerging from the partitioning and, as such, the original whole does not place limits on the number of iterations.

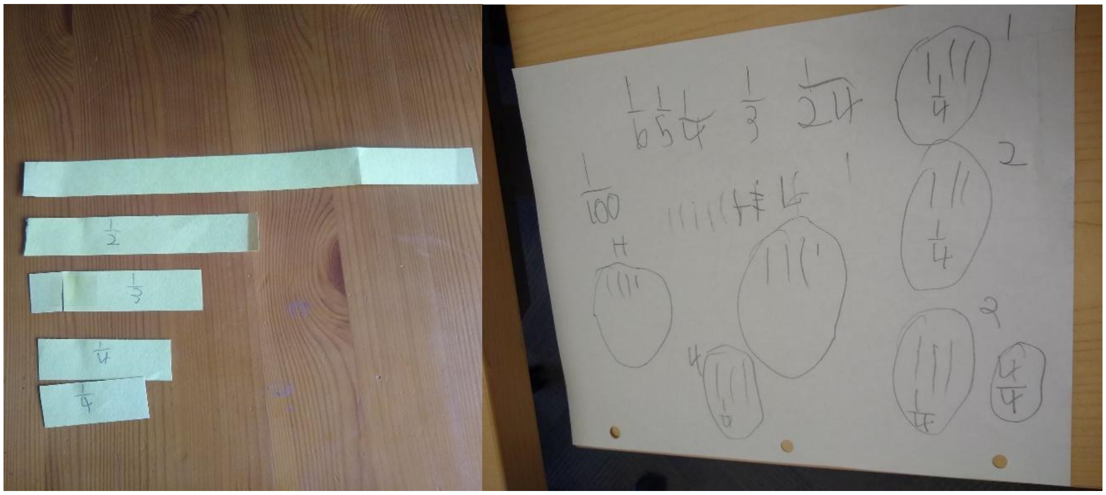

Figure 2. The image on the left shows the shares of a french fry created for a changing number of sharers. The image on the right shows Macey's solution to the task of four children sharing three licorice ropes. Circles representing each child are shown on the right and bottom center in four circles, labeled 1–4, and each containing three tally marks and the inscription, "¼".

Task 4: Sharing Multiple Continuous Wholes

I presented Macey with three long strips of red construction paper and told her they represented long licorice ropes. I then asked her to share the licorice among four children. Figure 2 shows four circles labeled 1-4, representing each of the four children (additional notations on the page are related to a previous task). The circled 4/4 in the bottom right of the picture is her final answer to how much licorice each child gets. Macey's response contains errors that are potentially informative about her understanding. Her solution process is presented in the following transcript:

> So, let's take and put them together [lining up one end of each strip].
> That would be about even. So [marks the middle of each strip to generate halves].
> So, one, two, three, four, five, six [counting halves].
> One, two, three, four, [pointing to each of the circles as she counts, pauses] five, six [returning to point at the first two circles].
> Each of these [unintelligible] again [marks halves of halves on the construction paper strips].
> So, one, two, three, four, [pointing at the circles on paper, looking back and forth from circles to construction paper strips] five, six, seven, eight [pointing again to each of the four circles] nine, ten, eleven, twelve [pointing again to each of the four circles]
> So, one two, three, four, five, six, seven, eight, nine, ten, eleven, twelve [putting a tally mark in each circle one-by-one as she counts].
> Each of them get a ¼, 2/4, ¾, 4/4 [pointing to the partitions in the first strip of construction paper].
> So, so ¼, ¼, [pointing to the first circle and second circle, then writing ¼ in each circle]. That equals 4/4.

When Macey found halves did not distribute evenly across sharers, she used her knowledge that halves of halves create fourths. She ensured the pieces would distribute equally across sharers and then marked tallies for each piece given. Her activity of guess-and-check with halves and then fourths does not indicate that she recognized she could partition each whole into fourths to match the number of sharers. We note this is in contrast to the case of a single continuous whole when she seemingly could map the number of sharers to the number of partitions needed.

Regarding naming of the fractional share, Macey said each gets "a ¼, 2/4, ¾, and 4/4" and then writes ¼ in each circle, and in doing this she appears to be repeating her process of distributing the four partitions of the first licorice rope. With the statement, "That equals 4/4," Macey pointed only to the first licorice rope and appeared to be referencing the 4/4 in a single rope. Macey disregarded or did not notice that she had three tally marks within each circle.

We noted some similarities with Macey's responses to previous tasks. Macey's gestures indicate the numerator was identified by counting partitions in one licorice rope, but she had distributed these pieces one by one to each sharer. In both tasks her numerator corresponds to the number of sharers. Regarding the denominator, there was no reference to the other two licorice ropes as she named the fractional shares, and there is no indication she understood one rope as the referent whole. Given responses in previous tasks did not show attention to a referent whole, we suggest the denominator in this case is the number of partitions in a group she perceives as salient, something consistent with her naming of fractional shares of cookies and gold coins. Again, there are similarities in Macey's response to the persistent understanding of fractions as numbers rather than indicators of size

Abductive Inferences

We infer Macey held these fraction understandings based on these equal sharing tasks:

- Awareness of equipartitioning (number of shares, equal size, exhaust the whole)
- The part represented a new, iterable quantity that was not seen in relation to the whole
- Numerators identified counts of shares, corresponding to iterations in the context of a single continuous whole
- Denominators were understood as "size" meaning quantity, as in the number of parts within a single whole or a single salient object/group

Discussion

We consider our abductive inferences through the three frameworks – equipartitioning, mental actions in fraction schemes, and persistent understandings. We are unpacking Macey's responses in the spirit of exploration from multiple perspectives and welcome the uncertainty we find. Our purpose is to engage conversation with the mathematics education research community about connections and questions across these frameworks about fraction understanding. Next, we identify our questions about the abductive inferences clustered around three topics: discrete representations of fractions, continuous representations of fractions, and numerators and denominators. Finally, we pose questions related to Macey's neurodivergence.

Questions about Discrete Representations of Fractions

When Macey was working with models of discrete objects (e.g., cookies or gold coins), she attended to clusters of these objects (e.g., dots or cubes) rather than to the larger whole.

- Does this indicate Macey has yet to construct a part-of-a-whole and/or a part-to-whole (Confrey, 1992) understanding of fractional shares of collections? What are the implications of this as it represents the first level of the equipartitioning learning trajectory (Confrey et al., 2014)?
- Persistent understandings are constructed by neurodivergent students in socio-cultural interactions (Lewis, 2014). Given the perceptual saliency of counts groups and partitions within groups (as opposed to counts of shares and number of shares in a whole), how might Macey's naming have arisen in the context of instruction? What does this suggest about tasks and instruction involving fair shares of collections?

Questions about Continuous Representations of Fractions

When Macey was working with a single continuous whole, she was able to iterate and re-create a whole as well as create improper fractions.

- Does Macey understand what a whole is? If asked to iterate a ¼ piece seven times, she would likely draw a bar of length 7/4, but would she indicate 4/4 as the whole?
- Macey seems to regard parts as new quantities that add up to the same amount as the original whole but not as part of the whole. Does this confirm that Macey does not yet disembed (Steffe & Olive, 2010)?
- Does her understanding of fractional shares facilitate an understanding of improper fractions without the mental actions of disembedding and units coordination (Hackenberg, 2007; Steffe & Olive, 2010; Wilkins & Norton, 2018), and if so, how might this be useful in supporting her subsequent learning?
- Given that a student with understandings such as Macey's may provide correct answers for fractional parts of a continuous whole, when are these persistent understandings reinforced by instruction and when do they become problematic (Lewis, 2014)? How can they be identified?

Questions about Numerators and Denominators

When we try to characterize Macey's thinking about numerators across tasks, we infer Macey understood numerators as the count of the number of shares or iterations. We infer Macey understood denominators as the quantity of partitions. These understandings worked for her in some situations and not in others.

- In what ways will these understandings impact her development at more advanced levels of equipartitioning and fraction schemes?
- This seems to be consistent with the "more pieces" understanding identified by Lewis (2014), one in which the understanding of the denominator is as the number of pieces rather than the size of the piece. The student in Lewis's (2014) study applied this only to unit fractions. Macey applied this thinking to non-unit fractions. Is this an understanding that other students construct?
- Is this understanding precipitated by instruction that focuses on counting the partitions and does not attend adequately to the relative size of the partitions, a lack of clarity about size as quantity and size as dimensions?

Questions about Neurodivergence

Macey was able to complete each of the tasks she was given by using additive reasoning, applying counting, partitioning, and iterating actions. She did not evidence activity indicative of understanding fractions as either part-to-whole or part-of-a-whole relationships.

- Given the perceptual saliency of counts groups and partitions within groups (as opposed to counts of shares and number of shares in a whole), how might Macey's naming have arisen in the context of perceptual processes?
- Macey reached solutions to each task presented to her, though she did not evidence using anticipatory thinking to do so. How did Macey's visual-spatial, fluid, and deductive reasoning strengths serve as assets when solving fraction tasks? How can these assets be used to support her in recognizing fractional parts in relation to a whole?
- How might a persistent understanding of fractions as counts–that is as uncoordinated numbers rather than a size–be related to Macey's issues with executive function or abstract reasoning? Might other cognitive processes be implicated?
- How might this persistent understanding be constructed based on perceptual saliency of representations and instruction which leaves ideas of multiplicative relationships or disembedding implicit (Lewis, 2014)?

Finally, we wonder more generally which of Macey's understandings might be qualitatively different from those more typical of students in the learning of fractions. If they are qualitatively different, but emerge in the socio-cultural use of representations, how many other students develop similar understandings? And if they persist and contribute to future difficulty with more sophisticated fraction operations and relational thinking, how might we design tasks and instruction to address these persistent understandings?

Conclusion

We center the thinking of a neurodivergent student, viewing this as an opportunity for our learning as researchers and educators. We consider the student's thinking from a diversity of perspectives–three conceptual frameworks for fraction understanding, and in doing so we find numerous areas of uncertainty. This represents a unique approach to exploring the fraction understandings of students. This is of benefit to the field by considering how frameworks can come into conversation with one another and surface questions which offer productive lines for research. Further, this exploration aims to provide evidence that explicitly positioning difference at the center of a study, in this case a neurodivergent student's thinking, can provide a valuable contribution to knowledge development around how fraction understandings emerge.

juliana.utley@okstate.edu

We explored how background factors and mathematics-related beliefs were predictive of 5th through 12th grade students' mathematics identity through regression analysis. Results indicate both background factors (age, honors placement, tutoring received) and mathematics-related beliefs (mindset, anxiety, agency, nature of math, rules) were all predictive of students' mathematics identity. Student age, receiving tutoring, and mathematics anxiety were all negative predictors, while the rest of the variables in the model were positive predictors. This study highlights the variety of factors that play a part in a student's mathematics identity development and could provide insight into specific experiences or interventions that might be used to support students' identity development.

Keywords: Affect, Emotion, Beliefs, and Attitudes; Middle School Education; High School Education

Research notes the important role that mathematics identity has on students' achievement (Bohrnstedt et al., 2021) and persistence, as shown through career choice (Cribbs et al., 2021a, 2021b). However, limited research explores how various background factors and mathematics-related beliefs influence students' mathematics identity. This is partly due to the limited quantitative research in the field (Graven et al., 2019) and also due to the small sample sizes that are often used to explore the complexities of identity development such as through discourse analysis and/or positioning (Bishop, 2012; Sfard & Prusak, 2005). It is the purpose of this study to fill a gap in the literature by exploring connections between various factors and students' mathematics identity to provide a picture of potential overarching patterns that could inform the field. This is particularly beneficial given the growing number of calls by the field for teachers to attend to students' mathematics identity development (NCTM, 2018, 2020a, 2020b).

Theoretical Framework

This study draws upon prior work in the field aligned with core identity (Cobb & Hodge, 2011; Gee, 2001). From this perspective, identity is viewed as thickening over time (Holland & Lave, 2001), allowing for a snapshot of students' identity to be taken at a point in time, such as through a survey. Initial work in the field provides validity evidence for measuring mathematics identity with undergraduate (Cribbs et al., 2015) and 5th-12th grade students (Cribbs & Utley, 2023). That work supports the inclusion of three sub-factors for measuring mathematics identity: Interest (a student's desire or curiosity to think about and learn mathematics), Recognition (how students view themselves and how they perceive others to view them in relation to mathematics), and Competence/Performance (students' beliefs about their ability to understand and perform mathematics). In combination, these factors capture students' mathematics identity.

Mathematics identity and background factors

Given that mathematics identity is informed by social and cultural norms and experiences (Holland & Lave, 2001), it is important to consider students' gender, racial, and ethnic identities when exploring their mathematics identity. A wealth of literature highlights the ways that gender (Cribbs et al., 2016; Damarin, 2000; Mendick, 2005), race (Berry, 2008; Martin, 2000), and ethnicity (Adams, 2018; Gonzalez et al., 2023) inform how students position themselves or are positioned by others as a *math person*. In addition, other background factors, such as grade level are important to consider when examining mathematics identity development. Research has consistently shown that as students progress through K-12 their dispositions regarding mathematics declines (Musu-Gillette et al., 2015). Other research found that Honor's placement positively influences changes in academic identity and school belonging (Legette & Kurtz-Costes, 2021). In addition to these background factors, specific family background/experiences have been shown to relate to students' identity. For example, research shows a connection between STEM identity and students' participation in informal STEM experiences (Dou et al., 2019). Additionally, research indicates receiving mathematics tutoring could have a negative effect on students' mathematics identity (Cribbs et al., 2021a). Another important connection to explore further is the number of student's family members who are in a STEM field. With literature noting the role that parents have on their child's beliefs and decisions (Turner et al., 2017). Other work notes that while the level of influence by peers may be less for individuals pursuing mathematics-related fields, career choice is still strongly influenced by family members (Sasson, 2019). However, much of this work focuses on females due to the potential stereotypes that might influence students' decisions. Given that little research explores mathematics identity quantitatively, little is known about how these factors might relate to students' mathematics identity for groups of students or cross-sectionally across K-12.

Mathematics identity and mathematics beliefs

Other work provides evidence of connections between mathematics-related beliefs and mathematics identity. For example, mathematical mindset and mathematics anxiety were both predictive of mathematics identity (Cribbs et al., 2021b). However, that study was with undergraduate students, which leaves a gap in our understanding of how these constructs might be correlated for K-12 students. Literature proposes a strong connection between mathematics identity and mathematical agency (Aguirre et al., 2013; Atabas et al., 2020; Turner, 2012). However, until recently a measure for mathematical agency was not available for exploring this relationship quantitatively (Cribbs & Utley, under review). Another important aspect of students' mathematics identity is their perceptions of mathematics as a subject. Boaler and Greeno (2000) make this clear stating that "It is possible that many able students who could become world-class mathematicians leave mathematics because they do not want to author their identities as passive receivers of knowledge" (p. 189). This statement highlights how students' beliefs about what mathematics is as a subject might influence their mathematics identity. By exploring beliefs about the nature of mathematics along with mathematics identity, this relationship can be further explored. In addition to these other beliefs, students' perceptions of the type of support they receive in the classroom are important to consider. Fredricks et al. (2018) found that both teacher and peer support positively associated with students' mathematics engagement. Given the social aspects of identity development, teacher and peer support is likely to have an influence on mathematics identity as well. In combination, exploring mathematics identity along with these mathematics-related beliefs can provide a better understanding of their influence on students' identity development.

Methods

A cross-sectional survey design was used to collect data from 5^{th}-12^{th} grade students to explore their mathematics identity and other mathematics-related beliefs.

Participants

Data were collected from two districts in a mid-western state in the United States. Students in grades 5^{th}-12^{th} grade were asked to participate, resulting in 1,655 surveys. After data was cleaned and responses with large portions of missing entries removed, the sample included 1,394 participants. With regard to gender, 46% identified as Male and 54% as Female. Participants were between the ages of 9 and 18. Twenty percent of the sample indicated they were of Hispanic origin. With regard to race, 56% indicated they were White, 24% Native American, 6% multicultural, 5% were uncertain, 3% Black or African American, 2% African American and White, 2% Asian, and 1% Other. In terms of grade level distribution, 18% were in 5^{th} grade, 13% 6^{th} grade, 10% 7^{th} grade, 10% 8^{th} grade, 12% 9^{th} grade, 20% 10^{th} grade, 11% 11^{th} grade, and 5% 12^{th} grade. In the state where the data was collected, a fourth year of mathematics is not required for high school graduation, which aligns with a smaller percentage of students represented from 12^{th} grade in the sample.

Data Collection and Analysis

A survey was administered to participants in late spring of 2022. In addition to background factors (e.g., gender, race, age), the survey included items for a variety of mathematics-related factors, which will be detailed in the subsequent sections.

Background Variables. Two types of background variables were collected for the study: demographic variables and family background variables. The demographic variables include gender (0=female; 1=male), age, Hispanic, race, grade level ($1=5^{th}$; $8=12^{th}$), and advanced math class. Family background variables include English is the primary language at home, family working in the STEM field (total number of male guardian, female guardian, and other family working in STEM), math and/or science as a family hobby, family help with math schoolwork, family arranged tutoring in math (0=no; 1=yes), and number of STEM camps or programs in which participants participated (scale from 0 to 5+).

Mathematics Identity. Mathematics identity was measured through a 16-item Likert-scale (1-Strongly disagree; 5-Strongly agree). The factor is comprised of three sub-factors (interest, recognition, and competence/performance; Cribbs & Utley, 2023). Although the instrument can be used to explore the three sub-factors separately, it can also be used to create an overall mean for mathematics identity, taking a snapshot of students' mathematics identity at the time the survey is administered. This scale included items such as "I see myself as a math person" and "I look forward to taking math."

Mathematical Agency. Mathematical agency was measured using three sub-scales: Discipline/Conceptual (7-items; e.g., "I can correct or fix my math errors when solving problems"), Collective (4-items; e.g., "In math class, we listen to each other's math ideas"), and Critical (7-items; e.g., "Math has helped me make sense of the world around me."). Given that the sub-factors for mathematical agency are theoretically and statistically distinct, they will be explored separately in this study (Cribbs & Utley, under review). Items were on a Likert-scale with 1-Strongly disagree and 5-Strongly agree.

Mathematics Mindset. Mathematical mindset drew on Dweck's (2008) work. However, only the incremental beliefs subscale was used (Blackwell et al., 2007; De Castella & Byrne, 2015) and adapted to be mathematics specific as in other research (Degol et al., 2018). The mean of the four items was used to measure the factor. This scale included items such as “No matter who you are, you can significantly change how smart you are in math” and “You can always change even the basic level of how smart you are in math considerably.” Items were on a Likert-scale with 1-Strongly disagree and 5-Strongly agree.

Mathematics Anxiety. Two different scales were used to measure mathematics anxiety as the scales measured different aspects of the factor. The first measure of anxiety used the Single-Item Math Anxiety Scale (SIMA) asking students to respond to the prompt “On a scale from 1-10, how math anxious are you?” Prior research provides validity and reliability evidence for the scale (Nunez-Pena et al., 2014), and the scale was a way for us to efficiently assess students’ overall mathematics anxiety. The second scale used was the modified Abbreviated Mathematics Anxiety Scale (mAMAS), which has validity and reliability evidence from prior work (Carey et al., 2017) and was used to assess two sub-factors of mathematics anxiety. The first sub-factor is Mathematics Evaluation Anxiety (MEA) and includes four items asking participants to rate their level of anxiety in response to items such as “Thinking about a math test that day before you take it” and “Taking a math test.” The second sub-factor is Learning Mathematics Anxiety (LMA) and includes five items such as “Having to complete a worksheet by yourself” and “Starting a new topic in math.” Items were on a Likert-scale with 1-Not anxious and 5-Extremely anxious.

Nature of Mathematics. Beliefs about the Nature of Mathematics was measured using items from the Teacher Education and Development Study in Mathematics (TEDS-M; Tatto et al., 2012). This factor included two sub-scales: Mathematics as a set of Rules and Procedures (6-items; e.g., “Mathematics is a collection of rules and procedures that prescribe how to solve a problem”) and Mathematics as a Process of Enquiry (6-items; e.g., “Mathematics involves creativity and new ideas”). These sub-factors are considered separately as “it is quite possible for them [respondents] to endorse both sets of propositions” (Tatto et al., 2012, p. 155). All items were on a Likert-scale with 1-Strongly disagree and 5-Strongly agree.

Teacher and Peer Support. Teacher and Peer Support was measured using four sub-scales: Teacher Academic Support (4-items; e.g., “My math teacher cares about how much I learn”), Teacher Person Support (4-items; e.g., “My math teacher thinks it is important to be my friend”), Peer Academic Support (5-items; e.g., “Other students in math want me to do my best schoolwork”), and Peer Personal Support (4-items; e.g., “In math class, other students like me the way I am”). Consistent with how the factor was used in literature (Odoy, 2018), the sub-factors were considered separately in analyses. Items were on a Likert-scale with 1-Never true and 5-Always true.

Regression analysis was used to create a model examining how demographic variables, family background variables, and mathematics beliefs were predictive of students’ mathematics identity. Prior to data analysis, simple random imputation was used to create a complete dataset, which is a better option than using listwise or mean imputation (Schlomer et al., 2010).

Results

A stepwise regression analysis was conducted in blocks, where background (demographic and family background) variables were regressed on mathematics identity first. After all non-significant items were removed from the model, mathematics-related beliefs were regressed on mathematics identity (also retaining the significant background variables). Items were removed from the model until only significant variables remained.

Table 1 shows that the only significant demographic variables were students' age and advanced/honors placement for mathematics class. Estimates indicate that students' age was a negative predictor, and honors placement was a positive predictor of mathematics identity. Only one family variable was a significant predictor for mathematics identity. Students indicating that their family arranged for them to get tutoring in mathematics negatively predicted their mathematics identity.

Table 1: Background Variables and Mathematics-Related Beliefs Predicting Mathematics Identity

N=1,394	Estimate	SE	t-statistic	Sig
Intercept	0.82	0.16	5.17	***
Student Age	-0.03	0.01	-3.52	***
Honors	0.35	0.05	7.50	***
Tutoring in math	-0.14	0.05	-2.56	*
Math Mindset	0.08	0.02	3.93	***
Overall Math Anxiety	-0.02	0.01	-3.26	**
Math Evaluation Anxiety	-0.08	0.02	-4.39	***
Learning Math Anxiety	-0.05	0.02	-2.03	*
Math Agency – D/C	0.54	0.03	21.21	***
Math Agency – CR	0.17	0.02	7.81	***
Nature of Math – Rules	0.11	0.02	5.48	***
Teacher Academic Support	0.04	0.02	2.03	*

*p<0.05 **p<0.01 ***p<0.001

In terms of mathematics-related beliefs, eight factors/sub-factors remained in the final model. Mathematics mindset, the discipline/conceptual and critical sub-factors for mathematical agency, rules sub-factor for nature of mathematics, and teacher academic support sub-factor for teacher and peer support were all positive predictors for mathematics identity. As one might expect, all three mathematics anxiety scales were negative predictors for mathematics identity. As a check for multicollinearity, the variance inflation factor (VIF) was assessed. The highest VIF was 2.3, well below the recommended value of 4 (Hair et al., 2010). Thus, all items were retained in the model.

Discussion

Results provide evidence for a variety of background and mathematics-related beliefs influencing students' mathematics identity.

Background Factors

Student age being a negative predictor for mathematics identity aligns with prior work noting a decline in students' beliefs and/or attitudes as they progress through school (Musu-Gillette et al., 2015). However, the estimate was relatively small ($\beta = -0.03$) indicating that this relationship might not be as strong as with other affective measures. This finding could be due to core identity being more stable over time (Cribbs et al., 2022) than other aspects of identity or a mediating relationship that was not tested in this study. Perhaps more targeted interventions for mathematics identity development are needed. Research found that changes in identity can occur when targeted practices are employed (Hima et al., 2019). However, little is known about interventions employed with large groups of students. Honors placement was a positive predictor for mathematics identity which aligns with prior work exploring academic identity (Legette & Kurtz-Costes, 2021). Students who are in honors courses might get reinforcing messages regarding their competency in mathematics as well as recognition by family, teachers, and peers. Additionally, the family background variable, tutoring in mathematics, had a similar result from prior research (Cribbs et al., 2021a), which might be indicative of students feeling they are not competent with mathematics because they are receiving tutoring. However, that study also found that students who tutored others positively predicted mathematics identity, so the act of tutoring supports identity development, but not vice versa. It is worth noting the non-significant variables, which were gender, race, ethnicity, English as the primary language spoken at home, number of family members working in a STEM field, math and/or science as a family hobby, family helped with schoolwork, and participation in STEM camps or programs. It is possible that exploring mediating relationships or interaction effects, not tested in the current study, could provide a more nuanced understanding of the role these variables might have on students' identity development.

Mathematics-Related Beliefs

Given that mathematics mindset was a significant predictor for mathematics identity for undergraduate students (Cribbs et al., 2021b), it was not surprising to see a significant relationship with 5^{th}-12^{th} grade students. Further work is needed to better understand the direction of this relationship. All three measures for mathematics anxiety were negative predictors for mathematics identity, similar to prior research with undergraduate students (Cribbs et al., 2021b). Although the estimates are relatively small, it is interesting to note that Mathematics Evaluation Anxiety had the largest estimate ($\beta = -0.08$), potentially highlighting the negative effects of assessment on students' anxiety and subsequent identity. This study hints at the potential negative ramifications student assessment has that goes beyond immediate performance as previous research highlights (Barroso et al., 2021) to mathematics identity, which impacts students' future choices (Boaler & Greeno, 2000; Cribbs et al., 2021a, 2021b). Two of the sub-factors of mathematical agency were significant predictors of mathematics identity. Discipline/Conceptual agency had the largest estimate in the model ($\beta = 0.54$), indicating a strong correlation between mathematics identity and the sub-factor. This could be partly due to the alignment between elements of the competence/performance sub-factor of mathematics identity. Critical agency was also a positive predictor for mathematics identity. Turner (2012) described critical mathematical agency as involving "students' capacity to: understand mathematics; identify themselves as powerful mathematical thinkers; [and] factor and use mathematics in personally and socially meaningful ways" (p. 55). Results from this study align with prior work (Aguirre et al., 2013) noting that agency plays an integral part in students' mathematics identity development. Interestingly, collective agency was not a positive predictor, particularly given the quorum effect that interest has on career choice in STEM (Hazari et al., 2017). The Rules sub-factor for nature of mathematics was a positive predictor for mathematics identity; the inquiry sub-factor, however, was not. This sparks some points for consideration. As many students are likely to experience direct instruction in their classroom as opposed to inquiry instruction, could this be indicative of students' experiences in their classrooms? Does this perception of mathematics potentially act as a barrier to students who might otherwise develop a mathematics identity? Finally, only one sub-factor of support was significant, teacher academic support. This finding highlights the important role that teachers have in students' identity development, as noted in multiple calls by the field (NCTM, 2018, 2020a, 2020b).

Connecting to the Conference Theme

In line with the conference theme, this line of research endeavors to use a different methodological approach to exploring mathematics identity than is commonly used (survey vs. positioning and/or narrative) by the field. This approach builds on theoretical perspectives from the field and provides a way to better understand how identity is being influenced by larger groups of students in varying contexts and backgrounds.

In transition to proof courses for undergraduates, we conducted teaching experiments supporting students to learn logic and proofs rooted in set-based meanings. We invited students to reason about sets using three representational systems: set notation (including symbolic expressions and set-builder notation), mathematical statements (largely in English), and Euler diagrams. In this report, we share evidence regarding how these three representations provided students with tools for reasoning and communicating about set relationships to explore the logic of statements. By analyzing student responses to tasks that asked them to translate between the representational systems, we gain insight into the accessibility and productivity of these tools for such instruction.

Keywords: Logic, multiple representations, Euler diagrams, undergraduate

Introduction

Using multiple representations to support student reasoning and problem solving has long been acknowledged as a cross-cutting theme in mathematics education (e.g., NCTM, 2000). Working within and across representations is often a productive means of supporting student reasoning and promoting communication in the classroom. In the realm of mathematical logic, there is a long tradition of developing various visual and symbolic representation systems (e.g., Venn diagrams, Euler diagrams, truth tables, logical calculus), which would suggest this is a ripe space for using visual and symbolic representations to support student learning. However, in our experience, the use of spatial representations such as Euler or Venn diagrams to teach undergraduate transition to proof (TTP) students is rare (see Dawkins et al., 2022). One explanation for this is that diagrammatic representations of logic generally rely on set relationships (Mineshima et al., 2012), but common approaches to teaching logic in undergraduate TTP courses generally base logical concepts on truth-values rather than sets (Dawkins et al., 2022). This is the case despite a body of evidence supporting the power of visual representations for student reasoning in logic (e.g., Stenning, 2002; Sato & Mineshima, 2015).

Based on a series of experiments (e.g., Dawkins & Cook, 2017; Dawkins & Roh, 2024; Dawkins et al., 2023; Eckman et al., 2023) involving a cycle of modeling student reasoning about logic and task design to support learning of logic, our team has developed a teaching sequence to foster learning of logic using set relationships. We use three primary representation systems (Goldin, 1998) to engage students in reasoning about set relationships: set theoretic symbols including set-builder notation, mathematical statements (rendered in English), and Euler diagrams. Figure 1 portrays how a subset relationship between two properties P and Q might be alternatively portrayed in the three representations. As Thompson (1994) explained regarding different representations of a function, we should not assume that students always see all of these as different representations of the same underlying object, even if that is our goal.

Set-theoretic symbolic representation
$A \subseteq B$
where $A = \{x \in S: x \text{ has property } P\}$
and $B = \{x \in S: x \text{ has property } Q\}$

Mathematical statement representation
Given any $x \in S$, if x has property P, then x has property Q.

Euler diagram representation

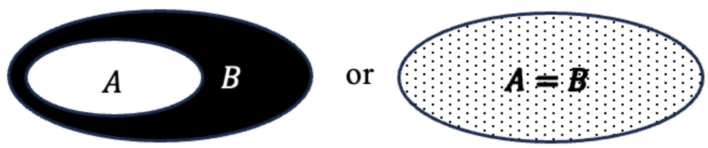

Figure 1: Expressions of a subset relationship in the three representations

As with much teaching using various representations, in our teaching experiments our research team did not want these representations to be the focus of instruction during most of the unit in which we taught logic. Rather, after they were introduced, we wanted them to be means by which students could reason and communicate about set relationships and the logic of statements. In two undergraduate TTP whole-class teaching experiments, we encouraged students to communicate within and across the three representational systems to learn set relationships, logic of statements, and proof techniques. We assigned a number of tasks in which students translated between the representations or generated new objects in one or more representations. In this report, we share our analysis of student work on such tasks to consider whether these three representations served as *accessible* and *mathematically productive* ways for students to reason about and communicate about set relationships. In particular, we share whether student use of these representations was normative – meaning the claims students made were mathematically accurate – and whether they were consistent – meaning a student's various claims for related tasks agreed, even if the interpretations or claims were non-normative. Our goals in this analysis are twofold: 1) to investigate the efficacy of teaching logic using these three representations for supporting student inquiry (as evidenced by the conditions in the previous sentence) and 2) pending positive evidence, to portray the potential of using these representations for instruction on logic and proof techniques (as it stands in contrast to common practice).

Relevant Literature

This section reviews literature relevant to our project before briefly reviewing our own line of research that informed the instructional approach employed in the teaching experiments.

Sets, diagrams, and the teaching and learning of logic

While Venn diagrams are perhaps the most well-known visual system for representing and reasoning about logic, a variety of such systems were developed, primarily in the 19th century. Research on how people reason with and learn from such systems is much more recent. Sato et al. (2010) compared how people solve syllogism tasks using a few different representation systems (see also Bronkhorst et al., 2022). In particular, they compared verbal solution methods (no diagrams), Venn diagrams (in which regions always overlap and regions are shaded), and Euler diagrams (in which possibilities are displayed by the overlap/non-overlap of regions, as in Figure 1), each with a short period of training in each diagram system. They found that the college student participants performed better with diagrams than with only verbal representations and performed better with Euler diagrams than with Venn diagrams. Those authors explain the value of diagrams by claiming, "we may plausibly assume that the semantic primitives of quantificational sentences in natural language are *relations* between sets, and that people's inferences with quantified constructions are sensitive to such a relational structure" (Sato et al., 2011, p. 2183). They assume that treating statements as relations among sets (as is portrayed in Venn and Euler diagrams) rather than relations quantified over ranges of individual objects (as is done in most standard treatments of logic, such as truth tables) is more consistent with natural language. Sato et al. (2010) further claims that Euler diagrams fostered better performance since they are in some sense "self-guiding" (p. 20) for minimally trained learners. We do not endorse such an interpretation of representational transparency as though learners must not engage in some constructive process of making meaning of the diagrams, but the evidence suggests that students find Euler diagrams easier to use with minimal training nevertheless.

Mathematics education studies of sets, diagrams, and logic

Deloustal-Jorrand (2002, 2004) provides a strong antecedent to the present work as she argued that student understanding of conditional statements should be built upon three viewpoints: formal logic (truth table definition and quantification), sets (represented by spatial diagrams), and implication (the conclusion can be inferred from the hypothesis). She hypothesized that "it is necessary to know and establish links between these three points of view on the implication for a good apprehension and a correct use of it" (Deloustal-Jorrand, 2002, p. 4). Similarly, Durand-Guerrier et al. (2012) emphasized that logic must be taught with attention to semantic and syntactic aspects. While they do not endorse spatial diagrams in particular, such diagrams are classically viewed as a representation of the semantics of statements which supplement the syntax of formal statements or symbolic expressions. These authors support the claim that students should reason about sets, likely expressed through spatial diagrams, to learn about the logic of statements and proofs – however, how students bridge between these representations has been explored less. In a forthcoming paper, Antonides et al. (in press) explore how students link spatial and logical structures, recognizing the challenge and opportunity posed by operating across these representational systems[4].

Our approach to teaching logic is consistent with these other studies, but only indirectly drew upon them. Our focus on sets arose from observations of productive student reasoning about mathematical statements (Dawkins, 2017). This led us to depart from the common truth conditions for statements defined by truth tables, and to adopt truth conditions based on sets. Specifically, the truth of a conditional corresponds to a subset relationship between the truth sets

[4] Both Sato et al. (2010) and Antonides et al. (in press) use Euler diagrams in which regions do not have existential significance. This means that in Figure 1, the left-hand diagram could represent both the case where $A \subset B$ and $A = B$. We do not adopt those conventions, but rather use the two diagrams in Figure 1 to separately express the two cases. This creates a two-to-one mapping between the diagrammatic representation and the symbolic and sentential representations in the way we teach, as portrayed in Figure 1.

of the two predicates, as portrayed in Figure 1. As we explored how to use sets to support students to reason about the logic of statements and proofs (e.g., Dawkins et al., 2023; Dawkins & Roh, 2024), we saw the need to more directly teach basic set theory beforehand (Eckman et al., 2023, provides examples motivating this need for instruction). The three-representation approach investigated in this report arose as a tool for enacting this teaching sequence. Two other aspects of our approach worth mentioning are that 1) we focus on sets defined by mathematical properties, not arbitrary sets such as $\{1, \pi, \text{Ford Taurus}\}$ and 2) we focus on mathematical statements rather than everyday, nonsense, or purely symbolic statements.

Methods

As part of a larger project investigating student abstraction of logic (NSF DUE #1954768 and #1954613), we conducted two whole-class teaching experiments (Steffe & Thompson, 2000) in undergraduate TTP courses. These courses occurred at two large Southwestern, public universities and were taught by the first and second authors. The data gathered consisted of videos of all class meetings in which sets, logic, and proof techniques were covered, student homework and exams, group interactions in target small groups, task-based interviews on logic with members of the target groups both before and after instruction, and pre- and post- logic assessments delivered online. Consistent with teaching experiment methodology, outside observers were present at all class meetings and the research teams at the two sites met weekly to discuss and conduct iterative analysis and planning.

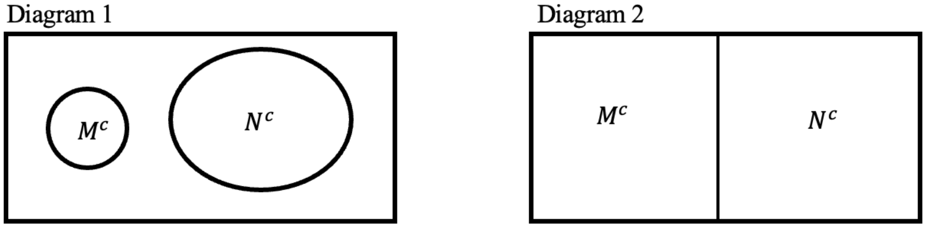
All students were invited to provide informed consent to participate in the study. The data analyzed in this report is limited to homework and exam work from students who opted into the study (13 students in each class), which represents 87% and 100% of the students in the two classes. This portion of the data was deemed most appropriate for analyzing all participating students' use of the three representations. The homework and exam tasks were not the same across the two classes, though some tasks were shared. This creates an asymmetry in the available data at the two sites. While this might be a problem if we tried to make claims about student learning over the course of the teaching sequence, our goals in this report are more modest. We want to consider the extent to which the three representations provided accessible and mathematically productive ways for students to reason and communicate about set relationships. We provide an example to illustrate what we mean below.

To answer this question, the third and fourth authors analyzed all homework and exam tasks from the portions of the courses on sets, logic, and proof techniques. We looked for all the tasks that invited students to operate between representations, often providing input in one and asking students to respond in one or both of the others (see Fig 2 for an example). The research team then selected a subset of these tasks for student response analysis, giving preference to those tasks used in both classes. The third and fourth authors then analyzed all consenting student responses to these tasks. Responses were coded for whether the response 1) made normative claims in the representation, 2) was internally consistent, and 3) exhibited any recurring feature observed in other responses and salient to translation between representations. As allowed by the structure of each task, we attended to whether students were internally consistent in the claims they made about sets across the representations. In other words, we sought to discern whether they used different representations as ways to express the same underlying relationship. Though many of the tasks in the courses were in a particular mathematical context (e.g., quadrilaterals), many of the tasks we analyzed dealt with arbitrary sets and properties. Such tasks were assigned to support student abstraction. These tasks are useful for this study to see how students related the three representations without underlying reference to the specifics of some underlying mathematical context.

Consider the task in Figure 2 to illustrate our coding. The normative responses for the first question were 11a – true-true, 11b – false-true, and 11c – false-true. To us, the three statements in question 12 corresponded to the set relationships in question 11: 11a~12b, 11b~12c, and 11c~12a. Since we know one of the two diagrams is the case, but we are not sure what is the precise state of affairs between these properties, the normative answers to question 12 are that statement b must be true while statements a and c may be true or may be false. Even if students did not give those normative answers to these questions, their answers to question 11 may be consistent with their answers to question 12. We interpret this to mean that they linked the statement and the set relationship normatively, but they might have read the diagram non-normatively. This is an example of what we would have called consistent, though not normative responses. These codes were then tallied to provide descriptive summaries that allowed us to survey student use of the three representations, as we shall share in the following sections. Since it is not our goal to compare the two classes, we aggregate all of the codes across the two classes for tasks used at both sites.

Assume that for the sets M and N, we know that one of the following two set diagrams is the case, but we are not sure which.

Diagram 1 Diagram 2



11) Determine whether the following set relationships is true or false in each of the two diagrams (in other words, give two answers, one for Diagram 1 and one for Diagram 2).
    a. $M^c \subseteq N$
    b. $M^c = N$
    c. $N \cap M = \emptyset$

12) For each of the following statements, circle the best explanation of its truth value based on the diagrams above.
    a. There exists some $x \in S$ such that x is in M and x is in N.
       i. Must be true. ii. May be true or may be false. iii. Must be false.
    b. Given any $x \in S$, if x is in M^c, then x is in N.
       i. Must be true. ii. May be true or may be false. iii. Must be false.
    c. Given any $x \in S$, x is in M^c if and only if x is in N.
       i. Must be true. ii. May be true or may be false. iii. Must be false.

Figure 2: Translation between representations task from a midterm exam

Results

In this section, we present our findings from analyzing student responses to three tasks (though each is multi-part). The first two tasks were given in both classes. The third (in Figure 2) was only given at one site. While we identified other tasks relevant to our investigation, space does not permit us to report more in this conference paper. When possible, we share instances of interesting student thinking to support the claim that the three representations were productive for student inquiry into logic.

Task 1: Building sets containing the given set

Figure 3 presents Task 1 in which students were asked to build sets containing the given set. This was both an opportunity to use set-builder notation and to think about how properties influence the membership of a set. While this task did not include either statements or Euler diagrams, we consider the coordination of properties and sets of objects another key aspect of constructing set relationships. Table 1 presents the results of the coding analysis. Most students used set builder notation as intended. Furthermore, more than 81.7% of the responses identified a superset of the given set (even if equal to the given set). Set D proved to be the most challenging for many students because there are no familiar sets of quadrilaterals that contain all trapezoids. Student responses tended to lean heavily on familiar conditions (i.e., those taught in school) to construct their supersets. One interesting pattern in some of the non-normative responses is illustrated by the student whose response for set D was the set of quadrilaterals in which all four sides are parallel. This produces a subset of D, but the student was likely thinking about how having two parallel sides is "contained in" having four parallel sides. This way of reasoning arises on other tasks, such as when students think the set of equilateral triangles contains the set of isosceles (defined inclusively) since three equal sides contains two.

Let $\mathbb{T}$ denote the set of all triangles. $\mathbb{Q}u$ is the set of all quadrilaterals.
$\mathbb{Z}$ is the set of integers. $\mathbb{N}$ is the set of natural numbers, which is $\{1, 2, 3, 4, \ldots\}$.

For each of the following sets, use set-builder notation to construct another set that contains the given set. In other words, the set given should be a subset of the set you define. (My answers are that $A, B \subseteq \mathbb{Z}$, $C \subseteq \mathbb{T}$, and $D \subseteq \mathbb{Q}u$, so you may not use those answers.) Each task is worth ½ point.

$A = \{x \in \mathbb{Z}: x\ is\ a\ multiple\ of\ 2\ and\ a\ multiple\ of\ 11\}$.
$B = \{x \in \mathbb{Z}: when\ x\ is\ divided\ by\ 4, it\ has\ a\ remainder\ of\ 2\}$.
$C = \{\Delta XYZ \in \mathbb{T}: \Delta XYZ\ is\ obtuse\}$.
$D = \{LMNO \in \mathbb{Q}u: at\ least\ two\ sides\ of\ LMNO\ are\ parallel\}$.

Figure 3: Task 1, which invites students to use set-builder notation

Table 1: Features of student responses to Task 1 (n=26)

Response Feature	Set A	Set B	Set C	Set D	Total
Used set builder notation	73%	81%	88%	85%	**81.7%**
Did not use set builder notation	27%	19%	12%	12%	**17.3%**
Superset	62%	81%	70%	23%	**58.7%**
Equivalent Set	31%	8%	27%	27%	**23.1%**
Subset or Incorrect Set	8%	12%	4%	50%	**18.3%**

Task 2: Constructing diagrams and new set relationships from them

Task 2 (see Figure 4) invited students to translate a set expression into Euler diagrams and then to use those diagrams to produce new set expressions. We had noted in our previous experiments that students often struggled to think about complement sets as the inside of regions in Euler diagrams. For this reason, we purposefully asked them to draw diagrams where the given information contained a complement and chose to provide them a diagram where the complement was inside of an oval region. There are two normative diagrams for this arrangement similar to those in Figure 1, but a range of other diagrams may be drawn if students represent S as the inside of a region or if they imagine any sets to be empty or universal. Accordingly, as displayed in Table 2, some students produced three diagrams. About one quarter of students could only produce one normative diagram.

Task 2 (2 pts): Assume for the sets S, T, which are in the universal set Ω, that we know $S^c \subseteq T$

a) Draw as many different diagrams as you can portraying the possible relationships between S and T.
b) Identify 2 other set relationships that must also be true among the sets S, T, S^c, T^c.
c) Suppose another student drew their diagram as shown to the right. Are your answers to part b still true in this diagram? How could you shade the diagram to show how your set relationships are true in this diagram?

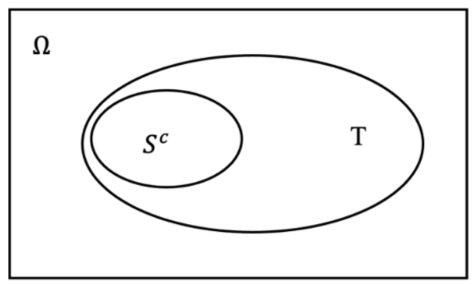


Figure 4: Task 2, which asks students to connect set notation and Euler diagrams

Table 2: Features of student responses to Task 2

Number of Normative Diagrams Produced		Set Relation Normativity		Internal Consistency	
Three	11.5%	Normative set relations	53.8%	Fully internally consistent	57.7%
Two	57.7%	Non-normative set relations	46.2%	At least one consistent	88.5%
One	26.9%				

The intended answers to part b (based on what was discussed in the classes) were that $T^c \subseteq S$ and that $S^c \cap T^c = \emptyset$ since these are both logically equivalent to the given condition, though other statements were possible. As the third column of Table 2 displays, 88.5% of students generated a set relation that was consistent with at least one of their diagrams. We interpret this as evidence of some fluency between the representations. The lower performance indicated in other cells points to the challenge of this task caused both by the presence of the complement and the many-to-one pairing between diagrams and set relationships. Less than 60% of student responses presented a set relation that matched all of their diagrams (according to our interpretation thereof). Since student diagrams were either non-normative or did not capture all of the possibilities, this meant that almost half of their given set relationships were non-normative (not necessarily true given $S^c \subseteq T$).

We want to highlight two types of responses reflected in this data. One student only drew a diagram in which S and T are complements of one another. This is consistent with the given information but does not show all possibilities. As a result, her first set relation, $S \cap T = \emptyset$, is consistent with her diagram, but is not normative since it is untrue when $S^c \subset T$. Her other set relation, $S \cup S^c = \Omega$, is a tautology. It is consistent with the given information, her diagram, and is normative, but it would be true of any set and does not depend upon the given information. A second type of response we noticed was when students generated other types of equivalent conditions, such as $S^c \cap T = S^c$. We had not taught these other conditions equivalent to a subset relation, so we infer that the Euler diagrams supported students in noticing new, normative relationships. Both these equivalent conditions and the tautologies suggest that the Euler diagrams were productive for students' ability to identify new set relationships.

Task 3: Evaluating set relationships and statements from given Euler diagrams

Task 3 appeared in Figure 2. As with Task 2, we purposefully introduced complement sets into this task to see if students could reason about them as sets much like any other set. Table 3 below presents how frequently student responses were normative and consistent with corresponding other responses. The codes group the parts of question 11 and question 12 that correspond according to normative logic. The data show that students frequently gave normative answers to most tasks, though responses to 12c were often neither normative nor consistent. We interpret this to suggest that the language of "if and only if" was still not being coordinated with the other representations in the manner intended. On the other tasks, students were consistent with their diagrams on nearly 4 out of 5 responses, suggesting relatively strong fluency between the representations.

Table 3: Student responses to Task 3

Problem Pair 1				Problem Pair 2				Problem Pair 3			
	D1	D2	Claim		D1	D2	Claim		D1	D2	Claim
Normative	100%	79%	86%	Normative	93%	93%	50%	Normative	71%	93%	79%
Non-Normative	0%	21%	14%	Non-Normative	7%	7%	50%	Non-Normative	29%	7%	21%
Internally Consistent		79%		Internally Consistent		36%		Internally Consistent		79%	

Discussion

This paper analyzed how students in two undergraduate TTP courses, which were designed to foster set-based meanings for logic and proof, used the three representations of set relationships to reason about and communicate about logic. This was done by analyzing student responses to tasks that particularly asked them to operate within and across the representations. Student responses were coded both in terms of whether they were, first, normatively correct and, second, internally consistent with students' responses to other parts of the task. Third, we also noted when students gave responses that were mathematically accurate even if logically less interesting, such as tautologies. While we are pleased by normative responses, we take consistent and tautological responses as supporting evidence that the three representations were productive for student reasoning and communicating.

Much of the data shows that a majority, but not all, student responses were normative and/or consistent. We draw two implications from this. We claim that operating in the representations was accessible and productive for students since most of them were able to demonstrate productive reasoning about set relationships on these tasks. By reasoning within and across the representations, we hoped students could construct and abstract set relationships both between particular properties and arbitrary properties. The second implication we draw is that reasoning between representations is non-trivial. By contrast, Sato et al. (2010) claim that Euler diagrams are self-guiding and certain inferences can be read directly from diagrams. We agree that they are facilitating, but we claim learning to operate in these representations is a meaningful accomplishment. Further, our tasks reveal how task features such as complement sets, coordinating different cases, and needing to generate non-familiar sets all increase the challenge of student reasoning about logic. We hope that future work will continue to explore student learning in this arena and future instruction will seek to make use of these three representations to support student progress.

For many college students, mathematics poses a significant academic challenge, particularly in courses like Calculus, which can become gatekeepers hindering their pursuit of STEM-oriented degrees. To address this issue, we advocate for innovative pedagogies such as Specifications Grading that we posit promote Latina/o students' mathematics identity development. In this study, we examine the mathematics identity development of 350 Latina/o students enrolled in Specifications Grading Calculus I compared to traditional grading. Using a validated survey and Repeated Measures ANOVA, we explore changes in recognition, and overall mathematics identity. The study highlights the impact of alternative grading systems, such as Specifications Grading, on Latina students' mathematics identity .

Keywords: Calculus, Instructional Activities and Practices, Undergraduate Education, Assessment

Purposes of the Study

The primary objective of this study is to investigate the influence of Specifications Grading on the development of Latina/o students' mathematical identity and contribute to the field of mathematics education by offering informed perspectives on pedagogical practices that positively shape students' mathematical identities. By comparing Calculus 1 students in Specifications Grading and traditionally graded classes, we aim to provide insights into the relationship between grading methods and their impact on self-concept, confidence, and motivation in mathematics. Specifications Grading, an alternative grading method, is characterized by transparent learning outcomes and assessment criteria (Nilson, 2015). The following research question guided our study: What impact, if any, does a specifications-graded Calculus 1 course have on students' mathematics identity development in comparison to students enrolled in a traditionally graded Calculus 1 course?

Theoretical Framework

The study adopts a theoretical framework emphasizing the importance of mathematics identity in students' academic journeys. Drawing on Cribbs et al.'s (2015) model, we focus on two of the four key constructs: *recognition* and *mathematics identity* (See Figure 1). In our study, Specifications Grading is posited as a pedagogical tool fostering stronger mathematical identities. For a qualitative study of the development of these four key constructs on a student taking Specifications Grading and a student in a traditionally-graded Calculus course, see the work by Fernandez, et al. (2023).

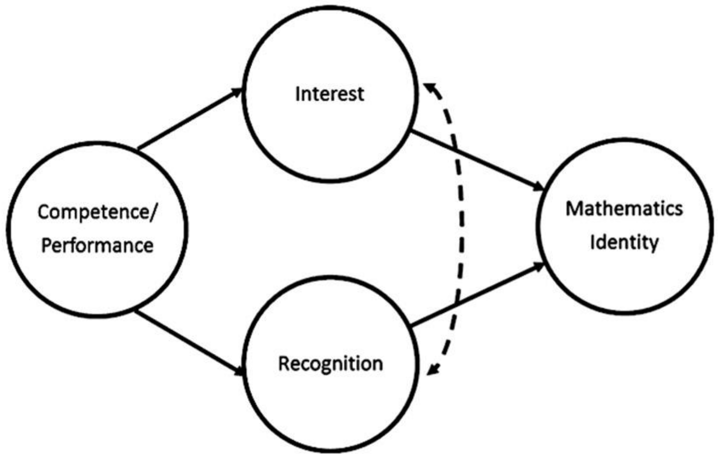

Figure 1. Cribbs et al. (2015) Establishing an Explanatory Model for Mathematics Identity

Methods

During two semesters, we implemented Specifications Grading to a subset of Calculus 1 classes consisting of 8/13 (or 62%) in-person sections in Fall 2022 and 11/14 (or 79%) in-person sections in Spring 2023; the remaining sections were taught in-person and considered traditionally-graded classes. We identified 27 learning outcomes/targets and grouped into 10 core, 11 supplementary, and 6 non-testing learning targets. Assessments consisted of weekly worksheets, four exams, and online homework associated with the learning targets. Worksheets and exams were graded on a pass/no-pass scale. Full credit for a learning target was earned by obtaining credit on the associated worksheet and exam problem. Worksheets could be resubmitted for full credit. If students failed to pass a learning target on an exam, retesting periods were available weekly on Fridays if they attended tutoring. Students from the Specifications Grading classes and traditionally graded classes who completed both the pre-survey during the second week of classes and the post-survey during the last week of the semester served as the participants of this study. In essence there were a total of 350 participants with 43.1% identifying as sophomores and 24%-25% identifying each as freshmen or junior students. For this study we adopted a comprehensive statistical methodology that included Structural Equation Modelling (SEM), specifically Confirmatory Factor Analysis (CFA) and Repeated Measures Analysis of Variance (ANOVA) to analyze the data collected from the participants. In this study, CFA was used to verify the mathematical identity construct, which was based on the work of Cribbs et al. (2015). The comparative fit index (CFI) was used as the metric to measure the accuracy of the construct, and it had a value of 0.941, indicating the goodness of the construct. Repeated Measures ANOVA was used to compare the means of the same group of subjects under different conditions at different times (Girden, 1992, as cited by Beins, 2017). Repeated Measures ANOVA was used to analyze the Mathematical Identity pre- and post-survey scores of students to determine whether there were statistically significant differences in the development of mathematical identity before and after taking the Calculus I course. ANOVA also helps to evaluate whether the differences observed are related to the intervention (Specifications Grading) or if they could be attributed to chance.

Results

Recognition: Specifications Grading vs Traditionally Graded Groups

Preliminary findings show that even when the Specifications Grading and traditionally graded groups started at different estimated marginal means in the pre-timeframe, participants from the Specifications Grading group had a slightly higher measure of ***recognition*** (that is, students' perception of being seen as a math person by others) in comparison to those in the traditionally graded group (See Figure 2). Although the observed differences between the two groups are not statistically significant as indicated by a *p*-value of 0.922, further investigation is needed to determine the factors that influenced these changes.

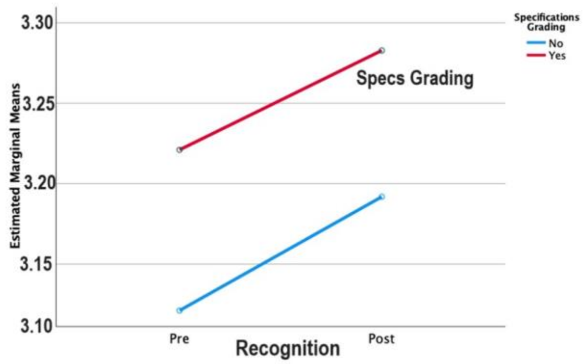

Figure 2. Comparison of Recognition among Specifications Grading and Traditionally Graded Groups

Mathematical Identity: Specifications Grading vs Traditionally Graded Groups

Preliminary findings indicate that even during the pre-timeframe, both groups have distinct estimated marginal means, with the traditionally graded group showing a slightly higher sense of ***math identity*** (that is, students identifying themselves as a math person). However, during the post period this group showed a notable decline in Math Identity, while the Specifications Grading group exhibited a slight increase (See Figure 3). Although the changes are not statistically significant, further investigation is needed to determine the factors influencing those changes. Studying math identity is important as it is correlated with student mathematics achievement (e.g., Fernández et al., 2022; Gonzalez et al., 2022; Matthews, 2020).

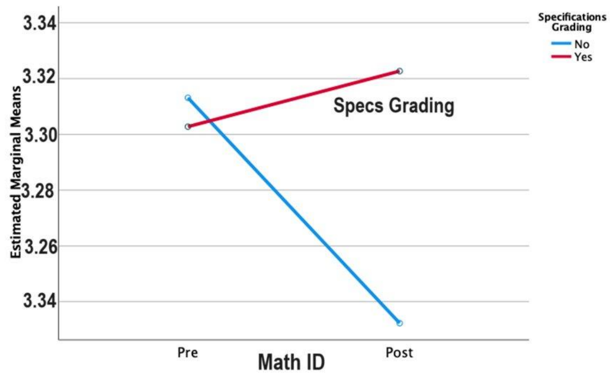

Figure 3. Comparison of Math Identity among Specifications Grading and Traditionally Graded Groups

Recognition: Specifications Grading Male vs Female

Preliminary findings indicate that from the students enrolled in Specifications Grading classes, both male and female students show a slight increase in their ***recognition*** levels (See Figure 4) with female students showing more gains.

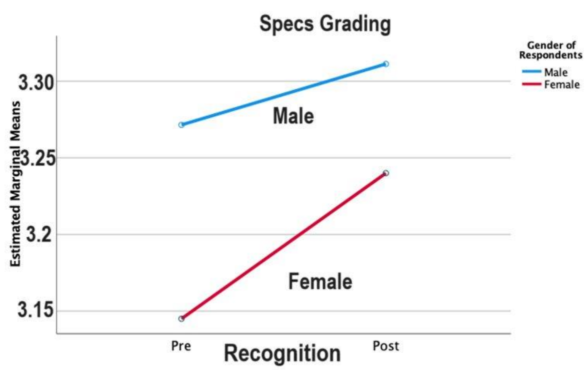

Figure 4. Comparing Recognition among Males and Females in the Specifications Grading Group

Mathematical Identity: Specifications Grading Male vs Female

Preliminary findings indicate that from the students enrolled in Specifications Grading classes, male participants showed a slight decrease in their ***math identity***. On the contrary, female participants showed a notable increase in math identity (See Figure 5).

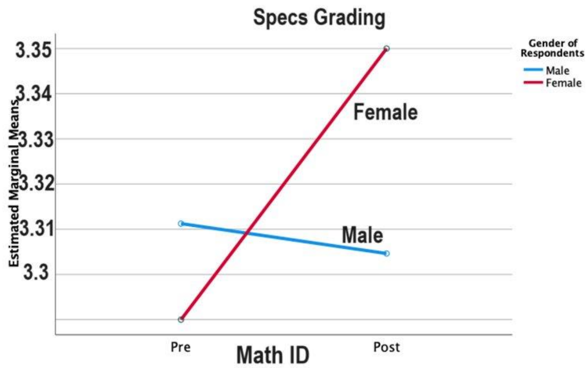

Figure 5. Comparing Math Identity of Males and Females in the Specifications Grading Group

Discussion and Conclusion

This research contributes to the ongoing dialogue on equitable mathematics education for Latina/o students, particularly in gatekeeper courses like Calculus I. The adoption of Specifications Grading emerges as a promising pedagogical strategy to positively influence mathematics identity development. The observed differences in*, recognition,* and overall *mathematics identity* between Specifications Grading and traditionally graded groups underscore the potential of innovative grading approaches in creating a more supportive learning environment.

COLLEGE STUDENTS' USE OF LANGUAGE RESOURCES IN MATHEMATICS

Melissa A. Gallagher, Ph.D.

mgallagher@mathrecovery.org

Shaimaa Scrivner, Ph.D.
University of Houston
sabouzeid@uh.edu

Language serves as a crucial tool for communication, comprehension, and problem-solving. People use language as a resource when they approach new problems, including in mathematics classes. In this study, we examined the language resources used by five college students as they solved a mathematics word problem in a language unknown to them. We found the most commonly used resources among the students were contextual (e.g., scaffolds provided by the teacher), cognitive (e.g., their background knowledge), and social (e.g., meaning co-constructed with their peers).

Keywords: Equity, Inclusion, and Diversity; Affect, Emotion, Beliefs, and Attitudes; Instructional Activities and Practices

Classrooms in North America are becoming increasingly multilingual (He & Yu, 2017). As mathematics education researchers envision a future for our field, we must continue to explore the ways in which language can be used as a resource in mathematics classrooms (Adler, 2000; Moschkovich, 2012; 2021). This is particularly crucial for multilingual learners (MLs) who may need to access additional language resources if they do not yet have access to the language of the classroom (Moschkovich, 2012). When asked to participate in a mathematics lesson in a language they do not speak, many teachers would assume their students would not be successful (Gallo et al., 2014). However, if language is viewed as a resource, and if the teacher supports comprehension appropriately (Krashen, 1992), then students may be able to be successful. The purpose of this study was to explore the language resources used by college students when solving a mathematics task in a language they do not know. The following question guided this study: *What language resources do college students use when solving a mathematics word problem in a language they do not know?*

Perspectives

Language and Mathematics

There is a robust body of research on the role of language in the mathematics classroom, especially with regard to MLs' mathematics learning (Barwell et al., 2016; Barwell et al., 2017; Halai & Clarkson, 2015; Moschkovich, 2010; Prediger & Schüler-Meyer, 2017). These studies take different views of language as a resource in the mathematics classroom, but overall have found that multilinguals, especially in classrooms where the language of instruction is not their home language, draw on what they know about language to interact with their peers and their teacher and make meaning (Moschkovich, 2008).

Many researchers have taken up the perspective of language as a resource in mathematics learning to counter deficit narratives about students whose home language is different than the language of instruction (e.g., Adler, 2000; Barwell, 2018; Planas & Civil, 2013). Here we take up Moschkovich's (2015) conceptualization of the multiple resources that MLs use in the mathematics classroom, which draws on a sociocultural perspective, including "not only oral and written text, but also multiple modes, representations (gestures, drawings, tables, graphs, symbols, etc.), and registers (school mathematical language, home languages, and the everyday register)” (p. 44).

In contrast to Moschkovich’s work, which was largely situated in English medium classrooms and focused on students who had at least some English language proficiency, our objective was to investigate the resources students would use to make sense of and solve a mathematics task in a language unknown to them. One critique of Moschkovich’s work is that her definition of language as a resource is all-encompassing to such an extent that it is challenging to discern the specific resources students accessed (Barwell, 2018).

Language Resources

Language resources can refer to external material and technologies, such as dictionaries, online translators, and writing resources (Oh, 2020) or the individual’s language-related resources (i.e., learners’ skills and strategies used to access and produce language). These latter resources include strategies that can be classified into cognitive, affective, social, and contextual resources (see Figure 1). Additionally, researchers have recently argued for the positive association between metacognitive (Hulstijn, 2015, 2019; Teng & Zhang, 2022) and metalinguistic awareness in students’ language learning. Thus, we consider these as resources too (see Figure 1).

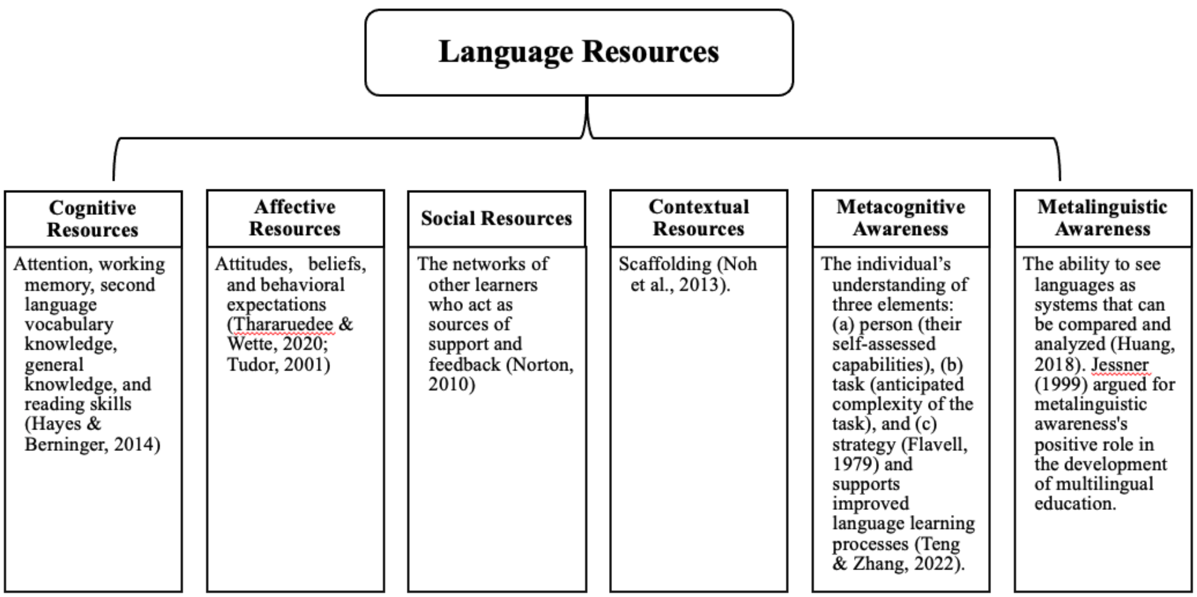

Figure 1: Individual Language-Related Resources as Reported in the Literature

The purpose of this study was to examine how the participants’ language resources allowed them access to a mathematics word problem in an unfamiliar language.

Methods

Participants

We invited undergraduate college students enrolled in a Southern urban university to participate in this study. We had five participants, four of whom identified as females, and one identified as a male. Two participants were sophomores, and three were juniors. Two participants identified as West African, two as Hispanic, and one as Asian. All five participants described having significant exposure to multiple languages and cultures in their lives. Participation included attending (a) an in-person mathematics session and (b) a focus group interview.

We had two in-person, video recorded, 30- minute mathematics sessions: three participants attended the first, and two attended the second. During the sessions, we presented a word problem in Arabic (a language none of them spoke) to the participants and asked them to try to solve it. Following this task, we led a 30-minute focus group interview for the participants to reflect on their feelings, thoughts, and strategies used during the task**.** The task– the population of Midtown is three times that of Karburg. The difference between the two populations is 2184. How many people live in each of the cities? (see Figure 2)– was presented in Arabic. The teacher spoke and wrote in Arabic throughout her presentation.

The participants were allowed to access any materials in the room (e.g., manipulatives, calculators, each other) apart from translation technology to solve the problem. Slowly, the teacher presented additional scaffolds, such as pictorial vocabulary instruction (see Figure 2), manipulatives, and a number translation sheet. We recognize that translanguaging– the ability to seamlessly transition between languages and a teaching approach where educators foster this skill (García & Kleifgen, 2020)– is a key practice to leverage students' language resources, and we allowed translanguaging among the students, but we chose not to have the teacher translanguage in order to emulate the situation in many classrooms where the teacher speaks the majority language and students' dominant languages are minority languages.

Figure 2: The word problem as presented to the students with math and vocabulary representations.

Data Analysis

We coded the transcripts of the videos for the language resources the participants either demonstrated as they worked on the problem or those that they told us they used during the focus group interview. We began with a priori codes derived from the literature review (see Figure 1). Together, both authors coded the entire dataset over multiple sessions. We maintained a code book and a data analysis log, which we referred to when making coding decisions. After applying these high-level a priori codes, we went through the excerpts within each code and open-coded them more descriptively. For example, some of the excerpts under social resources were coded “co-constructing a strategy” and “co-constructing understanding.” All coding at this level was done together so that 100% consensus was reached.

Findings

We observed the participants utilize *cognitive* resources such as “background knowledge” and “mathematical knowledge.” For example, Tiwa mentioned that because the second author introduced herself as an Arabic speaker at the beginning of the session, she was able to recognize that the task was in Arabic. That allowed her to deduce that since writing in Arabic goes from right to left, then perhaps numbers follow the same rules. Additionally, *metalinguistic* resources, such as “knowledge of the written form” and “metanumeric awareness,” were strongly present. For instance, Elena recognized the place value table that the researcher used during the presentation. Although the table showed the Arabic numbers, Elena made the connection and realized the similarities between the rules of place value as she knew them in English and in Arabic as they were presented. Making a connection between two different number systems demonstrates metanumeric awareness (Gallagher, 2021). These findings underscore the importance of language resources in providing access to mathematics tasks.

Additionally, we found that the participants relied most heavily on social resources. Indeed, “co-constructing understanding” was an ongoing activity between all team members. They did that by listening to each other’s thinking and discussing clues. For example, Salman said,

> I find that it's easier when you have a group to do it with, right? Because we build up on other people's ideas, right? So, she knew something that I didn't know. And when she told me, it started making sense to me. So, you know, it's good to work with the group.

Additionally, we observed the participants “co-construct strategy” together. The following exchange presents an example of this particular resource.

Tiwa: So, I think we set up a proportion to figure out how many people live in Midtown compared to the other places. So the first number would be 2184 over … because… I’m not good at proportions. Do you guys know how to set up the proportion?
Valeria: So, are you … are you thinking like one-third equals 2184?
Tiwa: Yes, but also no, but yes, something along that line.
Valeria: Like that structure?
Tiwa: Yeah, because the two is … 2184. So, we need to figure out that one to get the total and then compare it to the other city.
Valeria: [pointing at the problem in the sheet] So, if that number is 2184, then wouldn't that 2184 be 2/3?

Despite none of the participants speaking Arabic or having experienced the language in an academic setting before, they supported each other’s learning by co-constructing their understanding and strategies. Through their use of these multiple strategies, especially *contextual, cognitive*, and *social* resources, the participants were all able to make sense of the task and solve the problem, both arriving at a correct mathematical answer and writing that answer using Arabic numerals.

Discussion and Limitations

The purpose of this study was to examine the language resources that college students use to help them access mathematics tasks in a language unknown to them. Our findings echoed previous research on students' use of cognitive resources (de Araujo et al., 2018; Peng et al., 2020); metacognitive resources (Jessner, 2018); metalinguistic awareness (Reder et al., 2013); contextual resources, such as scaffolding (Noh et al., 2013); and social and contextual resources (Klang et al., 2021). The small sample size poses a limitation for this study. Additionally, we recognize that college-age students may have had more experience needing to make sense of new situations and therefore may have more resources than younger students. We hope to expand the study in the future and encourage researchers to examine the language resources used by students in mathematics classrooms across schooling, K-16.

APPLYING ENACTIVIST EPISTEMOLOGY TO MATHEMATICS CLASSROOMS: AN INTERACTIVE PARADIGM FOR RESEARCHING STUDENT COGNITION

Allison L. Gantt
University of Delaware
agantt@udel.edu

Keywords: Cognition, Learning Theory, Research Methods

Researchers in mathematics education and educational studies have argued from post-positivist, constructivist, and emergent epistemological vantage points that understanding students' interactions is central to understanding their cognitive experiences in mathematics classrooms (e.g., Cobb & Yackel, 1996; Cohen et al., 2003; Mok & Clarke, 2015; Nuthall, 2007). In this poster, I explore how another epistemological perspective, enactivism, can further unify this body of work with implications for the conceptualization and design of mathematics classroom research. Enactivists posit that cognition *is* an interaction between an individual and one's environment, as cognition is an enacted phenomenon consisting of perceptually guided actions (Maturana & Varela, 1992; Reid & Mgombelo, 2015; Varela et al., 1991). Although enactivism has been applied in mathematics education research previously (see Simmt & Kieren, 2015), I seek to distill concepts and premises for researching students' cognition in mathematics classrooms to inform an *interactive paradigm* for mathematics classroom research. Indeed, paradigms "provide frameworks that describe, interpret, analyze, and in some cases explain both the knowledge that is being produced as well as the processes that are used to produce it" (Collins, 2019, p. 52). Thus, the articulation of an interactive paradigm for mathematics classroom research has implications for both the content of what one can conceive of researching as well as the methodologies and approaches one applies in investigation.

In this theoretical poster, I explore the following research question: *What does enactivist epistemology imply for how we might conceive of researching students' cognition in mathematics classrooms?* I will present an interactive paradigm in response, including my definitions for three core concepts—students, environment, and cognition—united around two guiding premises:

1. Classroom environments are actively constructed by each student as they relate to other actors and features of their environments.
2. Students' cognition is both agentic and interdependent with their classroom environment.

To contextualize the concepts and premises described above, I will draw connections not only to the extant literature but also to the research methodology and preliminary results of a case study I conducted in alignment with this interactive paradigm. I designed the case study to focus on the cognition and mathematical interactions of three eighth-grade students with their environment (including one another) in an algebra classroom during an instructional unit about linear equations (Premise 1). Through an embedded case structure and targeted analysis of transcript data, I sought to produce findings about algebraic cognition reflective of students' agency and interdependence (Premise 2). Through this poster, I will discuss how an interactive paradigm in this case study contributed to results around student cognition in classrooms that differ from non-enactivist research centering interactions. Importantly, by highlighting how an interactive paradigm might be applied as well as what it might contribute, this poster will share affordances of incorporating enactivist epistemology explicitly into mathematics classroom research agendas.

FACTORS INFLUENCING WOMEN'S SENSE OF BELONGING IN UNDERGRADUATE CALCULUS

Casey R. Griffin
University of La Verne
cgriffin2@laverne.edu

Keywords: gender; affect, emotion, beliefs, and attitudes; calculus; undergraduate education

Women continue to be underrepresented in undergraduate STEM majors, and this gender gap is due at least in part to women's decisions to major in STEM (Carmichael, 2017). Fewer women than men enter into STEM majors and women leave STEM majors at a higher rate than men, especially after taking Calculus I (Chen et al., 2013; Eagan et al., 2016; Ellis et al., 2016). One major reason for women's decisions to leave STEM is that they feel a low sense of belonging (Seymour & Hunter, 2019; Shapiro & Sax, 2011). Sense of belonging is the extent to which one feels like an accepted member of an academic community, whose presence and contributions are valued (Good et al., 2012). Scholars have identified characteristics of sense of belonging such as its malleability (Anderman, 2003; Griffin, 2023), as well as factors that influence one's sense of belonging, including perceived competence, social connectedness, and learning environment (Anderman, 2003; Rainey et al., 2018; Rainey et al., 2019). Perceived competence is the extent to which one *feels* like they understand the material. Social connectedness is the extent to which one has relationships with their classmates and/or instructor. Learning environments have features such as classroom climate and classroom activities.

This report aims to explore the roles that perceived competence, social connectedness, and learning environment play in influencing women's sense of belonging in Calculus. This study takes place at a mid-Atlantic research university during the Fall 2022 semester. The university offers a year-long Integrated Calculus course that covers both Pre-calculus and Calculus and was designed to incorporate frequent opportunities for students to engage in active learning. In the Fall 2022, two sections of the course were offered, with 63 and 64 students enrolled in each. The sample for analysis was narrowed to students who self-identified as women, N=41. Participants were surveyed twice during the semester. They were asked to rank the following constructs from most to least impactful on their sense of belonging in mathematics: social connectedness with classmates, social connectedness with instructor, perceived competence, classroom climate, and classroom activities. They were then asked to describe why they chose their top two most impactful constructs. Frequencies of rankings were calculated to explore which constructs were most impactful for women's sense of belonging. Descriptions were analyzed using open coding to explore how and why these constructs impacted women's sense of belonging.

Results show that women consistently included social connectedness with classmates and perceived competence as one of their top two most impactful constructs on their sense of belonging. While classroom activities was not the most popular construct, when women did include this in their top two, they described its impact on social connectedness and perceived competence rather than its direct impact on their sense of belonging, suggesting that perhaps participants viewed classroom activities as farther removed from sense of belonging than social connectedness and perceived competence. These findings suggest that while students' perceptions of their own social connectedness and perceived competence have much influence on their sense of belonging, instructors may be able to influence students' social connectedness and perceived competence, and in turn their sense of belonging, via their pedagogical choices.

IMPROVING METACOGNITIVE MONITORING IN MATH USING CUETHINKEF+

MEJORANDO EL MONITOREO METACOGNITIVO EN MATHEMÁTICAS USANDO CUETHINKEF+

Antonio Gutierrez de Blume	Sam Rhodes	Rick Bryck

Metacognition (MC) has been found to be a critical component of mathematical problem solving (PS; Rhodes et al., 2023). We report on the results of a study that employed an ANCOVA to examine the impact of a PS intervention that included MC supports (e.g., journaling) on students' objective MC within a sample of 276 middle school students. The results suggest that the intervention group significantly improved in their MC.

Keywords: Metacognition; Problem-Solving

Research has suggested that mathematical problem solving (PS) should be embedded within core instruction and should not be isolated from other factors such as content and metacognition (MC; Cai & Lester, 2010). Moreover, MC has been found to be a crucial factor influencing PS proficiency (Rhodes et al., 2023; Lester, 2013). Specifically, MC is thought to support problem solvers in nearly every aspect of the PS process, such as making sense of the problem, selecting and applying strategies, and reflecting and revising their thinking (Tan & Limjap, 2018).

Given these findings, it is unsurprising that interventions that include metacognitive training have been found to significantly improve students' PS performance (e.g., Kramarski et al., 2002). Metacognitive training is operationalized here-in as any support designed to help students utilize MC in the moment (e.g., being more intentional in heuristic selection, self-generating feedback based on their progress, etc.). Indeed, research has suggested that it is ineffective to attempt to isolate instruction on PS from the cognitive and metacognitive factors that influence it (e.g., Cai & Lester, 2010; Lesh & Zawojewski, 2007). However, few studies have explored whether interventions that interweave PS instruction with metacognitive supports result in improved MC. Thus, the purpose of the present study was to examine the effects of a web-based application, CueThinkEF+, that intentionally integrated scaffolds and supports that targeted MC, executive functions, and PS, on students' MC as operationalized by miscomprehension accuracy (the degree to which a person is able to accurately predict performance on a given task or measure).

Learning strategy use emerges from both contextual, cognitive, and personal factors (Panadero, 2017). Research differentiates between types of learning strategies that are hypothesized to improve metacomprehension accuracy, such as when judgments of comprehension are delayed (Shiu & Chen, 2013), individuals receive feedback (Brannick et al., 2005), and learners receive practice (Bol et al., 2005; Gutierrez & Schraw, 2015; Gutierrez & Price, 2017; Hacker et al., 2008; Thiede et al., 2012). Similarly, Nietfeld and Schraw (2002) and Gutierrez and Schraw (2015) found that students who received learning strategy instruction showed superior learning and more accurate monitoring. In the Nietfeld and Schraw (2002) study, which involved performance on probabilities, participants received an instructional sequence of five learning strategies (e.g., self-generated feedback, planning, self-questioning, etc.) discussed during instruction. Gutierrez and Schraw (2015) adapted these strategies and added others. The CueThinkEF+ intervention employs, among others, prompts that encourage self-questioning and intentional planning and reflection.

Additional work such as that of Nietfeld et al. (2006) found that distributed learning strategy instruction with feedback produced higher performance, confidence, and metacomprehension accuracy among college students, while Huff and Nietfeld (2009) found that strategy instruction with 5th grade students improved performance and metacomprehension accuracy. Bensley and Spero (2014) demonstrated that the direct infusion of learning strategies increased students' posttest metacomprehension accuracy while Schleinschok et al. (2017) reported that students who were taught to diagram as a learning strategy improved their metacomprehension accuracy of how well they thought they learned. However, students in the control condition also showed improved monitoring at posttest, although smaller than the treatment condition. This research supports the hypothesis that diagramming, as an example of a specific learning strategy, can improve metacomprehension accuracy. Furthermore, Miller and Geraci (2011) found that strategy instruction was only successful at improving metacomprehension accuracy for lower-performing students because higher-performing students already exhibited high metacomprehension accuracy. Taken together, these findings uniformly supported the hypothesis that metacomprehension accuracy was trainable and could be improved because of learning strategy instruction in various contexts and levels of specificity, including math.

Given the literature surveyed, the purpose of the present study was to answer the following research question: what is the effect of the CueThinkEF+ intervention on middle school students' metacognitive monitoring accuracy?

Conceptual Framework

Efklides (2011) devised the Metacognitive and Affective Model of Self-Regulated Learning (MASRL) in which metacognitive and motivational processes are key, centered on task, person, and task by person levels. The present study employs Efklides' (2011) MASRL as a theoretical guide because this model focuses on the central role metacognitive monitoring and control processes play in learning. More specifically, this model helps us better understand how person-level characteristics (e.g., motivation, engagement, interest, autonomy, task value, etc.) interact with the task (in this case, the CueThinkEF+ platform) and how metacognitive skills like monitoring and control help the moderate this interaction.

Method

Description of the Intervention

Over the course of one academic year, students in the control group continued with business-as-usual instruction while the intervention group used CueThinkEF+ approximately 5-7 times. Incorporating elements from the research noted above, CueThinkEF+ intentionally targeted MC during each phase of the PS process. Exemplifying this several of the supports, students were asked to: 1) consider what they noticed and wondered; 2) restate the question being asked in their own words; 3) create a journal of their plan for solving each problem which could then be updated or revised as they solved the problem; 4) record themselves explaining how they solved the problem, showing their work on a digital whiteboard including various tools and manipulatives; 5) watch the recordings of their peers and write annotations (e.g., "My strategy is like yours because…").

Participants

Three middle schools from a suburban school district participated in the study with one school serving as the intervention group and the other two schools serving as the control group. The district was located on the West Coast and all mathematics teachers at the three participating schools who taught grades 6-8 were invited to participate in the study. Ten teachers signed up to participate in the study and all students of participating teachers were then invited to participate in the study. Of the participating students, 278 students had complete data on the measures utilized within the present analyses. Given that only two of the students with complete data were 8th graders, the present analyses were confined to students in grades 6 and 7. Of the 276 remaining students, 188 students were in the intervention group and 88 students were in the control group. Within each group, the students were evenly split between 6 and 7th graders. Additional demographic data on the students is provided in Table 1 and Table 2 below.

Table 1: Number of Participants by Group and Gender

	n	Female	Male	Non-binary	Other/Did not Specify
Intervention	188	106	73	1	8
Control	88	36	39	2	11

Table 2: Participants by Group and Ethnicity

	Asian	Black/ African American	Hispanic/ Latin(x)	Middle Eastern	White	2 or More Races	Other/Did not Specify
Intervention	7.4%	4.3%	33.5%	24.5%	1.6%	16.5%	12.2%
Control	4.5%	4.5%	22.7%	36.4%	3.4%	17.0%	11.4%

Instruments and Materials

Problem Solving. PS items were compiled from items written by Illustrative Mathematics (IM) and aligned by the researchers to district pacing guides. For each grade level, three cognitively demanding items were selected with the only modification being that directions were added to require students to show or explain their thinking, when needed. Each item was scored for correctness using answer keys that were developed by IM. The interrater agreement on scoring was calculated using Fleiss' kappa and was .961 for 6th grade and .880 for 7th grade.

Metacognition. Prior to completing the PS measure, students were given a list of the mathematical topics that would be covered by the problems on the measure. Students were then asked to predict how well they would do by writing a numerical answer between 0 and 100, inclusive. Prediction accuracy scores were calculated by comparing participants' confidence in performance judgments before the performance assessment against their actual performance. Comparing prediction confidence in performance judgments against actual performance yielded continuous, absolute accuracy scores, as described by Schraw (2009). A score of "0" indicates perfect monitoring; conversely, the further a score is from "0," the greater the inaccuracy.

Data Analysis

Data were first tested for requisite statistical assumptions and tested for univariate outliers using box-and-whisker plots. The data met the assumptions of normality using skewness and kurtosis metrics, homogeneity of variance, and homogeneity of regression slopes. Further, the data did not contain any extreme outliers that would otherwise undermine the trustworthiness of the findings. Hence, data analysis proceeded without making any statistical adjustments.

To answer our research question, we employed a one-way analysis of covariance (ANCOVA), with condition (intervention, control) serving as our fixed factor, pretest prediction accuracy scores serving as the covariate, and posttest prediction accuracy scores serving as the outcome. The results of this analysis demonstrated that pretest prediction scores did not significantly influence posttest prediction scores, and hence, the analysis reverted to a one-way analysis of variance (ANOVA). Eta square (η^2) served as the metric for effect size estimate. Cohen (1988) was used for interpretative guidance on effect size within the present study.

Results

Results of the one-way ANOVA revealed a statistically significant main effect for condition on posttest prediction scores, $F(1,273) = 13.23$, $p < .001$, $\eta^2 = .045$, indicating a small-to-moderate effect size. Table 1 contains the descriptive statistics for the intervention and control groups, and it indicates that the intervention group manifested significantly higher posttest prediction monitoring accuracy compared to the control group.

Table 1: Descriptive Statistics of Posttest Prediction Monitoring Accuracy for the Intervention and Control Groups

	M	*SD*
Intervention (*n* = 188)	32.19	22.09
Control (*n* = 88)	41.98	22.77

Discussion and Limitations

The purpose of the present study was to investigate the effect of CueThinkEF+ on students' metacognitive monitoring accuracy in math. Results revealed a small-to-moderate effect of CueThinkEF+ on students' prediction accuracy when compared to business-as-usual instruction. These results extend the extant literature on metacognitive monitoring accuracy in a math context. They are also congruent with the body of literature that concludes that learning strategy interventions are successful at improving not only learners' performance, but also their monitoring accuracy using control processes to adjust their confidence in performance judgments (e.g., Gutierrez & Price, 2017; Nietfeld and Schraw, 2002; Thiede et al., 2012).

Moreover, the results of the present study provide additional evidence that MC and PS instruction should be intertwined in instruction (e.g. Lesh and Zawojewski, 2007). Specifically, the present study demonstrates that the intervention led to improvements in students metacognitive monitoring accuracy, extending prior analyses showing that the intervention also resulted in increases in student's PS proficiency (Rhodes et al., in preparation). Thus, it is possible that intentionally intertwining metacognitive training and supports with PS instruction may lead to meaningful gains in both areas.

Despite these promising results, the generalizability of the findings is limited by the fact that the study only included samples of students from grades 6 and 7 from a single district. In addition, the present study operationalized MC as metacomprehension monitoring accuracy. Future research should consider using additional measures of MC as well.

Acknowledgments

The research reported here was supported by the EF+Math Program of the Advanced Education Research and Development Fund (AERDF) through funds provided to CueThinkEF+. The perspectives expressed are those of the authors and do not represent views of the EF+Math Program or AERDF.

THE RELATIONSHIP BETWEEN BILINGUALISM AND CHILDREN'S SELF-EFFICACY BELIEFS IN MATHEMATICS THROUGH A SITUATED-SOCIOCULTURAL PERSPECTIVE

Yuhwa Hong
University of Massachusetts Amherst
yuhwahong@umass.edu

This paper explores the relationship between bilingualism and children's self-efficacy in mathematics from a sociocultural perspective. Utilizing an explanatory sequential mixed methods approach, the study examines how diverse cultural contexts and experiences, related to varying language uses and community affiliations, influence children's self-efficacy beliefs in mathematics. Quantitative analysis of TIMSS 2019 data indicates that bilingual children exhibit significantly higher self-efficacy in mathematics than the nonbilingual students, even when controlling for other factors such as academic achievement. Grounded theory analysis of four bilingual families in the U.S. suggests that a bilingual, multicultural identity fosters a positive learning identity across subjects, enhancing self-efficacy in mathematics. Bilingual children also appear to encounter more meaningful challenges and mastery experiences, which strengthen their learning beliefs. Additionally, their unique contexts provide more opportunities to connect and compare diverse cultural perspectives in mathematics, and they receive more interest, attention, and support from parents, teachers, and communities, aiding in overcoming obstacles and developing positive beliefs.

Keywords: Affect, Emotion, Beliefs, and Attitudes, Equity, Inclusion, and Diversity, Culturally Relevant Pedagogy, Early Childhood Education, Self-Efficacy in Mathematics

Children's perceptions of their abilities significantly influence their motivation, performance, and achievement across various domains (Bandura, 1997; Schunk & Pajares, 2002; Wigfield & Eccles, 2000; Barroso, Ganley McGraw, Geer, Hart, & Daucourt, 2021). The self-efficacy beliefs, "the belief in one's capabilities to organize and execute the courses of action required to produce given attainments" (Bandura, 1977, p. 3), drive the 'will' to succeed, motivating individuals to invest time and energy in areas where they believe they can succeed.

Inevitably, self-efficacy is crucial for maintaining motivation in mathematics, enabling students to persist in skill development until reaching their potential (Bandura, 1977, 2012; Pajares & Miller, 1994; Zimmerman & Schunk, 2001). Instead of focusing on its significance of further potential development and growth, however, a prominent trend in self-efficacy research is the investigation of its role as a predictor of students' future academic achievement, course choices, and career trajectories, especially in context of science, technology, engineering, and mathematics (STEM) education (Lee & Stankov, 2018; Muenks et al., 2017; Pajares & Miller, 1995; Wang, 2013; Zeldin & Pajares, 2000). In young children, particularly, self-efficacy's significance extends beyond predictions for future outcomes to understanding how positive beliefs can be cultivated and solidified to thrive their potential. These beliefs, characterized by a future-oriented and malleable nature, hold theoretical and operational importance, emphasizing perceived confidence over competence (Bong & Skaalvik, 2003; Zimmerman, 2000). Therefore, this study aims to deepen the understanding of children's self-efficacy development within their sociocultural contexts, particularly in the circumstances of bilingual children.

Theoretical Perspectives

Traditionally, self-efficacy beliefs are seen as internal mental representations (Gee, 2008), with psychological perspectives emphasizing universal human functioning and mental processes. This view posits that well-designed sources of self-efficacy generally enhance these beliefs. However, the assumption of uniform internalization contradicts observed variations in children's learning and thinking (Gee, 2008; Usher, Weidner, Liem, & McInerney, 2018). Self-efficacy beliefs emerge from the interplay between personal and environmental factors, where situational and cultural elements lead individuals to interpret information uniquely, shaping their self-perceptions. Therefore, developing self-efficacy involves integrating information from multiple sources (Oettingen, 1995; Usher, 2009; Usher et al., 2018).

Mastery experiences are the most powerful source of self-efficacy beliefs (Bandura, 1986; Butz & Usher, 2015; Zimmerman, Schunk, & DiBenedetto, 2017; Sheu et al., 2018; Joët, Usher & Bressoux, 2011). However, it is not merely the existence of mastery experiences but students' interpretations of these experiences within specific contexts that shape their self-efficacy. Additionally, the circumstances under which a student gains mastery experiences can influence the interpretation, evaluation, and weight of these experiences (Gao, 2020; Usher, 2009; Usher et al., 2018). Usher and Pajares (2008) called for further studies to "capture the personal, social, situational, and temporal conditions under which students cognitively process and appraise their beliefs and experiences" (p. 784). This study emphasizes the importance of sociocultural influences in developing self-efficacy beliefs in mathematics.

Focusing on language as a significant construct of children's sociocultural circumstances, this study examines bilingual children. Language is fundamental to cognitive growth and mediates higher-order thinking (John & Brader-Araje, 2002). Vygotsky's sociocultural theory posits that language significantly mediates sociocultural forces, influencing mediated activity and experiences (Fernyhough, 2013; Rubik, 2017). Thus, modifying the cognitive tools accessible to a child, such as language, can fundamentally reshape their mind (Vygotsky, 1978). This paper investigates bilingual children's self-efficacy beliefs in mathematics through a sociocultural perspective, emphasizing the role of language as a cognitive and sociocultural mediator.

Research on students' self-efficacy has largely focused on high school and college-aged individuals in predominantly White settings. However, some studies highlight the significant impact of contextual and demographic factors, such as gender, ethnic background, and learning domain, on self-efficacy outcomes (Usher, 2009; Britner & Pajares, 2006; Lent, Lopez, & Bieschke, 1991; Usher & Pajares, 2006). Limited research has explored these factors' influence on efficacy beliefs, emphasizing the need to consider cultural dimensions in diverse settings (Klanssen, 2004). Klanssen's (2004) study of 270 Grade 7 students (Indo Canadian and Anglo Canadian) found that Indo Canadian students displayed a more hierarchical orientation in mathematics efficacy beliefs, influenced by social comparison. The study did not explicitly address language but suggested it as a factor. Clifton-Sprigg's (2015) research on bilingualism's impact on early childhood performance found bilingual and monolingual children performed comparably, with parental background contributing to variations in cognitive and non-cognitive skills development.

Methodology

This research employs an explanatory sequential design, starting with a quantitative phase followed by a qualitative phase to delve deeper into notable results (Creswell et al., 2011).

In the quantitative study, data from American 4th-grade students in the 2019 TIMSS is analyzed, focusing on the United States. To address missing data, all variables, primary sampling unit, strata variables, and appropriate weights were included in the imputation models. The study uses the Students Confident in Mathematics (SCM) scale from TIMSS as the dependent variable. Bilingualism is determined by students' use of the test language at home, with 23% identified as bilingual. Control variables include gender, achievements, engagement, and socioeconomic status. The quantitative phase examines the relationship between bilingualism and children's self-efficacy beliefs in mathematics, comparing variables between bilingual and non-bilingual students, followed by OLS regression to predict math self-efficacy beliefs.

In the qualitative phase, data is collected through interviews with two Spanish-English bilingual families and two Korean-English bilingual families, involving one 45-minute parent interview and two 30-minute child interviews per family. Parents discuss their family's identities, values, beliefs about language, culture, math, and their child's experiences. Children are interviewed about their understanding of family values, language and mathematics, and self-efficacy. Semi-structured interviews and grounded theory analysis explore how children interpret sources of their self-efficacy beliefs and how their environment and experiences influence these beliefs. The study investigates why bilingualism positively relates to children's self-efficacy in mathematics and how bilingual children develop higher self-efficacy in mathematics.

Results

In the quantitative phase, bilingual students score lower than non-bilingual peers (Table 1), yet there is no significant difference in self-efficacy beliefs. Bilingual children, often from socioeconomically disadvantaged backgrounds, reflect this in school SES. This socioeconomic disadvantage potentially impacts their math self-efficacy as prior achievement influences self-efficacy development.

Table 1. Means and standard errors of the estimates, for all variables[5]

The OLS analyses (Table 2) confirm a statistically significant positive correlation between bilingualism and children's self-efficacy in mathematics. Model 2 reveals significant associations between gender, achievements, interactions with math teachers, and school SES with children's self-efficacy, aligning with existing research. Initially, the link between bilingualism and self-efficacy appears negative but not statistically significant. However, when controlling for achievement, the relationship shifts to a significant positive correlation, indicating that bilingualism positively affects self-efficacy when accounting for achievement.

School SES			−0.20***	(0.03)

From the qualitative study aiming to find how bilingual, multicultural students' experiences influence their self-efficacy beliefs in mathematics, the impact of bilingualism on children's self-efficacy in mathematics cannot be simply attributed to individual factors like prior proficiency, observational learning, social influences, or emotional attitudes towards math, typically seen as key determinants in Bandura's social cognitive theory. Instead, it must be understood in the broader context of their upbringing and environment within families, communities, schools, and societies as bilingual individuals. Essentially, the connection between bilingualism and self-efficacy in math goes beyond mere direct experiences with the subject; it is intertwined with their familial and self-identities, cultural values and expectations, and overall disposition as bilingual children in specific settings. One interesting theme that emerged among the bilingual, multicultural children in my cases is that they see their families and themselves as special and valuable because they are different from other monolingual families or friends. They appreciate the challenges they have encountered and the effort and resilience they have demonstrated in various situations. These values and appreciations are initially supported by their parents at home and solidified by teachers and peers. Based on these wholistic beliefs and values in their families and themselves, bilingual students' self-efficacy beliefs in mathematics are shaped. Cognitively, bilingual students tend to use both languages to understand mathematics, which might give them more flexibility. Culturally, they likely have access to more contexts and resources that come from different languages and cultures.

Conclusions and Educational Implications

While the qualitative analysis had a small sample size and may not fully represent the entire population of the quantitative phase, this study revealed a significant link between bilingualism and children's self-efficacy beliefs in mathematics. It provides insights into how and why bilingual children develop positive self-efficacy beliefs within specific sociocultural contexts. The study underscores the importance of understanding how children's environments and experiences influence their self-efficacy beliefs, not just focusing on achievements.

EXAMINING COMPLEX NUMBERS WITH LEARNING THROUGH ACTIVITY

Gülseren Karagöz Akar

Simon and his colleagues' (2010, 2018) development of Learning Through Activity (LTA) offered a theory for explaining a mechanism for mathematics conceptual learning and an approach to the instructional design to foster it. LTA was an empirically based framework that was developed studying mainly rational number concepts. Taking a step forward, in this paper, we elaborate on and exemplify LTA instructional design principles using an advanced mathematics topic. For this purpose, we share an articulation of the Cartesian form of complex numbers as a mathematical concept and a task sequence to learn this concept. Also, we share an example of the reflective abstraction of this concept with data from teaching experiments with a prospective secondary mathematics teacher. Providing ways to utilize the LTA framework for an advanced mathematical topic, we discuss implications for teaching and learning.

Keywords: Mathematics Learning, Learning Through Activity, Complex Numbers

Conceptual mathematics learning for all students is the main goal of mathematics instruction (Common Core School Mathematics, 2010). Planning effective instructional designs is at the heart of conceptual learning (Gravemejier, 2004; NCTM, 2000; Simon & Tzur, 2004). Over the last three decades, Simon postulated the construct of hypothetical learning trajectory (HLT) for describing key aspects of planning mathematics lessons for promoting conceptual learning from a constructivist perspective (Simon, 1995) and extended it by postulating a mechanism for mathematics learning and instructional design principles for students' learning of mathematics through their own activity (Simon & Tzur, 2004; Simon et al., 2010; Simon et al., 2018).

Learning Through Activity (LTA) design principles deepen and extend HLT steps by further explicating the reciprocal relationship between tasks and learning goals. LTA design principles allow the teacher, first, to delineate "..an activity that students have currently available that can be the basis for the abstraction specified in the learning goal (Simon et al., 2018, p. 104). The activity refers to students' two or more goal-directed mental actions (Simon et al., 2018). Secondly, the teachers design or choose a task sequence intended to foster the particular activity and abstraction on the part of students. The tasks based on LTA design theory are as such: "… the learner can already solve that causes the learner to coordinate actions corresponding to prior concepts in such a manner that the intended new concept is inherent in this coordination" (Dreyfus, 2018, p. 217). In addition, the tasks neither explain nor mention the intended learning goal; however, they have the underlying goal of leading the students to grasp the logical necessity of the learning goal on their own (Dreyfus, 2018). Therefore, for both research and teaching purposes, researchers took attention to two important aspects of the instructional design: 1) an awareness and articulation of the learning goals through students' own activity, and 2) the creation or choice of tasks that have the potential to foster such activity based on which mathematics conceptual learning might be promoted (e.g., Dreyfus, 2018; Simon et al., 2018; Tzur, 2018). Further research is suggested to investigate the applicability of LTA to other levels of mathematical learning (e.g., advanced mathematics) (Dreyfus, 2018; Simon et al., 2018). Taking this as a challenge, in this paper, we elaborate on and exemplify LTA instructional design principles to promote conceptual learning of an advanced mathematics concept, the Cartesian form of complex numbers. Thus, we attempted to answer the following theoretical and empirical questions: What might be a possible example of LTA design principles used with respect to learning goals for the Cartesian form of complex numbers? What might be a possible learning goal for a Cartesian form of complex numbers as a mathematical concept? What might be a possible sequence of tasks affording the learning goal through one's own activity for a Cartesian form of complex numbers?

Learning Through Activity and Complex Numbers

Learning Through Activity instructional design is composed of four steps: The first two steps for the generation of HLT are determining students' current knowledge and identifying a learning goal. The third step is specifying "…an activity that students have currently available that can be the basis for the abstraction specified in the learning goal… The fourth step is the design of the task sequence" (Simon et al, 2018, p. 104). In particular, the trajectory for complex numbers is based on the assumption that, at the outset, the students currently can define any quadratic function with real coefficients and graph them on the Cartesian coordinate systems and know that given any quadratic equation, $ax^2 + bx + c = 0$ where $a, b, c \epsilon R$, $a \neq 0$ the two roots of the quadratic equation are of the form $x_{1,2} = \frac{-b}{2a} \pm \frac{\sqrt{\Delta}}{2a}$, where $\Delta = b^2 - 4ac$ and is called the discriminant (Δ). They also know that x_1 and x_2 can be located on the Real number line, as $(\frac{-b}{2a} - \frac{\sqrt{\Delta}}{2a}, 0)$ and $(\frac{-b}{2a} + \frac{\sqrt{\Delta}}{2a}, 0)$ respectively. Here, the component $\frac{-b}{2a}$ indicates $(\frac{-b}{2a}, 0)$, the abscissa-of-the-vertex (as well as the symmetry axis) and has a distance to the origin and a distance to the roots, that is $\frac{\sqrt{\Delta}}{2a}$ (Hedden & Langbauer, 2003). Regarding the learning goal, we first elaborate on the following: Mathematically, any complex number $z = x+iy$ is an ordered pair (x,y) of real numbers x and y, with $i = \sqrt{-1}$. However, mathematical definitions or theorems are not necessarily the same as mathematical concepts (Vergnaud,1997). Simon (2017) defined a mathematical concept as " a researcher's articulation of intended or inferred student knowledge of the logical necessity involved in a particular mathematical relationship" (p. 123). So, we concur that a researcher's articulation of such a learning goal might be as follows: "Complex numbers, located in the complex plane as the solutions of a quadratic equation f(x)=0 with a fixed apsis of the vertex, vary continuously with the coefficients of f(x) such that the continuous changes in directed distances of the solutions to the apsis of the vertex and to the origin result in the changes in the locations of the solutions in the complex plane". In the LTA design, the third step starts with asking the question, "What activity, currently available to the students, might be the basis for the intended learning?" (Simon & Tzur, 2004, p. 96). Thus, for the learning goal, we identify the specified activity as continuously varying the locations in the complex plane of the roots of any quadratic equation with the same apsis of the vertex. For the fourth step in LTA, Simon et al. (2018) stated, "The task sequence must both elicit the intended student activity and lead to the eventual coordination of actions on the part of the students" (p.104). Thus, we generated the following tasks: *The first set of tasks: 1)* How many parabolas are there with the same abscissa of the vertex? 2)Draw what you imagine in the first question. 3) What changes and remains invariant in the parabolas you have drawn given the algebraic form, $f(x) = ax^2 + bx + c$? Why? 3a) How are the distances of the roots to the-apsis-of-the-vertex changing or not changing? *The second set of tasks*: 1) Given a set of quadratic functions such as $x^2 + 2x$ -8, $x^2 + 2x$ -4, $x^2 + 2x$ -1, $x^2 + 2x$, and $x^2 + 2x$+1 and their graphs as parabolas on a) Desmos and b) colored copy, what changes and what remains invariant? Why? 2) How are the distances of the roots and the abscissa-of-the-vertex changing or not changing? 3) Locate the roots on the Real number line from #1. How do the changes in the distances of the roots to the abscissa of the vertex relate to the different forms of Δ? 3a) How do you relate the changes in the distances of the roots to the abscissa of the vertex when the increment is bigger than zero, is zero, and is smaller than zero? 4) How could you re-write and locate the roots when the value of $\Delta = b^2 - 4ac$ becomes negative?

Methods

We report results from a teaching experiment (Steffe and Thompson, 2000). The first author acted as the teacher-researcher in the teaching experiment, which consisted of three 75- to 120-minute sessions. Data sources included transcripts formed from the video data and written artifacts. The study's participant was one prospective secondary mathematics teacher, Esra, who was in the fourth year of her five-year undergraduate program. Following the teaching experiment methodology, analysis was both ongoing and retrospective (Steffe & Thompson, 2000). Ongoing analysis occurred during data collection and involved formulating hypotheses of student thinking between sessions and designing subsequent sessions to test those hypotheses. For the retrospective data analysis, we followed three-level approach to abductive process (Simon, 2019). For the first level, we read the transcripts line-by-line, focusing on sequences in which Esra's actions and utterances provided information about her thinking. Then, "*we use the results of the first level as the "data" for the second level*, making inferences for chunks of these new data" (Simon, 2019, p. 119) by answering the questions such as what understandings Esra seems to have and how we can characterize her thinking. The third level involved our use of explanatory constructs, such as learning as a reflection on the activity.

Results

In lieu of space, we describe Esra's evolvement of ideas on the second set of tasks. For the second set of tasks, 1 and 2, given the examples on Desmos, Esra stated that the values of 'a' and 'b' and so, $\frac{-b}{2a}$, remained invariant in the examples and the values of 'c' changed, decreasing the roots' distances to the abscissa of the vertex (from out to inwards). She also commented on the roots, stating, "…with respect to the symmetry axis, they [*the different roots*] have the same, umm, they [*the roots*] are symmetric, exactly". Also, she further commented on the roots' distances to the abscissa of the vertex as changing. For 3 and 3a in the second set of tasks, Esra drew the following (*See* Figure 1). She did not use the exact values of the roots, but she marked some of the roots on the real number line as (x_1,0), (x_2,0), ($x_{1'}$,0), ($x_{2'}$,0), ($x_{1''}$,0), ($x_{2''}$,0), ($x_{1,2'''}$,0).

Figure 1. Esra's showing the roots on real number line she drew

a *b* *c*

Figure 2. Esra's pointing to the real numbers as possible roots, re-writing the roots of the quadratic equations and plotting the roots of the quadratic equation on the plane

Furthermore, Esra re-wrote the roots for 4 in the second set of tasks (*See* Figure 2b) and stated: "Let's say there are infinitely many [*quadratic*] functions, and the abscissa-of-the-vertex of any quadratic function is t...and m is the distance from one of the roots to the abscissa-of-its-vertex…" Then, albeit with struggle, she positioned the roots on the plane(*See* Figure 2c) and commented on what (t,m) represented:

E: Umm, the root of the equation. The roots. They are the roots of the equation, quadratic equation. Umm, when they are not real, the delta is smaller than 0. Umm, when they are real, delta is greater than 0.

R: What do you call the algebraic expressions when delta is smaller than 0?

E: Umm complex numbers.

R: Okay. Where do you get those complex numbers?

E: From real numbers. All real numbers, on the real x-axis…Umm, I obtain them from the real roots of quadratic equations. If they are umm...okay, I obtain them from their real roots. Okay, I obtain from non-real ones as well […] Yes, they are complex numbers. The numbers obtained from the roots of all quadratic equations are complex numbers. Exactly. They give complex numbers.

Importantly, the data showed that Esra enacted the activity several times, such as in the first set of tasks, on the examples provided on Desmos and the colored-print copy (*See* Figure 2a), and when placing them as points on the real number. This way, her repeated mental runs through the activity of varying continuously the roots' locations on first the real number line and then on the plane allowed her images to become operative such that reflecting on the activity with the three cases of discriminant allowed her to anticipate that all the roots constituted the elements of a set of the roots of quadratic equations with real coefficients.

Conclusion and Discussion

We presented learning through activity design principles focusing on an advanced mathematical topic, the Cartesian form of complex numbers. Tasks designed with the principles of the LTA framework are distinguished from other task designs (e.g., Smith & Stein, 1998) in explaining the relationship to students' learning processes. Data indicated that engaging in the task sequence, Esra's enactment of the activity of varying continuously the locations of the roots of any quadratic equation allowed her to anticipate the logical necessity that any quadratic equation having both two real and two non-real number roots constitutes the elements of the set of complex numbers. Results suggest that the LTA design principles might be used to study advance mathematical concepts. We also argue that the learning goal shared in this paper might constitute a considerable change in students' conception of complex numbers. Previous research suggests that learners from different stages of schooling seem to struggle with the idea that any real number is a complex number (Nordlander &Nordlander, 2012). Thus, we argue that the aforementioned learning goal with the design of the tasks might allow to conceptualize real numbers as a subset of complex numbers.

Acknowledgments

Opinions and conclusions in this paper are those of the authors. Data in this paper came from Merve Saraç's Master Thesis as part of a larger project conducted under the supervision of Gülseren Karagöz Akar. CHILDREN'S EXPOSURE TO MULTI-DIGIT MULTIPLICATION ALGORITHMS AND ITS EFFECT ON THEIR MULTIPLICATIVE REASONING

Karl W. Kosko
Kent State University
kkosko1@kent.edu

Multi-digit multiplication is an important, yet understudied, topic in mathematics education. There are numerous algorithms that children may be exposed to, but it is commonly recommended that children transition from the area model to the box model to the partial products model before leaving the primary grades. The current study reports on pilot data exploring the effect of students' self-reported exposure to these algorithms on their multiplicative reasoning. Results reveal that participants in this sample were exposed to these algorithms in isolation of each other, and this led to negative effects of certain algorithms on their multiplicative reasoning.

Keywords: Elementary School Education; Number Concepts and Operations.

Students begin to learn multi-digit multiplication in the later primary grades (ages 9-11). There are numerous algorithms and approaches (Fuson, 2003; Hickendorff et al., 2019; Schulte, 2015)—many of which are largely unchanged from their development in India nearly 2000 years ago (Datta & Singh, 1938). Pedagogical innovations, such as the area model (using pictorial & concrete representations) and modifications to existing algorithms have emerged over the past century as means to facilitate meaningful understanding of the standard algorithm (Giles, 1975; Fuson, 2003). Despite the wide variety and history of algorithms and models for multi-digit multiplication, study of children's engagement with such algorithms is lacking (Amborse et al., 2003; Fuson, 2003; Izsàk, 2001). Rather, "there is little research into children's solution strategies use in multi-digit multiplication (Hickendorf et al., 2019, p. 553), as well as examination of how exposure to such algorithms affect children's multiplicative reasoning. Given the repeated calls for additional scholarship on multi-digit multiplication, the present paper reports on an exploratory study examining fifth-grade students' self-reported exposure to specific algorithms and this exposure's effect on their multiplicative reasoning.

Review of Literature

Multiplicative Reasoning via Scheme Theory

Multiplicative reasoning is a key mathematical concept for children's development of latter mathematics (Harel & Confrey, 1994; Norton et al., 2015). This study adopts Hackenberg's (2010) description of three multiplicative concepts to describe how multiplicative reasoning develops and may be characterized. Students operating at the first multiplicative concept (MC1) can anticipate one level of units while coordinating two levels of units in activity. Such students may solve 4×15 by repeatedly adding four 15s until they get to 60 (Steffe, 1994). The second multiplicative concept (MC2) involves anticipating two levels of units while coordinating three levels of units in activity (Hackenberg & Tillema, 2009). A student at MC2 may solve 8×15 by recognizing that 2×15 is 30 and 8×15 includes four sets of 2×15 (so it would be 4×30). The *third multiplicative concept* (MC3) involves coordinating three levels of units, but all levels of units are anticipated (Norton et al., 2015). Thus, a student at MC3 solving 8×15 is more likely to consider it by partial products (i.e., 8×10 + 8×5). This is because such children can consider multiple composite numbers simultaneously (Kosko, 2019).

Multi-Digit Multiplication

Children learn multi-digit multiplication in a variety of settings, using various algorithms. However, students’ algorithm use tends to follow what is emphasized by a particular curriculum or teacher (Hickendorff et al., 2018). While recall of basic multiplication facts is advocated as a prerequisite by some (Lin & Kubina, 2005), Hurst and Hurrell (2016) observed that despite “facility to recall multiplication facts was not an indicator that the students had a conceptual understanding of multiplication” (p. 37). Indeed, students need to develop an understanding of partial products to move beyond basic multiplicative reasoning (Ambrose et al., 2003; Hickendorff et al., 2019; Lampert, 1986).

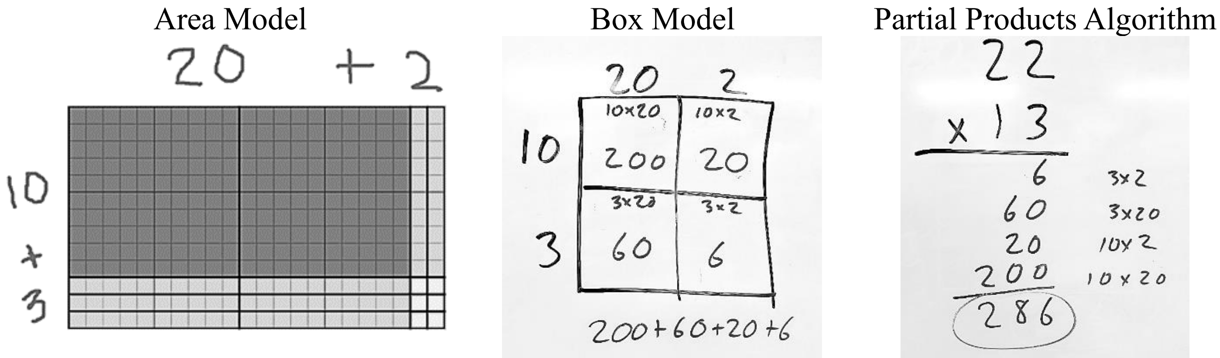

Figure 1: Three Algorithms for Multi-Digit Multiplication

Various scholars have advocated for the use of area and array algorithms, paired with the box and/or partial products algorithms for developing conceptual understanding of partial products (Fuson, 2003; Izsàk, 2001; Young-Loveridge & Mills, 2009). Working with a small group of fifth-grade students, Izsàk (2001) found that beginning with an area algorithm that included arrays in the visualization and then transitioning to a box model before using a partial products algorithm supported students’ understanding of partial products. Others have proposed the same pedagogical approach (Fuson, 2003; Kristen, 2021; Young-Loveridge & Mills, 2009). Although such scholarship is useful in characterizing a recommended pedagogical approach, there is little scholarship evaluating the effect of children’s exposure to these algorithms. The present paper reports on a pilot project assessing this phenomenon. Specifically, the purpose of this paper is to evaluate students’ self-reported exposure to the area model, box model, and partial products algorithm on their multiplicative reasoning.

Methods

Sample and Measures

Participants included 55 fifth-grade students (age 10-11 years) from two teachers’ classes. The sample included 47.3% self-identified females and 52.7% self-identified males. Participants completed the Multiplicative Reasoning Assessment (MRA) and a brief survey rating their familiarity and use of the three multi-digit multiplication algorithms of focus in the present study (area model, box model, partial products algorithm). Results indicated that all students had exposure to the box model. Interestingly, only 14.5% of participants had seen and used all three algorithms. Given this low percentage, exposure to these algorithms were examined as separate variables.

The MRA is a 21 item measure designed to assess children's multiplicative concepts at-scale. Validity evidence has been collected across multiple studies including, but not limited to, psychometric data for test content and internal structure, cognitive interviews on the items, and correlation of scores to other metrics for concurrent validity (Benjamin & Kosko, 2019; Kosko & Singh, 2018; Kosko, 2019; Kosko, 2020). MRA raw scores were transformed via a Rasch model to provide a continuous scale. Participants' scores in the current study were lower than average (*M*=-1.08, *SD*=2.45) indicating 50.9% operated with pre-multiplicative (count-by-1s) schemes, 16.4% at MC1, 20.0% at MC2, and 12.7% at MC3. A sub-sample of 16 students participated in clinical interviews to examine their strategy use for multi-digit multiplication, with findings planned to be reported elsewhere after analysis.

Table 1: Student-Reported Exposure to Multi-Digit Multiplication Algorithms

	Area	Box	Partial Products
Never Seen/Used	48.0%	0.0%	18.0%
Seen/Not Used	14.0%	3.8%	34.0%
Seen & Used	36.0%	96.2%	48.0%

Analysis & Results

Multiple regression was used to examine the effect of students' self-reported exposure to multi-digit multiplication algorithms on their multiplicative reasoning. The regression model is illustrated below with students' Rasch-based MRA scores as the outcome. Independent variables include a series of dummy-coded variables to model the statistical effect of having seen and used, or seen but not used, specific algorithms. Self-identification as male was included as a covariate. The illustrated model meets basic assumptions for regression: a predicted probability plot confirms normality of residuals and distribution of residuals meets criteria for homoscedasticity. Thus, linearity is assumed. Variance inflation factor (VIF) statistics were calculated to test for multicollinearity in the model. VIF statistics ranged from 1.123 to 2.091 across all independent variables. Thus, risk of collinearity was minimal and these variables were retained for analysis.

The final model is presented below. The intercept of the model, β_0, can be interpreted as the average MRA score for a female student who reported never having seen nor used the area model partial products algorithm, and who had seen but not used the box model. All other coefficients are interpretable as the effect of being male or having a certain form of exposure to these algorithms.

$$MRA\ Scores_i = \beta_0 + \beta_1 \cdot (dMale)_i + \beta_2 \cdot (Area_{Seen\ \&\ Used})_i + \beta_3 \cdot (Area_{Seen\ NOT\ Used})_i + \beta_4 \cdot (Box_{Seen\ \&\ Used})_i + \beta_5 \cdot (Partial\ Products_{Seen\ \&\ Used})_i + \beta_6 \cdot (Partial\ Prodcuts_{Seen\ NOT\ Used})_i + r$$

Results from the regression model were statistically significant (R^2=.293, F[5, 41]= 2.768, p=.024), and are presented in Table 2. Three independent variables were found to be statistically significant at the .05 level and one at the .10 level. Specifically, seeing, but not using, the area model (*B*=-2.271, *p*=.019) and using the box model (*B*=-3.936, *p*=.025) were both found to have a statistically significant and negative effect on children's multiplicative reasoning. By contrast, use of the partial products model had a positive effect on multiplicative reasoning (*B*=1.868, *p*=.052). To put these results in context, these Beta coefficients are unstandardized and represent changes in the logit-based scores on the MRA. A change of 1.00 logits is roughly equivalent to the difference between two adjacent multiplicative concepts. Thus, results here suggest that use of the box model, without exposure to either the area model or partial products algorithm, has a very large and negative effect on children's multiplicative reasoning. Similarly, exposure to the area model, but without actual use, also has a large and negative effect. Use of the partial products algorithm was the only algorithm found to have a positive effect associated with children's multiplicative reasoning. One surprising finding was that self-identified male participants demonstrated higher multiplicative reasoning in this sample than their peers (*B*=1.592, *p*=.017). This finding has not been observed in other administrations of the MRA and no data was available to explain the finding in the present study.

Table 2: Results from Multiple Regression

		B	Std. Error	*p*
Intercept		1.333	1.627	.417
d_Male		1.592	.638	.017
Area Model	Seen & Used	-.848	.683	.222
	Seen *not* Used	-2.271	.928	.019
Box Model	Seen & Used	-3.936	1.689	.025
Partial Products Algorithm	Seen & Used	1.868	.932	.052
	Seen *not* Used	1.338	.949	.166

Discussion

"Multi-digit multiplication is an important, though underrepresented, area of research" (Izsàk, 2001, p. 187). One key aspect of facilitating children's multiplicative reasoning in multi-digit multiplication is supporting their learning of partial products (Fuson, 2003; Hickendorff et al., 2019). The most commonly advocated approach is to introduce multi-digit multiplication with array-based area models before transitioning to a box model and then a partial products algorithm (Fuson, 2003; Izsàk, 2001; Young-Loveridge & Mills, 2009). To be clear, the present paper does not evaluate this approach. Rather, results presented here evaluate the isolated use of particular algorithms that can be used to facilitate the recommended pedagogy. Only eight of 55 participants surveyed reported having seen and used all three algorithms (area model, box model, partial products algorithm), with 32.0% of participants having only used the box model of the three. Thus, isolated exposure to these algorithms was the norm and there was no evidence of a sequenced progression from concrete to abstract. Results should be interpreted with this feature of the sample in mind. Thus, implications of these results suggest that isolated use of the box model, as well as demonstration of the area model without actual use, have a negative effect on children's multiplicative reasoning. By contrast, the partial products algorithm was found to be beneficial in the current sample. These results suggest further research is needed to better understand not only the appropriate pedagogy for teaching multi-digit multiplication, but the pitfalls of teaching particular algorithms without connections to other mathematical representations. Additionally, the present paper reports on an exploratory analysis of a pilot project and is limited due to sample size both regarding number of students and the classrooms they are sampled.

Keywords: Flexibility, Strategies, Self-regulated learning, Ratio problem solving

Research Background

Flexibility has garnered significant attention in educational practices as a crucial element of students' higher-order thinking skills and creativity (Star et al., 2022). To explore and explain flexibility, researchers have examined the correlation between flexibility and various factors from different perspectives. In particular, evidence has shown that flexibility is related to a variety of factors, including task factors, personal factors, and environmental factors (Hong et al., 2023; Verschaffel, 2024). This paper aims to explore the relationship between learners' self-regulated learning and flexibility from a psychological perspective to better understand flexibility.

Research Questions and Procedures

Research Questions: What is the relationship between self-regulated learning and flexibility in solving ratio tasks? What are the self-regulated learning characteristics of problem solvers with different levels of flexibility?

Research Procedures: (1) Methodology: A mixed-method research design was employed. Learners' flexibility level was measured across three dimensions: multiple strategies generation, appropriate strategies identification and appropriate strategies switching. Learners' self-regulated learning characteristics were measured using the Motivated Strategies for Learning Questionnaire (Wang et al., 2023). (2) Convenience sampling was used, in a middle school in eastern China, with students in grades 7-9. (3) Math content: ratio problem solving.

Data Analysis and Conclusions

Data analysis examined the self-regulated learning characteristics of students across different flexibility levels. Structural equation modeling was used to explore the relationship between flexibility and self-regulated learning. The research results indicate that the relationship between flexibility and self-regulated learning is complex, intriguing, and worthy of continued investigation.

In this presentation, we examine the theoretical underpinnings of how young children reorganize their whole number understandings to construct fraction understandings (Steffe, 2001). By examining these reorganizations, we aim to inform instructional approaches in early childhood education, as well as build early forms of collaborative efforts between scholars with expertise in upper elementary mathematics education and early childhood mathematics education. Discussions focus on the conceptual resources that children carry into their mathematics activity, and, how, by taking up an asset-based frame, early childhood educators are better positioned to design equitable instruction for their children.

Keywords: Early Childhood Education, Learning Trajectories and Progressions, Learning Theory.

Often, early childhood educators must differentiate their instruction to support wide degrees of children's early number development. These efforts are often guided by curricula materials, locally developed resources, or national research-to-practice initiatives (e.g., U.S. Mathematics Recovery Council). In response to these efforts early elementary aged children may experience different instructional approaches in mathematics, some focusing on narrow ranges of mathematical content (Ginsburg et al., 2008). Many posit that learning differences are not only a reflection of children's cognitive differences, but the societal constraints we have in our school system to differentiate our instruction effectively for all young children (Baroody & Purpura, 2017). In this theoretical contribution, we push back on these societal constraints to discuss the significance of examining the underpinnings of children's whole number knowledge in terms of their construction of fraction understandings. Our objective is to emphasize and inform this developmental focus to be at the center of the early childhood classroom planning and instructional practices.

Theoretical Foci

To examine students' conceptual resources and the developmental process, we situate our work under Steffe's (2001) reorganization hypothesis which draws from a recognition template described as scheme theory; explaining how the conceptual resources within a child's mathematical reality are utilized to develop fraction understandings. Steffe and Olive (2010) describe scheme theory as drawing from a four-part model: an experiential situation, an overarching goal, an anticipated action(s), and an expected result(s). When the actual result(s) and expected results(s) do not align, a child will accommodate their scheme to change one of the four components within their model. An accommodation of a scheme explains learning, as an individual reorganizes their scheme to make sense of this misalignment. Scheme theory explains that as a student reorganizes their scheme, they also revisit earlier developed components of their schemes with the implicit goal to extend these components in new experiential situations. For instance, when introduced to equal sharing tasks (i.e., How much of this chocolate bar would each person receive if shared by three people?), children have the potential to use their activity from their whole number schemes to develop fraction schemes (Steffe, 2001). To better understand how scheme theory can frame children's reorganization of their conceptual resources, we examine the literature focusing on children's units construction and coordination.

Theoretical Framework: Units Construction and Coordination

We frame our discussion with constructs embedded in the units construction and coordination literature with regard to whole number schemes, fraction schemes, and relationships between them both. Hackenberg and Sevinc (2024) define units as, discrete 1s or lengths. Essentially, young children first construct units by isolating sensory-motor activity (i.e., motor activity, verbal utterances), providing them discrete units to carry into their earliest whole number activity. Children then construct length units through a similar unitizing process for fraction development, where experiential units are developed with length models (i.e., string, lines in sand). Children use partitioning to construct units and then iterate or copy units to create new units (Hackenberg & Sevinc). Children's organization of units provides constant relationships which can be coordinated for operation development, better positioning themselves with assimilatory structures for whole number to develop fraction schemes. Steffe (1992) also describes units coordination as the distribution of elements from one set of units across the elements of a second set of units. This is explained in more detail in the next section. As children's number understanding becomes more sophisticated, children progressively develop abstract units to facilitate coordination forming assimilatory structures described as a "units of units of units" (Steffe, 1992; Ulrich, 2016). Elementary-age children reorganize their assimilatory structures to develop fraction schemes and revisit their earliest activity informing educators of children's underlying activity developed in their the early childhood years.

Whole Number Scheme Development

Framing counting and number sequence development in the units construction and coordination literature, Steffe and Cobb (1988), describe counting as a scheme, whereby a student will approach a situation (e.g., perceiving items to count), develop an overarching goal (e.g., determine "how many altogether"), decide on an action (e.g., pointing at items in correspondence to number words stated in sequence), and decide upon an expected result (e.g., the final number in the counting sequence). This describes the process through which young children may construct, engage with, and reflect upon pre-numerical units (e.g., perceptual units, figurative units, motor units, and verbal units) before developing abstract units, marking an understanding of number as a quantity. Olive (2000) explains that once children strip away the contextual features of an operation, they interiorize number and develop abstract units. Once children interiorize their whole number units, they re-interiorize their number schemes by producing operations (e.g., partitioning, iterating, unitizing, and disembedding), with which to inform the results of their actions associated with their number schemes. For instance, children counting items can take the counting action and apply it to the result by understanding these items are "something to be counted" (Olive, 2000, p 5). Through a process of interiorization and re-interiorization, children develop assimilatory structures whereby "units of units of units" are understood. These three-level structures of number explain children's coordination of three units, such as, six twos relative to 12 (Olive, 2000, p. 7). Here children may be coordinating relationships between six, twos, and 12. By coordinating three levels of units, children anticipate the relations between three arithmetic units prior to constructing a solution of a mathematical task (Hackenberg & Sevinc, 2024). Additionally, when developing assimilatory structures, children rely primarily on their partitioning or iterating development. These operations can inform educators of meaningful conceptual resources to elicit for future mathematics instruction (see Figure 1).

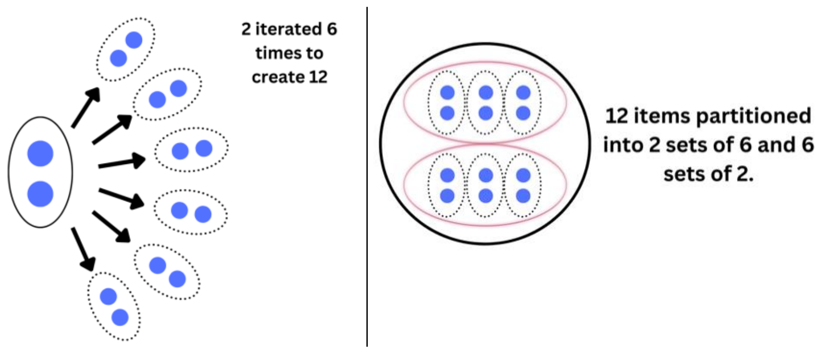

Figure 1: On the left, how children may iterate discrete units. On the right, how children may partition sets of discrete units.

While some children may have a "units of units of units" structures, other children may not yet have developed three levels of units, evidencing a reliance on pre-numerical units through a counting all strategy, a reliance on internalized number sequences through a counting on strategy, or a reliance on skip counting by keeping track of the third unit in activity (Olive, 2000; Ulrich, 2016). Examining these wide degree of variances found in early childhood classrooms allow educators insight into children's developing actions, which can be used for future instruction.

Reorganization for Fraction Scheme Development

When children develop three levels of units, they are much more capable of accommodating their whole number schemes to develop fraction schemes. Due to the inverse relations between whole number units and fractional units, children revisit some of their earliest actions when developing fractions (Olive, 2000; Steffe, 2001). In short this means children assimilating a three level units structure of *units of units of units* reorganizes their assimilatory structures and associated operations to develop *units in units* understandings. For instance, Olive (2000) explains that a student coordinating three levels of units with whole numbers is only able to carry in an assimilatory structure to solve a fraction of fraction activity (e.g., what is one-half of one-fourth? – see Figure 2). This is often because children developing fractional units coordination require inverse understandings of their whole number units coordination. For most children, this can be a rich and meaningful opportunity to examine the inverse relationships between whole number and fractional units. Children not yet coordinating three levels of units can oftentimes struggle understanding fractions. Yet, we posit children not yet coordinating three levels of units are still developing meaningful activity, which can inform their fraction development in a variety of ways. This activity can also inform the design of early childhood mathematics learning trajectories.

Contributions to Early Childhood Mathematics Learning Trajectories

Developmental learning trajectories, or representations of "learning that shed light on how children might engage with tasks, reflect on tasks, and develop knowledge through work on tasks" (Weber et al., 2015, p. 254) are effective tools when establishing early childhood curricula. We posit by examining children's reorganization of their assimilatory structures, early childhood educators gain insight into children's earliest operations. For example, when a student solves the task, how many fives does it take to make 30? They may first create a line of 30 counters before grouping them into random-sized groups before determining they need to create a group of five each time and then count the groups. This suggests the student relies on an internalized number sequence because they can produce 30 items, but their partitioning of these items is emergent, meaning they can reflect on their partitioning and the total number of items, but cannot do this along with their unitizing, evidenced in their unequal group development before reflecting on the size of the groups.

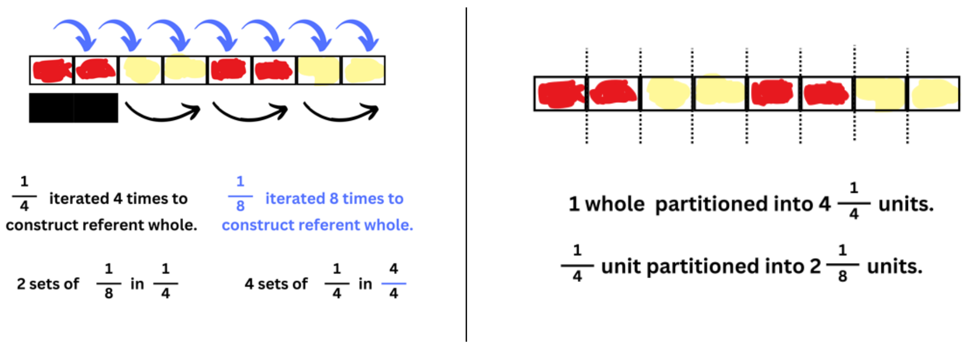

Figure 2: On the left, how children may iterate fractional units. On the right, how children may partition referent wholes and fractional units.

When reorganizing this to solve fraction tasks, educators would expect to see this emergent partitioning when the student solves the task, such as: "How much of this fry would each person receive if shared by three people?". We would also see the student resort to their pre-numerical units when applying their partitioning to the fry and the other materials and activity (e.g., auxiliary items, drawings, cutting, folding). As such, this can be used for future activity with fractions. By examining this activity with many students, educators are also given "typical" activity associated with children's earliest activities and operation development. For instance, if educators teaching eight and nine-year-olds see children partitioning or iterating but struggling with their unitizing, they may be able to discuss with their early childhood educator colleagues varying ways they can leverage more sophisticated grouping tasks, allowing children opportunities to use their partitioning or iterating to construct, engage, and reflect on their unitizing activity. By observing this reorganization, early childhood educators have the possibility to use this activity to design curricula materials and resources grounded in child-centered learning trajectories.

Discussion and Conclusion

Young children develop meaningful activity through their units construction in the early childhood classroom. By taking up scheme theory, educators and researchers are better positioned to revisit this activity by observing the children's conceptual resources that they use when solving whole number and fraction tasks. Observations of children's scheme reorganization, has the potential to design intentional discussions among educators and researchers in a variety of different fields (e.g., early childhood, upper elementary). Through these partnerships, educators can design trajectories that are student-centered and purposeful. By differentiating instruction in this way, early childhood educators can utilize an asset-based frame to differentiate and widen their classroom mathematics for all children.

STRUCTURAL MODEL OF LEARNING RETENTION AND MOTIVATION OF UNDERGRADUATES IN FLIPPED AND NONFLIPPED COLLEGE MATHEMATICS

Florence F Obielodan
University of Wisconsin - Platteville
obielodanfl@uwplatt.edu

Dr. Ji-Won Son
University at Buffalo - SUNY
jiwonson@buffalo.edu

Keywords: flipped instruction, direct instruction, college, precalculus

Background and Objectives

Previous studies have documented the benefits of learning in flipped instruction over the traditional lecture method (Akçayır & Akçayır, 2018; Nielsen, Bean, & Larsen, 2018). Some researchers attributed the successes to other factors rather than the pedagogical approach itself (Backlund & Hugo, 2018). For example, Kay and McDonald (2016) reasoned that the students learn more in flipped instruction because the model incorporates active and collaborative learning techniques. While Backlund and Hugo (2018) described the teaching method as multi-dimensional or a combination of multiple strategies. Thus, this study contrasted learning opportunities in flipped instruction (FI) with another non-passive method, identified as customized-direct instruction (CDI). This poster investigated whether students who received FI perform better than students taught using CDI on all assessments given in two introductory college mathematics courses after controlling for prior achievements and peculiarities.

Flipped instruction allowed learners to interact with all or part of the instructional activities independently outside the classroom. Then the grouped space is used to for cooperate and higher-order learning (Akçayır & Akçayır, 2018). While CDI encourages active participation (Voskoglou, 2019) by utilizing explicit instruction and group work for content presentation and learning. We focused on precalculus and calculus because of their gate-keeping roles for many college students (Rasmussen et al. 2019).

Methods and Data Analysis

We created a structural model (Figure 1) explaining how teaching methods, motivation beliefs, and past experiences contributed to learning retention and achievement. Model construction followed recommended standards by Schumacker and Lomax (2016). The participants were ninety undergraduates; 33 from FI and 57 who received CDI in precalculus at a four-year college. Students covered same topics, took same midterms and final exams, similar but different homework and quizzes, and had different instructors.

Two-steps structural equation modeling (SEM, Schumacker & Lomax, 2016) and MANCOVA were used to analyze and interpret collected data, which included students' precollege assessment reports, course grades, and self-reported end of semester course evaluation.

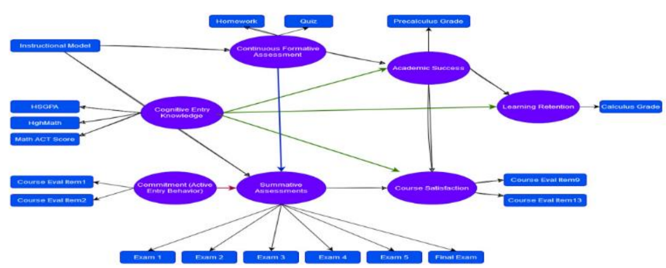

Figure 1: The Hypothetical Model

Results and Implications

Findings showed moderate to strong relationships between most of the variables considered. While a modified version of the theorized structural model indicated that no one instructional method is superior to the other for learning retention, the MANCOVA results show that the flipped model supports short-term learning achievement, while the direct instruction facilitates learning retention (see Tables 1 and 2).

Any active learning method and/or combinations of teaching approaches have the potential to increase learning retention and the achievement of desired goals.

Table 1: Direct, Indirect, and Total Effects of Model's Predictors on Retention.

Variable	Direct Effect	Indirect Effect	Total Effect
Method	0.145 ns	-0.339***	-0.194 *
Cognitive Entry Knowledge	-	0.031 ns	0.031 ns
Affective Entry Behavior	-	-0.572***	-0.572***
Formative Assessment	- 0.450*	0.305***	-0.146 ns
Summative Assessment	1.015***	-0.147 ns	0.867***
Academic Success	-0.157*	-	-0.157*

Table 2: Pairwise Comparison for Teaching Method

Dependent Variable	Adjusted Mean Difference by Teaching Method	
	Direct Instruction	Flipped Instruction
Formative Assessment		**0.565***
Summative Assessment	**0.667***	
Academic Success	0.065 ns	
Course Satisfaction	0.425 ns	
Learning Retention	0.161 ns

QUALITATIVE REVIEW OF INTERVENTIONS USED TO MITIGATE MATH ANXIETY

Lori Ogden
West Virginia University
Lori.Ogden@mail.wvu.edu

Marjorie Darrah
West Virginia University
Marjorie.Darrah@mail.wvu.edu

Math anxiety is pervasive in our society, and it is causing problems for students who want to enter a science, technology, engineering and mathematics (STEM) pathway. Recent research has suggested that math anxiety, and not math ability, is a better predictor of performance and perseverance in STEM. Interventions to mitigate this anxiety must get to the root of the problem and provide students tools to help ease these feelings when they come to disrupt performance. Our approach uses techniques from mindfulness and self-compassion, which have been linked to reducing anxiety. We have developed modules that can be used in a math (or science) courses to help students understand the anxiety they face. In this paper we examine one of the interventions used, the pre-exam writing, and how it showed a 75 percent increase in statements of confidence and a doubling of statements of positive feelings over the semester.

Keywords: math anxiety, self-compassion, mindfulness

Tobias (1976) coined the phrase “math anxiety” to describe the feelings of panic, anxiety, paralysis, and mental confusion that occur when people face computational challenges. Math anxiety is a major barrier to broadening participation in STEM. First year college mathematics (math) courses are a gateway to STEM majors (Schleicher, 2018) and nearly one third of STEM-intending students in the U. S. enroll in remedial math courses at the college level (Chen & Simone, 2016). Math is a major source of stress and anxiety for many college students (Ramirez et al., 2018). Many students have the cognitive ability to carry out mathematical tasks successfully, but their fear and anxiety regarding math gets in the way (Tobias, 1976; Beilock & Maloney, 2015: Brunyé et al., 2013; Henslee & Klein, 2017; Samuel & Warner, 2019). Neuroscience research has established that the worries and anxiety that arise in math-anxious students usurp cognitive resources needed for thinking, reasoning, working memory, and maintaining focused attention (Beilock & Maloney, 2015; Brunyé et al., 2013). This causes students to perform below their actual ability and affects their motivation and interest in math (Brunyé et al., 2013).

Researchers have been examining ways to address math anxiety through non-academic interventions (Beilock & Maloney, 2015; Brunyé et al., 2013). Factors such as grit, mindfulness, self-compassion, and self-efficacy have been studied and are associated with anxiety, resilience, and academic achievement (Jarukasemthawee et al., 2021; Neff et al., 2005; Neff & Germer, 2013; Tubbs et al., 2019). In addition, research findings have indicated an inverse relationship between grit and math anxiety in college students (Holtby, 2018; Darrah et al., 2023) suggesting that increasing grit may foster resilience and perseverance by reducing math anxiety.

Our research team, including mathematics professors and a counselor who specializes in mindfulness and self-compassion, has developed and implemented modules aimed at reducing math anxiety in college students enrolled in entry level mathematics courses. The seven student modules focused on three main topics (math anxiety, mindfulness, and self-compassion) and were titled: Math Anxiety Introduction, Introduction to Mindfulness, Mindfulness as a

Superpower, Math Anxiety Writing, Introduction to Self-Compassion, Self-Compassion (Part 2), and Reflection. This research is part of a larger study (Leppma & Darrah 2022; Darrah et al., 2023) and in this paper, we focus on the Math Anxiety Writing assignments and the last module Reflection. We were interested in how student engagement with these modules influenced how students felt about their ability to learn mathematics. Our research questions for this paper were as follows:

1. How did student perceptions of themselves as learners of mathematics change over the course of the semester?
2. What was the students' reaction to the Math Anxiety Modules?

Background

Math anxiety not only interferes with academic performance, but may contribute to STEM attrition (Ahmed et al., 2017; Ramirez et al., 2018). Students who earn lower grades in STEM courses in their first year of college are more likely to switch to non-STEM majors or drop out of college altogether (Chen & Soldner, 2013). Recent research (Daker et al., 2021) suggests that math anxiety is a better predictor of students' participation and perseverance in STEM majors, as well as performance in math classes, than actual math ability. Results indicated that higher math anxiety was associated with avoidance of STEM courses and lower grades in STEM courses when tracking students over a four-year period.

Research demonstrates that mindfulness-related practices are effective in cultivating internal resources as protective factors against the distress associated with math anxiety, which may help attract more students to pursue and persist in STEM-related majors (Ahmed et al., 2017). Mindfulness – the intentional and nonjudgmental awareness and observation of the present moment, including thoughts, feelings, and physical sensations one is experiencing – is positively associated with improved emotional regulation (Meyer, et al., 2019) and inversely related to depression, anxiety, and severity of anxiety symptoms (Tubbs et al., 2019).

A related construct, self-compassion, is the ability to show kindness and caring toward oneself in the face of discomfort, failure, or suffering. Self-compassion encompasses three components: self-kindness, common humanity, and mindfulness. Rather than being critical and judgmental toward oneself when making mistakes, self-compassionate people recognize that personal failures are part of the human experience and recognize their negative internal states without judgment or overidentification (Neff, 2003).

Students who develop internal resources, such as perseverance, grit, hope, emotion regulation, and motivation can overcome math anxiety and persist in math classes (Beilock & Maloney, 2015; Duckworth, et al., 2007; Snyder et al., 2002). Mindfulness and related self-compassion practices have been shown to alleviate anxiety, including math anxiety, and improve resilience, grit, hope, well-being, and emotional and cognitive functioning (Beilock & Maloney, 2015; Doorley et al., 2022; Leppma & Darrah, 2022; Weed et al., 2021). Mindfulness and self-compassion practices help to develop valued skills in academic achievement, such as concentration, memory, focus, and test performance. They also cultivate skills associated with occupational success and wellbeing, such as resilience, emotion regulation, interpersonal skills, grit, and hope for goal attainment (Chiesi et al., 2022; Leland, 2015; Shapiro et al., 2015; Strohmaier et al., 2022). Moreover, mindfulness diminishes the experience of stress and fear

(Tubbs et al., 2019), and self-compassion increases intrinsic motivation to learn and improve (Akin, 2008; Manavipour & Saeedian, 2016; Neff et al., 2005). Thus, higher levels of mindfulness and self-compassion are associated with higher levels of grit and hope, and lower levels of math anxiety.

Methods

The research took place at a large public research university upon institutional review board approval. The participants in the project were a convenience sample of 59 students who were enrolled in an entry-level college algebra course and a college algebra co-requisite support course in the spring semester of 2022. Student placement into college algebra courses (with or without co-requisite support) is based on their SAT/ACT Math scores or how they performed on a Math Placement Exam (ALEKS). The co-requisite course focused on prerequisite skills including operations on real numbers and simplifying algebraic expressions, and metacognitive skills such as mindfulness, coping with math and test anxiety, and self-compassion. The co-requisite course was mainly taught by graduate assistants under the supervision of the course coordinator. The coordinator provided training on how to implement the modules mentioned in the Introduction.

For this paper, we focused on the Math Anxiety/Mindfulness pre-exam writings and the last student module titled Reflection. The purpose of the Math Anxiety/Mindfulness pre-exam writings was to help students acknowledge their thoughts as they prepared to take an exam. These writings were designed to help students practice mindful writing to bring awareness and clarity to their thoughts prior to taking an exam. These writing assignments took place before a practice exam given in the co-requisite support course but coincided with three exams taken in their 3-credit algebra course. Data collected were student responses on these three writing assignments. The prompt students were given was "Please take the next 7 minutes to write as openly as possible about your thoughts and feelings regarding the math problems you are about to perform." These writings were completed in February, March and April (before algebra exams 2, 3, and 4).

The researchers used the Content Analysis method to look for common ideas and themes in the student response data. Analyses began with the preliminary reading of the responses, followed by the development of preliminary codes based on ideas and themes that emerged within the responses to the writing prompt. The development of codes was also guided by the overarching research ideas of the student' perceptions of their ability in math and feelings of anxiety. The codes were grouped into three major categories: (1) confidence or lack of confidence in mathematical knowledge or ability to succeed on the pre-assessment, (2) specific feelings of anxiety or stress, and (3) positive feelings. The writing was not mandatory, so 97 students completed at least one of the writings, with 45 students completing all three writings. These 45 students were used as the analysis group, since we could compare across all three writings for changes.

Additionally, to determine students' perceptions of the modules themselves, we presented the student responses from the last module, Reflection. This module asked students to reflect on the experience of learning about these ideas and practices (mindfulness and self-compassion) throughout the semester. Forty-seven students completed the final Reflection module at the end of the semester. Questions included "Will you continue to utilize some of the practices discussed in the modules in the future? If not, why not?", "What is your reaction to the series of modules?" The researchers used descriptive statistics to determine the percentage of students who found the modules useful and considered the open-ended responses for information about student perceptions and to extract ways to improve the modules or make them more useful to the students.

Discussion

We summarize the findings based on our two research questions.

Research Question 1: How did student perceptions of themselves as learners of mathematics change over the course of the semester?

For the 45 students who completed all three Math Anxiety/Mindfulness pre-exam writings we looked for change from February to April. Figure 1 below shows a summary of the analysis of the coding. We found that the number of students who made statements of confidence in their ability had a 75 percent increase. The number of students who made statements about positive feelings more than doubled, showing a 110 percent increase over the semester. On the flipside, the number of students expressing specific feelings of anxiety had a 34 percent decrease. For these 45 students, by April, they were making as many positive statements as negative statements about their feelings and more of them had statements of confidence than had statements of lack of confidence.

	Confident	Not Confident	Feelings of Anxiety	Positive Feelings
February	16	16	32	11
March	17	21	30	13
April	28	21	21	21

Figure 1: Summary of Coding of Math Anxiety/Mindfulness Pre-Exam Writing

Table 1 below is a sample of a few student responses that show the changes in the students' perceptions of themselves as learners. From the matched responses in the table, it can be seen that students took these few minutes before the exam to really think through what they were feeling. They talked about what was going on in their lives, sometimes mentioning other situations not related to math that were troubling them. This activity gave them a mechanism to let go of these thoughts and then to focus on the task at hand: taking the math test. Note the "VL" in the comments in the table stands for Video Lectures.

Table 1: Example Student Responses to Math Anxiety/Mindfulness Pre-Exam Writing

PROMPT: "Please take the next 7 minutes to write as openly as possible about your thoughts and feelings regarding the math problems you are about to perform."		
February	March	April
I feel like I am struggling because I don't really know what is going on. The word problems confuse me. And the VL are not anything like what the problems are, they do not help me when I do homework. They are completely different. Most of it does make sense to me at all and I am really not good at math or understand it.	**I am struggling so bad in math**. I do not like it because it is hard. I don't understand anything we are doing I literally do not comprehend it. The VL do not help me at all and I feel like it is not the same as the stuff we learn in class.	**I feel confident** because when I did the VL I actually understood what I was doing. I thought I understood though and then in math 126 I was so confused because he taught it a different way. I am not nervous because I felt comfortable and now I am not really sure.
I do not feel as prepared as I would like to for this upcoming assessment. I don't feel very confident in my knowledge on the current problems and material we are working on in Math 126. Though I am beginning to pick up how to do partial aspects of current material, I don't think I know enough to perform as well as I could on this diagnostic.	**I definitely feel more confident** going into this next diagnostic test than the previous ones. Before others I felt certain I would not do well at all and was very worried about how it would affect my grade. I am hopeful that this one will have a better outcome and relieve some of that stress regarding my grade.	**I feel prepared and good about the math diagnostic** that I am about to complete. Other times I have been quite anxious for the diagnostics because I didn't feel that I would score well on them and was worried about the effect that it would have on my grade in the class.
I am kind of confident but also nervous at the same time to do the math problems because there are parts that I am super familiar	**I am a bit nervous but also a bit confident** as I kinda know how to do the problems but I also am just am unsure of them. I think	**I feel okay about it** as I am going to be able to know the majority of what is on this.
I honestly have no idea what is going on, the second you get one second behind with a specific topic regarding the material we have went over thus far, you are just SOL. You just get behind so fast, if you struggle with one little thing it is honestly	**I barely understand what's going** on with anything we are going over in 126 right now, and honestly 106 doesn't help whatsoever. 106 is repetitive and we get lil to no help in either class. Feels	**I feel better about this module than I have any other**, it still scary because were getting close to the end of the semester. I feel like I should have felt better about this math a lot sooner.

impossible to continue with anything else. …	very pointless

Research Question 2: What was the students' reaction to the Math Anxiety Modules?

Forty-seven students completed the final reflection module at the end of the semester. When students were asked if they will continue to utilize some of the practices discussed in the modules, 81% of students said "yes". When asked, "What was your reaction to the modules?" students elaborated on their thoughts and feelings regarding the modules. Some example quotes included:

- "I felt like I learned a lot from these modules this year whether it was my least favorite or my absolute favorite. I felt like learning all these unique ideas and lessons, I can use them to make myself a better student, etc."
- "These modules made me improve my math scores throughout the semester. I kept improving as a student, and I will continue to do these practices."
- "I found the information in the modules more useful than expected. Learning not only about anxiety, mindfulness, and self-compassion, but how to apply them to real life made a huge difference. While one would not think the modules would not have a huge impact when coming to learning math, it created a difference mentally, and how one begins to think."
- "I loved them, I actually tried to apply what they were teaching me into my life."

Student responses from those who said that they would not continue to utilize these practices included:

"Probably not as I'm confident in my ability to work out math problems and I'm confident in my abilities already and don't need self-help."

"They all felt the same as they seem to just be about how I feel about math even though I enjoy math."

"Self-compassion felt silly, but I enjoyed the ted talk like videos."

Student feedback will be used to redesign modules or better explain their purpose to students. This feedback will also help inform professional development for instructors who will be implementing the modules.

Conclusion

Math anxiety is a problem for many students in our college courses (Tobias, 1976; Beilock & Maloney, 2015: Brunyé et al., 2013; Henslee & Klein, 2017; Samuel & Warner, 2019) and is causing a problem in our STEM pipeline (Ahmed et al., 2017; Ramirez et al., 2018). While the authors understand that these modules are not a silver bullet that will eradicate math anxiety in all students, we were pleasantly surprised by the number of students who took them seriously and who said they benefited from them. Over the years, we have not seen many resources that address the idea of anxiety in the math classroom and feel we have developed something to offer instructors who are faced with the student who suffers from math or test anxiety. We have also found through this research and reviewing the comments from the writing modules that the overwhelming majority of students in the co-requisite course started out with negative feelings, even though it may not have shown on their faces. We also note that these feelings, if addressed, can change throughout the course of the semester. The introduction of mindfulness techniques and self-compassion can make a difference in their perceptions of themselves as a learner.

We are continuing to redesign and improve the modules based on student feedback. Another aspect of the work is to create and provide professional development for faculty who would like to use the modules as part of their course. These modules can help instructors learn more about math anxiety and equip them with tools they can use to help their math anxious students persist in their studies. Lastly, we will continue the process of testing all the modules with students to determine their effectiveness at reducing math anxiety and increasing student persistence and performance. Future research will explore mechanisms, interventions, and effectiveness in a broader population.

AN EMERGING THEORETICAL FRAMEWORK FOR USING COMICS STORYTELLING IN K–8 MATHEMATICS EDUCATION

Ruth Nneoma Oliwe
The Ohio State University
oliwe.1@osu.edu

In this research report, the author draws on her diverse experiences in research and teaching to present an emerging theoretical framework for integrating comics storytelling as a pedagogical tool in K-8 mathematics education. The framework, deeply rooted in mathematics identity and funds of knowledge, serves as a bridge between students' mathematical experiences outside and inside the classroom. This framework carries significant potential to cultivate a supportive environment that fosters collaborative problem-solving, encourages students to share their unique stories, and enhance mathematics identity development. Through sharing insights from her learning experiences and her vision for comics storytelling, this research report aims to contribute to the ongoing discourse on creating inclusive learning spaces in mathematics education.

Keywords: Elementary School Education; Middle School Education; Integrated STEM/STEAM; Classroom Discourse.

Drawing from my experiences in research and teaching, I propose a theoretical framework that leverages comics storytelling to bridge the gap between in-school and out-of-school mathematics learning and to shape students' mathematics identities. This emerging framework has the potential to create a supportive environment that encourages students to share their unique stories, promotes collaborative problem-solving, and enhances the development of mathematics identity. Additionally, this report seeks to contribute to the ongoing discourse on fostering inclusive learning spaces in mathematics education.

Researcher's Positionality

I observed a recurring challenge among my students as a mathematics tutor in Nigeria – the challenge of connecting mathematical problems with their real-life experiences. To address this, I turned to the power of storytelling, specifically utilizing comics stories as a medium to intertwine mathematical concepts with indigenous lived experiences. Incorporating indigenous terms and characters in these comics stemmed from recognizing that many available mathematics resources were entrenched in western perspectives, featuring characters, language, and settings unfamiliar to the average child in my community. This led to the initiative "*Learning Mathematics Through Storytelling* (LEMATS)" (Oliwe & Chao, 2022). The foundation of this report rests upon my experiences with LEMATS and my ongoing theorizing of comics storytelling in K-8 mathematics education.

Conceptual Frameworks

Mathematics Identity

Researchers have indicated the significance of students' identities, especially in mathematics (Martin, 2000). Mathematics identity is defined as "the dispositions and deeply beliefs that students develop about their ability to participate and perform effectively in mathematical contexts and use mathematics in powerful ways across the contexts of their lives" (Aguirre et al., 2013). In mathematics education, the focus should extend beyond the development of essential skills and conceptual understanding to encompass the support for students in perceiving themselves as legitimate and capable participants in mathematics (Aguirre et al., 2013).

Recognizing the identities that students bring into the learning environment provides educators with valuable insights into the reasons behind students' positive or negative connections with mathematics. This understanding enables educators to implement necessary improvements, offering support and reinforcing a student's mathematical learning and their role as a mathematics learner. Also, students' experiences with mathematics in their classrooms significantly influence their perceptions of mathematics and their self-identification as mathematics learners and doers (Aguirre et al., 2013).

As mathematics identities can expressed through storytelling (Aguirre et al., 2013), I argue that the way students encounter mathematics in the classroom and connect these experiences with their home and community environments plays an even more substantial role in shaping their perspectives on mathematics and their self-perception as mathematics learners and practitioners. In fact, Sfard & Prusak (2005) proposed a correlation between mathematics and storytelling, asserting that identity formation is influenced by impactful narratives that provide understanding into one's experiences in learning mathematics. These identities comprise intricate and adaptable narratives individuals construct about themselves, rooted in diverse life experiences such as education, family, and media.

Funds of Knowledge

The concept of funds of knowledge in teaching recognizes the significance of "historically accumulated and culturally developed bodies of knowledge and skills essential for household or individual functioning and wellbeing" (Moll et al., 1992, p. 133). It acknowledges that students consistently bring these bodies of knowledge into the classroom and honors students' families, communities, and the knowledge they contribute to classroom mathematics. In the context of my work, these bodies of knowledge are mathematically enriched resources that can address the challenge of bridging out-of-school mathematics with in-school mathematics. Students' motivation to learn mathematics increases as they bring in their identities into the learning space and establish connections between the mathematics evident in their families and communities and the mathematics encountered in the classroom (Aguirre et al., 2013; Oliwe & Chao, 2022). However, the question arises: What kinds of opportunities and channels are available for students to share this wealth of knowledge they possess or to make meaning of it in relation to mathematics during their lessons?

Rehumanizing Mathematics

Gutiérrez (2018) outlines eight key dimensions that can contribute to the rehumanizing of mathematics education. These dimensions encompass (1) fostering inclusive participation and positioning, (2) valuing diverse cultures and histories, (3) providing windows into unfamiliar experiences and mirrors reflecting personal identities, (4) recognizing mathematics as a living practice embedded in everyday life, (5) encouraging creative expression and innovation, (6) broadening the scope of mathematical topics and perspectives, (7) acknowledging the role of the body and emotions in mathematical learning, and (8) empowering individuals to take ownership of their mathematical journey.

Connecting the above conceptual frameworks to inform the theoretical framing of comics storytelling in K-8 mathematics education, there is the emphasis that educators ought and should be encouraged to actively contribute to shaping positive mathematics identities among students by recognizing and acknowledging the various identities students develop, the wealth of knowledge they bring into a learning space, and creating opportunities for students to take an active role and ownership of the mathematics they are learning as they share their stories, engage in rich mathematical thinking and strategies dialogues with one another, and eventually create their own math comics creations.

Key Elements in the Emerging Theoretical Framework for Using Comics Storytelling in K–8 Mathematics Education

Definition

According to Eisner (1992), comics are a form of sequential art. McCloud (1993) elaborates on this definition by describing comics as images juxtaposed in a deliberate sequence to communicate an idea and/or evoke an aesthetic response, providing clarity to the expansive term "art." Notably, Abel & Madden (2008), addressing the absence of the term "text" in previous definitions, incorporate text in their working definition of comics.

My current working definition of comics storytelling in mathematics education is – a form of storytelling that involves using images and text to create stories in a juxtaposed sequential layout that not only give educators the leverage to create opportunities for students to explore, interpret, and solve mathematical problems but also invites the students to connect and share stories from their homes and communities wherein their mathematics thinking is situated, engage in rich problem-solving conversations, and visually represent their mathematical thinking through comics. These stories may be lived experiences, fictional, or a mix of both. The representation of these stories may be aesthetically pleasing or in simple format.

The Comics Structure

In the scope of my research, I find Eisner's (1995) narrative structure, encompassing the introduction/setting, problem, addressing the problem, solution, and conclusion, along with Chao et al.'s (2021) "*Math in My World*" model rooted in the Funds of Knowledge Theory (González et al., 2001), to be valuable structures for introducing both students and teachers to the art of storytelling and its connection to mathematics. Using this model not only positions students as learners and doers of mathematics but also gives them a sense of ownership of the mathematics they are learning. Furthermore, taking into consideration McCloud (2006) storytelling goals, educators and students should aim to (1) develop stories rooted in lived experiences and perspectives of oneself or the reader's (2) ensure authenticity in the creation of characters and their roles within the story's world (3) captivate readers by introducing them to unfamiliar places, cultures, and strategies (4) potentially evoke emotions by tapping into shared heritage and experiences, and (5) instill a sense of care and engagement in the readers toward their narrative.

Reading Between the Gutter

Reading between the gutter in comics storytelling involves two techniques – closure and transitions. McCloud (1993) defines "closure" as the phenomenon of perceiving the whole by connecting and making sense of individual parts. It occurs when a reader seamlessly links two or more comics panels into a continuous story (Abel & Madden, 2008). According to McCloud (1993), readers actively engage in the storytelling process by making decisions and filling in the gaps between depicted moments and perspectives chosen by the author (Figure 1). Closure, as described by McCloud (1993), can be a powerful force within individual panels and as well as between panels – known as the gutter, an empty area between panels (Abel & Madden, 2008). Embracing McCloud's (1993) concept of closure in comics storytelling in mathematics education, I argue that this presents an opportunity to invite students to contribute their perspectives and insights to the ongoing conversations by filling in the narrative gaps. Educators play a pivotal role in this closure process. To encourage students to actively participate by sharing their stories or strategies, educators must determine the extent of information expected from students to fill in and the types of mental jumps the students will need to make between panels. These jumps are referred to as "transitions" (Abel & Madden, 2008).

Looking at Figure 1, we can envision potential approaches an educator might tailor additional prompts or classroom activities to align with the intended lesson objectives, elicit students' funds of knowledge and perspectives, and facilitate mathematical dialogues.

Figure 1: Example of a 4-panel Math Comics

Story Circles

In my previous teaching and research endeavors, students primarily engaged in independent work or collaborated with their immediate seat partners. However, this approach had its limitations, particularly considering my aim to cultivate collaborative conversations within the learning space. Reflecting on these experiences, the story circle is central piece to my theoretical framing of comics storytelling as a pedagogical tool in K-8 mathematics education.

Story circles, characterized by small groups that emphasize active listening, provide a safe platform for individuals to share their evolving stories and offer feedback to one another (Lambert, 2013). Through this process, feedback from fellow participants aids in shaping and deepening the narratives until the central focus of their stories becomes evident. The goal of story circles is to empower all participants to embrace their roles as storytellers and cultivate collaborative conversations within the learning space. Additionally, story circles in mathematics education inspire educators and students to perceive and weave their mathematics stories uniquely, expressing their mathematical stories in their own voices (Chao, 2023).

Data Interpretation

In examining the students' comics stories, the data analysis concentrates on these elements: (1) the story plots, focusing on the central theme and setting; (2) characterization, which includes the names, personalities, physical traits, and expressions of the characters; (3) mathematics, identifying the types of mathematical problems and concepts present in the comics and analyzing how students use storytelling to showcase their understanding of mathematics; (4) the nature of dialogues; and (5) the relationships depicted in the comics. This approach enables one to identify and articulate significant patterns and themes that emerge from the analysis.

STRETCHY MINDS: BUILDING FOUNDATIONS FOR DEEP CREATIVITY THROUGH EARLY EXPERIENCES WITH QUALITATIVE GEOMETRY

Simply stated, *STEM needs creativity*. From equity to the economy to the environment, addressing major global issues demands both "deep creativity" and STEM knowledge and skills. Innovative solutions to address these large-scale problems can be derived through creative processes fundamental to scientific thinking (Cropley & Cropley, 2010). However, creativity is almost absent from mainstream approaches to STEM learning. If we do not resolve the disconnect between creativity, innovation, and the sciences, STEM graduates will be ill-equipped to tackle the most critical and persistent global issues. The "Stretchy Minds" project brings together elementary math teachers and researchers working in mathematics education, creativity, and embodied and emergent design to resolve this disconnect. *Conceived with an eye toward some imagined future,* this poster unveils this novel project and shares its findings.

Deep creativity yields novel forms of change, which have both quantitative and qualitative dimensions. Change-in-degree is an incremental *quantitative* change. Change-in-kind is a wholly and genuinely novel *qualitative* change. Configurations of Speks magnetic toys in Figure 1 demonstrate these forms of change using "number of loops" and as the criteria for equivalence (i.e., sameness in kind) and "size of loops" as the criteria for difference in degree. Shapes A-C are different in kind, since they each contain a different number of loops. Shapes B and D are different in degree in that the loop in D is larger than the loop in B, and size is a matter of degree.

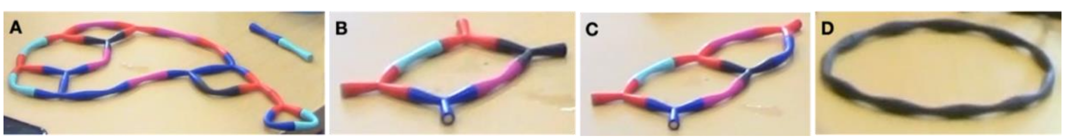

Figure 1: Configurations of the Speks toys express differences in kind and degree.

The Stretchy Minds project is undertaking design-based research (Brown, 1992; Collins, 1992) to produce responsive (Jacobs et al., 2011) curricular experiences (Dewey, 1925; Pinar, 2012) that engage and develop learners' thinking about deep creativity. We have conducted two pilot studies with elementary-age children to explore whether we could support the development of deep creativity through qualitative difference. The findings of these pilot studies have 1) established that qualitative geometry (Greenstein, 2014, 2018) is a viable context for research into children's thinking about qualitative difference; 2) determined that the Speks toys can be effective for mediating children's thinking towards more sophisticated understandings of differences in degree and in kind; and 3) revised initial tasks into game-based learning activities (Nguyen, 2020) that support even the youngest children's agentive and creative explorations. These findings have convinced us of the viability of a game-based approach to nurturing children's deep creativity for novel innovation. They will also enable us to contribute to the expansion of the theoretical understanding and instructional practice of creativity in the space of elementary mathematics education, and in STEM education more broadly.

First-year college mathematics courses serve a wide population of students with various mathematical backgrounds and experiences. Students' experiences shape the way they view themselves as mathematical learners and their mindsets toward mathematics. In this study, we analyzed reflections written in Fall 2023 by students in a college algebra course. We report our findings on students' mathematical perspectives and past mathematical experiences. Our work sheds light on students' dispositions towards mathematics at the start of a first-year mathematics course and provides valuable insights for practitioners and researchers.

Keywords: Affect, Emotion, Beliefs, and Attitudes

First-year college mathematics courses serve a wide population of students with various mathematical backgrounds and experiences. These experiences shape the way students view themselves as mathematical learners and their mindsets toward mathematics. The research presented here is part of a larger study that examines students' experiences in a first-year college mathematics course. As part of this work, we first sought to understand students' mathematical experiences and their perceptions of their mathematical abilities at the beginning of the semester. The research question we address is: *What prior experiences and perceptions of mathematics do students have at the beginning of a first-year college mathematics course?*

The primary data in this proposal come from written student reflections, which we call "mathographies." The prompts used in the mathographies were based on work done by Drake (2006) and offer insights into how students view themselves as individuals in the classroom. As described by Sawyer and Buckmeyer (2024), mathographies offer a human-centered perspective on students and their past encounters with learning and practicing mathematics that can contribute to the creation of a learning setting that is more inclusive. Moreover, writing a mathography often evokes emotions in students, particularly those students who identify as having struggled in the past (Sawyer and Buckmeyer, 2024). This research is critical to better understand how students' perceptions about mathematics have been shaped by recent challenges such as COVID-19 and mental health issues. By assigning and analyzing mathographies, instructors can better understand the circumstances under which students walk into a first-year college mathematics course and use this information to inform how they interact and support students in the classroom.

Theoretical Framing

Our work draws on the theoretical framework of students' mathematics-related beliefs set forth by Op't Eynde et al. (2002). Their framework describes how students' beliefs about mathematics fall into three categories: beliefs about the discipline of mathematics and mathematics education, beliefs about themselves, and beliefs about the social context of learning. These beliefs are present in the student mathographies we discuss in this proposal and underlie their past experiences and perceptions of mathematics.

Methods

Data for this study come from a written mathography reflection that was assigned to 611 students enrolled in 15 sections of a corequisite college algebra course at a large, Midwestern, metropolitan university during Fall 2023. The assignment was graded based on completion and included math-specific prompts such as “What do you think it takes for a student to be good at math?” as well as more general questions such as “What are your strengths as a student or as a person?” In this proposal, we report on 55 of those mathographies, which were selected based on responses from a Qualtrics survey with items from Cribbs et al. (2021) relating to mathematics mindset and self-efficacy. Mathographies were analyzed using MAXQDA 2022 (VERBI Software, 2021). To establish a preliminary set of codes, deductive coding was conducted with an initial set of codes based on previous work (Uhing & Bennett, 2023; Uhing et al., 2021; Wright & Uhing, 2023). At least two researchers tagged each response to prompts in the mathographies. Researchers then met to discuss and reconcile until agreement was reached. Excerpts were then sorted by initial codes and open, data driven coding (Saldaña, 2016) was used to create sets of themes for each of the codes that illustrate the mathematical mindsets and beliefs students have entering a first-year college mathematics course.

Findings

Mathematical Perspectives

In their mathographies, many students wrote about their beliefs about themselves and their abilities to do mathematics, relating to self-efficacy and control beliefs (Op’t Eynde et al., 2002). By the time students arrive in a first-year college mathematics course, these beliefs have been shaped by several years of past education. As one student wrote, “In general, my experience with math has been pretty poor. My intelligence favors the English [or] Reading side of education by a vast margin.” Another student expressed a similar viewpoint remarking, “I do not enjoy math it makes me frustrated how it doesn’t come easy to me and how I can’t understand it.” Other students described a common belief about the discipline of mathematics: “I believe that there are people who understand math more easily than others.” Similarly, another student said, “I know that some people are just ‘naturally’ good at math.” While many student mathographies that we analyzed had a somewhat negative outlook on the discipline of mathematics, there were a few students who had more positive dispositions. One student wrote, “I will use a positive attitude toward math and keep an open mind when I don’t understand something.” Another student commented, “I try my best in math courses, simply because math has always been a more difficult subject for me rather than others.” These quotes illustrate a growth-oriented mindset towards mathematics and students' learning abilities.

While analyzing students’ mathematical perspectives, we noticed that some students used passive language to describe what it takes to excel in math, while others used more active, first-person language. For example, one student discussed what makes someone successful at math: “I think anyone can be successful at math, I just really think it depends on the student. Are they patient? Do they understand it? If they are not, are they asking for help? Are they going to tutoring?" The passive language in this example shifts the focus away from the student and emphasizes beliefs and actions indirectly, referencing a third party (i.e. "anyone" and "they"). While many students used this passive language, there were a few who spoke in first-person terms. One student wrote, "especially in math, it has taught me that you're going to make mistakes. It's taught me how to accept these mistakes, learn from them, move on, and ask for help next time." Another student reflected,

> For me being good or decent at math has always required me to ask questions, understand every step to a problem, and practice. Because I am the type of person who is not the best at math but has applied themselves.

Overall, it was much less common for students to use this active, first-person language. The students who did, however, seemed to have growth-oriented mindsets towards their abilities to learn mathematics.

When discussing their mathematical perspectives, students also often discussed limitations of mathematical abilities. For example, one student wrote, "I think that anyone can be successful at math to an extent, but I do feel like if you enjoy math, you are more likely to succeed." Another student stated,

> I used to think that some are born with the ability to do math and some aren't. Although I feel that still applies to a certain extent, it's not that black and white. It's true that for some people, it just clicks and for others it doesn't.

Both students in these examples used the word "extent" to describe the ability to succeed and learn mathematics. This language may suggest a deeper belief about potential limits to a person's ability to grow in their mathematical understanding.

Past Mathematical Experiences

While sharing their perspectives on mathematics, students also often described their past experiences with learning mathematics. Many students wrote about their previous assessment experiences, specifically describing high stakes testing as a source of anxiety. For instance, one student discussed their disappointment after taking the ACT, "My low point in my math career was taking the ACT. I had always done good in math and gotten all A's. I took the ACT only one time because of COVID." This student went on to say, "I was very disappointed in myself after I got my score back and I did not perform to the level that I thought I would in math." Other students expressed similar sentiments, highlighting how standardized testing often has negative effects on students entering first-year college mathematics courses.

In addition to assessment, some students discussed how their mathematical experiences had been characterized by rigid, formulaic approaches to learning. For example, one student wrote, "public school has a very rigid, one-way-to-get-an-answer of doing things which caused some struggle for not only myself but a few classmates I've had throughout school." This student went on to compare this experience to their current course saying, "I do very much enjoy how in this Algebra class it is encouraged to seek different ways of getting an answer and to inquire to others as to how they got an answer especially if that process differs from yours." Thus, as illustrated by this example, past mathematical experiences shape students' beliefs about mathematics education and the social context (Op't Eynde et al., 2002), which can affect their expectations for college mathematics courses.

Another reoccurring theme in many students' reflections about their past mathematical experiences was the disruptions in their education due to the COVID-19 pandemic. One student described how they were turned off from math because of COVID:

> It was during Covid-19, and we were at home doing online class. I remember that I was taking algebra and to me it was so hard […] I did not understand but I didn't want to tell my teacher so for the first time even I got a F on my report card. When I looked at that F and looked at what class it was, I was so sad because I have always been good at math. I was thinking that math has changed so much and now I don't feel the joy about math anymore.

Unfortunately, this student's experience was not unique, with several students citing COVID as a low point in their mathematical trajectories.

Discussion

Students' beliefs about their abilities in mathematics are shaped through their myriad experiences with learning mathematics. These beliefs can be categorized in various ways, including beliefs about mathematics, beliefs about themselves as learners, and beliefs about the social context (Op't Eynde et al., 2002). As it relates to students' beliefs about themselves, we found that students in a first-year mathematics course often described self-perceived limitations using language such as "...can be successful at math to an extent..." and compared themselves to "people who are just 'naturally' good at math." This comparison of themselves to other, more gifted, mathematicians suggests that students may view themselves as being behind others when beginning a first-year college mathematics course. Moreover, when asked, "What do you think it takes for a student to be good at math?" some students responded in a passive second- or third-person voice rather than a more active first-person. While the way the question was phrased may have contributed to this effect, it is interesting to note that some students did use first-person language. This phenomenon warrants more investigation and further analysis is ongoing.

Experiences in previous mathematics courses lay a foundation for students' beliefs about mathematics education. Often students talked about how their assessment experiences were negative, causing many of them to have test anxiety. Students also discussed how meaningless formulas and rigid "one-way-to-get-an-answer" methods plagued their previous mathematical experiences. For some students, these inflexible ways of thinking and expectations caused them to lose interest and struggle with learning the material. Students' beliefs about mathematics education have been further shaped by the COVID 19 pandemic. Multiple students talked about how the shift to virtual learning was detrimental for them. Students described how they felt disengaged and how COVID-19 affected their enjoyment of mathematics. As one student said, "...I don't feel joy about math anymore." Students felt isolated and were often left to teach themselves the complexities of the mathematical content they were learning. Overall, these experiences shed light on the negative consequences that the COVID-19 pandemic had for many students in their beliefs and perspectives towards mathematics. These findings elicit questions regarding the widespread, continued impact of COVID-19 on student learning.

Students arrive in their first-year college mathematics courses with a variety of past experiences and perceptions of mathematics. These educational and emotional experiences affect their views about mathematics, themselves and the social context of learning (Op't Eynde et al., 2002). Assigning mathographies at the beginning of the semester can help instructors better understand the students in their classroom and help foster a more comfortable, creative, and supportive environment. Indeed, one of the goals of the corequisite college algebra course that these mathographies were collected from was to help students develop into confident, flexible problem solvers. Future research aims to assess how students' mathematical perspectives and beliefs may have changed over the semester using these initial perceptions as a reference point for comparison.

SUPPORTING LEARNING THROUGH INTERPRETING OTHERS' SOLUTIONS FROM A RADICAL CONSTRUCTIVIST PERSPECTIVE: A THEORETICAL REPORT

In this theoretical report, we leverage a radical constructivist perspective to explain how designing learning environments in which students work towards making sense of others' mathematical solutions may support learning. We elaborate on radical constructivist constructs—social goals, cognitive perturbations, and reflective abstraction—and use these constructs to model how engagement with others' mathematical solutions may engender learning. We illustrate our model with a task we designed to promote students' meanings for spatial coordinate systems. We conclude with implications for research and teaching.

Keywords: Learning Theory; Cognition; Problem-based Learning

Students working to make sense of worked examples (e.g., Barbieri et al., 2023) or classmates' solutions to mathematical problems (e.g., Webb et al., 2014) have been positively associated with mathematics achievement. Although researchers have described reasons why such activity may translate to achievement gains (Brown et al., 1992; Webb et al., 2023), they have not provided explanatory mechanisms for how such learning occurs for an individual. As a theory of learning focused on ways individuals develop knowledge, radical constructivism can provide such explanations (von Glasersfeld, 1995). In this report, we consider how students' working to make sense of others' mathematical solutions may support learning from a radical constructivist perspective. Additionally, we consider implications of our analysis for task design.

Learning in Radical Constructivism and Connections to Social Interactions

In this section, we present radical constructivist constructs and coordinate them to yield explanatory mechanisms through which a student may learn from others' solutions. First, we conceptualize that in a classroom, a student prompted to interpret a solution can experience a disturbance to their settled cognitive state (i.e., a perturbation). Second, as the student works to understand a solution, they can enact schemes relevant to their understanding of, and goals for, interpreting the solution. If the student experiences a cognitive perturbation, they may modify or reorganize their schemes to neutralize the disturbance. Such reorganizations can result in learning at a higher cognitive level (i.e., reflective abstraction). Next, we offer more detail about each construct and how they relate in the context of students examining others' solutions.

Schemes, Goals, and Perturbations

To begin, as students engage with others' solutions, we posit they would draw upon *schemes*, which entail "a situation, an activity triggered by how the person perceives the situation, and a result of the activity that a person assimilates to her or his expectations" (Hackenberg, 2014, p.

87). Any interaction prompting the student to draw on one or more schemes is a *disturbance* to the student's settled (equilibrated) state. A student uses their schemes as part of their goal-directed activity. Moreover, in classrooms where sharing solutions is prioritized, the student may conceive they are working toward a *social goal* with others (see Steffe & Thompson, 2000, for criteria to determine if a student is working towards a social goal). We note that even if other students are working toward a different goal (i.e., only intending to obtain a correct solution), a student's perception of a social goal can drive their goal-directed activity.

If a student works to interpret classmates' solutions, they have experienced a disturbance to their equilibrium; von Glasersfeld (1980) broadly defined a *perturbation* as any input that creates a disturbance in a student's equilibrium. Not all perturbations are *cognitive perturbations*. Students might be able to neutralize some perturbations with their current schemes without experiencing any discrepancies as they activate and anticipate the results; such perturbations are not cognitive perturbations. Neutralizing other perturbations may involve a student experiencing discrepancies in their use of a scheme (Steffe & Olive, 2009; von Glasersfeld, 1995). Such perturbations are cognitive perturbations. Cognitive perturbations are important because they can lead to a student reorganizing or modifying their existing schemes to achieve an equilibrated state (Steffe, 1991a, 1991b; Tillema & Gatza, 2024; von Glasersfeld, 1995).

When a student experiences a cognitive perturbation through engagement with others' solutions, they may experience a minor or major cognitive perturbation. Many researchers have equated perturbations with major cognitive conflict or the individual experiencing a 'problem' (e.g., Booker, 1996; Lerman, 1996; Simon et al., 2010). Although cognitive conflict is one type of cognitive perturbation, students can also experience minor cognitive perturbations without (consciously) experiencing cognitive conflict or a problem (Steffe, 2011; Steffe & Olive, 2002, 2009). To exemplify this distinction, we again turn to a student working to make sense of others' solutions. A student might experience a minor cognitive perturbation when a solution has some feature or way of reasoning that is novel for the student and the student is able to neutralize the perturbation with minor modifications to their current schemes. If an observer infers that the interpreting student undertakes a major modification or reorganization of their schemes, then the observer could characterize the perturbation as major. Finally, the student may experience a non-neutralizable cognitive perturbation if the student's current schemes do not support them in satisfactorily interpreting (from the student's perspective) the solution.

Reorganization of Schemes and Reflective Abstraction

To further describe the reorganization of schemes that may occur after a perturbation, we use Piaget's (2001) notion of abstraction. Abstraction is a mechanism explaining an individual's modification of their schemes toward greater cohesion and generality. In this report, we use the concept of *reflective abstraction*. In broad strokes, reflective abstraction entails two processes: a projection of actions or schemes to a higher level of thought and a reorganization that occurs at this higher level (Ellis et al., 2024; Piaget, 2001; Steffe, 2024; Tallman & O'Bryan, 2024; Tallman & Uscanga, 2020; von Glasersfeld, 1995). The reorganization can involve the creation of a coherent relationship or network of relationships between existing schemes as well as with new schemes (Piaget, 2001; Tallman & Uscanga, 2020). Such a reorganization involves taking prior meanings as input for further operating and thus can be considered a "higher" level. We note the cognizing subject need not be consciously aware of any reorganization.

Other researchers have argued for the importance of supporting reflective abstraction and have provided suggestions for doing just that. First, offering students repeated opportunities to develop schemes relevant to particular meanings can support their connecting their schemes and reasoning across similar (and different) contexts (Tallman & O'Bryan, 2024; Thompson, 2013). Second, offering explicit occasions for students to compare activity across tasks can support reflective abstraction (Ellis et al., 2024; Piaget, 1976, 2001; Tallman & O'Bryan, 2024). Taken together, we conjecture students' repeated opportunities to create solutions, consider others' solutions, and to explicitly reflect on solutions can also create opportunities for reflective abstraction. We illustrate these considerations with the following task design.

Exemplifying the Constructs: X-marks the Spot

We designed the *X-Marks the Spot Task* leveraging the above radical constructivist constructs to support students' work with spatial coordinate systems (described below). Our conjecture was that multiple rounds of describing (to classmates) and interpreting descriptions (written by classmates) of locations in space could occasion major or minor cognitive perturbations. Further, we offered deliberate opportunities for students to reflect on location descriptions at a higher level of thought. We intended these experiences to support students in engaging in reflective abstraction as they reorganize their meanings for organizing space.

Task Background: Spatial Coordinate Systems and Conventions

In this report, we focus on a task designed to support students' developing meanings for spatial coordinate systems (Lee, 2017; Lee & Hardison, 2016; Lee et al., 2020; Paoletti et al., 2022). A *spatial coordinate system* is a coordinate system (CS) that entails either mentally overlaying a CS onto some perceived space or overlaying a space onto an already established CS. In either case, objects within the space can be located via coordinates. Radar on a ship and GPS are different examples of spatial CSs (i.e., polar and Cartesian CSs, respectively).

We note conventional coordinate systems involve choices often developed or adopted for the purposes of efficiency and communication (Moore et al., 2019; Zazkis, 2008). Given the communicative value of such conventions, we conjectured that we could support students in developing a *social goal* by offering them repeated prompts to describe locations in space, with the anticipation of classmates' interpreting it, and to interpret classmates' descriptions of locations. This goal could lead to activity that supported students in reorganizing their schemes for organizing space towards more clear and efficient strategies.

The Design of the X Marks the Spot Task

In the *X Marks the Spot Task* (Figure 1), we provide students with the map and buttons shown in Figure 1a with the prompt, "Play with the different overlays. In the next slides you will use the overlays either (a) to describe the location of an X or (b) interpret classmates' descriptions." Students can try each button and observe different overlays.

After exploring the different overlays, we task students (individually or in groups) with marking an X on the map. To support the creation of a *social goal*, we prompt students to use the overlays to provide a written description for the location of their marked X that classmates will interpret to determine the location of the X. In particular, a student may assume their classmates have the same shared goal of marking two Xs in the same location. To achieve this *social goal*, a student may try to write a description that is clear enough for their classmates to follow while also being descriptive enough to mark a precise location for the X. The student assumes their classmates will try to interpret the description and mark an X in the described location.

The act of interpreting real and hypothetical classmates' responses may result in a student experiencing a *cognitive perturbation*. We conjecture students would be able to interpret many descriptions using their current schemes (i.e., *without cognitive perturbation*). We also conjecture interpreting vague descriptions or observing discrepancies in the location of marked Xs for the same description could create *cognitive perturbations* for students. Further, we task students to provide feedback to the author of each description as we conjecture such activity can engender *reflective abstraction* as students reorganize their meanings for organizing space.

Contribution, Implications, and Areas for Future Research

In this theoretical report, we described how radical constructivist constructs can explain how a student's engagement with others' solutions can support their learning. We elaborated on our understanding of social goals, cognitive perturbations, and reflective abstraction. Given the emphasis on collaborative group work in mathematics education, such learning is likely to occur in classrooms where students interpret others' responses positively and reorganize their own meanings as a result of these interpretations.

We described how we designed the *X Marks the Spot Tas*k to support students in creating a social goal that could occasion cognitive perturbations. We conjecture that the use of classmates' descriptions to potentially provoke cognitive perturbations can be productive in this task due to the communicative nature of the mathematics at hand. We conjecture offering students repeated opportunities to first generate their own descriptions and then interpret (real and hypothetical) descriptions that communicate more or less effectively and efficiently increases the chances students would experience cognitive perturbations that could result in reorganizations of their schemes for organizing space. We conjecture there are other mathematical concepts that rely heavily on communicative goals such as conventions, in which students could be supported in learning via the use of (real or hypothetical) student solutions. We call for additional research exploring this possibility. This and other research could build on prior work showing how examining others' solutions to mathematical problems (Barbieri et al., 2023; Webb et al., 2014) can support learning. Further, such research could leverage the constructs outlined in this theoretical report to provide explanations for *how* examining others' solutions can lead to learning.

A TOULMIN COMPARISON OF TEACHER'S AND STUDENT'S PROOFS

Matt Furuta Park
Virginia Tech
mfpark@vt.edu

Abstract: This paper takes data from the Proofs Project which was designed to address epistemological obstacles (Sierpińska (1987), Brousseau (1997)) related to mathematical induction and logical implication and uses Toulmin's model for argumentation to compare the structures of a proof presented in class from the instructor and the students. Under the assumption that math instructors set norms for and model ideal mathematical behavior, it is reasonable to look at how closely students adhere to the implicit or explicit norms set by the instructor.

Keywords: Undergraduate Education, Reasoning and Proof, Advanced Mathematical Thinking

In this report, we draw on the framework developed by Fukawa-Connelly (2014) and Inglis et al. (2007) to analyze the structure of verbal proofs toward answering the following research question: How are the proofs of math students similar or different from the proofs of their instructor? This report is also meant to contribute to an emerging interest in the role of mimicry in mathematical learning.

The data comes from a class part of the second cycle of a design-based research (DBR) study called the *Proofs Project* (Kokushkin et al. 2023). From the first cycle, the researchers replicated findings from existing literature (Brown, 2008; Dubinsky,1986; Dubinsky, 1990) emphasizing the difficulty of mathematical induction specifically from the induction hypothesis. A graded assignment for each student was the presentation of their proofs. Presentations consisted of a formal presentation and subsequent feedback from the instructor. So our use of the phrase "verbal proofs" refers to both the spoken and digitally displayed components of their presentations. Our unit of analysis is the proofs formally presented to the whole class represented by Toulmin diagrams, as it is hypothesized that the norms the instructor models for presenting proofs and his prior feedback are what the students emulate and the norms the students develop for their group work are more distinct from what the instructor models.

While Fukawa-Connelly (2014) used the Toulmin model to analyze only a teacher's arguments in an abstract algebra course, this paper uses the model to compare both the teacher's arguments and his students' arguments. For consistency's sake in both the wider study the data comes from and comparisons of proof, we look at their arguments regarding mathematical induction.

Literature Review & Methods

Toulmin's model was specifically adapted to a math education context around the turn of the century. While it was originally developed by Toulmin (1969), Inglis et. al. (2007) attribute Krummheuer (1995) for adapting it for a math education context. It was specifically adapted for the presentation of mathematical proofs by Fukawa-Connelly (2014) and additionally adapted for an evaluative context by Hancock (2019).

The paper from Fukawa-Connelly (2014) showcases an application of the model in understanding an instructor's proof while looking at both verbal and written forms of proof representation. Fukawa proposes that Toulmin's model of argumentation could be used to improve undergraduate proof teaching by detailing the constructions of the instructor's proofs. From his data, particularly the observations that the instructor implemented an "inconsistent use of backing and warrants" (p. 86), he distinguishes between proofs that convince and proofs that explain. Unlike Fukawa-Connelly's (2014) data, the episodes I analyzed consist of consciously distinguished proofs, whereas Fukawa-Connelly's (2014) study considered the presentation of proof as a more spontaneous affair.

We report on the similarities and differences between the following statements, with pseudonyms in parenthesis:

1. If the kth, k+1th, and k+2th terms of the Fibonacci sequence are odd, odd, and even (respectively), then so are the k+3th, k+4th, and k+5th terms. (F)
2. If k lines in the plane (none parallel and with no three intersecting at a point) form 1+(k(k+1))/2 regions, then k+1 such lines form 1+((k+1)(k+2))/2 regions. (P)
3. If the sum of the first k odd numbers is k^2, then the sum of the first k+1 odd numbers is (k+1)^2. (I)
4. If k!>2k, then (k+1)!>2k+1. (S)
5. A valid formula for the sum of the first n integers is n(n+1)/2. (Instructor, M)

Methods

I adopt and modify the methodology employed by Fukawa-Connelly (2014) to determine which aspects of a given proof correspond to the Toulmin components. As I am comparing the proofs of both instructor and student, we then compare the corresponding components of their resulting Toulmin diagrams or look for what common arguments arise as different components.

Although the proofs were written, because they were presented verbally, I also infer qualities of their modal qualification from implicit factors (Alcock & Weber, 2005) such as if they use hedging language in their delivery, including phrases such as "I think" or "It should follow that…". As the Toulmin diagram includes transcribed speech, but not the nuances of the speech, aspects such as inflection will be ignored. I also took their counterarguments to feedback from the instructor as rebuttals, but not the feedback itself.

Analysis

The instructor started his proof by commenting on a prior student's board work as data for his argument, pictured below in Figure 1. In linking the data to his final claim, he pointed out "the only thing you're adding is this k+1th term." Although his data was detailed algebra, the instructor did not explicitly break down every step. His modal qualification contained little information in terms of mathematical statements, but might be understood better in terms of his role as the instructor when he ended his commentary with: "That's how these arguments work. This is the whole creative part of mathematical induction." Finally, his argument was not followed by questions and thus had no verbalized rebuttals.

$$\sum_{i=1}^{k} i = \frac{k(k+1)}{2} \rightarrow \sum_{i=1}^{k+1} i = \frac{(k+1)(k+2)}{2}$$

$$\frac{k(k+1)}{2} + k + 1$$

$$\frac{k^2}{2} + \frac{k}{2} + k + 1$$

$$\frac{k^2}{2} + \frac{3k}{2} + \frac{2}{2} \rightarrow \frac{(k+1)(k+2)}{2}$$

Figure 1: Writing Used in Instructor's Proof

Students L, M, and S presented similarly to the instructor in that they spoke with absolute mathematical certainty and were not pressed to provide a rebuttal. The students spoke with absolute authority in that they were reading directly from their presentation in contrast with the instructor who was speaking evaluatively. As they were questioned by neither their peers nor the instructor, their backing was nonexistent. Since their presentation was written as formal proof, we also assign them maximal certainty in terms of modal qualification. On the other hand, the other students, M and P, had backings or warrants in terms of entire alternate proofs, and thus required second Toulmin models to describe their proofs in full.

P's second proof functioned as a backing since it provided an additional interpretation to his warrant. Although M also uses a second proof to her claim, it is not related to the warrant of the first proof and is closer to a warrant to her claim than a backing, nor was it presented to the class. Their backings and warrants also used illustrations, while L had neither despite his statement admitting a geometric proof. The proof from P was also notable as it was the only one that included a backing in the form of a non-algebraic illustration, shown below. This is despite the statements from M and I also admitting geometric proofs. It also meets the definition of a modal qualifier as it utilizes the base case(s) to understand the inductive step.

The proofs by L and F lacked backing in their written portion. There was a rebuttal in F's argument motivated by a question from a fellow student, but only to clarify the parity of the sum of successive Fibonacci numbers.

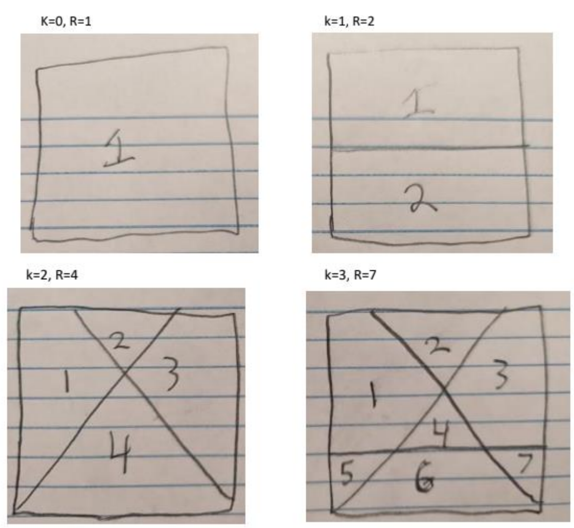

Figure 2: Illustrations from P's Backing

Finally, a common backing in all proofs was a claim that the warrant followed from that "you can kinda see how it works out through algebra." Verbal proofs use handwaving justifications via algebraic manipulations even if the written proof shows it explicitly (in the case of F) suggesting that the norms for speaking a proof, writing a proof, and reading off a proof may be subtly different. It is possible that a tendency to “handwave” algebraic manipulations was influenced by the instructor’s proof from the prior class session.

Regarding induction proofs specifically, it is notable that although the class and the wider project were about the proof schema of induction and the assigned proofs were only about the induction step, one student, S nevertheless presented a full induction argument of the base case, inductive case, and the relationship between them and still claimed to only prove the inductive step. Although he claimed that the property holds for integers greater than 4 and not all integers, this is still a claim about the set of integers, not about an implication. Generally, students would use the universal statement as backing for an inductive implication. During the presentations from S and P, they argued using the full universal statement as a backing for the induction step. However, this could also be understood in terms of both a mimicking strategy and a theme from Kokushkin et al. (2023) who found “students must develop an intellectual need to generalize the logic involved in building the quasi-inductive chain of inferences” (pg. 5) as the quasi-inductive arguments (Harel, 2002) in P’s proof aligned backing of a full induction argument and instructor’s illustration from the prior class session, recreated in Figure 3.

P’s proof gives another similarity between student and teacher. Compare the backing from P’s proof (Figure 2) to the class discussion from the prior class session, where the instructor drew Figure 3 in discussion a proof of the statement “If 3 lines in the plane (none parallel and with no three intersecting at a point) form 7 regions, then 4 such lines form 11 regions.”After drawing this diagram, he uttered “And this is the kind of thing you have to explain.” It is plausible that an emphasis on illustrations for geometric proofs from an instructional authority pushed P to provide illustrations as a backing even with a valid algebraic proof.

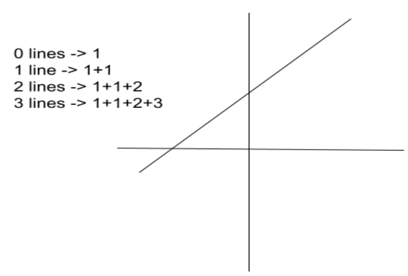

Figure 3

Conclusion

In his original study, Fukawa-Connelly (2014) suggests that Toulmin’s model and its application in his study could help instructors improve on proof teaching by examining their instructions concerning expected student outcomes. This report contributes to this suggestion by extending findings from Hazzan et al. (2003), who argued for the significance of proof mimicry by pointing out the abstract nature of many Linear Algebra concepts. As found by Zhou & Guo (2016), math students rely on the imitation of their teachers to support their learning more than students of other subjects. Zhou (2012) also argues that imitation is a cognitively sophisticated technique both students and teachers employ to support students' learning. Mimicry by both students and teachers can positively affect students' learning outcomes, as demonstrated by Zhou (2012), who found broad, positive, and statistically significant effects on student outcomes, especially among math and science students. Students were seen to mimic their instructor in a variety of ways, such as their language. But the Toulmin model also allowed us to identify that both parties refer to algebraic manipulations as a backing. The familiarities we observed in terms of similarities of backings, and modal qualifiers, support our main hypothesis that students mimic proofs to support their learning. Our work also shows a need to expand the theory from Zhou (2012) as mimicry seemed to occur not only between student and teacher in both directions but between students. And our methodology is not powerful enough to determine if mimicry was occurring, or if all the students were practicing the same sociomathematical norms. Generally, the boundary between norm adherence and mimicry should be investigated further.

STUDENT THINKING AND ATTITUDES WHEN WORKING WITH DATA IN AN INTEGRATED, PLACE-BASED CURRICULUM

Franziska Peterson
University of Maine
franziska.peterson@maine.edu

Christina Siddons
University of Maine
christina.siddons@maine.edu

Developing students' data literacy skills through an integrated place-based curriculum is important for creating informed citizenry as well as building student confidence around mathematical and statistical thinking. Initial results from attitude and assessment surveys from 74 sixth-grade students in a rural, coastal school district in the Northeastern United States reveal that students entered the school year with positive attitudes towards mathematics. While students hold more novice conceptualizations of what constitutes "data," their confidence in their math skills and performance offer an opportunity to sustain these positive attitudes as they encounter more challenging statistical thinking tasks across math and science classrooms.

Keywords: Middle School Education, Integrated STEM, Data Analysis & Statistics

Purpose of the Study

The oceans define our planet and are central to many challenges human populations face; addressing these challenges requires citizens who are ocean literate **and** data literate. We established a research-practice partnership (RPP) with teachers and community members from rural coastal communities in the Northeastern U.S. to promote integration of ocean science, data, and technology-related competencies into science curricula. This study reports initial findings regarding middle school students' conceptualizations of data, and characterizes their attitudes towards STEM (Science, Technology, Engineering, Math) subjects at the start of the school year.

Theoretical Framework

While many research studies indicate that integrated STEM instruction can benefit students and teachers alike, educators face significant challenges in implementing integrated instruction (Mayes, 2019; Ríordáin et al., 2016). Considerable research also supports the idea that STEM subjects should be taught in an integrated, authentic way that reflects the day-to-day practices and competencies of experts and scientists (Kelley & Knowles, 2016; NGSS Lead States, 2013; Roehrig et al., 2021). We draw upon the data science framework proposed by Lee and colleagues (2022) and the positioning of data literacy at the intersection of data science, authentic context, and quantitative reasoning proposed by Kjelvik & Schultheis (2019). These frameworks guide our investigation of students' reasoning when working with data and their conceptualizations about data, specifically regarding variability, measures of central tendency, and interpretation of data visualizations, aligning with the GAISE report principles (Bargagliotti, 2020).

Furthermore, we position our project within a marine context to make it relatable and accessible for students in a state with a substantial "blue economy." Linking learning to initiatives such as Powering the Blue Economy (PBE; Office of Energy Efficiency & Renewable Energy, n.d.) helps ground students' data literacy development in real-world applications that can focus on the innovative yet sustainable use of ocean resources to boost economic growth while preserving ocean ecosystems, which has direct impacts on their local communities.

Methods

This study took place in the context of a large grant-funded RPP exploring ways to integrate authentic research and technology into grade 6-12 classrooms, with a particular focus on marine science and data literacy. Key objectives include (a) providing professional learning for teachers to support the development of community-relevant, authentic student research, (b) studying the impacts of authentic research infused with technology on diverse students' knowledge of and engagement with the material, and (c) expanding students' career knowledge and awareness by establishing local community partnerships. Following the first series of professional learning sessions in Summer 2023, teachers developed lessons based on existing classroom instruction that incorporated these elements into instruction for the 2023 - 2024 academic year.

Participants

Student participants were recruited from grade 6-12 classrooms enrolled in the project; Institutional Review Board approval was obtained prior to any recruitment and data collection activities. This study focuses on pre-instruction data from participating 6th graders. Pre-instruction survey responses were collected from 74 6th grade students enrolled in Earth Science; post-instruction surveys will be deployed by the end of the 2023-2024 school year. Respondents include 38 females, 21 males, and 15 students who left the gender question blank or preferred not to answer.

Data Collection and Analysis

Data was collected using two pre-post surveys targeting both student reasoning about data and their attitudes towards STEM. Student attitudes were assessed using the Student Attitudes Towards STEM (S-STEM) survey (Friday Institute, 2012). The S-STEM survey conceptualizes student attitudes as representing both student self-efficacy and expectancy-value beliefs (Unfried et al., 2015). The research team created a Data Assessment survey that included a mix of Likert items and multiple-choice items drawn from previously published instruments (*e.g.*, Gormally et al., 2012; Zoellick et al., 2016) aimed at understanding students' views on what "counts" as data (Bargagliotti et al., 2020) and how they think about data in their lives.

Survey data was analyzed using SPSS statistical software (IBM, version 28.0.0.0). S-STEM analysis focused on the Math subscale and associated career/course question items. Likert answer choices to subscale items were scored from 1-5, with 5 representing the most positive views; averages and standard deviations from subscales are reported based on the recommendations by the survey developers (Friday Institute, 2012). For the survey item predicting class performance, simple contrast coding was used to run linear regression with categorical predictors to determine if responses were associated with Math subscale scores. Responses to the Data Assessment were summarized using descriptive statistics. Further analysis examining both classroom observation notes and artifacts for evidence of student thinking and reasoning is currently underway and will be complete by July 2024.

Results

Student Attitudes: Middle School S-STEM Results

Middle school students' attitudes were the most positive on the 21st Century Skills subscale, with a pre-instruction mean of 3.82 (SD = 0.50), followed by Math (3.47, SD = 0.69), Engineering (3.25, SD = 0.65), and then Science subscales (3.17, SD = 0.65). A one-way ANOVA revealed there was no significant difference between scores by gender ($F_{2,71} = 0.762$, $p = 0.514$). Subscale items around future plans for pursuing careers in math and/or doing advanced math had less positive student views than those about students' current mathematical self-efficacy. For example, only about 30% of students Agreed/Strongly Agreed with the statement "I would consider choosing a career that uses math," whereas "I am good at math" had over 70% of students Agreeing/Strongly Agreeing.

Students also predicted how well they expected to do in the current school year in their math, science, and ELA classes. Math had the highest percentage of students predicting they would do very well (31%), followed by ELA (28%), and Science (20%). Only 8% of students predicted "Not at all well" for both math and science; ELA only had 4% of students predicting such. Categorical linear regression analysis revealed that students' expectations for performance in math class was a significant predictor of their attitude score on the Math subscale (Adjusted $R^2 = 0.513$; $p < 0.001$). Students in the "Not at all well" prediction category scored an average of 1.75 points lower on the Math subscale than those who thought they would do "Very well," while those in the "OK/Pretty well" category scored an average of 0.84 points lower ($p < 0.001$).

Student Thinking: Middle School Data Assessment Results

Data Assessment responses ($n = 70$) to Likert statements indicated 70% of students agreed with statements characterizing data as useful for understanding the environment; 67% acknowledged descriptions/observations and 63% said stories from people with local/historical knowledge as useful data. Only 34% agreed data were part of their everyday life, and the remaining statements regarding data collection and analysis had large percentages (36–53%) of students selecting the neutral answer choice.

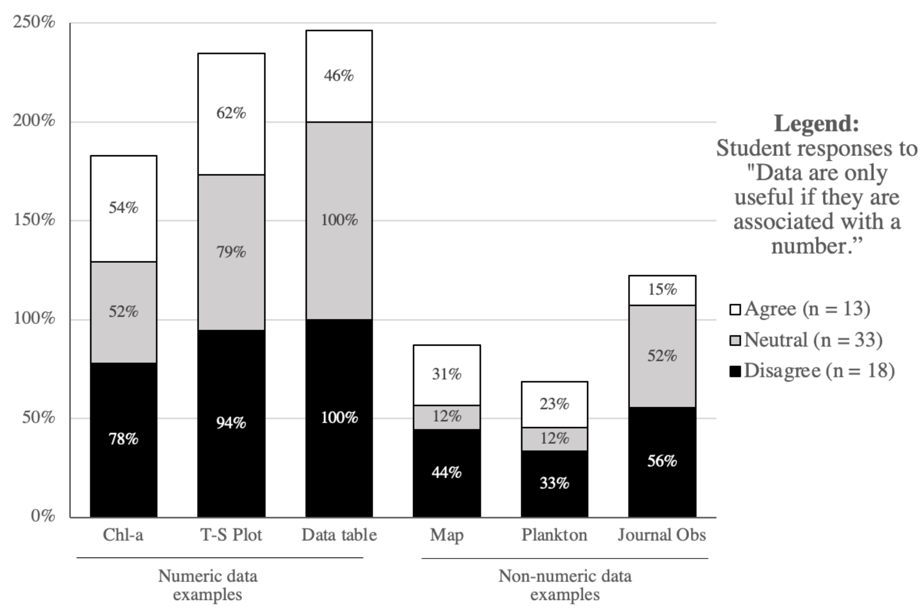

Figure 1: Percent of Students Within Each Response Category Who Identified Numeric vs. Non-Numeric Examples as "Data"

Students were shown six different images containing both numerical and non-numerical marine data sources and asked to choose all images they would classify as "data." Numerical examples included a satellite image of sea surface chlorophyll-a concentrations (Chl-*a*), a time-series plot of sea surface temperature and salinity (T-S Plot), and a table of temperature and salinity data at three locations (Data Table). Non-numerical examples included a map of a local bay (Map), a photo of a phytoplankton cell (Plankton), and a journal entry detailing intertidal observations (Journal Obs). The most popular images selected by students were the numerical sources: Data Table (81.4%), T-S Plot (72.9%), and Chl-*a* (55.7%). Less than half of the students (41.4%) chose Journal Obs as a kind of data; few chose Map (24.3%) or Plankton (18.6%).

Because of the small number of students who classified the non-numerical examples as representing types of data, we investigated their responses to this item in light of how they answered the Likert statement "Data are only useful if they are associated with a number" (Figure 1). 64 students responded to this survey question; 18 disagreed, 33 were neutral, and 13 agreed. Students who disagreed (i.e. held a more expert-like view of what "counts" as data) were more likely to choose non-numeric data examples over those who were neutral or agreed. For example, 44% of the Disagree students (black bars) identified the Map as a type of data, as compared to only 12% of Neutral students (gray bars) and 31% of Agree students (white bars). Because students could choose multiple options, percentages add up to more than 100%. In the final series of questions around handling hypothetical data dealing with outliers and variability, 54.3% of students correctly answered how to handle outlier data in a dot plot, but only 28.6% chose the correct description of variability in non-technical terms. 32.9% of students chose the distractor choice "The number of different values in the data set" for describing variability.

Discussion & Conclusions

We conclude that the average Math subscale score of 3.47 indicated more positive views towards math than science, when considering both subscale averages and prediction of performance in both classes in the coming year. Since participants were enrolled in their first standalone science class of their academic careers, uncertainty about what this course looks like could contribute to less confident attitudes towards science. The overwhelmingly positive responses to self-efficacy-type Math items were encouraging and suggest that younger middle school students may hold a more positive mathematical mindset than expected.

With the regression analysis indicating significant differences observed in overall math attitudes between the performance prediction groups, our results reinforce recommendations from previous work (e.g., Boaler, 2015) that building confidence and self-efficacy amongst the students who have negative performance predictions is critical to future success, especially as studies continue to demonstrate math anxiety having negative impacts on performance (Barroso et al., 2021). Efforts to build positive, growth-mindset oriented mathematical attitudes need to happen beyond math classrooms. More explicit opportunities for students to engage with mathematical thinking and reasoning in other subjects (like Earth Science) may help break down stigmas students have towards math and allow these practices to be more accessible.

Students' responses to the Data Assessment Likert questions had several statements with which students neither agreed nor disagreed; these may reflect more uncertainty than a true neutral stance. Modifying the survey to eliminate the neutral option and/or following up with an open response question or individual student interviews could be a way to better understand these responses. Despite students' agreement that data did not have to be numeric, Figure 1 shows that the majority of students still gravitated to data examples that had quantities attached to them, which may be a result of their familiarity with these types of representations.

DESARROLLO Y REFINAMIENTO DE MODELOS MATEMÁTICOS POR ESTUDIANTES DE BACHILLERATO EN UN PROBLEMA DE DEFORESTACIÓN

DEVELOPMENT AND REFINEMENT OF MATHEMATICAL MODELS BY HIGH SCHOOL STUDENTS IN A DEFORESTATION PROBLEM

Arely Romo Becerra	Verónica Vargas Alejo	Dinorah Méndez Huerta
Universidad de Guadalajara	Universidad de Guadalajara	Universidad de Guadalajara
arely.romo.37@gmail.com	veronica.vargas@academicos.udg.mx	dinorah.mendez7682@alumnos.udg.mx

Se presenta el análisis de los resultados de una investigación cualitativa relacionada con la modelación de una actividad cercana a la realidad por estudiantes de bachillerato. Se describen los modelos desarrollados por las estudiantes al abordar la actividad titulada "Deforestación en Jalisco". El marco teórico fue la Perspectiva de Modelos y Modelación, por lo que la actividad fue diseñada con base en los seis principios de diseño de una MEA (Model Eliciting Activity). Participaron dos estudiantes de sexto semestre de bachillerato quienes abordaron la MEA mediante la plataforma Zoom. Como resultado se observó que las estudiantes tuvieron oportunidad de conectar su conocimiento matemático con la situación de deforestación y reflexionaron sobre la importancia de los recursos forestales en términos de las implicaciones de su pérdida.

Palabras clave: Modeling, High School Education, Algebra and Algebraic Thinking, Online and Distance Education.

Introducción

Uno de los objetivos del acuerdo de París, adoptado dentro de los Objetivos de Desarrollo Sostenible (ODS) es contrarrestar la deforestación debido al impacto que la superficie forestal terrestre tiene como regulador climático natural (Organización de las Naciones Unidas [ONU], 2023). La Organización de las Naciones Unidas para la Educación, la Ciencia y la Cultura (UNESCO, 2021) señala que es necesario tomar medidas al respecto y el aula es un espacio donde se puede iniciar la sensibilización. Los ambientes de aprendizaje de matemáticas basados en la modelación promueven no sólo que los estudiantes desarrollen conocimiento matemático y habilidades para modelar (Corum & Garofalo, 2019; Lesh, 2010; Garfunkel & Montgomery, 2019), sino que también promueven la reflexión sobre la problemática del contexto (Vargas Alejo & Montero Moguel, 2023). En este estudio se describen los modelos generados por estudiantes de bachillerato al resolver una actividad cercana a la vida real diseñada en el contexto de la deforestación. La pregunta de investigación fue ¿qué conocimiento matemático sobre la función lineal, habilidades y reflexiones exhiben las estudiantes de bachillerato al enfrentarse a la MEA "Deforestación en Jalisco"?

Marco teórico

De acuerdo con la Perspectiva de Modelos y Modelación [MMP, por sus siglas en inglés Models and Modeling Perspective] los estudiantes deben aprender matemáticas de manera que su aprendizaje no se reduzca a su utilidad al aula (Lesh, 2010). Las matemáticas que aprenden deben apoyarlos a reflexionar sobre situaciones que trasciendan al salón de clases para entender su entorno (Lesh & Doerr, 2003). En lugar de enfocarse en la memorización o la mecanicazación de algoritmos, se debe priorizar el desarrollo de conocimientos y habilidades para usar ese conocimiento en la interpretación, descripción, explicación y predicción de fenómenos. Se considera que el proceso de aprendizaje es más relevante que el producto en sí, es decir, el modelo mismo. Lo importante es propiciar el proceso de refinamiento de conocimiento por los estudiantes al diferenciar, integrar, modificar y reorganizar conceptos (Lesh & Yoon, 2004) a través de ciclos de modelación donde los estudiantes usualmente matematizan.

En este sentido, la MMP propone el uso de actividades basadas en situaciones cercanas a la vida real, conocidas como MEAs, las cuales se diseñan con base en seis principios (Lesh et al., 2000; Sevinc, 2021; Sevinc & Lesh, 2018): el principio de realidad, el principio de construcción de modelos, el principio de documentación, el principio de autoevaluación, el principio de generalización de modelos y el principio de prototipos. Las MEAs permiten que los estudiantes desarrollen sus propias ideas matemáticas, teorías, procesos y habilidades para dar una respuesta ante un problema cercano a la realidad (Doerr, 2016), por lo tanto, el contexto es relevante, dado que influye significativamente en la matemática que se emplea, y por ende forma parte de los modelos que los estudiantes construyen.

Metodología

La metodología empleada en esta actividad fue un estudio de caso, participaron dos estudiantes de 18 años aproximadamente, quienes estaban cursando sexto semestre de bachillerato en una escuela privada.

La MEA "Deforestación en Jalisco" se diseñó con base en los seis principios de diseño (Sevinc & Lesh, 2018). Se implementó en un ambiente virtual mediante la plataforma Zoom. Las fases de implementación fueron las siguientes: a) Sesión virtual síncrona de una hora, para la lectura de la nota periodística de la MEA "Deforestación en Jalisco", b) Resolución de la MEA "Deforestación en Jalisco" mediante una carta, como tarea extraclase, c) Sesión virtual síncrona de una hora para discutir la carta y d) Refinamiento de la carta como tarea extraclase.

La MEA solicitaba a los estudiantes apoyar a la Comisión Nacional Forestal (CONAFOR) con la elaboración de una carta que incluyera una descripción del cambio del territorio forestal en Jalisco en los últimos años y para ello se les proporcionaba una tasa de deforestación constante curiosamente tomada de fuentes gubernamentales. También se pedía que la explicación sirviera a la CONAFOR para describir en el futuro cualquier otro territorio forestal con condiciones similares.

Los instrumentos de recolección de datos fueron videograbaciones de las sesiones, las cartas elaboradas por los estudiantes y la bitácora del docente. El análisis se realizó tomando en cuenta los modelos construidos por las estudiantes. Se codificó la información tomando en cuenta el conocimiento matemático exhibido, habilidades de modelación y reflexiones de las estudiantes sobre la problemática. La primera autora del artículo implementó la actividad e hizo un primer análisis el cual fue discutido con las dos siguientes autoras, lo cual permitió refinarlo.

Resultados

La evolución del conocimiento matemático, habilidades y reflexiones que exhibieron las estudiantes al enfrentarse a la MEA "Deforestación en Jalisco", se describe a través de las cuatro fases de la implementación.

Fase a

Durante la primera sesión virtual síncrona las estudiantes leyeron la MEA en voz alta. Se percibió gran interés y conocimiento en las alumnas respecto a la importancia de los territorios forestales para la conservación de la biodiversidad y, también, sobre acciones que se pueden tomar para evitar que se extienda el daño. En los siguientes extractos se observan algunas de sus reflexiones sobre la problemática.

E1: Se debería hacer un poco más de conciencia a la sociedad, bueno a los mexicanos, para saber el daño que se hace a los árboles por algunas empresas para su beneficio propio

E2: Se deberían hacer campañas para reforestar las áreas afectadas … iniciativas como por ejemplo con La Primavera, de tal manera que el espacio quemado no se pueda fincar en 10 años … para restringir el daño con estas reglas

En esta sesión las alumnas señalaron la necesidad de buscar más información sobre el territorio forestal en Jalisco en los años 2019, 2020 y 2021.En esta fase se observa cómo las estudiantes reflexionaron con base en su conocimiento del bosque cercano La Primavera. Esto concuerda con los hallazgos de Lesh y Doerr (2003) quienes señalan que cuando los estudiantes empiezan a resolver las MEAs, generalmente, hacen referencia a experiencias personales. También se relaciona con el principio de realidad (Sevinc & Lesh, 2018).

Fase b

Las estudiantes elaboraron su carta, solicitada en la MEA, para apoyar a la CONAFOR. En ella utilizaron el territorio forestal de Jalisco de $226{,}581\ ha$, $174{,}190\ ha$ y $167{,}811 ha$ correspondiente a los años 2019, 2020 y 2021, respectivamente. Realizaron cálculos comparativos para obtener el decrecimiento en porcentaje. Por ejemplo, para obtener el porcentaje de deforestación en el año 2020 con respecto al año 2019 realizaron la siguiente operación:

$$Porcentaje\ de\ deforestación = \frac{174{,}190ha * 100\%}{226{,}581ha} = 76.87\%$$

Con este dato calcularon la disminución porcentual de deforestación.

$$Disminución\ porcentual\ de\ deforestación = 100\% - 76.87\% = 23.12\%$$

De manera análoga, procedieron para obtener el porcentaje de deforestación para el año 2021 (74.06%) y la disminución porcentual de deforestación (25.93%). Enseguida obtuvieron la tasa de deforestación de $17{,}104.42\ ha/año$ correspondiente al periodo 2001-2021 y la compararon con la tasa de deforestación de $15{,}997\ ha/año$ indicada en la nota periodística, señalando que afortunadamente la deforestación había disminuido en 0.01%.

El conocimiento matemático utilizado fue razones, proporciones y porcentajes. Exhibieron habilidad para relacionar datos de manera multiplicativa y tomar decisiones. La MEA permitió a las estudiantes analizar matemáticamente la situación lo cual se relaciona con los principios de construcción y documentación del modelo (Sevinc & Lesh, 2018).

Fase c

Durante la fase c las estudiantes leyeron su carta a la profesora. Se concentraron en describir de manera cuantitativa la problemática de la deforestación en Jalisco y en la necesidad de difundirla, mediante una campaña. Reflexionaron sobre la importancia de incluir en su campaña las cifras obtenidas, ya que habían identificado un alarmante decrecimiento en la cantidad de hectáreas de bosque. Decidieron comparar estas cifras con el área de estadios de fútbol, de manera que fueran más significativas para la población.

E2: Aunque sí bajó, está bajando muy poco, y aunque es una diferencia que se escucha como 0.01%, en territorio son 2,000 ha, que son no sé qué tantos estadios de fútbol.

Adicionalmente, las estudiantes consideraron que para que la información generara un mayor impacto, las personas debían relacionar las cifras con acontecimientos negativos. Por ejemplo, debían conocer el tiempo restante para que los recursos forestales se agoten.

E2: Podríamos sacar estimaciones… [para mostrar que] podríamos perder en tanto tiempo toda nuestra diversidad forestal. Como el reloj de NatGeo, creo, o GreenPeace. Ellos tienen un reloj biológico de que en tantos años llegaremos al punto de no retorno… Que sean datos más fáciles de digerir para el público.

Fase d

Después de la sesión virtual síncrona las estudiantes refinaron su carta como tarea extraclase. En ella se observaron las dos reflexiones siguientes.

- Una comparativa de las hectáreas perdidas en promedio en el 2021 en relación con el área de una cancha de futbol soccer $(100m * 50m)$, que corresponde a $34{,}208$ canchas $(171{,}040{,}000m^2 / 5000m^2)$
- El comunicado del reloj climático en Nueva York para recordar el tiempo que nos queda para actuar, antes de que los cambios climáticos nos afecten irreversiblemente

El conocimiento matemático utilizado en las fases c y d siguió siendo razones, proporciones y porcentajes, conocimientos asociados a la función lineal; también realizaron estimaciones para describir el decrecimiento del territorio forestal en términos de estadios de fútbol. Las estudiantes en cada paso autoevaluaron sus procedimientos, lo cual se relaciona con el principios de autoevaluación (Sevinc & Lesh, 2018). Las alumnas tenían claro qué era lo que estaba cambiando (la cantidad de hectáreas de bosque), cómo estaba cambiando (constante y de manera decreciente) y cuánto estaba cambiando (0.01%). De acuerdo con investigadores como Carlson et al. (2002) saber qué cambia, cómo cambia y cuánto cambia son elementos fundamentales que permiten a los estudiantes profundizar en el concepto de variación y de función.

Discusión y conclusiones

Respecto a la pregunta de investigación ¿qué conocimiento matemático sobre la función lineal, habilidades y reflexiones exhiben los estudiantes al enfrentarse a la MEA "Deforestación en Jalisco"? En el primer modelo se observó el uso de razones, proporciones y porcentajes así como habilidades para buscar información en internet, identificar datos y relacionarlos mediante comparaciones multiplicativas para describir la deforestación. En el segundo modelo, el conocimiento matemático utilizado fue de nuevo razones, proporciones, y estimación. Las estudiantes identificaron una variación decreciente. Las reflexiones sobre la problemática y la necesidad de hacer una campaña de difusión fueron determinantes para abordar la situación y que surgiera en el segundo modelo la necesidad de realizar estimaciones para describir el decrecimiento del bosque en términos de estadios de fútbol.

Tal como menciona Lesh y Doerr (2003) las estudiantes durante el proceso de descripción de la situación lograron diferenciar e integrar información y datos, así como desarrollar un modelo el cual no solo contempló datos, sino también información sobre la problemática. La MEA "Deforestación en Jalisco" posibilitó que las estudiantes matematizaran de manera simultánea a su reflexión sobre la problemática, lo cual es importante ante el llamado de la UNESCO (2021) para apoyar la sensibilización sobre los problemas ambientales. El análisis cuantitativo permitió a las estudiantes corroborar la existencia de la problemática y pensar en acciones para afrontarla.

MATH ANXIETY AND EMOTIONAL SKILLS: A PILOT STUDY IN MEXICO

Beatriz Ruiz Ordoñez
Universidad Iberoamericana, Mexico
beatriz.ruiz@correo.uia.mx

This research project aims to investigate the relationship between specific emotional skills and a student's ability to solve mathematical tasks in the presence of math anxiety. The study concentrates on primary school students, particularly those in the 3rd and 4th grades, as research indicates that math anxiety could appear in these age groups. Math anxiety hinders academic and professional development and has long-term implications for decision-making and daily activities. A pilot study using a mixed quantitative-qualitative methodology design was used to test various instruments to measure the involved variables. The sample consisted of 103 children from a school in Mexico City. This initial study is the first step towards conducting further research on a larger scale to determine the strength and direction of the relationships between emotional skills, the construct of math anxiety, and its effects on performance.

Keywords: Affect, Emotion, Beliefs, and Attitudes.

The construct of math anxiety and its dimensions

Learning mathematics can be challenging and stressful for many individuals, often leading them to avoid subjects related to numbers and problem-solving. This aversion can adversely affect professional development and the ability to manage everyday tasks (Ashcraft, 2002).

Math anxiety is a construct that can account for these blockages and negative attitudes toward mathematics. It is "a feeling of tension and anxiety that interferes with manipulating numbers and solving mathematical problems in everyday and academic situations" (Richardson & Suinn, 1972). The difficulties associated with learning mathematics are not solely due to learning problems but also negative emotional factors (Dowker et al., 2016; Mammarella et al., 2019). It has been observed that adults experience mathematical anxiety while performing simple numerical tasks like counting and estimating magnitudes. This suggests that the anxiety may have developed before the sixth grade (Maloney et al., 2015).

I conducted a systematic literature review on mathematical anxiety and its two defining dimensions to develop the theoretical framework. The cognitive dimension directly impacts executive functioning and is linked with learning mathematical concepts or topics that require greater utilization of working memory and attentional control (Ashcraft & Kirk, 2001). The emotional dimension, on the other hand, considers socio-emotional skills, such as self-regulation and perceived self-efficacy (Kaskens et al., 2020; Luttenberger et al., 2018), as well as intrinsic motivation, which can interact with mathematical anxiety (Karamarkovich & Rutherford, 2021).

There is a strong connection between the cognitive and emotional factors involved in learning mathematics and the generation of anxiety, which can affect mathematical performance (Barroso et al., 2021; Hembree, 1990; Namkung et al., 2019). This situation can result in poor academic performance (Rossnan, 2006), impacting students' interest levels, values, self-concept, and self-esteem (Gabriel et al., 2020). Therefore, developing specific emotional skills can provide children with the tools to manage anxiety while working on math tasks. Regarding the emotional dimension of math anxiety, a cyclical behavior has been observed wherein students experiencing continuous failures develop significant insecurity, which subsequently generates anxiety. Pekrun's (2006) reciprocal model explains this behavior, suggesting that control and value appraisals towards learning can predict academic anxiety, thereby affecting performance. The literature provides extensive support for using the Cognitive-Motivational Model of Achievement Emotions (Pekrun et al., 2018) and the Control-Value Theory (Pekrun et al., 2007) as theoretical frameworks.

Research Objective

The pilot study aims to evaluate the tools and techniques used and obtain initial results to address the research question: "How do specific emotional and cognitive abilities influence the relationship between math anxiety and mathematics performance?" Additionally, the study seeks to confirm the hypothesis that low emotional skills increase math anxiety and negatively affect math performance.

Method

An exploratory sequential design with a mixed methodology approach was implemented for the project, starting with a pilot study conducted at a private school in Mexico City. It included 103 students from third and fourth grades, comprising 71 girls and 32 boys, with an average age of 10.3 years and a standard deviation (sd) of ±0.65 years. The parents or tutors provided written consent for their participation in the study. Prior to the program, cognitive focus group assessed the duration and structure of the instruments, confirming their sustainability in terms of length and clarity. The program consisted of two sessions, conducted in separate days. The students were not informed about math anxiety to avoid bias.

Session one: Emotional Dimension. An instrument comprising five different tools to measure the abilities was designed using a Likert scale from 1 to 5 with emojis to answer. It was applied simultaneously to all students per group with a duration of 35-40 minutes:

1. Perceived Self-Efficacy: The Self-Efficacy for Self-Regulated Learning Scale, developed by Zimmerman, Bandura, and Martínez-Pons (1992).
2. Beliefs and Expectations Related to Mathematical Competence: The questionnaire developed by Wigfield and Eccles (2000).
3. Intrinsic Motivation: measured with the Spanish adaptation of the "Academic Self-Regulation Questionnaire" (SQR-A) developed by Conesa and Duñabeitia (2022).
4. Emotional Intelligence: measured with the Brief Emotional Intelligence Scale (BEIS-10) developed by Davies et al. (2010).
5. Mathematical anxiety was measured using the SEMA scale by Wu et al. (2012), translated into Spanish by Sánchez-Pérez et al. (2021), where responses ranged from no nervous to very nervous.

Additionally, general anxiety was measured to exclude students with trait anxiety using the Child Anxiety Scale (Gillis, 2003). Consequently, nine students were excluded from the study, and the sample size was reduced to 94.

Session Two: Cognitive Dimension. Children were individually assessed in a private room. The session included an interview with eight questions about their attitudes towards math, which took 5 minutes, and a performance test with ten items, which lasted 15 minutes. The test was developed in-house using items from the ENLACE standardized test (SEP, 2013). The sample size was reduced to 91 due to the absence of three students.

Interviews were transcribed and analyzed qualitatively. Responses were structured in tables to compare themes and students. Open and axial coding were conducted, and a comparative analysis observed differences and similarities. The emotional skills five-section instrument was scored and analyzed descriptively and statistically.

Results

I administered all tests to 91 students over the course of three weeks. Below is Table 1, which displays the main statistical data of the instruments and their results.

Table 1: Variables and Measurement Instruments Data

Variable	Mean (n=91)	Standard deviation	% students above average	Likert Scale Level	Cronbach's **α**
Self-efficacy	38.4	±6.58	52%	3.8	0.833
Perceptions and beliefs	46.3	±5.37	54.8%	4.2	0.823
Motivation	43.0	±6.81	52%	3.9	0.755
Emotional intelligence	44.1	±6.10	54%	4.0	0.788
Math anxiety	33.7	±10.94	40%	1.7	0.896

Based on the collected data, the participants obtained high emotional skills, with an average score of 4 on the Likert scale. On the other hand, the respondents reported a level of math anxiety, 1.7 on the Likert scale. In addition, the average score obtained on the math test was 7.4 out of 10, with a sd of ±1.52. It is important to notice that, in the case of math anxiety, the mean obtained is similar to the one achieved by Wu et al. (2012) in designing the SEMA scale, equal to 33.79 points (sd = ± 10.22) and by Sánchez-Pérez et al. (2021) equal to 27.92 points (sd = ±8.08) for 3rd-grade and 29.15 points (sd = ±8.54) for 4th-grade children.

A correlation matrix analysis using Spearman's correlation coefficient identified significant associations between factors related to math anxiety. Self-efficacy, perceptions and beliefs, motivation, and emotional intelligence were negatively correlated with math anxiety, indicating that higher emotional skills are associated with lower math anxiety. Specifically, self-efficacy ($\rho = -0.527$, $p < 0.001$), perceptions and beliefs ($\rho = -0.392$, $p < 0.001$), motivation ($\rho = -0.268$, $p < 0.05$), and emotional intelligence ($\rho = -0.244$, $p < 0.05$) showed significant negative correlations with math anxiety.

In addition, it was possible to identify certain concepts that posed challenges for students when solving problems. Third graders struggled with fractions and division reasoning, while fourth graders found problems involving fractions most difficult.

In the interviews, it was found that most students like mathematics but also feel nervous about it. The questionnaire revealed that only 9% of the students reported feeling nervous about math. However, during the individual interviews, students could differentiate between fear, nerves, and stress related to mathematics. Out of the 91 children who were evaluated, 33% reported that they did not feel any fear or nervousness. 43% of the children acknowledged feeling nervous, 17% indicated they felt stressed in different situations, and 7% admitted feeling fear. These results indicate that 67% of the children experience an emotion that generates nervousness or fear, whether termed nerves, stress, or fear.

The children perceive themselves as competent in performing mathematical tasks. Even when they found tasks difficult or their grades were not very good, their initial response was that they were good at math. Also, it was rare to find children who valued math for its real-life applicability or intrinsic pleasure, although there were exceptions as a 4th grader expresses: "...if you need a building, you can use them (math), for a video game as well." A pattern of disconnection with the practical relevance of mathematics also emerged, with children expressing that math problems seemed distant and unrelated to their personal experiences. A 3rd grader describes: "Reasoning is boring; they are not my problems."

Discussion

The pilot study collected quantitative and qualitative data about children's attitudes and perceptions towards math. Researchers spoke with the children before the study, creating a trusting environment that made them feel at ease in expressing their true feelings. The children showed interest and enthusiasm, sometimes admitting to not liking math.

Specifically, the situations that cause nerves in students are primarily related to exams, new class topics, difficulty understanding or knowing how to solve a problem or operation, time pressure or the required response speed, and the fear of failure. These findings align with what Hunt et al. (2014) report about the situations that can generate math anxiety. Some children have trouble paying attention in math class, especially if there is noise or their peers speak loudly. As Eysenck et al. (2007) note, attentional control is affected by the presence of math anxiety due to intrusive thoughts or external stimuli that cause worry and distract working memory.

According to the results, children find two-digit division, fractions, word problems, and reasoning the most challenging concepts in mathematics. This coincides with the literature suggesting that these concepts require more working memory and may increase math anxiety (Ashcraft & Krause, 2007). Also, it was observed that children tend to focus on basic mathematical operations and mechanization. This suggests that the mathematical topics covered in class may be limited to the basics, resulting in boredom and frustration. (Boaler, 2016). However, according to the beliefs and values appreciation results, students gave mathematics an average rating of 4.5 points. This indicates that they believe that mathematics is both useful and interesting, and they also consider it to be an important subject. So, one way to increase their interest in mathematics could be to link it with real-life problems that are relatable and relevant to them. This approach might help reduce their perception of the subject as difficult.

Upon investigation, emotional competencies such as perceived self-efficacy, intrinsic motivation, and emotional intelligence were found to be high among the children of the focal school. Scores averaged around four, indicating that the children are emotionally well-adjusted. This study's findings also show a negative correlation between mathematical performance and math anxiety, consistent with previous research (Ashcraft & Moore, 2009). This pattern suggests that a strong emotional foundation can alleviate math anxiety, improving students' mathematical performance. Therefore, the research hypothesis can be supported.

Limitations

Participants might have minimized their true math anxiety to fit social norms, possibly underestimating their actual anxiety levels due to desirability bias. Exam conditions were not included to avoid pressure biases. Although informal interviews were conducted to ease tension, they may not fully reflect real evaluation settings. Therefore, the findings should be interpreted cautiously, considering the differences from actual performance situations.

Conclusion

The pilot test was successfully conducted, allowing for the trial of all instruments with numerous students. Gathering their feedback was crucial for refining the final version, enhancing the quality of the content and the clarity of instructions and questions. The results from this pilot have strengthened the motivation to proceed to a scaling phase, aiming to broaden the research to include a more diverse sample with varying socioeconomic and academic backgrounds. This next phase will help verify whether a lack of emotional skill development is linked to a higher prevalence of math anxiety.

Past studies on children's spatial language have focused on block play or guided play with a focus on monolingual English speakers. In our study, we engaged preschoolers in shape composition guided play tasks with shape blocks. In particular, we present results for five emergent bilingual preschoolers who told stories using tangram puzzle pieces and played a tangram copycat game with a puppet. Results indicate that preschoolers' spatial language focused on different elements between the two tasks, and they code-switched their language mostly when naming shapes or when describing locations or the spatial features of their design.

Keywords: Geometry and Spatial Reasoning; Communication; Early Childhood Education.

As efforts to increase the diversity of STEM professionals continue, attention has turned to the importance of spatial reasoning, particularly with younger students (Taylor & Hutton, 2013). Much of our knowledge about preschooler's spatial reasoning comes from studies that focus on their engagement with blocks and puzzles, demonstrating a correlation between these experiences and their spatial development (e.g., Jirout & Newcombe, 2015; Levine et al., 2012; Verdine et al., 2014). Block and puzzle play naturally encourages the use of spatial language and terminology and gives students tangible experiences with spatial concepts (Ferrara et al., 2011; Levine et al., 2012). Further, these experiences facilitate the formation of mental representations and transformations of spatial relationships among objects in the world (Levine et al., 2012; Reifel, 1984). The use of pattern blocks and tangrams (blocks that emphasize mathematical shapes and are used in shape puzzles) offers additional opportunities for building and supporting spatial reasoning, while also promoting the composition of shapes and the application of shape language, underscoring the importance of language in these educational interactions (Clements & Sarama, 2009; Hallowell, 2020). This research engaged five preschoolers (emergent bilinguals), in two types of shape composition and guided play tasks with tangrams. Our study takes an initial step toward deeper exploration into language and shape composition and seeks to offer unique insights into the co-development of language and spatial thinking in emergent bilingual preschoolers.

Theoretical Framework

Composing Shapes and Spatial Language

In their analysis of spatial language across tasks with caregivers and children, Cannon et al. (2007) developed a system for analyzing spatial language across a series of dimensions, including spatial dimensions or sizes, shape names, locations and directions, deictics (e.g., this, that), orientations and transformations, amounts, spatial features or properties, and pattern words. Ferrara et al. (2011) compared caregivers' and preschoolers' spatial language depending on if they freely played with blocks, followed a set of directions to make a specific block structure, or played with a model made out of blocks. Caregivers and preschoolers used significantly more spatial language when building based on directions than when freely playing. Further, the preschoolers tended to use more location and deictic words across all conditions, while shape and orientation words were used the least (Ferrara et al., 2011).

Instead of having students work with caregivers, Cohen and Emmons (2017) investigated monolingual English students' (ages 4-5 and 8-12) language while they built predetermined types of block structures. For example, they might have to build something a certain number of inches wide and tall with a specific number of blocks. Similar to results found by Ferrara et al. (2011), students used location words the most; however, their second most references were to continuous amounts. Further, students rarely used shape and orientation words, and they also did not refer to spatial features much.

Use of Storytelling in Mathematics

In her analysis of storytelling in mathematics, Rodríguez (2007) asserts that storytelling in mathematics initiates early in childhood, influenced by cognitive development, language modeling, and expressive opportunities. She suggests that storytelling concurrently enhances literacy and mathematical skills by providing structured narratives with recognizable characters and language patterns, fostering crucial imagination and abstraction. This method in math education offers various benefits including contextualizing concepts, fostering connections, developing competencies, and motivating young learners aged 3 to 6.

Furthermore, Julca Fernández (2019) utilized storytelling alongside tangram puzzles to assess geometric skill development in Peruvian kindergarten students. Twenty participants were equally divided into experimental and control groups. Following the story presentation, experimental group students employed tangram shapes to recreate story scenarios. While pre-test results indicated moderate geometric skills in the experimental group, post-test outcomes demonstrated significant improvement, particularly in recognizing, representing, and distinguishing two-dimensional shapes, along with problem-solving related to object positions and movements. Notably, advancements were observed in identifying and graphically representing object positions relative to others.

Code Switching and Translanguaging

English immersion programs often adhere to the "two solitudes" assumption, favoring exclusive instruction in the target language (L2) while overlooking students' first language (L1) (Cummins, 2008). However, extensive research by Baker (2011), Creese & Blackledge (2010), Cummins (2008), and Lindholm-Leary (2006) underscores the transferability of literacy-related skills across languages, particularly affecting literacy development and math education. Recognizing emergent bilingual students' oral language development in STEM subjects is pivotal for favorable academic outcomes, yet their language practices are frequently marginalized, stifling their authentic voices (Flores, 2013). To counteract this, Flores advocates for embracing the fluidity of language to mitigate "linguistic Othering." This project adopts an ecological perspective on multilingualism (van Lier, 2004; Hornberger, 2002) and the Dynamic Model of Multilingualism (Herdina & Jessner, 2002), viewing emergent bilingualism as a cohesive dynamic system rather than distinct populations. Furthermore, García's (2009) notion of languages as dynamic processes informs the exploration of how translanguaging strategies correspond to mental imagery, spatial analysis, and verbal explanations in shape composition and embedding among emergent bilingual students.

Translanguaging acknowledges the utilization of various modalities and semiotic resources beyond linguistic signs, facilitating the "resemiotization" process (Iedema, 2003), where actions are reconceptualized across different semiotic modes, perpetually generating new meanings. Adopting a transmodal approach, which involves the movement of ideas across different communication modes (Murphy, 2012), challenges traditional cognitive-centric views of learning by recognizing the holistic nature of language acquisition, incorporating physical, emotional, linguistic, and artistic dimensions. This perspective promotes a dynamic construction of meanings through simultaneous engagement with multiple modalities, allowing learners to flexibly navigate diverse modes and enhance adaptability and expressiveness in constructing and conveying meanings (Newfield, 2014).

Current Study

We build on prior research by focusing on preschoolers' spatial language when working with two different types of shape composition tasks. In particular, we focus on emergent bilinguals whose home language is Spanish, Mandarin, or other languages. Our research questions include the following: (1) How do preschoolers' use spatial and shape language in a storytelling versus shape creation task? (a) In what ways does background knowledge support their explanations? (b) How does code switching play a part in emergent bilingual use of language in the tasks?

Method

Participants and Setting

We recruited 18 preschoolers between the ages of 3 and 5 from a midwestern city, targeting preschoolers who speak home languages known by our researchers: English, Spanish, or Mandarin. We chose 5 of these preschoolers to focus on to represent those whose home language is Spanish (2 preschoolers), Mandarin (2 preschoolers), and Hindi (1 preschooler). Notably, of the six researchers, two speak Spanish, two speak Mandarin, but none speak Hindi.

Preschoolers whose home language was Mandarin and Hindi were part of a daycare program that offered an English-only curriculum. Preschoolers whose home language was Spanish were part of a daycare that centered on free-play. Because the Spanish-speaking preschoolers were not yet part of an English-only curriculum, they resorted to speaking Spanish. To investigate a wide range of language situations, the researchers used English and the preschoolers' home language in different ways. For instance, our Spanish speaker researchers would begin implementing the tasks in Spanish but would switch to English if the preschooler would begin using English. They also would use English strategically if they suspected the preschooler did not know the Spanish vocabulary. In addition, both researchers speak a different variety of Spanish (Argentinian and Mexican) and adjusted the language to the one used by the preschooler. Our Mandarin researcher also used languages strategically. She used both English and Mandarin, often switching to Mandarin if the preschooler was not verbally responding.

Design and Materials

Overall, we worked with each preschooler across four sessions. In Session 1, we worked with them individually on tasks to help us understand their spatial reasoning and initial strategies and language around composing shapes and solving tangram puzzles (Figure 1). In Session 2, they worked with a partner to make different shapes from the tangram pieces and play a copycat game where one child would make a design and explain to the other child how to make it. In Session 3, preschoolers listened to the story *Three Pigs, One Wolf, and Seven Magic Shapes* and created their own version of the story by making additional objects from the tangram pieces to protect the pigs from the wolf. In Session 4, preschoolers did similar activities as in Session 1.

Figure 1: Pieces of a Tangram Puzzle

The focus of this paper is on the storytelling activity in session 3 and puppet task from session 4. For the storytelling task, preschoolers listened to the story *Three Pigs, One Wolf, and Seven Magic Shapes.* The Mandarin and Hindi speaking preschoolers heard the story in English, as was typical at their daycare. However, the Spanish speaking preschoolers wanted to hear it in Spanish, so the Spanish researchers translated it while reading. In this story, three pigs receive tangram pieces from a "magical creature" that instructed them to create an object to protect themselves from the wolf. The first and second pigs create a "cat" and a "candle," respectively, and are not successful at protecting themselves. The third pig, however, defends himself from the wolf by constructing a house and later sails away with his wife by creating a "sailboat" using the magical tangram pieces. At the end of the reading, the preschoolers used the tangram pieces to create more objects to protect more pigs from the wolf.

For the "puppet task," preschoolers created a design using the tangram pieces and then explain to a hand puppet (controlled by a researcher) how to copy their design. The puppet asked them prompting questions in order to do its design. In both tasks preschoolers were able to use whichever language they felt most comfortable, which resulted in researchers sometimes switching between languages to accommodate the preschoolers' linguistic choice. At times, some of our English-only researchers worked with emergent bilinguals, in these situations preschoolers were only using English during their explanations.

Analysis

To analyze the language the children used during the tasks, we used the framework developed by Cannon et al. (2007) but added additional codes. During our analysis, we nested their *Spatial dimension* and *Spatial features* codes into one *Spatial Features/Properties* code to better capture any reference in our particular tasks that would be intrinsic to the properties of the shapes we gave the preschoolers. To capture names that they gave to either individual shapes or composites of shapes that did not align with standard 2D or 3D shape names, we created a *background knowledge* code. This code also captured additional details preschoolers provided about the shapes that were descriptive (e.g., it shoots fire) but not standard *shape features*. We also added subcodes within each category so that we could capture their gestures, corrections, and references to the materials we used (e.g., storybook, paper with colored blocks). Because we were working with emergent bilinguals, we also included *code switching* and *translanguaging* codes to indicate when they switched between languages and/or used a dynamic and transmodal use of language. Finally, we included *leading* and *misleading* codes to help us locate points where the researchers were prompting for more information either by asking directly or purposely saying or doing the wrong thing in order to get preschoolers to correct them with additional language. See Figure 2 for descriptions of the codes.

We coded the first transcript together, then transcribed and coded all other transcripts, and went back through them together to address any questions. We coded the transcripts using a computer assisted qualitative data analysis software program (Dedoose). We included a coding scheme drawn from Cannon et al. (2007) as well as themes emerging from the data in the codebook. The codebook included 15 major categories and 41 subcodes.

Code	Description and Examples
Background knowledge	Participant uses background knowledge (experiences) to retell or explain. Makes connections with their everyday world / self
Code-switch	Participant alternates between two or more languages or varieties of language in conversation
Translanguaging	Participant draws upon different linguistic, cognitive, and semiotic resources to make meaning and make sense
Continuous amount	Words that are used to describe amount (including relative amount) of continuous quantities (including extent of an object, space, liquid, etc.).
Deictics	Words that are place deictics/ pro-forms (i.e., these words rely on context to understand their referent).
Location/direction	Words that describe the relative position of objects, people, and points in space.
Shapes	Words that describe the standard or universally recognized form of enclosed two- and three-dimensional objects and spaces.
Spatial features/ properties	Words that describe the size of objects, people, and spaces (e.g. small, large, big) *AND* the features and properties of 2D and 3D objects, spaces, people, and the properties of their features (e.g., round, bump, strong).
Spatial orientations/ transformations	Words that describe the relative orientation or transformation of objects and people in space.
Pattern	Words that indicate a person may be talking about a spatial pattern (e.g., big, little, big, little, etc. or small circle, bigger circle, even bigger circle, etc.).
Gesture	Participant moves of part of the body, especially a hand or the head, to express an idea or meaning (e.g., pointing)
Leading	Investigators prompted for more information by asking directly in order to get students to respond using additional language
Misleading	Investigators prompted for more information by purposely saying or doing the wrong thing in order to get students to correct them with additional language
Self-correct	Participant gives wrong answer and self-corrects with correct answer
Use of book/mat	Participant uses the storybook, or the 4-color mat provided in order to complete or add more information to his/her explanation

Figure 2: Language Codes (based on Cannon et al., 2007)

Results

The preschoolers' use of spatial language varied drastically between the two tasks (Storytelling and Puppet) we analyzed. First, we present results for preschoolers' language use in the two tasks, highlighting specific examples of their language use. Finally, we discuss results related to their code-switching and translanguaging.

Storytelling Task

In line with the descriptive nature of the storytelling task, the preschoolers mainly focused on using names for the shapes that were not standard shape names but reflected their *background knowledge* of objects (Rodríguez, 2007). For example, Mister used the shapes to make a house to protect the pig. She then pointed to the parallelogram and said, “This is a chimney.” Next, she pointed to the medium triangle and explained, “This is the roof” (See Figure 3A).

Preschoolers also discussed *spatial features* of their shapes more in this task, often to explain the objects that they created. Rosa did this when she decided to create “*manos fuertes*” (strong hands) to defend the pig from the wolf, later adding that she wanted to make “una mano larga” (a long hand) and then “una mano gigante” (a gigantic hand) to her spatial features descriptions. When asked by one of the researchers to describe how her design looked like a hand (prompting her use of *background knowledge*), Rosa replied by stating that the shapes were “*los huesos*” (the bones) while the invisible/transparent part of her design (“*transparente*”) was the actual hand, a feature that would allow the pig to trick the wolf who would be unable to see the hand approaching (See Figure 3B).

Figure 3: Mister’s (A) and Rosa’s (B) Storytelling Pictures and Snow’s (C) Fox for Puppet

Puppet Task

In the puppet task, compared to storytelling, preschoolers more frequently utilized specific shape names, location words, and language related to spatial orientations to guide the puppet in replicating their design. They complemented their spatial language with gestures for clearer expression. They recognized all shape names from session 1, except for the more complex parallelogram. For instance, when prompted, "What’s this?" Snow responded, "The big one, the big triangle" while pointing to it.

They expressed abundant spatial feature words to explain their pieces and designs. For example, they used dimension words like small, medium, big to distinguish different sizes of triangles as well as color words. For example, Snow said, “This orange one goes here.” It's noteworthy that the researchers’ leading language included more deictics in this task too, which may have encouraged the students to speak more deictically. In fact, while they used fewer spatial orientation words, many of their orientation instructions combined deictics with gestures.

Some preschoolers used numerous location words. For example, Mister utilized a 4-color mat to clarify locations to the puppet, stating, "You need to put it at the middle" (glancing at the mat), then correcting to "At the bottom…no…at the top…" finally deciding on "No, at the middle top," and "put next to…" followed by "you make closer to these."

Their use of deictics was rich in spatial meaning, aiding the puppet's understanding of their references, going beyond just spatial orientation and location. They were also more likely to draw on deictics as they tried to get the puppet to move shapes “here” or “there” or “like this” or “that way.” When referencing specific shapes such as "parallelogram," they used "this" along with gestures to enhance their instructions. For example, Snow made a “fox” design for the puppet to copy. She placed the parallelogram and two big triangles and then said, “Then the two small triangles, one goes here, and one goes like this” (she used her finger to draw the outline of the triangle's orientation). She used "small" to distinguish which triangles to use but used deictics to help explain their location and orientation (along with hand gestures, Figure 3C).

Preschoolers' exploration of spatial descriptions was not confined only to the manipulation of the tangram shapes. Rather, they demonstrated a heightened awareness of positioning in reference to themselves and others. For instance, Rosa guided the puppet (handled by R3) on where to stand even before beginning the task. Employing deictic expressions such as "*párate aquí*" (stand here), Rosa showed her proficiency in conveying spatial instructions to have the puppet move next to her, thus sharing her vantage point. Additionally, she displayed her knowledge of location and direction by instructing the puppet to move "*más cerca*" (closer) when dissatisfied with the position chosen by R3 for the puppet.

Language Features

Code switching. We decided to identify as *code-switching* every time preschoolers alternated between two or more languages or varieties of language in conversation. For instance, Figure 4 shows part of the storytelling task when Mister is describing the houses she created to protect the pigs from the wolf. Here (Lines 4-6), Mister describes her houses as a strong house and a stick house. R4 (Lines 7-10) wants Mister to be more specific about what she means by "stick house" and prompts her to use and think in Chinese. Mister responds "wooden house" which provides more detail as to the way the house is built and adds to the *Spatial features/ Properties* of her design.

Translanguaging. Just like we coded for instances where speakers alternated between languages, we also identified instances where translanguaging instances were observed, where preschoolers drew upon different linguistic, cognitive, and semiotic resources to make meaning and make sense of the world around them.

Figure 5: "Los Triangles"

Figure 5 shows how Olivia used both *code-switching* and *translanguaging* in order to explain to the puppet (handled by R3) how to copy her design. We observed that Olivia *code-switched* between Spanish and English mostly when referring to *Shapes* (Lines 1, 7, 8) and *Spatial Features/Properties* (Line 8). Since Olivia does not receive any formal Math instruction in her daycare, we are uncertain as to how she has acquired her English vocabulary, and we hope to be able to explore this further by performing parent interviews regarding home practices. Nevertheless, Olivia would display *translanguaging* elements by making use of semiotic resources, such as specific hand gestures and movements [Lines 12 & 14], in order to make meaning and be able to better express her answers. Therefore, to comprehend the task and communicate effectively, Olivia would not only utilize her linguistic/bilingual abilities but would also draw upon her complete range of semiotic resources.

Discussion and Implications

In examining preschoolers' engagement with storytelling and puppet tasks, we observed distinct uses of spatial language. The storytelling task saw the creative labeling of shapes based on background knowledge, enriching narratives with imagination. In contrast, the puppet task saw a more precise use of spatial language, with children employing specific shape names and location words, often accompanied by gestures, to guide a puppet in replicating a design. This contrast underscores the adaptability of young learners in applying spatial reasoning and language differently across contexts, moving from imaginative storytelling to detailed, instruction-based communication.

Overall, preschoolers' use of spatial language was closely aligned to the perceived needs of the tasks. As found by Ferrara et al., (2011), our preschoolers did not use shape names as much when storytelling because they were more focused on describing the resulting object (coded as *background knowledge*) that they composed with the shapes, which falls in line with the descriptive nature of the storytelling task (Rodríguez, 2007). Further, they named *parts* of their objects using this background knowledge rather than the individual shape names (e.g., chimney instead of parallelogram). This suggests that investigations into spatial language need to account for these contextual differences. At the same time, the preschoolers were very excited to share about their objects, leading them to provide more context for the object and description of the spatial features. Therefore, their background knowledge supported additional language use, even if the language did not focus on specific spatial terms. Future storytelling tasks could encourage more shape and location language in two ways. First, we could modify the story to include more language about which shapes the pigs used and how they composed them to make the objects to defend themselves from the wolf. Second, we could have preschoolers narrate a manual for creating their object so that other pigs could make the same thing. Similar to the puppet task, creating a manual could encourage preschoolers to use more location and shape names.

In this study, we also adopted a dynamic and fluid perspective on bilingualism, framing translanguaging as a bilingual approach focused on observable practices where linguistic features from different languages intertwine (Garcia, 2009). Translanguaging encompasses various discursive practices through which bilingual individuals navigate their linguistic realities, surpassing mere code-switching and translation, and involving the performance of bilingualism across diverse modalities (Garcia, 2009). Consequently, we categorized instances of *translanguaging* as any occurrences where preschoolers utilized different linguistic, cognitive, and semiotic resources to construct meaning and interpret their environment. Throughout our project, we observed numerous instances of *code-switching* and *translanguaging* practices among emergent bilingual preschoolers, particularly when paired with researchers who shared their native language. Preschoolers would often switch between languages when naming or describing shapes or designs, with researchers following their lead by continuing in the chosen language. Alternatively, researchers sometimes encouraged the use of the preschoolers' native language if they encountered difficulty in naming or describing something specific. This approach is significant, especially in language immersion settings like ours, where preschoolers are typically encouraged to respond only in English. By adopting a *translanguaging pedagogical lens* (Cenoz & Gorter, 2022), we aimed to soften the boundaries between languages and support the development of all languages utilized by the preschoolers.

MATH IDENTITY AND MATH APPS: WHAT IN COMMON?

Micah Swartz
Texas State University
mas762@txstate.edu

In recent years, mathematics app use (e.g., DreamBox, Prodigy, Reflex) has continued to become more prevalent in K-12 and most math app research has examined achievement-related outcomes. The present study is part of a larger exploratory multiple-case study examining students' mathematical identity as it relates to math app use. Utilizing Cribbs et al. (2015) framework for math identity, I analyzed one student's math identity separated from technology (math identity) and related to technology (math technology identity). This paper introduces the case of Sarah, a third grader whose math identity, particularly her view of math, is impacted by her weekly use of math apps.

Keywords: Technology; Online and Distance Education; Affect, Emotion, Beliefs, and Attitudes.

Introduction

In recent decades, the adoption of blended learning (BL) has increased both nationally and globally (Barbour, 2018). BL has evolved into a comprehensive term encompassing programs that incorporate online learning (Hrastinski, 2019). Among the technologies commonly employed in BL programs, math apps have become particularly prevalent (Cleveland-Innes, 2018) and have been acknowledged as an influential part of learning mathematics (Griffith et al., 2020; Laato et al., 2020). Math apps have gained substantial popularity worldwide with over 14 million students using IXL worldwide (IXL, n.d.), one in four elementary students in the U.S. using Zearn (Zearn, n.d.), and six million students in the U.S. engaging with DreamBox (DreamBox Learning, 2022). A 2022 national survey of U.S. teachers revealed that more than a third of the additional instructional materials used for teaching math were comprised of math apps (Doan et al., 2022). Existing literature indicates that identity is an important aspect of students' learning experiences as it impacts their success and well-being in the classroom, and identity "play[s] a fundamental role in enhancing (or detracting from) [students'] attitudes, dispositions" (Bishop, 2012, pp. 34-35; National Research Council, 2001; McCarthey & Moje, 2002). Presently, there exists only one research paper on the relationship between math identity and math apps. Crossley et al.'s (2020) yearlong investigation of upper-elementary students' use of the math app *Reasoning Mind* revealed no substantial evidence indicating a change in math identity throughout the study period. This suggests that (a) little is known about the ways widely used math apps such as Reflex and Prodigy may influence identity, and (b) consequently, my proposed study can fill an important gap in the literature. The following research question guided this study: What is the relationship between math apps and a student's mathematical identity? I now describe my theoretical framework and the literature that guided my study.

Literature Review and Framing

The focus of the current study is to examine the relationship between math app technology and students' mathematical identities. My working hypothesis is that technology, a key part of students' learning environment, impacts the way students relate to mathematics and others in their class. Thus, technology impacts students' mathematical identity development and formation. It follows that I view identity as situated—that is, identity is a product of being, learning, and interacting within one's environment (Holland et al., 2001; Lave & Wenger, 1991; Wenger, 1998). This view of identity is also related to one's membership in a community (Lave and Wenger, 1991; Wenger, 1998) and the shared experiences of this group. Thus, I utilize Cribbs et al.'s (2015) framework for mathematics identity and view of mathematics identity as composed of the three interrelated factors of interest, recognition, and introspection (Figure 1). I chose Cribbs et al.'s identity framework because a key component of their framework focuses on how students perceive others to view them in relation to mathematics (Recognition). Their framework not only places an emphasis on recognition as a key factor of mathematics identity, but it also explicitly links Recognition to students' views of themselves related to mathematics—what is labeled Introspection in Figure 1—and students' view of math (what is labeled Interest in the figure).

In utilizing Cribbs et al. (2015) framework for mathematics identity, I use their factors of interest and recognition without any alterations or modifications to how they define these constructs (see Figure 1). However, I combine their factors of competence and performance, into one factor that I rename Introspection. Cribbs and colleagues define competence as "students' beliefs about their ability to understand mathematics" (p. 1051) and performance as students' "beliefs about their ability to perform in mathematics" (pp. 1051-1052). I combine Cribbs et al.'s factors of competence and performance into the single term Introspection for simplicity and ease of operationalization and broadly define this term as a student's view of themself related to math.

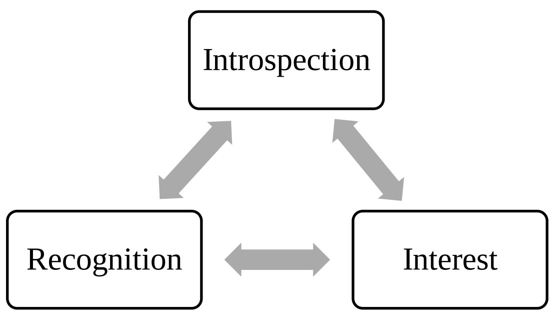

Figure 1. Cribbs et al. (2015) mathematics identity framework with Introspection in place of competence/performance.

Methods

This preliminary report was part of a larger exploratory multiple-case study that examined third graders' math identity and motivation related to their weekly use of math apps. The multiple-case study consisted of eight cases that were carefully chosen from a pool of participants in a classroom, each representing diverse mathematical identities and motivations. The focus of this preliminary investigation was on Sarah's case due to her insightful reflections and the revelatory nature of this case (Yin, 2016). Particularly, Sarah clearly articulated how the different utilized math apps related to her view of math, view of self, and how others viewed her while other third graders had a harder time expressing their math identity as it related to math app use. The two math apps utilized every week in Sarah's class were Reflex and Prodigy. Sarah's classroom is a part of X Elementary School, a large public elementary school located in the southern United States. X Elementary School has an economically disadvantaged student enrollment of 16% and over 70% of the school's students scored at or above the proficient level on the state math test. Drawing on the three components of math identity outlined by Cribbs et al. (2015), I used interest, introspection, and recognition as a priori codes (Miles et al., 2014) to analyze Sarah's responses to two sixty-minute semi-structured interview protocols (Rubin & Rubin, 2011). The first interview took place in the fall of semester 2023 while the second interview was conducted in the spring semester of 2024. Using interest, introspection, and recognition to serve as column heads of the math identity profile I created for Sarah, I analyzed her two interviews by creating a meta-matrix (Miles & Huberman, 1994) to keep track of her math identity separated from technology (math identity) and related to technology (math technology identity).

Findings

I start by summarizing Sarah's math identity and math technology identity (see Table 1). Several features of the math apps Reflex and Prodigy afforded varying opportunities for self-recognition, recognition, and shaping Sarah's view of math. In the sections that follow, I further explore Sarah's math identity and her math identity related to math apps.

Table 1. Overview of Sarah's Math Identity and Math Technology Identity

	Sarah's Math Identity		
	Interest	*Introspection*	*Recognition*
Interview 1	Sarah felt math was frustrating when she struggled, but experienced joy from getting correct answers.	Sarah viewed herself as good at math and a mathematician, but "not the best person at math."	Sarah believed her teacher, friends, and parents view her as good at math, but was clear she would not be voted as the best at math.
Interview 2	Sarah believed doing math meant solving problems you may have not seen before.	Sarah expressed confidence in her ability to do math, but no longer viewed herself as a mathematician.	While Sarah felt many people in her class are better than her at math, her peers would still view her as good at math.
	Sarah's Math Technology Identity		
	Interest	*Introspection*	*Recognition*
Interview 1	Reflex and Prodigy made doing math more fun, but Sarah acknowledged there is little math on Prodigy.	Prodigy and Reflex did not affect how Sarah saw herself as a math student.	Prodigy has a multiplayer game feature, but Sarah felt seeing avatars made it harder to understand her classmates' emotions.
	Sarah felt frustrated that math	Sarah felt good about her math ability	Prodigy is an app Sarah does not play when

Interview 2	was too much of a game when playing the math app.	when playing Prodigy but felt stressed by the timer on Reflex.	given the change and feels math apps have no bearing over how she is recognized.

Sarah's Math Identity

Sarah's view of math, or interest, was tied strongly to her performance and success. When asked what it meant to do mathematics, she responded, "to be fluent on most of your addition and subtraction facts." She also described the "feeling when I finish, um, a math question of get it correct" as the moment that mathematics is most enjoyable. During the second interview, Sarah's view of math had shifted to reflect an algorithmic and computational view of mathematics similar to that of the math played on Reflex. Sarah said, "I do not like showing my work when I could do the algorithm easily." Her enjoyment was still rooted in her success, and she said, "I like solving math problems because I'm good at it." Sarah's view of herself, or introspection, remained largely unchanged from the first to the second interview. In both interviews, she expressed viewing herself as good at math but was quick to point out there were several students better than her. However, during the first interview, Sarah considered herself a mathematician, but by the second interview, this was no longer the case. While her grades indicated she was good at mathematics and gave her confidence in her ability, she no longer felt she was a mathematician. Sarah was recognized by her classmates, teacher, and parents as good at mathematics in both interviews. She noted that while her peers all recognized her as good at mathematics, they also wouldn't vote her as the class mathematician at the end of the year.

Sarah's Math Technology Identity

During the first interview, Sarah expressed the math apps as having a significant role in how she viewed mathematics. Prodigy and Reflex made doing math more enjoyable, but by the second interview, she seemed to no longer enjoy the math apps. Further, she was frustrated by how much they had transformed math into games, saying "Math apps just kind of make it too fun when math is supposed to work. I kind of like, I like work." Sarah's view of herself remained unchanged by doing math on Prodigy and Reflex. This was in part due to the math apps not "really having that much of an effect on learning," but also because of Sarah's unchanging confidence in her ability to do math. However, certain attributes of the math apps such as the problem timer on Reflex stressed Sarah out and caused her to feel more anxious about doing mathematics. A multiplayer game feature of Prodigy allowed students to recognize each other but for Sarah, the avatars made it harder to understand the emotions of her classmates. She said, "Some of the avatars, they're just frowny faces the whole time, and then like mine just has the same expression." Because of these virtual characters, Sarah felt Prodigy allowed for fewer opportunities to genuinely interact and be recognized by classmates.

Discussion and Conclusion

While these results are preliminary, they suggest features of math apps relate differently to components of a student's math identity. For Sarah, the gamified nature of Prodigy and Reflex was at odds with how she viewed mathematics. This caused her distress as she experienced dissonance between how she was experiencing mathematics and what she believed mathematics was. Sarah also detailed features of Reflex and Prodigy that related to her views of herself and how others viewed her, but she felt neither app impacted her learning. One limitation of this study is its singular focus on the math identity of a single student, which precluded a comparative analysis of math identity across multiple participants. Future investigations and reports might expand their scope to include a broader range of participants, such as additional elementary students or individuals from diverse grade levels. I view research concerning elementary students' math identity in the context of math app usage as a crucial yet insufficiently explored domain within K-12 mathematics education. Given the growing prevalence of such technology, it is essential to persist in exploring various facets of students' math identity.

As the demand for STEM jobs increases, central to the success of STEM education and careers is a strong foundation in mathematics. However, students' interest in mathematics is often very low. Thus, it is imperative to cultivate interest in mathematics among high school students. To promote students' interests and positive attitudes in mathematics, we implemented informal learning using design-based research (DBR). We show that DBR is a compelling and suitable methodology for our research aims. Then we report how DBR can extend from previous studies in using informal learning for mathematics and foster motivating learning ecology in a school setting. Our DBR project has completed four iterations.

Keywords: Informal Education; Design Experiments; Affect, Emotion, Beliefs, and Attitudes; High School Education

It is well known that global job growth will be mostly concentrated in the high-skilled areas of healthcare and STEM (McKinsey & Company, 2023). For example, the US Bureau of Labor Statistics (2023) projected a 15% overall growth of computer and mathematical jobs in the next eight years, with jobs in data science and statistics experiencing 35.8% and 32.7% increases, respectively. However, education statistics imply that the supply of mathematicians and scientists entering those fields may soon be insufficient to satisfy the demand. The awarded mathematics and statistics bachelor's degrees growth rate is significantly lower than other STEM fields, despite an increasing trend of the overall STEM fields. According to Digest of Education Statistics (2023, Table 322.10), over the past decade, the annual growth rate of awarded bachelor's degrees in computer and information sciences was 22 times higher than that of mathematics and statistics, engineering growth 12 times higher, and biological and biomedical sciences growth 9 times higher. The number of high school students completing advanced mathematics courses (i.e., calculus) declined in the decade of 2009-2019 (NCES, 2022). Thus, it is imperative to cultivate interest in mathematics among high school students, which will eventually align the number of college students pursuing STEM degrees with workforce needs.

Informal learning, a type of *less classroom-bound, free-choice education* (Falk, 2001), has recently gained traction for improving STEM learning and for improving engagement in mathematics (Denson et al., 2015; Pattison, Rubin, & Write, 2017; Waldock et al., 2016). The "informal" and "free-choice" characteristics of informal learning make it an ideal medium for delivering education in uncertain times, offering a "free-choice" approach to engaging with information and knowledge. Cultivating positive mathematics or STEM identities is often a central focus for designers of informal learning experiences (Bell & Bevan, 2015; Feder et al., 2009; Zimmerman & Bell, 2012). We suggest that design-based research (DBR) from the learning sciences is a compelling and suitable methodology for exploration of both informal learning of mathematics and its outcomes measurement among high school students. In this paper, we report how DBR can extend previous studies in using informal learning for mathematics and foster motivating learning ecology in school settings. To exemplify, we briefly report on an NSF-sponsored DBR project that completed four iterations.

Theoretical Framework and Research Aims

Drawing on theories of experiential learning (Kolb, 1984) and related to active learning programs that have been shown to increase performance and motivation in STEM (Freeman et al., 2014; Weinberg et al., 2011), informal learning, as a type of less classroom-bound and more free-choice education (Falk, 2001), includes a wide array of experiential learning instances that happen when students actively engage in learning opportunities outside of the traditional context of teacher and classroom. Much of the research on informal learning emphasizes identity, seeking to influence identity as well as to understand identity development (Bell et al., 2009; Pattison et al., 2017). Math identity is believed to be an important component of students' achieving success in mathematics (Allen & Schnell, 2016; Bohrnstedt et al., 2020; Gonzalez et al., 2020). Identity work can be conceptualized as a process of alignment, drawing upon Anderson's (2007) four-dimensional model of mathematical identity as well as Wenger's (1998) three modes of being – alignment, imagination, and engagement. Furthermore, studies have shown that peer and near-peer led activities have a strongly positive impact on students (Brownell & Swaner, 2010; Carrell & Sacerdote, 2013; Cracolice & Deming, 2001; Quitadamo et al., 2009; Trujillo et al, 2015; Williams, 2009). In our project, we combined the processes of mathematical identity alignment with the supporting structure of near-peer mentoring.

Differing from many existing educational studies on informal learning that focused on activities held mainly in certain out-of-school or after-school settings, we seek a design scheme or solution for the infusion of near-peer, informal learning of mathematics for high school students in the school setting.

DBR – Literature Review and Why

Brown (1992) defined DBR in her seminal paper, followed by many literature references to DBR, including earlier ones focusing on the "what" and more recent papers shifting to the "how" of DBR (Puntambekar, 2018). Extending Anderson and Shattuck's (2012) review of the potential of DBR, of the characteristics of good DBR studies, and of the growing popularity of DBR approaches in educational research, Fowler et al. (2022) reviewed DBR studies completed in the decade up to 2011. Beyond being a specific research method, DBR is an approach that centers a series of iterative (often educational) designs as the unit of investigation, and frequently employs mixed research methods and tools. Two recent studies (Hoadley & Campos, 2022; Scott et al., 2020) demonstrated DBR's implementations in online learning and biology education. Scott et al. (2020) summarized what DBR is and pointed out four differences between DBR and experimental approaches, which deserves readers' special attention because most researchers and scientists are well trained for experimental approaches rather than DBR method.

Why We Chose DBR?

Design-based research (DBR) from the learning sciences, although considered a relatively young (about three decades old) educational research methodology, is compelling and suitable for our research aims. DBR has no solid requirements of instructional intervention form or evaluation measurements. Rather, the intervention design as well as outcome measurements can be developed or employed during the design process (Anderson & Shattuck, 2012; Sandoval, 2014). DBR focuses on investigating what the design process is and how it can be generalized (Cobb et al., 2003). Due to these features of DBR, it is suitable for innovative research in certain learning scenarios, such as ours. Tailoring the intervention and implementation process needs multiple iterations instead of a one-shot deal. Furthermore, the DBR approach enables a flexible methodology that accommodates specific situations, proving resilient and robust even in highly uncertain times. Notably, our project commenced amidst the COVID pandemic, and the DBR approach facilitated the customization of each iteration to suit the unique circumstances of each time period, as well as the progressing of our research agenda.

Our DBR Project

Following preliminary explorations and a smaller scale pilot study (Wilson and Grigorian, 2018) showing that near peer interventions have the potential to positively affect attitudes to mathematics, we carried out an NSF-funded project on informal learning of mathematics. Over the course of three years, this project involved 1,258 students from four high schools in two majority-Hispanic school districts in South Texas.

DBR Iterative Redesign Process

The DBR iterative redesign process is visually represented in Figure 1. In each iteration, the evaluation of both the delivery of the experiences and the data collection processes provided insights that informed the subsequent iteration's design. This resulted in a continuous cycle of innovation, evaluation, and refinement that ensured the experiences and the associated research methodologies remained responsive and adaptable to the unique learning contexts and challenges encountered throughout the project duration. To illustrate our design process for informal learning of mathematics in a school setting, we summarize the iterations.

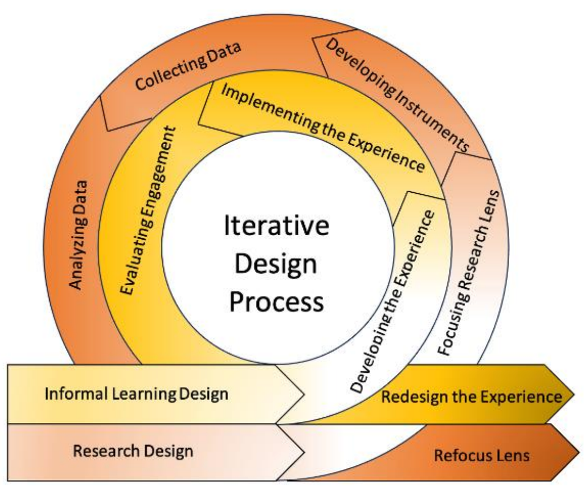

Figure 1: Iterative Informal Learning and Research Design Processes

The 1st iteration. We started in spring 2021 with fully online, synchronous MathShows presented to groups of classes via Google classrooms. The online modality was precipitated by COVID-19 pandemic restrictions. Viewing of brief pre-recorded video scenes produced by college student near-peers followed by live interactions with same near-peers via video and chat.

The 2nd iteration. An easing of COVID restrictions and resumption of in-person schooling required changes in the program design in Fall 2021. For this iteration, live, in-person MathShows were performed in a large school auditorium, with multiple classrooms in attendance simultaneously and combined viewing of pre-recorded video scenes and interactive activities with near-peer mentors.

The 3rd iteration. Live, in-person MathShows were performed in a large school auditorium, with multiple classrooms in attendance simultaneously. There were no pre-recorded video scenes, with more audience interaction, more prize opportunities for students, and more scripted acting by near-peers.

The 4th iteration. Live, in-person MathShows were performed by a smaller cast of near-peer mentors in individual classrooms, not in an auditorium. This allowed much more direct interaction between students and near-peer mentors, but each MathShow was shorter.

DBR-Iterative Instrument Design

DBR experiments are resource intensive (Scott et al. 2020). For the research aims of our DBR project, we collected large amount of qualitative and quantitative data via mixed methods. We hereby spotlight one instrument item for its iterative design process. During the 1st and 2nd iterations, as one of the main quantitative measures, this study used a mathematics identity survey item that was adapted from well-established attitude surveys. Students were asked to choose from a Venn diagram to describe how much they align with being a mathematician. In the focus group studies during the 1st and 2nd iterations, high school students shared their various perceptions of a mathematician. We followed up by asking them the reason for their response to the math alignment question. These qualitative studies revealed to us that when respondents saw the Venn diagram, the circle of "Mathematician" may have different meanings to them and also students have different reasons for making their choice. To capture these differences in perception, based on students' focus group input and using some of their exact words, we developed two novel items for surveys for subsequent DBR iterations to collect students' understanding of mathematician and reasons for their alignment choices.

Discussion and Conclusion

Our project shows that by employing DBR for designing and studying learning interventions, mathematics educators can develop both theory and practices for the informal learning of mathematics. For instance, the identity-measurement instruments developed in our DBR process exemplify how DBR invites utilization of mixed methods synergically. An example in this study of qualitative research informing quantitative research is that focus group interviews (qualitative research) captured students' perceptions of who a mathematician is. We then developed two more survey items (quantitative research) with choices written based on those high school students' words. On the other hand, as an example of quantitative research informing qualitative research, in later iterations, focus group studies consisted of participants pseudo-randomly recruited with a stratified sampling method based on certain quantitative data to ensure the inclusiveness of different types of students in the focus group. In addition, the design scheme developed in our DBR project is generalizable to broader learning settings. Middle and elementary schools are potential places for informal learning of mathematics. Moreover, math teachers may also be able to incorporate short and attention-catching informal learning components in their classrooms that nurture students' positive academic emotions. Similar expansion can be made to colleges as well.

Acknowledgments

We are grateful to the many teachers and students who participated in this research study. We are grateful for the generous support of this study provided by the NSF AISL grant #2006067. Any opinions, findings, and conclusions or recommendations expressed in this material are those of the authors and do not necessarily reflect the views of the NSF.

RELEVANCE FOR WHOM?: STUDENT REFLECTIONS ON RELEVANCE IN MATHEMATICS EDUCATION

Travis Weiland

Keywords: Curriculum, Data Analysis and Statistics, Culturally Relevant Pedagogy

Choice of Problem

There have been calls for decades in mathematics education to make curriculum relevant to students (Civil, 2007; Gutstein, 2006; Ladson-Billings, 1995). In this study we focus on a case of written instructional materials created with the mission of providing "free, nonpartisan, relevant math lessons that prepare all students to think critically as citizens" (Skew the Script, 2024). The following research questions guide this investigation: 1) How do AP statistics students view the relevance of the issues investigated in Skew the Script? 2) How do AP statistics students view the partisanship of the topics investigated in Skew the Script lessons?

Theoretical Framework and Modes of Inquiry

Priniski et al. (2018), drawing from a wide range of theories including culturally relevant pedagogy, defines relevance as, "a personally meaningful connection to the individual" (p. 12) and exists on a continuum from personal association to personal usefulness to identification. We used this framing to understand how students view the relevance of lessons. 15 secondary AP statistics teachers and their respective statistics students were recruited with data collection conducted post-AP exam administration with 70 students responding. To gauge students' views of lessons, the survey also included items asking students to rate the level of relevance of each lesson with a 5-point Likert scale. To collect data on partisanship we asked students, "on a scale of 1 to 5 how would you rate the overall partisanship of the topics in the curriculum," and also "of the topics you covered in class which topics, if any, did you find right leaning, …left leaning?" We used exploratory data analysis and qualitative coding to analyses the data.

Findings and Discussion

The issues students found most interesting where those related to issues of race/racism and sports. There were followed closely by gun violence/control, then policing and politics. Several also explicitly mentioned anything relevant or related to the real world. When asked to rate the relevance of each lesson they experienced, a majority of students rated most lessons 'relevant' or 'very relevant.' No lessons were rated as not relevant by students. Only 12 of 70 students referenced a topic in response to being asked which ones they would consider right leaning, all others could not think of one. Of those found right leaning the only common topics were polling examples. In contrast, 35 out of 70 stated at least one topic to be left leaning. 51.4% of students rated the partisanship of the lesson overall as neutral (51.4% of respondents) with 40% reporting a left lean. The students in this study felt the wide scope of lessons, ranging from politics to the environment, were insightful and significant to their lives. In many cases, the topics were not directly related to them, but students still rated lessons such as these as relevant. This finding suggests that these students responded favorably to lessons that were both "windows" and "mirrors," to better understand both the world and themselves (Gutiérrez, 2012).

EXPLORING DIALOGIC MATHEMATICS VIDEOS AS AN INSTRUCTIONAL TOOL FOR SUPPORTING SECONDARY SCHOOL STUDENTS' ALGEBRAIC REASONING

Isabel White
San Diego State University
iwhite1202@sdsu.edu

Keywords: Algebra and Algebraic Thinking, Design Experiments, Instructional Videos

Researchers have positioned introductory algebra as a determinant of future academic success, and thus, it serves as a gatekeeper to more advanced courses in secondary mathematics (Stein et al., 2011). There is a general consensus among mathematics education researchers that algebra should move beyond rote symbol manipulation to a focus on concepts, and yet students still revert to procedural thinking (e.g., Christou et al., 2022; Liang & Moore, 2021; Tondorf & Prediger, 2022; Wilkie, 2022). This procedural emphasis is reflected in most instructional videos available for K-12 learning, which are similarly procedural in nature and lack student voices (Bowers et al., 2012; Klinger & Walter, 2022). One solution is to turn to an alternative video tool— the dialogic mathematics video—-that is conceptually oriented and features student-student interactions.

Empirical studies indicate that students evidence higher learning gains when viewing dialogic videos compared to expository videos (e.g., Chi et al., 2017). These studies demonstrate the potential for dialogic videos to enhance learning but have predominantly been situated in science contexts and in laboratory settings. In mathematics contexts, studies have utilized a qualitative approach but have focused on investigating the experience of students' engagement (Lobato et al., 2019, Lobato et al., 2023). There is a need to explore the role of dialogic videos as an instructional tool for learning in a classroom setting. For these reasons, this study aims to investigate how dialogic videos as an instructional tool influences students' reasoning in an algebra classroom context. Specifically, this study uses videos from Project MathTalk.

This study draws on the theoretical construct of instrumental genesis. Broadly, instrumental genesis (Artigue, 2002) is the process by which an artifact moves from being a human-made object to something that is meaningful to the learner. Within a mathematical context, a mathematical artifact becomes a mathematical instrument (i.e., the artifact becomes valuable and useful) as the learner develops the skill to express mathematical ideas with it. In this study, I interpret instrumental genesis to mean the mediation of an artifact into a meaningful instrument (à la Alqhatani & Powell, 2017). Hence, the guiding research question is: in what ways does the artifact of dialogic mathematics videos mediate secondary school students' ways of reasoning about algebraic expressions and equations?

The study employed a classroom teaching experiment methodology (Cobb, 2000) with thirteen 9th grade students. To capture the ways in which the video artifact was influencing student reasoning in the classroom, whole-class video-taped observations, whole-class inscription, and participants' written work was collected. Data was analyzed using a Thematic Analysis methodology (Braun & Clarke, 2006). The results of this analysis will report on themes that relate to specific ways that the video mediated students' reasoning during key moments in the teaching experiment. This study contributes to the literature on learning from dialogic videos by documenting the mediational role of dialogic mathematics videos in shaping students' reasoning. Understanding how these videos shape students' learning trajectories can inform instructional practices and curriculum development in secondary mathematics education.

UNDERSTANDING FUNCTION TRANSFORMATIONS THRU TACTILE REPRESENTATIONS AND GESTURING WITH VISUALLY IMPAIRED AND SIGHTED STUDENTS

Paul Woo Dong Yu
Grand Valley State University
yupaul@gvsu.edu

Joy A. Oslund
Grand Valley State University
oslundj@gvsu.edu

Tasnim A. Alshuli
University of Arizona
talshuli@arizona.edu

This case study uses embodied cognition and universal design for learning to help three students, one with a visual impairment, understand the concept of function transformations. To accommodate students' learning, a group activity used tactile representational tools to give meaning to function translations on a coordinate plane. Results show that the learners constructed a conceptual and integrated notion of function transformations. In this paper, we illustrate how mathematical knowledge was understood and communicated through verbal discourse and gesturing and raise theoretical questions about embodied ways of knowing for both blind and sighted students in learning pre-calculus concepts. We propose these pedagogies be used with all students reflective of universal design principles.

Keywords: Algebra and Algebraic Thinking, Cognition, Students with Disabilities.

The use of interactive algebra and geometric systems to graph functions is well-researched in mathematics education to foster an integrated understanding of relationships between algebra concepts, graphs, and symbolic notation. While there has been progress in making this technology accessible to students with visual impairments (VI), learning experiences for students with VI are not equitable and often inadequate compared to opportunities for sighted students (Stone & Brown, 2023). There is a need to critique and rethink how to make mathematics accessible to all students using principles of Universal Design for Learning (UDL) in planning and implementing mathematics lessons (Abrahamson, et al., 2019; CAST, 2018). Mathematics educators have begun to understand mathematical experience as embodied; that is, mathematical ideas, physical objects, the environment, and our bodies are entangled in learning mathematics (de Freitas & Sinclair, 2014; Yu & Oslund, 2023) with gesturing as an enactment of embodied learning experience (Healy & Fernandes, 2011; Hostetter & Alibali, 2008). This case study looks at a lesson on algebraic transformations using tactile representational tools conducted with one student with VI and two sighted students in a collegiate precalculus course. In this paper, we report episodes from the lesson, describe students' emerging and integrated understanding of algebraic transformations on functions, describe the role of UDL, and connect these to the students' embodied learning experiences through tactile interactions and gesturing.

Theoretical Framework

This research study is grounded in Universal Design for Learning (UDL) (Gully, 2021) and embodied cognition (Alibali & Nathan, 2012; Healy & Fernandes, 2011; Lakoff & Nuñez, 2000). UDL principles include providing multiple means of representation, action, and expression (CAST, 2018); not all bodies have access to all representations or actions, therefore, multiple representations provide access to more students. The goal of UDL in mathematics classrooms is not to accommodate students with disabilities but to create learning environments benefitting all students (Gulley, 2021; Abrahamson et al., 2019). This can be particularly challenging for postsecondary instructors with limited exposure to UDL principles (Stone & Brown, 2023). In the case of students with VI learning precalculus mathematics, increasing use of computer algebra systems and interactive graphing technology poses a challenge given the visual acuity necessary. Abrahamson et al. (2019) suggest a reconceptualization of what it means to visualize that encompasses nonvisual learner experiences and provides necessary representational tools for students with VI. UDL considers how representational tools, visual, tactile, or technological, may benefit sighted students beyond the status quo curriculum and pedagogy.

Research has started to understand the mathematical learning of students with VI. Gerofsky and Zebehazy (2022) used motion to help elementary students with VI notice mathematically important features of graphs. Drawing from cognitive science research using fMRI techniques, Lakoff and Nunez (2000) suggest that visual systems in the brain are not restricted to visual input, stating, "...congenitally blind people, most of whom have the visual system of the brain intact, can perform visual imagery experiments perfectly well, with basically the same results as sighted subjects, though a bit slower," (34). They explicitly connect motor control and mathematical ideas; an *aspect schema* is a neural structure that controls both complex body movements and rational inferences about events and actions (Lakoff & Nunez, 2000). Of interest to this study are continuative, iterative, and imperfect aspect schemas (Lakoff & Nunez, 2000). In linguistics, aspect refers to expressions that denote temporal actions that may be perfect as in 'yesterday I rode my bike,' or imperfect as in 'when I was a kid, I rode my bike every day' (Smith, 1997). Specifically, we wondered how tactile representations of functions and students' associated gestures activate and mediate the aspectual nature of mathematics in a student with VI and sighted students. In keeping with the notion that bodies and their environments are not separate but influence one another (Chomney et al., 2019), we use *gestures* to refer to motions made by students as they learn, including those that involve manipulation of tactile materials. Research on gestures in mathematics education has sought to understand the relationship between gestures and mathematical understanding (e.g. Healy & Fernandes, 2011; Hostetter & Alibali, 2008). Hostetter and Alibali (2008) sought to understand mechanisms that give rise to gestures. They posit that gestures are based on mental images and actions. Nathan (2021) points out that gestures both reveal and influence the speaker's cognition. Lakoff and Nuñez (2000) described mathematics as arising from bodily experience. Although not specifically about mathematics, Johnson (2007) has posited that through movement we construct conceptual understandings, and the qualities of movement matter to the development of those concepts. The questions this study addresses are: (1) How does a UDL environment with tactile and other representational tools used in a novel way support mathematics learning for students with VI and sighted students? (2) How can the embodied notion of aspectual systems describe connections between physical action and conceptualization of mathematical ideas? (3) What role does gesture have in the communication and construction of mathematics in students with VI and sighted students?

Methodology

A naturalistic (Moschkovich & Brenner, 2000), multitiered teaching experiment (Lesh & Kelly, 2000) was conducted in an undergraduate precalculus course (n = 30) at a medium-sized Midwestern university. The professor of the precalculus course collaborated with one of the researchers, meeting once a week to discuss ways to provide instruction to a student with VI and sighted students using technology and manipulatives. The data consist of field notes and videos of whole class sessions, videos of individual student work sessions, and videos of selected small group sessions. The individual and small group sessions met once a week outside of regular class meetings and were led by the collaborating researcher, who assumed the role of teacher-researcher (Ball, 2000) and is identified as the instructor in this paper. There were nine video-recorded sessions, each session lasting approximately one hour.

This paper looks at one of the small group sessions, which was chosen for analysis because of the collaborative nature of the learning due to the use of the physical manipulatives and Instructor moderation of classroom discourse. This session included three STEM majors in the pre-calculus course (pseudonyms): Ian, Lexi, and Madelyn. Ian was a legally blind, male international student from Central Asia in his second year as a computer science major at the university. He was totally blind in one eye and had very limited vision in the other. Lexi was in her first year as an engineering major. Madelyn was in her first year as a secondary mathematics education major. The video was analyzed using iterative refinement cycles for video analysis (Lesh & Lehrer, 2000). The first iterative cycle was the transcription process. The second iterative cycle was a review of the video data with the transcripts by the first author to establish initial themes and time code those sections of video data for deeper analysis. The third iterative cycle was a review of the video and transcript data, by at least two researchers at once. The use of transcriptions with repeated viewing of the video, by multiple researchers, provided a means to obtain an increasingly reliable narrative (Gulley, 2021). This allowed for a deeper analysis of emergent themes, including the qualities of the participants' gestures, interactions with tactile materials, and the relationships between participants' movements and the group's discourse. For example, we noticed whether a student traced a tool with their fingers or tapped it into a certain position on their paper, the tentativeness or certainty of these motions, and how gestures either stood alone or were accompanied by verbal descriptions. The third iterative cycle was a review of video data by individual researchers to provide a deeper analysis of identified themes, including developing and refining written descriptions of the motions under study.

The Focal Episodes

In this section, we present two connected episodes from a small group lesson on exponential functions and transformations (translations). Before this small group session, in their precalculus class, students investigated function transformations. They used Desmos (Desmos, n.d.), a computer-based interactive graphical-algebraic system, to investigate how $y = f(x) + c$ would vertically shift the graph of $f(x)$ up or down by c units. Similarly, they used Desmos to explore function reflections in which $y = -f(x)$ and $y = f(-x)$ reflects $f(x)$ over the y-axis and x-axis respectively (Boelkins, 2019). Ian, being blind, was not able to do the Desmos-based lesson, which required the ability to visually perceive the movement of a thin-lined graph as different numerical values were input into the function using a 'slider' feature, which changes numerical values by dragging the onscreen slider left and right. At this point, Ian had limited understanding of the concept of function transformations. While Madelyn and Lexi had completed the Desmos activity, they had an emerging notion of the concept of function transformations.

This small group lesson used tactile graphs to explore how exponential functions would be affected by algebraic transformations. Each student was given large sheets of embossed graph paper (16" x 22") with Wikki Stix, which are made from yarn coated in wax, making them flexible and easily manipulated (Wikki Stix, n.d.). They can be made into sculptural elements or stuck onto paper to ‘draw’ 2D images and are typically used by children as a creative tool. Using principles of UDL, Wikki Stix provided a tactile representation to make graphing accessible to Ian while providing Lexi and Madelyn with an alternate representational tool to explore graphing and function transformations. Google Jamboard, a 55-inch digital touch screen and an online whiteboarding application, that allows for simultaneous group collaboration, was also used to record students’ mathematical ideas. Ian had enough sight though the outside corner of one eye, allowing him to write and read large block letters written on the 55-inch Jamboard digital touch screen. Lexi and Madelyn could also access, write, and read the Jamboard on digital tablets using the Jamboard application.

Episode 1 – Initial graph and finding the equation of $Y = A\,B^X$

When the instructor initially took out the large sheets of embossed graph paper and introduced the Wikki Stix, Lexi said, “These are my favorite when I was a kid… this is so exciting” indicating affective familiarity. Madelyn had also used Wikki Stix in elementary school art classes, and Ian had used Wikki Stix in a previous mathematics course. However, this was the first-time students had used Wikki Stix this semester so there was a brief acclimation period as they made sense of the tools. During this time, Ian ran his fingertips over the embossed graph paper feeling the physical boundary of the paper and locating the physical center.

The instructor put a Wikki dot at the physical center of Ian’s paper saying, “So the point right there is (0,0), OK?” Seeing where the dot was placed on Ian’s paper, Lexi and Madelyn drew their origin points at a similar spot on their graph papers. The instructor began by giving directions to the group, “Vertically on the Y-axis, pick a number either two or three [for the Y-intercept]. It's your choice, OK? [Then] go over to where X is equal to 10. And then you pick a Y value. The coordinate is going to be 10 comma, and your Y value can be anywhere from 6 to 10. So, you could do (10,6), (10,7), (10,5) ... then take one of the Wikki Stix and I want you to put what you think is an exponential growth graph through those two points.” The design of this activity allowed for each student to pick their own Y-intercept and point thru (10, y) so that each of their graphs were particular to their choice of points. The intent was to have three different, but similar exponential functions. Using his fingertips, Ian carefully placed the Wikki Stix through his points (0, 3) and (10, 6) (see Figure 1). The tactile nature of Wikki Stix made it possible for Ian to work at the same rate as Madelyn and Lexi. Ian and Lexi’s Wikki Stix graphs spanned both the first and second quadrant while Madelyn’s graph was only in the first quadrant.

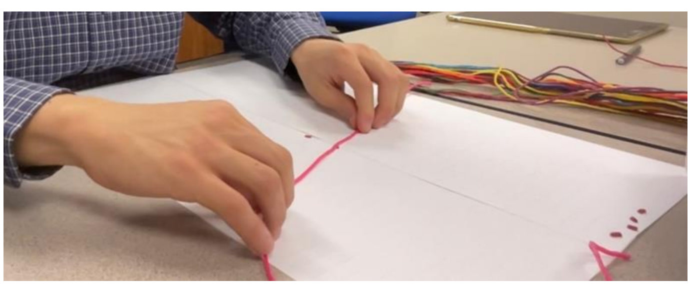

Figure 1: Ian’s placement of his graph on embossed graph paper with Wikki Stix

As they were simultaneously completing their graphs, the students were then instructed to find the exponential function that would go through their respective y-intercept and point (10, y), with the instructor saying, "[All three of you] get to your Jamboard [file]. Ian's on [page] 2, Madelyn, you can go to page 3. Lexi, you can go to page 4, and find the exponential function that goes through [your two] points. Get the formula for [your respective exponential functions.]" Each student spent 10 minutes working individually on algebraic calculations on the Jamboard to find the equation of their respective exponential functions. During this time, they were also instructed to use their exponential function to evaluate more points on their graph. The instructor said, "So now what you should be able to do is [to] use those [calculate coordinate] points to plot a few more of points on your graph…so you can really kind of dial [your Wikki graph] in…. Now we're done with the calculation, right? But try and make your graph as smooth exponential looking as possible." As Madelyn completed her calculations to find additional points on the graph, she reconfigured her Wikki graph so that it spanned both first and second quadrants. All three students used the coordinates from their algebraic calculations to create refined graphs for their exponential functions.

In this episode, we see the benefits of UDL in many ways (Gulley, 2021; Abrahamson et al., 2019). First, was the unintended, but positive affective response by Lexi and Madelyn in their recollection of using Wikki Stix as young children in creative and artistic contexts. For Ian, his familiarity with embossed graph paper and Wikki Stix provided a means for him to graph the functions at the same rate as the sighted students and with access to the same salient features of the representational tools as the sighted students. As a result, Ian's ability to reason mathematically was not hindered by the visual nature of graphing functions using traditional pencil and paper or digital technology. For all three students, the Jamboard provided a collaborative space to do mathematical calculations. In interviews, all three students have shared the benefits of Jamboard. Ian commented on how Jamboard was 'game changing' in providing a thinking space for his calculations. Lexi and Madelyn commented on how they like that all work done by their professor, small group instructor, and peers can be accessed via the Jamboard. Furthermore, this Jamboard became a mutual thinking space for all the students, which contrasts with working on scratch paper with pencil which would be inaccessible to a legally blind student like Ian. By thinking space, we mean a physical or cognitive space to wonder, postulate, calculate, or conceptualize. Thus, the Wikki Stix and Jamboard are reconceptualizations of ways to visualize emerging mathematical ideas for all learners (Abramson et. al., 2019).

Episode 2 – Moving the graph up two units to find $Y = A B^x + C$

For the next mathematical task, the instructor said, "translate the whole [exponential function] vertically 2 units up. But I want it to be as precise as possible." Ian took a second Wikki Stix, and starting at x = -14, and began to lay it adjacent to the original Wikki Stix function graph, but two units up. In doing so, his gestural motions were done in an artistic or sculptural way as he used his fingertips to 'feel' the two-unit difference, or space, between the two Wikki Stix. He carefully moved his hands from left to right along x = -14 to x = 14. By sculptural, we mean a wholistic and careful gestural motion, but mathematically intentional in preserving the two-unit distance. As he worked in the first quadrant, Ian was intentional about checking the two-unit distance at discrete points between the two Wikki Stix graphs. Lexi used a similar gestural motion, but more iterative. Starting from right to left, she tracked the two-unit difference at different points along the function with her fingers while looking at the graph paper, thus setting the second Wikki Stix a constant two-units vertically shifted up. After initially setting the second Wikki Stix, Lexi double-checked and refined her translated graph to be as precise as possible making incremental adjustments to the Wikki Stix graphs. Madelyn began her translated graph by starting at the y-intercept and setting the second Wikki Stix two units up from the original function at that point. Stretching the Wikki Stix, she then visually 'jumped' to a point on the first graph around x = 6 and translated that point up two-units. She then 'jumped' to a point around x = 10 and translated that point up two units as she stretched and placed the Wikki Stix to make her graph. She was very intentional about making sure that the point-to-point distance was two -units as she twice 'pulled up' the Wikki Stix along sections and reset it on the graph paper. In contrast, Lexi's revisions were more incremental, and Ian did not revise his translated graph due to his more deliberate gestural process.

In a few minutes, the instructor asked students to describe their process and thinking behind it. Lexi began, "I just took every unit and moved it two upward from wherever it was...so since 2 units is 1 box, first I just mirrored it. Not mirrored, but put it in the same place [two units up]."

Madelyn said, "I looked at the Y value [of the original function] and then added two and then put [the Wikki Stix] on the same X line." When asked how many points she checked, she replied, "Oh I looked at all of them, I only had seven points that I calculated but I looked at all of them."

When asked how he translated the graph, Ian said, "I looked at it, how wide is [it] with my fingers, and just go through, shoosh." Using his index and middle fingers as a measuring tool, he ran them together in the space between the two graphs in a smooth sweeping motion (See Figure 2).

The instructor commented to Ian, "OK. Yeah. You kind of did it almost [like] Desmos, almost like dynamically, right?"

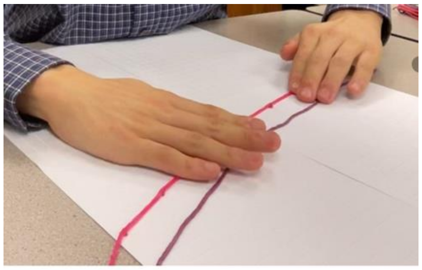

Figure 2: Ian's two fingered 'shoosh' motion

In this section, gesturing provided the means for all three students to both explore and explain their mathematical ideas. The students' mathematical reasoning related to translating the exponential function vertically two units can be explained using the aspectual structure framework (i.e., the structure of events) as described by Lakoff and Nunez (2000). An aspectual action is temporal and may be continuous or iterative. If the aspectual action is unending, or implies an infinite nature, it is considered an imperfect aspect. An example of an imperfect continuous aspect in this episode was when Ian described his approach of graphing the translated function, "I looked at it, how wide it is with my fingers, and just go through 'shoosh'," as he verbalized his gesture. His conceptualization of translating the function was through motor movements (gesturing and replacing the Wikki Stix) and being satisfied with the completion of the task. His gesture also had an imperfective aspect in that it was a continuous, unbounded, motion in which the 'shoosh' implied space between the Wikki Stix functions continuing to infinity. Mathematically, this imperfective aspect schema suggests that Ian had developed a notion of vertical translations to be holistic, smooth, continuous, and infinite. Lexi also used a gestural motion but was more incremental as if moving point by point along the x-axis from left to right on her Wikki graphs, which suggests an incremental imperfect aspectual structure. In her mathematics she was aware of a 'plus 2' relationship. This suggests Lexi had developed a notion of vertical translations to be discrete, incremental, and infinite. However, Madelyn's gestural motion as she placed the vertically translated Wikki Stix seemed more intentional at specific points along the graph, as she seemed to be intentionally translating specific points of the function. This indicates she had developed a notion of vertical translations to be structurally related to the values of the function. As suggested by Lakoff and Nunez (2000), students' motor movements reflected their mathematical conception of function translations, an imperfect aspectual structure for Ian and Lexi. Madelyn's gestures seemed to reflect the algebra of adding two units to each Y-value.

Then to the group, the instructor asked, "So that idea of how you added two to each one, right? What is the equation of that [second translated] function right there?"

Ian began by saying, "Whatever the Y is double +2? There is no formula because...."

Lexi added, "Well the rate of change [of both functions] is the same, so B is the same as what it was before, and A would be... plus two [to] whatever…A…so add two to you're A-value." Both Lexi and Ian concluded that the A value in their exponential equation would be 5.

The instructor then asked students to produce full formulas for their translated functions. Ian immediately said, "5 times 1.07 to the X power." Lexi affirmed that, saying her function would be 5 times 1.1 to the X power.

Madelyn then shared her idea saying, "I feel like you would just add [the 2] because it's a vertical shift and if you're adding...If you're multiplying by a large number, isn't your exponential going to be like? Messed up? Don't you just add 2 to the value that you get for Y?" As she said this, she gestured with her right hand tracing an exponential graph in the air.

Ian suggested, "What about if we do the reverse?" Placing his hands on his Wikki graph, Ian touched the Y-intercept of the translated graph, "It's already 5. Here in this point, it's already 5, not 3. We have nothing to do with the three, let's say, and we start from the five. What do we get?"

Realizing that the Y-intercept was a special case that afforded varied mathematical possibilities, the instructor said, "OK, let's go out to some arbitrary point…other than the Y intercept. There's two ideas, right? You could either multiply by 5 or we could add 2 to the whole thing." He then spoke to Madelyn saying, "and you said add 2 to which one?"

She replied, "Just add 2 to like the whole thing, because then your Y value would be up by two and then to be vertically translated up by two… So, I think you just add 2 to the end of the equation."

Touching the original graph at (14, 7.74), Ian said, "So you mean like the result of mine [the y-value of the original function at x = 14 is] 7.74, so [the y-value of the translated function would be] 9.74."

Madelyn confirmed, "Yeah, that's what I'm thinking."

Lexi added, "So mine would be 3 times 1.1 to the X power + 2."

The instructor said, “Now you can check values if you want, you can take a minute and like plug in values and verify it. But let's think about it conceptually… and seeing the function as the object itself… So, every single one of those points is representing your functional value and what you just physically did is you just kind of shifted [all of] them up [2 units] …You added two to each value.”

Madelyn concluded, “So it's function plus two,” with the instructor affirming her conclusion.

An important element of UDL in this episode is the discourse between students (Gulley, 2021; Abrahamson et al., 2019). All students could fully participate in the group’s construction of functional transformation. When students were asked to define the equation for the translated function, Ian offered, “Whatever the Y is of them, +2. Minus. there is no formula because…” At that moment in time, his graphical reasoning has been completed and he could not conceptualize a different approach (e.g., symbolic) of representing the translation. Lexi’s explanation focused on various aspects of the exponential function, like rate of change, initial value ‘A’, and growth factor ‘B.’ Lexi also had the concept of adding two to some part of the function and settled on adding two to A. Madelyn’s concept of the exponential function equation centered on adding two to ‘the whole thing.’ Through discourse, elements of Ian’s explanation of his motor movements and graphical explanation seemed to transfer to his conceptual development of symbolic representation. For example, later during group discussion, he used the word “reverse” indicating elements of his aspectual structural thinking-- taking the concept he already formulated and reversing it as a counterexample to explain his approach to translating the function. Towards the end of the discussion, in response to Madelyn’s suggestion to add two to the end of the equation, Ian concluded, “So, you mean the like result of, like mine got 7.74. so, it's 9.74...So then we don't have to touch the A then, right?” His use of “result” (to mean the solution for Y) and “touch” (to mean not changing the function’s initial structure) seemed to support him to structure his conceptual understanding of the symbolic representation of the function translation. Similarly, Lexi and Madelyn progressed in their symbolic formalization as they both reached a point of mathematical certainty, that the translated function was the original function plus two.

Conclusion and Implications

The purpose of this study was to investigate a UDL lesson with tactile representational tools (Abrahamson, et al., 2019) to understand embodied ways of learning mathematics. The questions we considered are: (1) How does a UDL environment with tactile representational tools support mathematics learning for students with VI and sighted students? (2) How can the embodied notion of aspectual systems describe connections between physical action and conceptualization of mathematical ideas? (3) What role does gesture have in the communication and construction of mathematics in students with VI and sighted students?

The UDL environment with novel tactile and technological representational tools supported mathematics learning for students with VI and sighted students. By the lesson’s end, all students were engaged in meaningful discourse to generalize their varied embodied ways of understanding function transformations into a symbolic representation. Interestingly, throughout the lesson, there was no mention or indication that one student had a visual impairment, nor did it appear to limit their participation. Activities focused on the mathematics task, interaction with tools, discourse with group members, and constructing mathematical knowledge.

The embodied notion of aspectual system (Lakoff & Nunez, 2000) was used to describe connections between physical actions with Wikki Stix and conceptualization of the mathematical concept of function transformations. Some aspect schemas of function transformation observed in this lesson were the before and after function transformation graphs, movement to get from one function graph to the translated function graph, and the mathematical conclusion that the resulting translated function is ‘function plus two.’ Ian and Lexi’s initial imperfect aspectual structures did not initially lead to the correct algebraic function formulas but did provide an experiential context that mediated the correct algebraic function with the help of Madelyn’s mathematical observation of adding two to the whole function.

The role of gesture in communication and construction of mathematics with VI and sighted students may be seen in the manipulation of the Wikki graphs and how those manipulations informed the student’s mathematical language (Alibali & Nathan, 2012) and mathematical understanding (e.g. Healy & Fernandes, 2011; Hostetter & Alibali, 2008). Moreover, the students’ gestural interactions with Wikki Stix gave insight into and influenced the students’ mathematical thinking (Nathan, 2021) in a manner we suggest differs from what might be elicited with interactive digital technology or pencil and paper graph construction alone.

UNDERSTANDING GESTURES IN A CONCRETENESS FADING VECTOR ADDITION LEARNING INTERVENTION

Yilang Zhao
University of Tennessee, Knoxville
yzhao97@utk.edu

Mitchell J. Nathan
University of Wisconsin–Madison
mnathan@wisc.edu

Abstract: In this study, we designed a concreteness fading intervention that taught middle schoolers vector addition. Our intervention allowed the participants to experience informal vector addition, solve the same problem in a simulation game, work on similar issues on a worksheet, and present their learning in a story creation activity. We examined their use of gestures during the intervention and discovered pointing and representational gestures mainly were used. The participants used pointing gestures to index objects related to the task and indicate the following representations, and their representational gestures simulated their actions, reflected their mathematical thoughts, replaced their speech, and performed abstract pointing. Our study provided a scrutinized way to inspect learning in a concreteness fading intervention.

Keywords: Cognition, Informal Education, Middle School Education

Introduction

Secondary mathematics educators often introduce mathematical concepts through formal notations (a "formalisms first" approach; Nathan, 2012) that often impede students' grounded meaning-making and transfer. Among various mathematical topics, Gubrud and Novak (1973) discover that vector addition causes learning difficulties for middle schoolers as they fail to develop a clear and stable concept of it. If students only learned those symbols of vector arithmetic from their math class, they would probably struggle with college-level vector arithmetic (see Knight, 1995). Therefore, developing an intervention that empowers students to gain a grounded understanding of vector addition is critical to secondary-level education. Another point worth mentioning is that most mathematical learning studies observe the participants' learning by comparing the performance of their pretest and posttest. Since mathematical understanding is usually embodied (Lakoff & Núñez, 2000), we think observing gestures in a vector addition learning intervention can enable us to understand better how students develop their mathematical thoughts.

Theoretical Framework

A vector is a highly conceptual idea and inaccessible in daily life. Bruner (1966) proposes three stages –enactive, iconic, and abstract– for learners to understand new concepts. Inspired by these three stages, there is an instructional approach called concreteness fading (CF) that refers to a learning process in which students start learning a new concept or skill with concrete learning materials related to their previous knowledge that gradually transitions to more symbolic learning materials (Fyfe et al., 2014). In a CF intervention, students will first encounter something that they are relatively familiar with, and then the same learning content will be presented to them in a way that gradually becomes more idealized so that it "involves the least effort of an agent to infer the invariant relation as part of generalization and transfer" (Fyfe & Nathan, 2019, p.6). Finally, formal notations can be introduced to students without intimidating them. With a CF learning process, students are expected to develop their understanding of the intervention. Previous studies explore the efficacy of the CF technique in teaching the equal sign (McNeil & Fyfe, 2012), basic circuits (Jaakkola & Veermans, 2018), and complex systems thinking (Goldstone & Son, 2005). Studies applying CF to vector addition among secondary students may have potential though it has not been researched before.

Regarding estimating students' understanding during a CF intervention, observing their use of gestures can be a good approach since people's developing ideas can be expressed by gestures (e.g., Hostetter & Alibali, 2019). Furthermore, focusing on gestures in an instructional intervention can reveal learners' mental representations of a concept (Nemirovsky & Ferrara, 2009) and indicate how learners ground the meaning of unfamiliar concepts and formalisms (Koedinger et al., 2008). For systematic analysis, McNeill (1992) categorized gestures into four types: 1) pointing, 2) iconic, 3) metaphoric, and 4) beat. Except for beat gestures, all the other three types of gestures convey semantic information relevant to learning contexts. Based on McNeill's categories, Alibali and Nathan (2012) distinguished between pointing gestures, which reflect grounded cognition in a physical environment; representational gestures, which demonstrate mental simulations of actions and perceptions; and metaphoric gestures, as a subcategory of representational gesture, which indicate body-based conceptual metaphors.

Previous research has discovered that iconic gestures can better help students embody mathematical concepts than pointing gestures (Swart et al., 2017) in a CF intervention. However, how different types of gestures allow students to construct mathematical thinking remains further examined. In this paper, we will use Alibali and Nathan's taxonomy to analyze the gestures in a CF intervention. Thus, our research question is how students use different gestures during a "concreteness fading" intervention that teaches vector addition.

Methods

Participants

We recruited six volunteer 8th graders (pseudonyms: Alice, Kevin, Jason, Emily, Anne, and Chris) from a charter school in a large Midwestern city in the U.S. Students' math performance in this school was below the state average, according to U.S. News & World Report. They had learned the coordinate plane in 7th grade and had never learned the concept of vectors before. According to our pre-study screening, none of them could conduct vector addition. They were randomly divided into two groups of three for this study.

Study Design

In this study, we designed an intervention to teach students vector addition using the vector components method. Reflecting Bruner's (1966) three stages of perceiving new concepts, the CF intervention has three stages (Enactive, Iconic, and Abstract), with one task per stage. After the three stages, we added an extra task (Constructionist Problem Design) to examine students' knowledge application in another setting.

Enactive stage. The task in the Enactive stage is called Physical task. The researcher will first ask the participants to tile the floor with cardboard tiles in two colors. Then, two students will step onto the tiles and randomly select two points to stand on and discuss how to describe their positions. After they come up with an approach to describe positions on the tiles, the researcher will give one participant a foam football and ask the participant to walk along the tiles to deliver the football to the other participant. Next, the researcher will ask the third student to use red sticks to measure the tiles that students walked leftwards or rightwards and blue sticks to measure the tiles that walked frontwards and backward. Then the researcher will ask the student who delivers the football to directly pass the football to the other student and ask the third student to measure the distance with yellow sticks (see Figure 1 left).

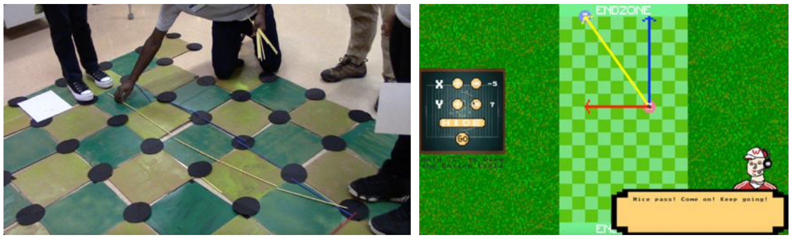

Figure 1: Physical task in Enactive stage (left) and Depictive task in Iconic stage (right)

Iconic stage. The task in the Iconic stage is called Depictive task. Students will play a football passing simulation game developed by the researcher (see Figure 1 right). In this game, students need to decide the units to add along the x and y axes (red and blue arrows) to make the quarterback pass the football to the wide receiver on a grid football field. If the ball is successfully delivered to the wide receiver, the wide receiver will move to a random place toward the end zone, and the quarterback will move to the place where the wide receiver stays before moving. Otherwise, the ball will be returned to the quarterback. Also, there is a button by clicking which students can see the projected trajectory (yellow arrow). The winning condition of this simulation is to have a touchdown pass. Each group will play two to three rounds.

Abstract stage. The task in Abstract stage is called Symbolic task. In this stage, students will have a worksheet that includes questions in a football context (see Figure 2). In addition, they will encounter formal vector notations on the Cartesian coordinate plane. Students will work separately on the questions first and then have a group discussion to share their answers and thoughts.

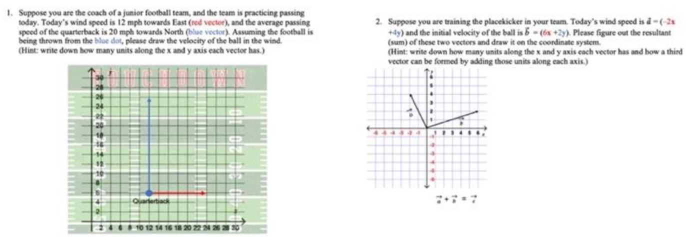

Figure 2: Symbolic task in Abstract stage

Task constructionist problem design. After three CF learning stages, there is an extra 30-minute task called "constructionist problem design" (CPD), in which participants built a story together to demonstrate their learning. The participants start with rough ideas by considering one of the learning objectives and selecting one of the contexts in the conceptual story design sheet we provided (see Table 1). They then use the materials–crafting sticks, IKEA artist's figures, color markers, and blank paper–to build a story related to the learning objective. When the participants make a rough story, the researcher will ask some prompt questions (e.g., how to describe the positions of your characters?) to let the participants iterate their story by adding more mathematical concepts. After they complete their iterative story building, the researcher asks every participant to retell the story and inform the mathematical concepts in their story.

Table 1: Conceptual Design Tool

Item	Option
Learning objectives	a. How to describe the movement (resultant) in terms of x and y? b. What are the most important things about vectors? c. What does your friend need to know about the coordinate system?
Contexts	a. Robotics b. Fashion c. Bicycling d. Soccer e. Basketball

Data Collection and Analysis

The researchers went to the middle school and conducted two study sessions in spring 2022. Each study session lasted approximately 2 hours after regular school hours. Alice, Kevin, and Jason were in the first study session, and Emily, Anne, and Chris took part in the other study session. Before each study session, we obtained consent from the participants' parents and the participants. During each study session, two video recorders were set up from different views to capture video and audio data.

We conducted a video analysis to analyze students' speech and gestures. We first captured every gesture in the videos and then segmented the videos into "clips" at the boundaries of verbal topic changes. If the participants had a couple of gestures when talking about one topic, these gestures were grouped but would be analyzed separately. Based on Alibali and Nathan's (2012) taxonomy, we developed a coding scheme (see Table 2) that included gestures. We first determined whether a video clip contained a pointing or representational gesture. For pointing gestures, we documented the object the participant was pointing to. For representational gestures, we examined whether it was metaphoric or iconic. If no clear metaphor was involved, we identified what the gesture depicted. If there was a metaphor, we identified the body-based concept this gesture represented.

Table 2: Gesture Coding Scheme

Gesture Type	**Pointing Gesture Target**	**Representation**	**Metaphoric**	**Metaphor**
Pointing or Representational	Specific target	Specific representations	Yes/No	Specific metaphors

Results

Pointing Gestures

This study analyzed 262 gestures from 248 segments. In response to our first research question, we discovered that students' pointing gestures were tightly associated with the surrounding physical environment and the undergoing learning materials. Most pointing gestures were used to link students' speech to referents. Concerning the concreteness level of referents, Fyfe and Nathan (2019) suggest examining the referent from three dimensions: physicality (whether an object is three-dimensional or two-dimensional), perceptual richness (how an object appears), and narrative context. During the Enactive stage (see Figure 3 left), participants pointed to the items of high physicality and perceptual richness (e.g., tiles and sticks they used) and real-world space (e.g., one side of the tile) highly contextualized in their conversation. When they were playing the football simulation game during the Iconic stage (see Figure 3 right), they still pointed at objects of high perceptual richness, such as buttons on the screen, but they also pointed at the arrows or the parameters of X and Y on the screen, which they realized had a relationship with the ball movement in the game. The targets the participants pointed to in the Abstract stage (see Figure 4) were mostly formalisms such as lines, axes, and dots on the coordinate plane. These gesture referents reveal that participants got more comfortable talking about idealized symbols on a coordinate plane across the CF stages. The similar contexts and problems across stages helped them transition from tangible physical learning to conceptual abstract reasoning.

Figure 3: Pointing Gesture in Enactive Stage (left) and Pointing Gesture in Iconic Stage (right)

Another noticeable use of pointing gestures is to help the participants explain mathematical thoughts in the Abstract stage. It might be because they lack accurate mathematical language and tend to use pointing gestures to assist their explanations. For instance, Figure 5 (left) shows the participant first used her pen to point at the red arrow and move to the location on the coordinate plane where she wanted the red arrow to move to and did the same thing to the blue arrow. In this excerpt, the participant had the idea of how the two arrows would impact the resultant, yet she did not have the concept of parallel vectors in mind, so she used pointing gestures to explain how to "copy-paste" arrows here.

The other function of pointing gestures is to index representations. This function of pointing gestures often takes place in the Abstract stage. For example, in Figure 5 (right), the participant pointed at 6 on the x-axis and then traced the grid line to point (6,2). In this example, his pointing at 6 was not referring to the number on the x-axis but helping him locate the coordinate point

(6,2) as he knew the number on the x-axis is a component of the coordinate space (6,2). Pointing at the axis and tracing the grid line helped him locate a position on the coordinate plane more easily.

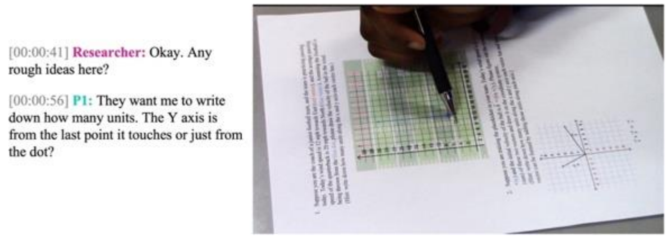

Figure 4: Pointing Gesture in Abstract Stage

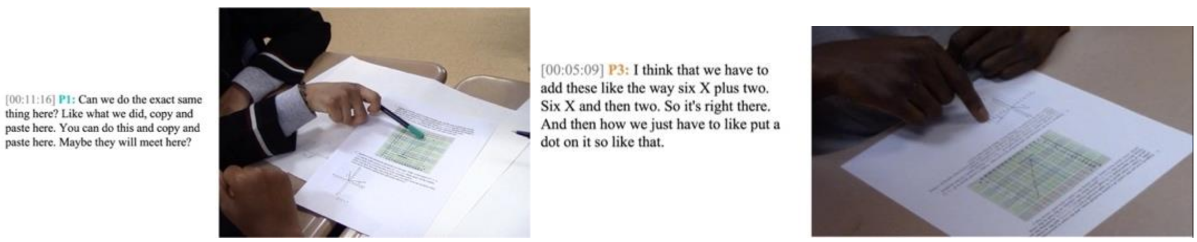

Figure 5: Pointing Gesture - Assisting Explanation (left) and Indexing Representations (right)

Representational Gestures

For representational gestures, we discovered four main functions. The first was to simulate actions. Hostetter and Alibali (2019) state that people automatically use gestures to reflect the motor activity that they are thinking about and speaking about, which is defined as Gesture as Simulated Action (GSA). GSA was also observed in this study. For instance, when Emily, Anne, and Chris were designing their own story to describe the movement in terms of x and y on a coordinate plane, they had a lot of details about how to pass a bouncing ball on a basketball court. When Chris said he needed a perfect angle and strength to pass the ball, he raised his hand and arm and gestured to throw a ball (see Figure 6).

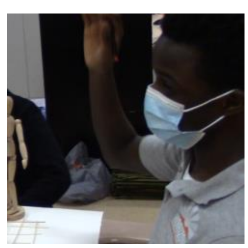

Figure 6: Throwing Gesture

The second was to simulate the behavior implied by a mathematical object. This type of representational gesture appears in every stage of the intervention. For example, in Figure 7, the participant was asked about the relationship between the yellow arrow and the red and blue arrows in the game. He waved his hand and said it was the diagonal line. In this example, the participant's waving his forearm to represent the yellow arrow meant he knew the direction of the yellow arrow was impacted by the blue and red arrows and it was like a diagonal line.

Figure 7: Representational Gesture-Mathematical Objects

The third was to replace their speech. Sometimes, when the participants would omit their words but had a gesture, this gesture delivered a clear message to others about what this participant intended to say. For example, in Figure 8, when asked about the relationship between the two vectors on the worksheet, Kevin used his pen to trace the right-angle symbol he drew between the two vectors and said, "it looks like..." His tracing of the right-angle symbol implied he wanted to say there was a right angle between the two vectors.

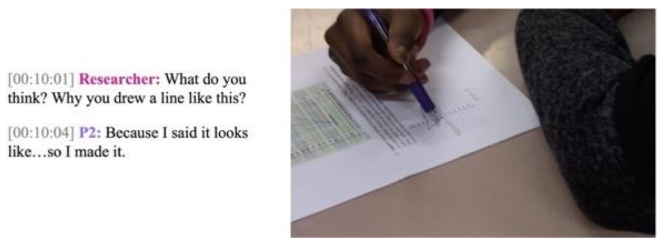

Figure 8: Representational Gesture–Replace Speech

The fourth was to have abstract pointing. Since the intervention in this study had three stages and an additional task, the participants sometimes would refer to some items that appeared before. They tended to point at the place where the item used to be. This was not a pointing gesture but a representational gesture, as their pointing represented the item they had encountered before. For example, in Figure 9, the participant was pointing at the table and said the question on the worksheet was like the game they did. He was paralleling the question and the simulation game, and this representational gesture indicated students made mutual referents among tasks.

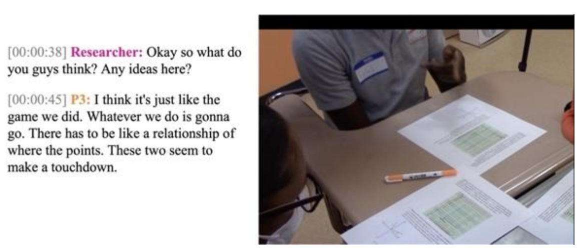

Figure 9: Representational Gesture-Abstract Pointing

Discussion

As mentioned above, the participants' use of pointing gestures is associated with the learning environment and the undergoing learning materials. This association leads the participants to a common ground. Common ground refers to knowledge, beliefs, and assumptions mutually shared by a group of people (Clark & Schaefer, 1989). When the participants worked on the tasks together, their brains established "a shared understanding" by temporally constructing a conjoint space in their social interaction (Gallese, 2003). In a learning setting, gestures can maintain the common ground among a group of people by referring to objects that are both physically present/non-present and introduced through language (Nathan et al., 2017). Thus, in every task of this intervention, the participants attempted to use pointing gestures to refer to the objects in the current learning context and created a common ground in their group to ensure everyone was on the same page.

The other two functions of pointing gestures are related to distributed cognition in their learning environment. Since pointing gestures for assisting mathematical explanation and indexing representations mostly emerged in the Abstract stage, the participants leveraged the learning environment and the elements in it (e.g., the coordinate plane grid on the worksheet) to help them develop their ideas and express their thoughts. Students' development of mathematical thinking is likely to be enhanced when they participate in mathematical activities that involve reasoning with tools and allow them to interact with the environment (Cobb, 2011). Moreover, by interacting with the learning materials and environment, they started to set up the prerequisite of developing a grounded understanding of the meaning and utility of generic symbolic representations.

The affordance of representational gestures was to communicate their ideas and demonstrate their mathematical thoughts precisely. Plausibly, the simulated action and abstract pointing gestures were for better communication during the intervention. In the CPD task, the participants had more representational gestures as simulated actions, and they had abstract pointing gestures in every task other than the first one. It was because they needed a clear image to let their teammates know what they were talking about by either acting it out or connecting to previously encountered elements. In addition, when the participants started to have gestures that implied mathematical objects, this could be the moment when they showed their grounded understanding of the concept they learned from the intervention. Because the topic in this study was fresh new to 8th graders, they lacked sufficient mathematical language to express thoughts and needed gestures as auxiliaries to help them precisely deliver their mathematical thoughts, which also led to their use of gestures to replace their speech. Sometimes, the learner cannot produce the exact mathematical word, so s/he uses a representation gesture to replace the speech, defined as direct consequence (Alibali & Nathan, 2012).

For the theoretical contribution of this study, we inspect CF learning through an innovative lens. There is no previous CF study incorporating gesture analysis to understand students' learning, so this study implies that examining learning in a CF study can be at a micro level besides assessing learning through a knowledge test (e.g., the content knowledge questionnaire in Jaakkola & Veermans, 2018). After identifying the way of using gestures in a CF intervention, the next step is to trace the train of reasoning of every learner and understand what representations are built during and after the course of a CF intervention. As for the practical contribution, we realize that students are uncomfortable with unfamiliar mathematical symbols. By asking them to explain their thoughts and observing their use of representational gestures, we can capture their trouble spots (see Alibali et al., 2013) and provide necessary scaffolding to help them get used to those symbols.

This study has several limitations. First, it is hard to capture every gesture when videotaping the learning process. Second, there is significant individual variability of gestural production. Third, due to the limited resources, this study only has two groups and six participants, making it hard to generalize a quantitative pattern to determine the relationship between the use of gestures and the different stages of a CF intervention.

Conclusion

Concreteness fading can be seen as a powerful and flexible instructional approach for teaching about vectors, which is an essential conceptual domain for mathematics and science. Gestures provide a rich window into children's intellectual development as they move through the stages of concreteness fading. By inspecting pointing and representational gestures in a concreteness fading intervention, we can better understand how students interact with the learning materials and environment and how they develop their mathematical thoughts. Future studies may consider conducting similar micro-level analyses to scrutinize learning in CF interventions.

EXPLORING STUDENT ENGAGEMENT WITH CHATGPT IN CALCULUS LEARNING: A CASE STUDY ON CONTRASTING PERCEPTIONS

Yuling Zhuang
Texas A&M University
ylzhuang@tamu.edu

Si Zhang
Georgia State University
szhang9@gsu.edu

This study explores students' perceptions of ChatGPT in a university-level calculus course and how their perceptions influence their actual use of the tool for calculus learning. Based on the Technology Acceptance Model (TAM), this study focused on how two students with contrasting perceived usefulness (PU) and perceived ease of use (PEU) engaged with ChatGPT. This study showed that with higher PU and PEU, the students are more likely to use ChatGPT in their calculus learning. We suggested that fostering positive perceptions of students is important to promote ChatGPT's potential as a learning aid.

Keywords: Calculus; Technology; Instructional Activities and Practices; Undergraduate Education.

The integration of artificial intelligence (AI) into education marks a significant turning point in the academic landscape. ChatGPT, a sophisticated AI chatbot launched by OpenAI in late November 2022, has demonstrated its innovative utility as an educational resource by answering academic queries, providing explanations, and generating both text and images (Lo, 2023). To date, research on the potential of ChatGPT in mathematics education is limited. Available studies suggested that ChatGPT's performance in solving mathematical problems varies based on the complexity of the questions and the specific subject area, with a tendency towards higher accuracy in simpler inquiries (Dao & Le, 2023; Wardat et al., 2023). In addition, ChatGPT was found to struggle with mathematical word problems, particularly when required to show its solving process (Shakarian et al., 2023). Research also found that ChatGPT's performance in mathematics is unsatisfactory compared to other subjects (Lo, 2023) and significantly below the level of a graduate student (Frieder et al., 2023). However, studies by Patero (2023) and Zafrullah et al. (2023) emphasized ChatGPT's positive impact on student attitudes and engagement in learning mathematics.

Previous studies have mainly focused on ChatGPT's performance in mathematics and there is a lack of research on students' perceptions regarding the use of ChatGPT in mathematics learning. Researchers (e.g., Chan & Hu, 2023; Kostka & Toncelli, 2023) have called for further exploration into students' perceptions and experiences with ChatGPT. This study explored how students' perceptions of ChatGPT influence their actual use of the tool in mathematical learning. The guiding research question for this study is: How do two college students with contrasting perceptions of ChatGPT engage with the tool for calculus learning?

Theoretical Framework

The Technology Acceptance Model (TAM) (Davis et al., 1989) has become a widely accepted framework for investigating the acceptance of learning innovations by various stakeholders in educational contexts (Abuhassna et al., 2023; Granić & Marangunić, 2019). TAM posits two primary factors that predict an individual's behavior towards accepting or rejecting technology: *perceived usefulness* (PU) and *perceived ease of use* (PEU). PU is defined as the degree to which a person believes that using a certain technology will enhance their performance (Davis, 1989). PEU denotes the degree to which a person believes that the benefits of technology outweigh the effort required to use or learn it (Davis, 1989). According to TAM, both PU and PEU are significant predictors of an individual's attitude towards, intended use of, and actual usage of a specific learning technology (Davis, 1989). Empirical studies in the educational domain have shown that PU and PEU can effectively predict the actual usage of learning technologies across various contexts (Hsu, 2012; Luan & Teo, 2009; Nagy, 2018; Teo et al., 2008; Ubaidillah et al., 2020), including in the study of mathematics (Zogheib et al., 2015). Researchers have reported that PU and PEU can significantly affect learners' acceptance of ChatGPT in education (Iqbal et al., 2022; Tiwari et al., 2023). However, there's a gap in the literature regarding how PU or PEU impacts students' actual usage of and interactions with ChatGPT, especially within mathematics learning contexts. In our study, we utilized the TAM model to explore how contrasting perceptions of PU and PEU among two college students influenced their actual use of ChatGPT for learning calculus.

Methods

This study was conducted in a university-level calculus course, which serves as the introductory class in a three-course calculus series offered by the mathematics department. During the semester, students were required to complete six lab assignments with topics such as derivative rules and related rates. These labs were designed to integrate ChatGPT 3.5 to support college students' conceptual understanding of calculus. Students were also required to use a validation framework (for more details, see Zhuang, 2020, 2023; Zhuang & Conner, 2022) to assess the correctness of ChatGPT's solutions to foster a rational and critical thinking approach when using AI tools for learning.

This critical case study (Yin, 2018) followed two undergraduates, Amy and Sue (pseudonyms), who had contrasting perceptions of ChatGPT as revealed by their attitude surveys. Both participants were White females majoring in STEM, with Amy receiving an A and Sue receiving a C at the end of the course. The data in this study included three attitude surveys, six lab assignments, ChatGPT chat history, and participants' assessment data. To fully understand participants' perceptions of ChatGPT's effectiveness and usability in calculus learning, we first reviewed survey results to assess students' PU and PEU of ChatGPT. Then, we conducted a constant comparative analysis (Corbin & Strauss, 2014) to analyze participants' lab assignments and chat history with ChatGPT. To examine participants' actual interactions with ChatGPT, we focused on the following three aspects: (1) the total number of interactions they had with ChatGPT, offering a quantitative measure of their engagement level; (2) their responses and evaluations when ChatGPT provided correct solutions to calculus problems; and (3) their responses and evaluations when ChatGPT generated incomplete or partially incorrect problem-solving solutions.

Results

This section presents the contrasting perspectives of the two participants on using ChatGPT for calculus learning and details of their actual use of the tool.

Case 1 – Amy

Amy's engagement with ChatGPT throughout the semester demonstrated a consistently positive attitude toward ChatGPT. According to the survey, she rated the usefulness of ChatGPT in learning calculus (PU) as 5 out of 5 at the beginning of the semester and 4 out of 5 at the end of the semester. As for the perceived ease of using ChatGPT (PEU), Amy rated 4 out of 5 at the beginning of the semester and 5 out of 5 at the end of the semester. For instance, after the first interaction with ChatGPT in first lab, she was surprised by the capability of ChatGPT in calculus (PU): "I think this thing has more power than I thought" (Survey 1). At the end of the semester, when we asked her about the biggest takeaway from using ChatGPT to learn Calculus, she stated in the survey, "I have been very impressed. I think overall, ChatGPT can help a lot of people with their calculus if you have a certain topic you are struggling with." (PU). Her lab reflections further revealed her intention to use ChatGPT for future calculus problems: "This is crazy…I am very surprised this [ChatGPT] worked so well. I might have to use it on some problems I get stuck on in the future!" (Lab 1 assignment).

Throughout the semester, Amy had 54 interactions with ChatGPT across six lab assignments. When ChatGPT provided a correct solution, Amy often followed up with requests beyond the solution generated by ChatGPT for additional supportive knowledge to deepen her understanding of calculus concepts and theorems. For instance, after ChatGPT used the intermediate value theorem to demonstrate that a function has a root, Amy asked, "Could you draw the graph of the function?" (Lab 1 chat history) to help her visualize the solution. After GPT3.5 indicated its limitation on graphic drawing and suggested she use a graphic calculator, Amy adapted her approach and attempted to achieve the same goal with a follow-up inquiry: "How can I put the interval in my graphing calculator?" (Lab 1 chat history). Moreover, Amy often asked ChatGPT to explain and demonstrate the additional problem-solving process to help her understand the application of certain calculus theorems. For example, she asked ChatGPT, "Can you show a more detailed version of step 4?" (Lab 5 chat history) to gain a clearer explanation of using the second derivative test in an optimization real world problem. When Amy noticed minor calculation errors in ChatGPT's solutions, she typically acknowledged the correct logic behind the problem-solving process without overly criticizing the errors in her evaluations. As she wrote in her evaluation, "The calculation was incorrect in finding the derivative using the chain rule. This was the only inaccurate part. All other steps were correctly applied…" (Lab 3 assignment). These comments showed that even though ChatGPT made mistakes in some instances, Amy was still willing to use ChatGPT to scaffold her learning in calculus.

Case 2 – Sue

Sue's engagement with ChatGPT throughout the semester showed a consistently conservative stance as she rated the usefulness of ChatGPT in learning calculus (PU) as 3 out of 5 at the beginning of the semester and 2 out of 5 at the end of the semester. In terms of the perceived ease of using ChatGPT (PEU), Sue consistently rated 1 out of 5 throughout the semester. Sue questioned the efficacy of using ChatGPT for calculus learning from the start: "I do not think this is a good tool for people trying to learn calculus." (Survey 1). She emphasized the limitation of using ChatGPT for calculus learning, as she commented, "ChatGPT understands the steps of how to do the math problem, but the actual algebra and easy math is where ChatGPT struggles." (Survey 1). Her conservative attitude towards ChatGPT did not change throughout the semester even though she gained more experience of using the tool for calculus learning through lab sessions. In her conclusion, Sue acknowledged that ChatGPT might be useful (PU) "for someone who knows the basics and needs more practice problems, this [ChatGPT] could be a helpful resource, but you must remember that the answer is often incorrect, and the theorems and definitions might also be incorrect." (Lab 6 assignment). Overall, Sue was reluctant to use ChatGPT for calculus learning: "I honestly did not enjoy these [ChatGPT] labs, but maybe they were helpful to others." (Survey 3).

Throughout the semester, Sue had a total of 38 interactions with ChatGPT. Sue often used minimal prompts that were provided by the instructor and asked limited follow-up questions when ChatGPT provided a correct solution. Her inquiries typically sought clarification on specific solution steps, such as: "Can you show and explain your work for step 5?" (Lab 5 chat history), rather than exploring broader conceptual understandings or the application of theorems. In addition, Sue's tolerance for calculation errors in ChatGPT's solutions was relatively low. Sue often provided critical feedback for simple calculation mistakes by ChatGPT, rating GPT-generated responses as partially correct even though the ultimate output showed the correct answer. For example, she commented "ChatGPT had the correct steps to solve the problem, however, they missed a simple math problem on the 3rd step. After I asked them to recheck this step, they replied with another incorrect answer. I told them the answer that I had gotten for step three, and then they finally agreed." (Lab 1 assignment). Sometimes when ChatGPT's overall problem-solving process was correct, excluding minor calculation errors or omissions in the final step, Sue expressed dissatisfaction with the tool's performance: "Although most of the work was done correctly, ChatGPT did not give a final answer. Although volume was given in the question, it left volume as V…" (Lab 5 assignment).

Discussion and Conclusion

We found that Amy, with higher PU and PEU, was more accepting of using ChatGPT for calculus, whereas Sue, with lower PU and PEU, showed less acceptance. These results are in coherence with the previous studies using the TAM model, which indicated that PU and PEU are valid predictors of actual usage (Poellhuber et al., 2018), learner satisfaction (Nagy, 2018), and learning motivation (Hsu, 2012). Our findings also extend previous research on the acceptance and utilization of AI-assisted tools in education to the context of mathematical learning. Learners with higher PU and PEU of ChatGPT engaged more frequently with the tool, tolerated its errors better, and showed greater motivation to use it for further support.

Our study revealed how students' perceptions towards ChatGPT affect their approaches to using it as an educational tool. Sue, who showed a conservative perception, posed fewer follow-up questions for understanding concepts or theorems and rarely inquired beyond the provided prompts for extra knowledge. In contrast, Amy, who holds a positive perception of ChatGPT, demonstrated more active uses of ChatGPT to support her learning of calculus. She often asked for further guidance from ChatGPT, including requests for geometric representations of solutions and definitions of specific mathematical concepts (e.g., critical points). In addition, Amy achieved a higher final course grade than Sue, indicating that Sue lacked a thorough understanding of certain calculus concepts and theorems. She strongly preferred to seek help from the instructor during office hours compared to asking ChatGPT for guidance despite the tool offering more convenience and flexibility regarding time and location. The cases of Amy and Sue suggest that fostering positive PU and PEU is important to help students maximize the potential of ChatGPT. Future research should explore teaching strategies to cultivate a productive disposition among students towards ChatGPT, thereby fully leveraging its power as an educational tool.

This study explored how two college students' approaches to using ChatGPT in a calculus class were influenced by their contrasting perceptions of the tool. When students possess a higher PU and PEU of ChatGPT, they are more inclined to use it for learning support. The contrasting case of Amy and Sue underscored the necessity for students to have a comprehensive understanding of both the capabilities and limitations of ChatGPT. The study also highlighted the importance of supporting students in developing an open-minded perception of ChatGPT as they integrate the tool into their mathematics learning.

THE EFFECTIVENESS OF AN INNOVATIVE MANIPULATIVE IN FACILITATING CHILDREN'S DEVELOPMENT IN CIRCLE PARTITIONING

Maryam Zolfaghari
Kent State University
mzolfagh@kent.edu

Peter Oyewole
Kent State University
poyewole@kent.edu

Karl W. Kosko
Kent State University
Kkosko1@kent.edu

The purpose of this study is to investigate the effect of using a play-dough fraction circle cutter manipulative in helping children partition circles into eight or fewer equal parts. Recognizing the challenges children face in partitioning circles, especially with odd numbers, this study leverages innovative tools to enhance understanding of partitioning. The study used a quasi-experimental, pretest-posttest design with children aged 5 to 6 years. Findings show significant improvement in partitioning skills post-intervention, particularly in dividing circles into odd numbers. The implications of this study for both teaching and learning partitioning are discussed.

Keywords: Rational Numbers; Geometry and Spatial Reasoning; Elementary School Education; Technology

When it comes to learning about fractions, elementary school students experience difficulties (Barbosa & Vale, 2021; Fazio et al., 2016; Sidney et al., 2019; Tunç-Pekkan, 2015). The ability to understand and work with fractions is not just a requisite for mathematical literacy at this stage but is also seen as predictive of success in higher mathematical pursuits, including algebra and calculus (Siegler et al., 2013; Soni & Okamoto, 2020). A lack of proficiency in fractions can significantly hinder a student's ability to grasp more complex mathematical concepts such as algebra and calculus, especially as they progress through higher grades (Flores et al., 2020; Wilkie et al., 2022).

In this context, partitioning – the ability to divide a whole into equal parts – is fundamental to learning fractions. However, many children encounter difficulty with this concept, particularly when they cannot grasp equity-related issues from the earliest years of primary education (Castro-Rodríguez et al., 2022). Recognizing this challenge, studies have established that innovative manipulatives are important to teaching fractions and they support children with learning mathematical procedures while also being more enjoyable in learning fractions (Fazio et al., 2016; Furman, 2017; Moyer, 2001).

This paper aims to leverage these insights, exploring how children used a 3D-printed play-dough fraction circle cutter that scaffolds children's use of radii as partitioning tools. Rather, the study investigated how such a manipulative can facilitate children's learning to partition in the context of circles. Through this exploration, the study seeks to contribute to a broader understanding of effective methods for teaching and learning fractions and partitioning in early mathematics education.

Review of the literature

Children develop an intuitive understanding of fair sharing at an early age (Empson, 1995). This understanding often emerges through practical activities like one-to-one correspondence and "dealing out" real-life objects among friends (Empson, 1995; Hunting and Sharpley, 1988). These experiences with fair sharing play an important role in introducing children to the basic principles of fractions, particularly the concept of partitioning. In the context of fractions, partitioning generally is defined as "the ability to divide an object or sets of objects into equal parts" (Pothier & Sawada, 1990, p.12). However, partitioning (also known as equal portioning) is not just about part-within-the-whole reasoning, but the ability to see the equal parts out of the whole and also recreating the whole by iterating the parts (Steffe and Olives, 2010; Hackenberg et al, 2016). Partitioning is also seen as a recursive process (Confrey et al., 2009), It is about breaking down a whole into equal parts and the process of reassembling these parts back into the whole. In the context of early fraction development, partitioning is concerned with two elements, number theory and geometric shapes (Pothier & Sawada, 1990). Several studies have been conducted on how children develop partitioning reasoning, either focusing on one of these aspects or on their combination (Hackenberg et al., 2016; Maloney &Confrey,2010; Pothier & Sawada, 1990; Steffe & Olives, 2010)

In the context of partitioning reasoning and number theory, research has identified different learning patterns among children. A number of studies have suggested that the process of learning partitioning is not necessarily numerically sequential. These studies highlighted that children typically find partitioning into halves and quarters more intuitive than partitioning into other fractions (Zolfaghari, 2023; Confrey et al., 2009; Gabriel et al., 2013; Pothier & Sawada, 1990). Pothier and Sawada's five-level theory illustrates a progression from basic sharing and halving concepts to more complex ideas of evenness and oddness, and eventually, to a multiplicative algorithm. Similarly, Maloney and Confrey's (2010) equipartitioning learning trajectory outlines a similar path, starting with simple 2-splits and evolving through more complex stages, including powers of two, even, and odd splits.

On the other hand, other studies contribute to a different perspective, suggesting that children's initial efforts at partitioning lengths can be sequential (Hackenberg et al., 2016; Steffe & Olives, 2010). These scholars have noted that children partition length into two or three parts, which might not be of equal size. As they progress, children develop the ability to create equal parts and exhaust the whole with a greater numbers of parts, eventually advancing to handling any number of parts and multiple wholes.

Children's partitioning development is also associated with the geometric shapes partitioned. A vast majority of research highlights the significant role of geometric shapes in teaching early fractions and partitioning (Cramer et al.,2008; Larson, 1980; Lesh et al.,1987; Ni, 2001). This approach is also prominently used in many elementary mathematics textbooks using different geometric shapes, but predominantly pre-partitioned (Pothier, 1991). According to Ni (2001), the most frequently used shapes in early fractions education are circles, rectangles, and length models. Of these, the circle is found to be more challenging for children to partition (Confrey & Maloney, 2010), despite being the easiest to recognize (Fisher, 2009). This paradox might stem from what Pothier (1991) observed in analyzing children's partitioning behaviors. Pothier (1991) found that children, when faced with various shapes tend to adopt specific partitioning techniques such as halving, drawing vertical or horizontal slicing, rather than focusing on the shape itself to determine the number of partitions. “The counting algorithm quickly focuses children on the parts, making the geometry of the whole ostensibly irrelevant” (Pothier, 1991, p.96). The issue of not attending to the whole geometric shape seems to be more evident with circles. Circles, in contrast to polygons (particularly rectangles), do not offer clear starting and ending points that might facilitate successful partitioning. This absence of clear linear guides in circles necessitates a greater emphasis on understanding the holistic shape, thus posing a greater challenge in partitioning tasks.

Given the challenges highlighted, especially those associated with partitioning circles, as well as the complexities involved in partitioning using different types of numbers (larger numbers or odd numbers), it becomes essential to investigate how children approach the task of partitioning circles and explore effective ways to support their learning process in partitioning circles. One of the important tools to scaffold children in partitioning development or mathematics, in general, is manipulatives. While models of manipulatives are diverse, physical and pictorial visual models have been argued to be crucial for scaffolding children's understanding of fractions (Martin et al., 2012; Wilkie et al., 2022). Moyer-Packenham et al. (2012) compared the use of static pictorial representations and dynamic virtual fraction manipulatives with 19 third graders with lower mathematics achievements scores, with evidence suggesting students using both manipulatives demonstrating growth. In contrast, Martin et al. (2012) observed that, when compared to picture models, the use of concrete manipulatives was more beneficial to students’ mathematics learning since the children could directly engage with how to arrange the materials. Similarly, physical manipulatives help children to have a deeper understanding of mathematical concepts including fractions while also being more enjoyable (Furman, 2017; Laski et al. 2015). Stigberg (2022) conducted a study on digital fabrication in mathematics education and claimed that manipulatives, primarily made of 3D printing, are a means of giving abstract mathematical concepts or operations in geometry, algebra, and fractions a more real experience.

Figure 1: The Play-Dough Fraction Circle Cutter

Despite extensive research on the effectiveness of manipulatives and the best practices for their use, there remains a gap in developing specific manipulatives for defined instructional purposes (Zolfaghari, 2023). To address this gap, we designed a manipulative that can be 3D printed and used with play-dough (Kosko et al., 2024). The play-dough fraction circle cutter is a 3D-printed circle with one fixed radius and several radii that may be inserted and then moved along the circle's edge. An additional circle cutter is included that cuts a circle template with the center marked by an indention. Thus, there are two primary ways children can employ this tool: they can press the radius-based cutter onto play-dough to create imprints of the partitions directly, or they can use the center-of-circle cutter to create a circle with only the center marked and then replicate these divisions (from the radius-based cutter). This latter approach is illustrated by a child in the right-hand image in Figure 1. Two arrangements with the radius-based cutter are illustrated in Figure 1. The radii on the circle can be adjusted by children to divide the circle into given equal parts.

With the design of this fraction circle cutter, we aimed to explore how children interact with and learn the concept of partitioning circles. Rather, the manipulative was designed with manipulatable radii to help scaffold children's use of the radius as a partitioning tool, and help young children intuitively understand the need to partition between the center and edge of the circle, instead of all the way across the shape. Specifically, the study aims to ask the following research question:

> How does the use of manipulatable radii, in a fraction circle cutter, affect children's ability to partition circles into different numbers of parts?

Method

The study involved 15 children, aged 5 to 6 years, enrolled in kindergarten in a childcare learning center within the mid-western United States. Among the participants, 7 self-identified as boys and 8 as girls. These children were divided into two groups for this study: an experimental group and a control group. The experimental group participated in teaching sessions focused on partitioning circles, utilizing innovative manipulative tools. These sessions were designed to enhance their understanding and skills in this area. Meanwhile, the control group students continued with their regular kindergarten curriculum and classroom activities during this period.

Pre-Experiment

Initially, students were asked to complete a survey with 7 questions about partitioning a circle into different parts (See Figure 2). The purpose of these open-ended questions was to assess whether students could equally partition circles into 2 to 8 parts. The survey items were designed based on previous studies and literature that explored children's understanding of partitioning (Confrey et al., 2014; Hackenberg et al., 2016; Hunting & Sharpley, 1991).

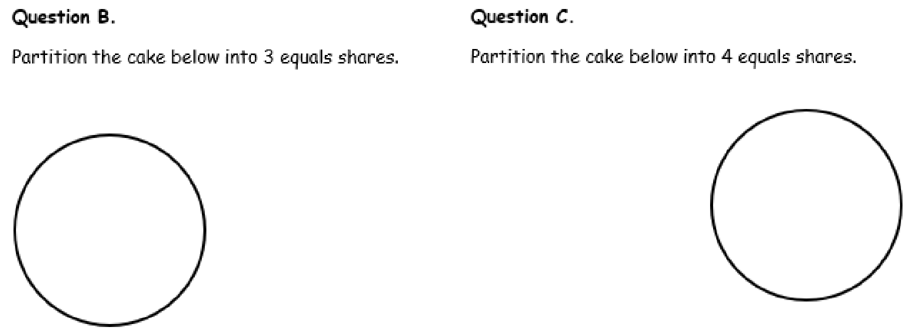

Figure 2: Example of Designed Items for Circle Partitioning Survey

To code students' responses to the survey, we utilized a transparent template that represents the acceptable range for partitioning circles into equal parts. This template was developed by Zolfaghari (2023) and helped determine the acceptable range to the extent to which students' partitioning could be considered equal. Utilizing this template, we assessed children's partitioning skills and assigned scores based on their accuracy: scores of 2 represented circles *equally partitioned* into the requested number of parts; scores of 1 represented circles *partitioned* into the correct number of parts but not equally sized; scores of 0 represented circles *incorrectly partitioned* either into incorrect number of parts.

Based on their survey scores, the first two authors selected two groups of four children each for the teaching sessions. The selection criteria for these students were based on their survey responses and encompassed the wide range of ability to partition, from unsuccessful to successful partitioning into various parts.

During the Experiment (Teaching Sessions)

In examining how children are involved with partitioning circles into different parts, we conducted a series of teaching sessions using an innovative manipulative (play-dough circle cutters), as shown in Figure 1. Eight sequential teaching sessions (Steffe & Thompson, 2000) were conducted over four weeks (two sessions per week). The intervention methodology is detailed in another study, as the current study's focus is on assessing the effectiveness of the manipulative and the emerging patterns in students' partitioning skills by looking only on their responses to the survey.

Post-Experiment

Upon completion of the teaching sessions, the same assessment was administered to the students. Of the children who participated in the teaching sessions, 5 were present and able to complete the post-survey. All 7 students from the control group were present and responded to the questions. Students' responses were scored using the same method explained above.

Analysis and Results

A Mann-Whitney U test statistic was computed to compare pre- and post-test scores between children who participated in teaching sessions using manipulatives and those in the control group. A Mann-Whitney test provided an appropriate statistical approach due to the small sample size (n=12) in this study as well as the ordinal nature of data for students' responses (Siegel & Castellan, 1988). Results indicated a statistically significant difference between the two groups

(U = 5.00, p = .039), indicating that the experimental group (Median = 11) was more likely to equally/successfully partition the circle into different parts than the control group (Median = 7). Results yielded a medium to large effect size (r = 0.586), suggesting a notable difference in partitioning between the two groups. However, it is important to note that these findings should be interpreted with caution due to the small sample size.

To further investigate how much change occurred within the experimental group due to having teaching sessions with the fraction circle cutter, a Wilcoxon signed-rank test was used to compare pre- and post-test scores for each group. For the experimental group, results indicated that there was a statistically significant improvement in the ability to partition circles post-intervention (Z = -2.201, p = .028), reflecting a significant positive effect of the scaffolding technique on the children's development of this skill. Such improvement was not observed in the control group in post-intervention (Z = -1.16, p = .246). We were also curious to know about the variation across different partitioning tasks and whether there was a specific pattern in students' responses to these tasks with and without the treatment. Figure 3 illustrates pre- and post-test scores for students in the control and experimental groups, but disaggregated by task (i.e., number of partitions requested for a paper-based circle). Recall that a score of 2 represents equally partitioned, a score of 1 was partitioned and 0 was incorrect number of parts or not partitioned.

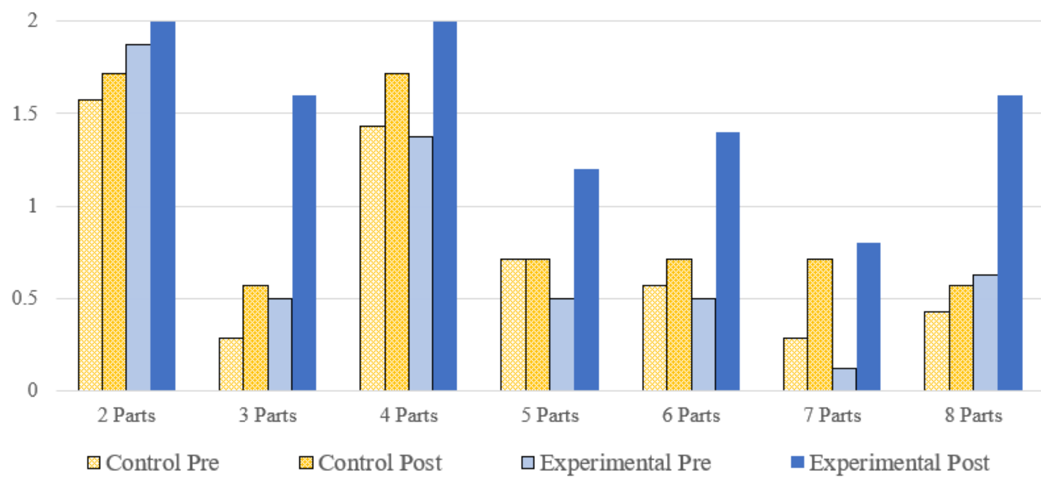

Figure 3: Changes in Task Partitioning Performance Before and After an Intervention for Control and Experimental Groups

Visual analysis of Figure 3 regarding responses from both experimental and control groups of students indicates a trend in their ability to partition circles. Tasks involving partitioning into 2 and 4 parts were the most successfully completed, as reflected by the highest mean scores. This suggests an initial comfort or familiarity with simpler partitioning tasks. Following these, tasks involving partitioning into 5, 6, and 8 parts showed moderate success. This is characterized by mean scores that range from .42 to 1.6. Lastly, partitioning into 3 and 7 parts proved to be the most challenging for students, as evidenced by the lowest mean scores (see Table 1).

The post-intervention data from the experimental group reveals a significant shift in trends from pre-intervention. The tasks of partitioning into 2 and 4 parts, which were already high, saw growth, with all children in this group demonstrating equal partitioning (*M* = 2.00, *SD* = .00). Interestingly, the task of partitioning into 3 parts, which was previously one of the least successful tasks for Kindergarteners, improved to become the second highest scoring task for students in the intervention (*M* = 1.6, *SD* = .54). This demonstrates a significant positive impact of the intervention on this specific skill. Tasks involving partitioning into 6 and 8 parts also showed noticeable growth. Tasks of partitioning into 5 and 7 parts, while still showing improvements, remained relatively more challenging for the students, as seen by the lower mean scores and higher standard deviations compared to other tasks.

Data for the control group on the post-intervention data did not exhibit growth in the way that the experimental group did. Specifically, in tasks involving partitioning into 2 (*M* = 1.71, *SD* = .75) and 4 parts (*M* = 1.71, *SD* = .75), the control group's mean scores did increase (from 1.57 to 1.71 and from 1.42 to 1.71, respectively), but not to the level of the experimental group. In other words, many Kindergarteners in the control group did improve in partitioning into 2 and 4 parts, but there were still students who could not partition into equal parts or even into the requisite number of parts requested on such tasks. The performance on tasks involving partitioning into 3 parts also improved (mean score from 0.28 to 0.57), but this was significantly lower than that of the experimental group (mean score from 0.5 to 1.6). This pattern was consistent across tasks, with the control group showing some improvement post-intervention but not to the extent of the experimental group.

Overall, results indicate that most Kindergarteners in both groups were capable of either partitioning or equally partitioning circles into two and four parts. However, when students were exposed to using the fraction circle cutter, they were much more likely to partition a circle into other requested number of parts. This was particularly the case with partitioning into three parts, with all students in the experimental group either partitioning or equally partitioning a circle into three parts, and very few of students in the control group doing so (see Table 1). In examining students' written work on the post-test, children in the experimental group focused more on using the center of the circle in attempting their partitioning whereas students in the control group did not use this property of the circle. This comparison highlights the effectiveness of using manipulatable radii on a play-dough fraction circle cutter in enhancing students' skills in partitioning circles.

Table 1: Mean Scores of Students on Partitioning Tasks Before and After Intervention

	Pre-intervention				Post-intervention			
	Experimental group		Control group		Experimental group		Control group	
	M	SD	M	SD	M	SD	M	SD
Partitioning into #2	1.87	0.33	1.57	0.72	2	0	1.71	.75
Partitioning into #3	0.5	0.5	0.28	0.45	1.6	.54	.57	.53
Partitioning into #4	1.37	0.85	1.42	0.72	2	0	1.71	.75

Partitioning into #5	0.5	0.5	0.71	0.45	1.2	.7	.71	.48
Partitioning into #6	0.5	0.5	0.57	0.49	1.4	.54	.71	.75
Partitioning into #7	0.12	0.33	0.28	0.45	.8	.44	.71	.48
Partitioning into #8	0.62	0.48	0.42	0.49	1.6	.89	.57	.53

Discussion

The purpose of this study was to explore the effectiveness of using a fraction circle cutter with manipulable radii in scaffolding children to partition circles into equal parts and to explore emergent patterns in their partitioning skills. Prior research has indicated that while circles are one of the first and easiest shapes for children to recognize (Ni, 2001), partitioning them into equal parts, particularly with odd numbers, is extremely challenging (Malony & Confrey; 2010). In this study, we used an innovative manipulative to help students focus on the task of partitioning and to examine the development of their skills in this area. The results showed a significant improvement in the experimental group's ability to partition circles into equal parts, aligning with prior research on the efficacy of manipulatives in education (Martin et al., 2012; Stigberg, 2022).

What sets this manipulative apart is its targeted design, which actively engages children in attending to the shape as they adjust the radii to create equal parts. This addresses a critical aspect identified by Pothier (1991), where students often neglect the geometry of the whole shape itself in determining the number of partitions. We believe that this tool helps students to focus simultaneously on both the counting algorithm (number of parts) and the geometric aspect of the circle, thereby integrating both aspects of the task. This integration suggests that types of representations that press students to interact with the geometry of the circle may provide a resource for teachers and students as they learn to partition shapes before formal instruction on fractions.

We observed distinct patterns in students' abilities to partition circles in both the experimental and control groups, before and after the intervention. Before the intervention, our observations revealed specific patterns in students' difficulties with partitioning circles into eight or fewer parts. Initially, students found it easiest to partition shapes into halves and quarters. This was followed by the challenge of partitioning into numbers that are powers of 2 (such as 6 and 8), and subsequently, they faced greater difficulty with odd numbers (3, 7). These observed patterns in students' abilities to some degree align with the patterns suggested by previous researchers (Pothier & Sawada, 1990; Maloney& Confrey, 2010). However, after the introduction of the fraction circle cutter, with manipulatable radii, this pattern changed significantly. While partitioning into halves and quarters remained the easiest tasks, dividing into thirds became the second easiest task for students in the experimental group. After this, tasks involving powers of 2 (such as 6 and 8) came next, and finally, the more challenging tasks were partitioning into the larger prime numbers 5 and 7. We conjecture that the changes with partitioning, especially with partitioning the circle into three parts, highlight the effectiveness of manipulatable radii in guiding students to focus not only on counting parts but also on engaging with the whole geometric shape of the circle. We believe this approach fosters out-of-the-box thinking, enabling children to conceptualize the circle in new ways. It encourages them to understand the limitations of common partitioning methods (Pothier & Sawada, 1990) and to explore alternative starting points (i.e. the center of the circle). This is a practice not typically emphasized in conventional school instruction for teaching fractions or partitioning. By focusing on such scaffolds—especially given that circles are commonly used to teach fractions (Ni, 2001)—we believe teachers can establish a strong foundation for students' partitioning in the early grades and better prepare them for learning fractions more effectively.

Despite these promising findings, we are still in the exploratory phase of examining this manipulative and pedagogical approach. Recognizing limitations, such as the small number of students involved, further investigation is needed to explore the broader effectiveness of this tool, especially when used by different teachers. Additionally, more data is needed to confirm the observed patterns. Ensuring the consistency of these patterns across a wider student population will provide a more comprehensive understanding of the tool's effectiveness in teaching and learning partitioning.

Group work is widely employed in mathematics classrooms to foster communication and enhance students' mathematical thinking. Drawing on principles of participatory equity, this study explores the role of group roles in promoting equitable participation. The study highlights the benefits and challenges of group work, foregrounded by the importance of culturally responsive teaching and open-ended tasks. Specifically, we attended to how group roles influence participation in a graphing scenario task conducted at a summer math camp. Data analysis reveals insights into students' communication patterns and the impact of group roles on participation. The findings suggest that group roles offer opportunities for students to engage and express their ideas, contributing to more inclusive mathematics classrooms.

Keywords: Middle School Education, Communication, Culturally Relevant Pedagogy, Equity, Inclusion, and Diversity

Group work is a common strategy to utilize in mathematics classrooms for students to communicate their ideas. Communication is one of the process standards in the National Council of Teachers of Mathematics' *Principles and Standards for School Mathematics* as a means for students to reflect on and modify their mathematical thinking (NCTM, 2000). However, a path forward to envision equitable participation in group work is a complex goal to achieve due to the nature of the social aspect that plays out. Yet, the National Council of Teachers of Mathematics' *Principles to Actions: Ensuring Mathematical Success for All* advocates that mathematics programs should aim to have access and equity in their classrooms (NCTM, 2014). That is, all students need to have the necessary support so that they reach their full learning potential (NCTM, 2014). However, the real question becomes how to translate such access and equity into a groupwork task where human interactions vary depending on the social dynamics of the group.

Shah and Lewis (2019) noted that inequity in collaborative learning tends to increase or decrease depending on the circumstances, but they recommended striving for participatory equity, when all students have an equal opportunity to participate in a learning interaction. That is, the authors emphasized that when two or more people enter a joint endeavor, factors, such as group norms, task structure, and the distribution of authority, can either promote equitable participation or reinforce inequitable opportunities (Shah & Lewis, 2019). One way to target productive groupwork and equal opportunities to participate among students is to develop different group roles that value different skills and interdependence (Cohen & Lotan, 2014).

Literature Review & Theoretical Framing

Many researchers have investigated the implications for learning and equity in using small groups in mathematics classes. Cohen et al. (1999) recorded gains in achievement for students who participated in small group classrooms, specifically on higher-order questions where students were asked to demonstrate more abstract knowledge beyond recalling facts. Cohen (1994) observed that students in groups who often take on the task of explaining to their peers have especially benefited in terms of achievement. Additionally, researchers have studied participation patterns and opportunities for students to be positioned as mathematically competent within their groups (e.g., Campbell & Hodges, 2020; Langer-Osuna, 2011; Esmonde & Langer-Osuna, 2013). For example, Esmonde and Langer-Osuna (2013) observed a student, Dawn, positioning herself with more power than she previously had opportunities to, by inserting her social talk to shift the figured world of the classroom and engaging in productive mathematical practices in the process.

While the literature has seen promise in group work, it is not a guarantee of positive outcomes. Cohen (1994) examined the complications of reaching productivity in group work as obtained "only under certain conditions" (p. 2); Esmonde (2009) also highlighted complexities such as classroom context, status indicators, task design, and the teacher's role. Even when group work seems to be leading to gains in participation, rich learning opportunities can be sacrificed. Campbell and Hodges (2020) identified "co-construction" group structures that allowed all group members to insert valued ideas, but meanwhile, in favor of agreement, students were not able take up productive mathematical debates with each other. Other researchers have also noted that students need to be guided in group work to work together as intended and these skills are not automatic, that is, "something must be done to provoke the desired behaviors" (Cohen, 1994, p. 7), and benefits will never be straightforward when students are "left to their own devices" (Heck et al., 2019, p. 437).

Moreover, researchers have studied the assignment of group roles as a provided structure in students' participation in groups. Heck et al. (2019) illustrated how reinforcement of group roles aided students in "enhancing the group's mathematical discourse" and "protecting" their contributions when others in the group attempted to be more dominant (pp. 439 – 440). While group roles are not enough to ensure equity, as several factors are at play (e.g., Langer-Osuna, 2011), they can be a start in guiding students to engage in group work in a purposeful way, as teachers continue to monitor and address group dynamics (Esmonde, 2009).

Throughout our design and implementation of our graphing task, we adopted the theoretical ideas of "culturally responsive teaching" to guide us (Gay, 2010; Ladson-Billings, 1994). Culturally responsive teaching asserts that to open opportunities for rich learning in diverse students, teaching should draw on students' own strengths by leveraging their cultural knowledge, prior experiences, and performance styles. In creating our task, we strived to include access for students to insert their personal experiences into the activity by creating our task to be open-ended and designing purposeful group roles (see Methods for the explanation of the task). Researchers have emphasized that open-ended tasks that have properties of uncertainty with no single right answer are beneficial for group work (e.g., Lotan, 2014; Heck et al., 2019), as they "increase the need for interaction since they force students to draw upon each other's expertise and repertoire of problem-solving strategies" (Cohen et al., 1999, p. 83). However, we acknowledge that even with culturally responsive teaching at the forefront of our design, there are many factors that could still impact student participation and ability to express their personal ideas into the task, including authority structures within the group (Cobb et al., 2009).

In this report, we share an analytical perspective on how group roles intertwine with the participation of group members' ideas and contributions in a graphing scenario task, where students alternated group roles three times but stayed in the same group. We are guided by the research question, "How do designated group roles influence the types and frequency of participation among middle school students during a collaborative graphing task?"

As the aforementioned literature has addressed many complexities to "participation" while students work in small groups, we kept this in mind and operationalized participation by considering students' engagement throughout the task in two main ways. We attended to students' patterns of contributions of idea proposals within each group role, but we also investigated participation by attending to the types of responses group members provided to these proposals. To do so, in our analytical choices, we adapted the coding frameworks for proposals and group member responses Barron (2003), Campbell and Hodges (2020), and Langer-Osuna (2011) developed and applied for investigating these participation dynamics within small groups.

Method of Study

The data for this study was gathered from a 2023 summer math camp in the southern United States, which provides a distinctive mathematical learning community for elementary and middle school students. The camp places students into one of five levels depending on their age and mathematical knowledge for a 2-week, half-day program. That is, the first level consists of students from grades third through fourth, while the fifth level consists of middle school students in grades seventh and eighth. Depending on the level, the mathematical content ranges from beginning concepts in algebra to advanced problem solving and discrete math.

Data Collection

To explore how students may participate within their groups, we designed a graphing scenario task with group roles (Table 1), in which students had to create an original story from suggested scenarios (e.g., pet following you to school), along with a sketch of the graph that aligns with the story. One thing to note is that students were building a distance versus time graph with no implied numerical values on the axes.

Table 1: Group Roles

Storyteller	Creates their own story to build the graph from suggested scenarios.
Screen Writer	Writes notes in their index card or sheet of paper on what the group notices about distance and time from the story and graph, which can include rate of change, constant speed/velocity, acceleration, or stationary conditions.
Grapher	Creates the graph on the poster from the storyteller and can ask the group if the graph aligns with the story.
Director	Presents the graph along with the storyline to the class.

This report focuses on one group of students from level five (seventh and eighth graders) working on the graphing scenario task. On the day of the activity, students were first introduced to standard nonnumerical graphs by having a class discussion on certain differences between the graphs. Namely, there was a discussion highlighting concepts like rate of change, constant speed or velocity, acceleration, and when the object is at a standstill. This took about 20 to 30 minutes before beginning the graphing scenario task. After the class discussion, students were placed into groups of four that were preplanned. Each group received written instructions for each group role, a large sticky sheet, a small white board, and markers. The Grapher used a large sticky sheet to sketch their graph, while the Screen Writer used a small white board to take notes. During the group activity, there were three rounds in which the group rotated different group roles. In other words, each group member had the opportunity to participate in three different group roles (Table 1) in the graphing activity. We video and audio recorded the groups as they worked on the graphing scenario task. The group of students focused on in this report consisted of three female students (Taylor, Katy, and Natalie) and one male (Chris). The dialogue during the group activity for the three rounds was transcribed to analyze.

Data Analysis

Each of the four authors acted as a coder. Three of the authors initially watched the video of the first round of the group activity to gain familiarity with the interactions. As a foundation, we started with the coding scheme proposed by Barron (2003), where codes recognize when a group member proposes an idea or contribution. However, we expanded the coding scheme with more codes and distinctions to reflect on specific types of student responses to a group member's idea or suggestion from our data; for example, we added a "resistant uptake" once noting properties of it in the videos and referring to Langer-Osuna (2011)'s codes of this. Additionally, completely new codes emerged such as distinctions in the type of "discussion" responses. We later brought a fourth author to code with us on the second round of video interactions to discuss some commonality in the code book and make minor modifications to be more concise. This resulted in a total of 9 codes (Table 2). Although the fourth author came into the coding of the second round of the group activity, we coded the first round of the group activity again to stay consistent with the modifications and to include the fourth coder.

Table 2: Coding Scheme for Student Responses & Examples

Code	Definition	Example
(1) Idea/ Contribution	A student verbally proposes a suggestion to include in the task.	Taylor: We should do murder mystery.
(2) Successful Uptake	A group member accepts the idea without any complaint.	Chris: Forgets how to get home. [Chris acknowledges the idea while writing down story.]
(3) Resistant Uptake	A group member accepts the idea with a complaint or hesitation.	Natalie: I'm not gonna do the line. Actually, I'll do it with a pencil. This is great.
(4) In Task Discussion	A group member who did not propose the new idea but initiates a discussion with the intention of	Katy: Yeah. Oh my God. That's what we should do. Draw an airplane and stick it to

	advancing the idea.	a pencil. Just have it go [hand motion].
(5) Clarification Discussion	A group member who did not propose the new idea but requests further information about the new idea or inquires about the rationale for considering it.	Natalie: He's late for school and his school is far away from home, right?
(6) Rejection	A group member verbally refuses the idea or requests another suggestion.	Taylor: No, normal stories are boring.
(7) Ignore	A group member was verbally (or non-verbal) switching the topic or not adding to the idea.	Katy: You should draw a thunderstorm. That's why turbulence happens. (code 1) Natalie: I've never been to an airport either. Actually, I have. (code 7)
(8) Individual Role-Reference	A group member comments or asks for directions about the task with explicit reference to their own group role.	Natalie: I know but I have to write it down. Do I make my graph already?
(9) Peer Role-Reference	A group member explicitly directs or reminds another peer to partake into the task in respect of the peer's group role.	Chris: You're the Grapher. You're the one that has to design the whole graph. It's none of our job.

In the coding phase, initially, each coder read the three rounds of the small group transcripts and independently assigned an appropriate code(s) on certain talk turns. Moreover, we did not code turn talks from the teacher or when conversations were off topic. Once every coder was finished coding one round of transcripts, we gathered to discuss everyone's codes to arrive at a consensus. As a group, we had a discussion to lay out the reasoning for everyone's code and to convince all coders of what the appropriate code was. During the deliberation, we either rewatched the small video segment as a group, reread the previous lines of dialogue to gain more context, and/or revisited the codebook to emphasize what the code is targeting. Once all four coders agreed on a single code, we moved on to the next coded turn talk. The unit of analysis was when a student introduced a new idea or contribution to the graphing activity (code 1). Codes 2 through 7 acted as consequential responses, following that idea code from other group members who did not initiate a contribution. This means the turn talks focused on the proposed idea or contribution (code 1) from the one who initiated the conversation were not coded, mainly because we were interested in how the other group members verbally responded to such suggestions. For example, the following conversation occurred during the third round of small group work:

Natalie: We should write Kobe with signs and then
Chris: Why are we doing basketball players. We did it. Michael Jordan Now on...Kobe
Katy: Stop

Natalie proposed a contribution to the group activity by suggesting a character in the storyline. This turn talk was coded as 1 by all coders, so there was already a consensus, and no further discussion was needed. Chris then inquired for justification for the continuation of a basketball player to be included in the story. Two coders coded that as 5, while the other two coders coded the turn talk as 3. We then discussed our reasoning and eventually came to a consensus for code 5. For Chris's turn talk, we agreed on a code of 5. As for Katy's turn talk, two coders had it as 6, while the other two coders had it blank. We then deliberated and agreed that Katy's turn talk was reflected as a code of 6. One thing to note is that we did not code turn talks from Natalie centered on her inclusion of Kobe with codes 2 through 7. We wanted to see how everyone else responded when certain group members initiated a contribution, given their group roles. As for codes 8 and 9, we were interested in parts of the conversation that were motivated by the students' group roles.

Findings

We organize our results first by reporting on findings for each of the three rounds in terms of how group roles intertwined with the participation of group members' ideas and contributions to the graphing scenario task. We then examine all three rounds and observe similarities or differences in the rounds as students changed their roles. We examined 93 total ideas proposed during the three rounds with 50 ideas from Round 1, 25 from Round 2, and 18 from Round 3.

Round 1

In Round 1, the story that evolved was about a cat that traveled from home to school at a certain distance away, taking breaks then running along and having incidents such as the loss of a wallet along the way. Figure 1 provides a visual representation of the participation for each role in Round 1 in terms of ideas suggested and responses contributed to others' ideas. Among the four roles of Storyteller (ST), Screen Writer (SC), Grapher (GR), and Director (DI), ST proposed the most ideas with code 1, followed by the SC, then the GR, and lastly DI. On the other hand, responses were those turn talks coded as 2 through 7. As indicated in Figure 1, SC contributed the most responses. The responses most frequently occurring for SC included agreeing with the idea (code 2) six times and seeking clarification (code 5) seven times. The GR followed with the most rejection (code 6) six times and seeking clarification (code 5) six times with only one agreement to an idea. DI's responses included seeking clarification (code 5) six times followed by rejection (code 6) four times. Lastly, the responses from ST were the least frequent with mainly agreement (code 2) four times and resistant uptake (code 3) twice.

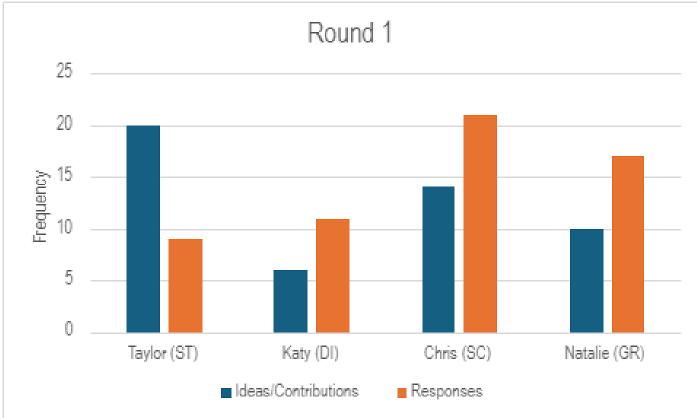

Figure 1: Round 1 Ideas and Responses by Roles

Round 2

For Round 2, the story was developed around Spiderman saving MJ, Michael Jordan, from a burning building. The story involved Spiderman going up to get MJ to bring him back down, and the time associated with those tasks. Figure 2 breaks down the number of new ideas suggested and responses to others' ideas from Round 2. Like Round 1, the ST contributed the most ideas in Round 2. However, in this round, the GR offered the next most new ideas followed by the DI, and then the SC. As responses to ideas went in this round, the DI led the number of responses with five of those being coded 2 and three codes of 5 and 6 each. Next was the ST largely coming from three successful uptakes and two rejections. Finally, the SC and GR responded to ideas the same number of times where all five of SC's where coded 5 and GR had two coded 2, two coded 5, and one coded 4.

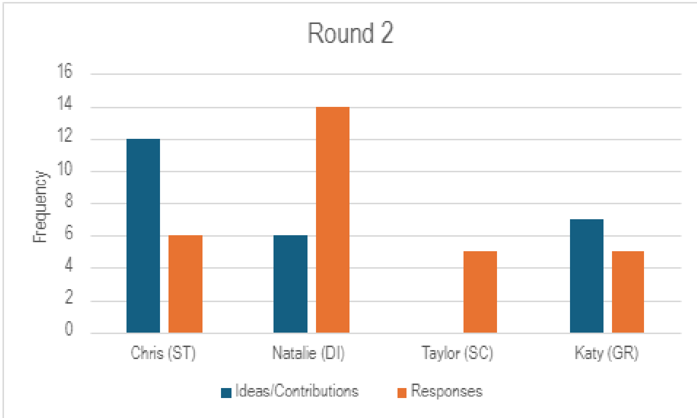

Figure 2: Round 2 Ideas and Responses by Roles

Round 3

The third and final round's story revolved around an airplane crashing due to turbulence and a thunderstorm. Figure 3 displays the number of new ideas and suggestions from each group member and their role. Again, in this round, the ST suggested the largest number of new ideas, followed by the SC and GR. The ST shared the lead in the responses category, primarily coming from three coded 2 and two ignore codes. GR had the same number of responses as ST where three clarifying questions were coded as the largest portion of responses. Lastly, DI responded the least with only one coded 5.

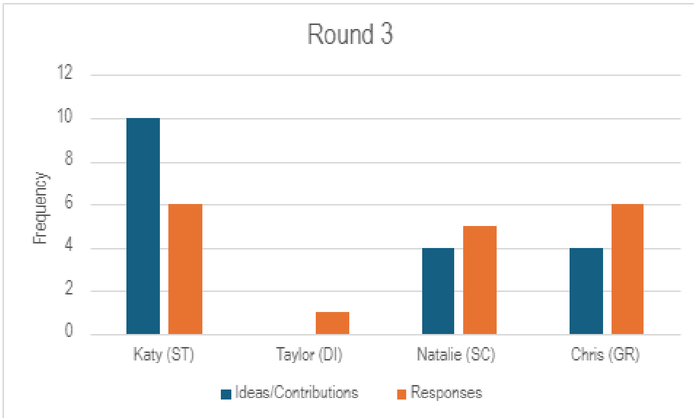

Figure 3: Round 3 Ideas and Responses by Roles

Role Acknowledgement

We noticed that acknowledging one's role (code 8) or another's role (code 9) were more prominent in round 1 and 2 with little being referenced in round 3. We did not consider this an explicit response to the idea but more to the group participation. However, there seemed to be an awareness that everyone's contribution was important in the ways defined by the roles. In round 1, there were 13 mentions of roles, two being code 8 and 11 code 9. Meanwhile, round 2 had eight mentions of other's responsibility and role (code 9) and ten mentions of one's own role (code 8). In the last round there was just one instance of code 8 and one of code 9. We conjecture this reduction in the final round is due to the development and understanding of each role from each group member as they progress through the rounds.

Discussion

The goal of the study was to gain insights on how middle school students communicate in a designed task, given group roles. Furthermore, we addressed the type of responses students engaged in and in what ways the group roles played a part in their participation. For instance, the Storyteller had the obligation to create a scenario for the group to sketch a graph, which contributed to the Storyteller having the highest number of proposed ideas/contributions on each of the three rounds. Although the other three group roles had distinct duties, there was not a specific group role that consistently had the highest number of responses (codes 2 through 7) to group members' proposed ideas/contributions. Round 1 had SC with the most, round 2 had DI with the most, and in round 3, there was a tie between ST and GR.

We also note that while we observed patterns discussed in the previous section, we maintain that these patterns interact with more than simply group roles. For instance, we hypothesize that group dynamics throughout the rounds and broader social factors could have impacted participation moving forward, such as in Langer-Osuna's (2011) work. We encourage future research for this complexity. Although there are some limitations this study holds, such as the focus on one group and not investigating the deeper social dynamics that also can influence participation, there are certain implications that the findings can inform educators to pursue equitable participation. Since literature suggests that at times mathematics classrooms create an atmosphere influenced by gender and race (Battey & Leyva, 2016; Leyva, 2021), our data indicates that a group role that positions students to constantly propose ideas can give those students who come from marginalized communities a chance to express their voice and "protect" their contributions (e.g., Heck et al., 2019). The role of the ST pushed students to take on the responsibility of sharing ideas with the group while the other members responded to them. Nevertheless, our study suggests that group roles can provide unique affordances for participation, which can pave the way to integrating students who typically do not express their ideas in a mathematics classroom. Such affordances for participation could be related to the design of the task being grounded in culturally responsive teaching via allowing opportunities for open-ended participation through the activity and given group roles. For example, stories in this group consisted of references to popular athletes, while created graphs incorporated students' own pictorial additions to the ST's created story. Our limited knowledge of the individuals' backgrounds prevents us from making strong arguments, but we anticipate that task design and group role choices could impact students' opportunities to insert their own personal experiences into the mathematical activities at hand.

Acknowledgments

We extend our heartfelt gratitude to the teachers for their invaluable assistance in implementing the task in their classrooms. Their dedication, support, and enthusiasm have been instrumental in the success of this endeavor.

This study explores how inclusive and differentiated instructional practices, specifically focused on designing and implementing mathematical tasks, influence student learning outcomes in mathematics education across Nigeria, Kenya, Ghana, and the USA. By integrating insights from prominent research in each context, the research aims to uncover the transformative potential inherent in mathematical tasks. Drawing from established concepts like higher-order thinking, problem-solving, scaffolding, and differentiated instruction, the study navigates diverse educational contexts, emphasizing the impact of socioeconomic contexts, inclusivity, and collaborative learning environments. The findings aim to offer practical guidance for educators and policymakers, contributing valuable insights to enhance mathematics learning environments.

Keywords: Instructional Activities and Practices, Problem-Solving, Mathematical Representations

Previous studies, such as those by Gravemeijer (1994) and Masingila (1993), emphasize the importance of aligning mathematical tasks with students' backgrounds and surroundings. This principle is not universally applied, yet research consistently shows significant differences in mathematics instructional practices between developed and developing countries. Educators in developing countries often face resource constraints that limit opportunities for scaffolding, problem-solving, and student-centered learning, leading to more teacher-centered approaches (Amoah, 2018; Ampadu & Danso, 2018; Fletcher, 2010). In contrast, developed countries offer various resources, such as computational tools, curated textbooks, and extracurricular facilities, enabling enriched mathematical tasks that foster creativity.

Mathematical tasks are essential for promoting problem-solving, critical thinking, and mathematical reasoning. However, Bature et al. (2016) observed that many developing countries prioritize rote memorization and procedural fluency over conceptual understanding. This underscores the need for interventions to ensure all students, regardless of location or socioeconomic status, receive high-quality mathematics education that encourages deep conceptual understanding and critical thinking skills.

In developing countries, mathematical tasks often emphasize algorithmic procedures and standardized test preparation. For example, in Kenya, educators design tasks based on standardized test items and assess students through high-stakes exams (Nandwa et al., 2015). Similarly, in Nigeria, traditional practices significantly impact student performance (Falebiba & Olofin, 2020; Ojonubah, 2016). Addressing diverse learning needs requires adopting differentiated, student-centered instruction that promotes conceptual understanding and problem-solving (Njagi, 2014; Amoah, 2018; Ampadu & Danso, 2018).

Conversely, developed countries prioritize student-centered approaches in mathematics instruction. These approaches actively engage students through hands-on activities, collaborative problem-solving, structured curricula, and real-world applications (Stecher et al., 2016; McGaffrey et al., 2001). Numerous studies highlight the significant influence of instructional practices on mathematics achievement (McDonald et al., 2013). Teachers in these contexts employ diverse mathematical tasks, from open-ended investigations to structured problem-solving, to deepen students' understanding of mathematical reasoning and concepts (Anderson, 2003; Henningsen & Stein, 1997).

Our study conducts a comparative analysis of mathematics instructional practices across Nigeria, Kenya, Ghana, and the USA, focusing on inclusive and differentiated approaches. The investigation aims to uncover how socioeconomic contexts create disparities that impact student learning outcomes. By examining these differences, this research seeks to inform educators, policymakers, and researchers about the contextual factors shaping instructional practices and student outcomes in various national settings. Our guiding question is: How do inclusive and differentiated instructional practices, particularly in the design and implementation of mathematical tasks, impact student learning outcomes in mathematics education across Nigeria, Kenya, Ghana, and the USA?

Mathematical Instructional Practices

Mathematical fluency and conceptual development are essential for students to navigate complex problems and real-world applications confidently. A comparative analysis of instructional practices in Nigeria, Kenya, Ghana, and the USA highlights the diverse approaches to mathematics education. In Nigeria, Bature et al. (2016) emphasize the importance of inclusive instruction, showing its positive impact on student outcomes through tailored tasks. Similarly, Nandwa et al. (2015) highlight structured instruction and collaborative activities in Kenya, fostering a dynamic learning community.

Teachers' attitudes toward differentiated instruction play a crucial role in shaping instructional practices. In Kenya, teachers' favorable attitudes toward differentiated instruction, evidenced by varied tasks catering to different readiness levels and learning styles, contribute to a supportive learning environment (Njagi, 2014). Teachers who tailor instruction to accommodate diverse abilities create an inclusive environment where all learners feel valued and supported, this aligns with Mayer (1999) emphasizes intentional task selection to enhance students' mathematical experiences. Effective mathematics instructional practices in the United States involve differentiated and individualized approaches, particularly benefiting students with difficulties (Morgan, Farkas, & Maczuga, 2015; McKinney et al., 2009). Emphasizing conceptual understanding over rote memorization is linked to higher student achievement, with innovative practices showing positive outcomes (O'Dwyer, Wang, & Shields, 2015; Osborne, 2021; Herbst & Chazan, 2020).

Challenges such as language barriers and individual differences necessitate a spatial justice lens in mathematics education (Larnell & Bullock, 2018). Khalo et al. (2022) and Gee (1999) discuss how language difficulties can hinder problem-solving, highlighting the need for practices that accommodate linguistic diversity. Mereku & Cofie (2008) and Rubel & Nicol (2020) advocate for spatial justice to address individual differences and ensure equitable access to learning opportunities. Recent research, such as Amoah (2018) in Ghana, focuses on practical tools like the AKIOLA Core Mathematics Series and Enriched Mathematics textbook to enhance instructional practices. Studies by Shultz (2022) and Villanueva & Prudente (2022) further contribute to the conversation on effective mathematics education by exploring teachers' knowledge, attitudes, and practices. These findings highlight the importance of evidence-based practices and continuous professional development to improve instructional quality and student outcomes globally.

Methods

The study utilizes a comprehensive comparative analysis approach to examine mathematics instructional practices in the USA, Nigeria, Ghana, and Kenya. Content analysis, as outlined by Bowen (2009), serves as the primary method for reviewing documents to extract meaningful passages. Leveraging the researcher's firsthand experiences in these countries adds a distinctive perspective to understanding instructional challenges and the influence of socioeconomic factors on mathematics education. Merriam (2009) and Krippendorff (2004) emphasizes the methodological rigor of employing content analysis for making replicable and valid inferences from textual data to their contexts.

Thematic coding and analysis were conducted on a curated selection of peer-reviewed publications, standards/practice documents, and curriculum frameworks. This process involved coding raw data and categorizing them into themes based on the content characteristics. Major themes identified included higher-order thinking (HOT), problem-solving activities (PSA), and open-ended assessment techniques (OEAT), emphasizing their significance in shaping student mathematical learning. This approach captures diverse perspectives on instructional practices and provides valuable insights into the challenges and contextual factors influencing mathematics education. The methodological approach ensures a comprehensive exploration of the subject matter, facilitating a deeper understanding of the diverse landscapes of mathematics instructional practices across the selected countries.

Findings and Discussion

The findings from an in-depth analysis of a curated selection of peer-reviewed publications, standards/practice documents, and curriculum frameworks from Nigeria, Kenya, Ghana, and the USA underscore the pivotal role of mathematical tasks in shaping student learning outcomes in mathematics education (Bature & Jubrin, 2015; McGaffrey et al., 2001; Spillane & Zeuli, 1999). While the curriculum standard documents are well-articulated, with clear content and learning objectives, there is a discrepancy observed in the curriculum objectives enactment and development and use of enriched mathematical tasks among teachers in Ghana, Nigeria, and Kenya compared to their counterparts in the USA. This difference may be attributed to varying access to necessary resources and ongoing professional development opportunities for instructional improvement.

Thematic coding reveals recurring themes such as higher-order thinking (HOT), problem-solving activities (PSA), and open-ended assessment techniques (OEAT), highlighting their influence on student mathematical learning. These findings resonate with Bature & Jubrin's (2015) emphasis on the importance of tasks stimulating higher-order thinking skills in Nigeria, facilitating meaningful connections between various mathematical concepts. Similarly, McGaffrey et al. (2001) in the USA advocate for activities of varying difficulty levels, fostering students' understanding and enhancing their ability to generate diverse solutions, aligning with the universal pedagogical goal of promoting critical thinking and creativity in mathematics education.

Furthermore, the significance of problem-solving activities, recognized across diverse educational contexts (McGaffrey et al., 2001; Spillane & Zeuli, 1999), plays a crucial role in developing students' mathematical proficiency. This aligns with the observations of McGaffrey et al. (2001) in the USA, highlighting the positive impact of presenting students with activities that involve varying levels of difficulty. The emphasis on problem-solving is consistent with Spillane & and Zeuli's (1999) exploration of patterns of practice in the context of national and state mathematics reforms.

Open-ended assessment techniques, implemented in Kenya and the USA (Nandwa et al., 2015; McGraffrey et al., 2001), encourage personalized, critical responses, fostering a comprehensive understanding of mathematical concepts. Nandwa et al.'s (2015) research in Kenya aligns with McGraffrey et al.'s (2001) insights, both emphasizing the importance of open-ended assessments in promoting a deeper understanding of mathematical concepts. These themes collectively underscore the global importance of adopting inclusive and differentiated instructional practices, particularly in the design and implementation of mathematical tasks, to enhance student learning outcomes.

Conclusion

Through an exploration of various studies conducted across diverse countries, including Nigeria, Kenya, Ghana, and the USA, this paper seeks to unpack the impact of such practices on student learning outcomes. The studies across Nigeria, Kenya, Ghana, and the USA collectively stress the importance of designing and implementing diverse mathematical tasks that accommodate diverse learning needs, foster collaboration, and create engaging student-focused environments. The design and execution of mathematical tasks are highlighted, emphasizing their function in meeting a range of learning goals, encouraging teamwork, and creating stimulating learning environments for students. the transformative role of scaffolding emerges as a critical factor in shaping students' understanding of moral mathematical knowledge. Through scaffolded support, educators can guide students towards mastery, providing the necessary assistance while gradually fading it as students become more proficient. This gradual release of responsibility empowers students to take ownership of their learning, ultimately leading to improved learning outcomes.

Implication

The insights gleaned from these studies have significant implications for mathematics educators worldwide. It emphasizes how crucial it is for teachers to intentionally construct tasks, taking into account the varied requirements and backgrounds of their students. Teachers may establish inclusive learning environments where all students feel valued and encouraged by including a variety of mathematical exercises that accommodate varied learning styles and abilities. Moreover, teachers are urged to use scaffolding as a teaching tactic to aid in their students' mathematical progress. Teachers can scaffold students' learning journeys and give them the confidence to tackle increasingly difficult mathematical concepts by offering focused support and coaching.

This report presents initial findings from a project aimed at enhancing equitable group work in undergraduate proof classes. The study explored student perceptions of these tasks compared to traditional group work, addressing questions about engagement and collaboration. Quantitative analysis, utilizing the Assessing Student Perspective of Engagement in Class Tools (ASPECT) instrument, indicated overall positive perceptions of the tasks. However, qualitative analysis signaled that structured task designs acted as a key factor in supporting collaboration and understanding. However, varying attitudes towards assigned roles suggest the need for further investigation into their impact on participation. This research underscores the importance of intentional task design in creating equitable learning environments in proof-based courses.

Keywords: Undergraduate Education, Reasoning and Proof, Equity, Inclusion, and Diversity

Overview & Purpose

In this report, we share some initial findings from the project Structuring Equitable Participation in Undergraduate Proof (STEP UP) aimed at supporting more equitable groupwork in undergraduate proof classes. Groupwork is becoming an increasingly common part of undergraduate proof classes with professional organizations (Saxe & Braddy 2015; the MAA Instructional Practices Guide, 2018) advocating for more student-centered approaches in undergraduate instruction. In fact, a recent survey of abstract algebra instructors found that over 90% used groupwork at least once in their course (T. Fukawa-Connelly, personal communication; Johnson et al., 2019). While groupwork can support richer student engagement, it is also a space where participation can be very imbalanced and students perceived as having higher status may dominate (e.g., Cohen et al., 1999; Esmonde, 2009). Proof-based courses have high potential to amplify status differences as students are enculturated into a new language and form argumentation (Weber & Melhuish, 2022) and where competence may be misperceived as unidimensional: ability to produce a formal proof (Hanna, 1991). Thus, there is a need to think about not just the quality of mathematics in tasks, but the nature of the activities and how the tasks may be designed to better support equitable participation.

During the first year of the project, we supported 10 mathematics instructors in designing tasks using principles of Complex Instruction (Cohen et al., 1999; Featherstone et al., 2011). For the scope of this report, we focus primarily on group worthy features of interdependence and individual responsibility. During the fall, four mathematicians implemented between 1 and 3 of these tasks designed for Topology, Linear Algebra, Analysis, and Introduction to Proof, respectively. To explore how students experienced these tasks, we take a mixed methods approach. The students took a brief Likert-scale survey, the Assessing Student Perspective of

Engagement in Class Tools (ASPECT) (Wiggins et al., 2017), designed to capture group work experiences. We then interviewed 11 students to both better understand their survey responses and get more in-depth information about their groupwork experiences. For the scope of this paper, we focus on the following research questions:

- RQ 1 In general, how do students perceive the STEP UP tasks in their proof classes?
- RQ 2 How do students perceive differences between their typical group work and STEP UP task days?

Background Literature & Theoretical Perspectives

There is a lot of potential for active learning and groupwork to support students in developing rich understanding and engaging in mathematical practices. However, the literature is mixed on the relationship between inquiry and equity in proof-based courses. For example, Laursen et al. (2014) showed more affective gains for women in inquiry-based classes; Johnson et al. (2020) found that inquiry-oriented abstract algebra was associated with men, but not women, outscoring a national sample on a conceptual assessment. Johnson et al. (2020) conjectured that groupwork may lead to a gendered hierarchy where men engage in a disproportionate amount of the mathematics. Brown (2018) further illustrated the ways that group work may serve to marginalize certain students in an inquiry class in which two women were "excluded" from participating in the group work. From our preliminary work, we have found that men may hold more authority during group work tasks (Hicks et al., 2020; Melhuish, Dawkins et al., 2022). Ernest et al. (2019) identified explicit instances in which student discourse was overtly sexist as well as implicitly aggressive towards women during small-group interactions in an inquiry setting. These scholars problematize the notion that group work necessarily creates equitable learning spaces, when in fact "small-group work can provide fertile ground for inequities to emerge" (p. 168). These results are consistent with K-12 literature establishing the presence of group work in classrooms as insufficient for fostering more equitable learning environments (Cohen et al., 1999; Esmonde, 2009a; Langer-Osuna, 2016; Shah & Lewis, 2019). When students discuss mathematics in small groups, status hierarchies may form, positioning some students as more expert helpers and others as novices in need of help (Esmonde, 2009b).

With these results in mind, we take the position that status, which is influenced by societal factors such as race and gender and comprised of both academic status (perceived mathematical ability) and peer status (social status and popularity) impacts opportunities to engage and learn in the classroom (Cohen & Lotan, 2014). If groupwork does not include features that may disrupt a status hierarchy, then it is likely that high status students will participate the most and thus learn the most. However, specific structures built into group work tasks have the potential to mitigate problematic status hierarchies from forming (Cohen & Lotan, 2014; Dunleavy, 2015; Esmonde, 2009a), which can reduce (rather than amplify) inequities in inquiry settings (Shah & Lewis, 2019).

In our work, we have emphasized a series of principles to support tasks being group worthy in proof classes stemming from complex instruction (e.g., Cohen et al., 1999; Featherstone et al., 2011) and an expansive view on proof activity (Melhuish, Vroom, et al., 2022; Weber & Melhuish, 2022). We consider a task to be group worthy if it allows for *multiple access points* and strategies, foster a sense of positive *interdependence* among group members, and have *structures to hold the group responsible for the participation and learning of each team member* (Cohen & Lotan, 2014). In the context of a proof-based class these structures need to be paired with opportunities for competency to expand beyond proof construction to include activities such as comprehending proofs, building and reasoning from examples, and comparing and modifying proofs (Melhuish, Dawkins, et al., 2022). That is, not only should tasks include social structures (such as group roles or different students being provided with different information), but the nature of the tasks needs to allow for students to engage in mathematics in different ways to support the recognition of different strengths at play. We conjectured that these features could support more positive group experiences that are less dominated by pre-existing status perceptions.

Methods

This data comes from a larger project STEP UP supporting proof-based instructors in designing and implementing more equitable group tasks. In general, the project borrows heavily from complex instruction and notions of group worthy tasks (e.g., Cohen et al., 1999; Featherstone et al., 2011). During summer workshops, instructors who teach different courses collaborated to design tasks where students engaged in theorem and proof comprehension, theorem and proof comparison and analysis, and proof construction (via conjecturing a major theorem and developing lemmas from visual representations.) The tasks were designed to elicit an array of mathematical strengths. They were all embedded with specific roles (e.g., definition manager) and/or responsibilities (e.g., become an expert on proof A, lead discussion about the focal question on your index card). The tasks were designed so each student had mathematical responsibility for components of the activity and that different needed knowledge was distributed throughout the group.

Sample and Procedure

The central research design for this study is an exploratory mixed method (Creswell & Plano Clark, 2011). The purpose for this method is for the qualitative data to explain the quantitative results. We include a quantitative instrument: Assessing Student Perspective of Engagement in Class Tools (ASPECT; Wiggins et al., 2017) and follow-up interviews to better understand and explain the student responses to the ASPECT instrument.

Students were recruited to participate in this study after their instructor (Fall 2023 and beginning of Spring 2024) agreed to run these group work activities in their proof-based courses. In all, we had 76 students consent to participate. Students who consented were recorded (all but one class) in their group work and asked to complete the ASPECT survey either directly after their groupwork task or the following class day. One class, Topology, completed 3 groupwork tasks, the Fall Intro to Proof course completed two tasks, and the Linear Algebra and Real Analysis completed one task. Thus, some students took the ASPECT survey three times. For this analysis, only their first ASPECT scores were analyzed.

Quantitative Measure and Validity Evidence. ASPECT is a 16-item construct with three factors: 1) value of activity (9 items), personal effort (3 items), and instructor contribution (4 items). The measure was designed to assess a student's perception of engagement in an active-learning classroom on a Likert scale (1 = *Strongly Disagree* to 6 = *Strongly Agree*). In this case, ASPECT was used to measure a student's perception of engagement regarding the STEP UP tasks. Only the first factor (value of activity) was utilized. The instrument has been previously validated in an introductory biology course. We used Rasch modeling to assure the validity of the tool in our context focusing on the value of the activity subdomain. An initial item analysis from the first survey responses (n = 77) indicated a slightly less than acceptable item reliability of .72 (above .80 is considered a high reliability index) and an item separation of 1.62 (less than 2.00 suggests a lack of breadth in item difficulty) for the 9-item sub-construct. However, as the score is over 1.5, it is not demeaning (Ariffin at al., 2010) even though it may not distinguish to the desired degree. Despite this, the psychometric results indicate that the data fits the model from the average infit ($MNSQ = 1.00, Z = -.20$) and average outfit ($MNSQ = 1.03, Z = .00$). Our person reliability was slightly above the ideal threshold (above a .80) with a .85, but an ideal person separation (greater than 2 suggests a range in abilities of the students) of 2.34 (Linacre, nd). The Wright Map (Figure 1) displays the spread of the participants (top) on the horizontal scale illustrating the variability in responses.

Follow-Up Interviews. Towards the end of the semester, we sent a survey to all three courses asking students who would volunteer to participate in individual interviews about their interactions with groupwork. We conducted 11 semi-structured interviews with all who volunteered: 5 students from the Introduction to Proof course, 4 students from the Topology course, and 2 students from the Linear Algebra course. We conducted interviews after their finals and interviewed students online via Zoom. During the interview session, there was one researcher leading the interview while a second researcher was taking notes.

The interviews lasted close to an hour, and we had an interview protocol composed of three major parts. The first part asked students to describe their experiences with typical group work, such as their description of the group work that happened in class and their interactions with their group members. The second set of questions in the interview were almost identical to the first part but were focused on the group work from the STEP UP tasks (e.g., thinking back to the tasks on the video recorded days, how do you think this group work was the same or different compared to a typical day?). The last part of the interview centered on asking the participants to elaborate on their reasoning for their score on certain survey items (e.g., could you elaborate on what you meant by this score to the statement: I made a valuable contribution to my group during the Proof Activity?). We shall note that all 11 interviewees were present on at least one day when the STEP UP tasks occurred.

Analysis methods

We report on the results of the Rasch analysis and present some descriptive statistics from the survey. We situated our interview participants based on the scores. For the qualitative portion, the first stage of analysis involved using the interview notes and going back to the video-recorded interviews. For each interview, one member of the research team identified all the instances that a student described a typical workday and instances of explaining the groupwork on the project day. For each individual, a set of key quotes were selected from the transcripts that provided insight into how group work was perceived and how project groupwork days were seen as similar or different. The next stage involved condensing themes (Braun & Clarke, 2006) based on whether the students were discussing either cognitive (learning) or social (participation) features. Additionally, we attended to whether the sentiment was positive or negative based on linguistic cues used to signal appraisals (Eggins & Slade, 2004).

Analysis and Findings

Quantitative Results

Rasch modeling was chosen over a classical approach due to Rasch transforming raw data into continuous data via a logistic transformation (Bond & Fox, 2015). The Rasch model utilizes the response patterns from the item and participants to create a logistic model to transform the data into logits (Bond & Fox, 2015). The visual spread of the logits can be seen in Figure 1 on the Wright Map. To note, typically a Wright Map is displayed as a vertical scale, here we report the map on a horizontal scale. The students on the right of the map (top squares and triangles) are interpreted as more favorable or seeing more value towards the STEP UP tasks. As seen on the Wright Map, the logit score of the students (*M* = 1.21, *SD* = 1.38) are higher, on average, than the items (*M* = 0.0, *SD* = 0.29). This suggests that most of the students are scoring these items highly (Likert scale value 4 or above) and agreeing to the value of the STEP UP tasks. As for the items, we see that the items are clustered together towards the left end of the horizontal scale. In Rasch, this means that these items are easier to endorse or agree with by the participants. In other words, all items are interpreted as agreeable. Since there are no items toward the right of the horizontal scale, this suggests that there aren't any items, as a whole, that are predicted by the model to illicit a disagreeable response. While ideally the mean Logit scores of the items and the participants are meant to be near each other, this suggests that the students are favorable of the [BLIND] groupwork tasks created and implemented in these courses.

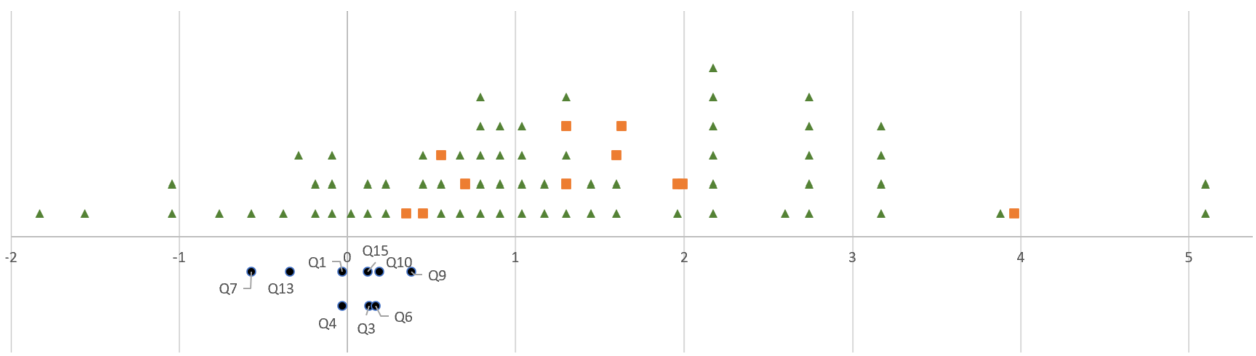

Figure 1. Wright Map

For this subscale, there were two items we focused on which were Q4 (group discussion during [the activity name] contributed to my understanding of the material) and Q9 (I would prefer to take a class that includes [group activity] over one that does not include this group activity). As seen from the Wright Map (Figure 1), item Q4 lies in the middle of the cluster which indicated that this item is agreeable (*M* = 4.59, *Mdn* = 5, *SD* = 1.38) but not as agreeable as item Q7 (the left most item on the horizontal scale). Item Q9 is the right most item on the horizontal scale. This means that item Q9 (*M* = 4.26, *Mdn* = 4, *SD* = 1.51) is not as agreeable or as likely to endorse as Q4. However given its position on the Wright Map, the Likert statement is still likely to be agreed with by the majority of the participants but less favorable than others with a median response of a 4 (neutral to agree).

Table 1: Interview Participants

Participant	Gender	Race/Ethnicity	Course	Score
Alexis	Woman	White	Topology	3.88
Lily	Woman	Hispanic	Topology	1.99
Lee	Man	Asian/Mongolian	Linear Algebra	1.96
George	Man	White	Intro to Proofs	1.60
Crocodile	Man	Hispanic/Latino	Intro to Proofs	1.60
Karli	Woman	Not Provided	Intro to Proofs	1.30
Gabi	Woman	Mixed/Latina	Intro to Proofs	1.30
Joy	Woman	Hispanic	Intro to Proofs	0.67
Julia	Woman	White	Topology	0.56
Joe	Man	Spanish	Topology	0.45
Marla	Woman	Not Provided	Linear Algebra	0.33

To understand some of the results from the ASPECT survey, we interviewed 11 students (Table 1). Our sample of students had a higher ASPECT logit average (M = 1.43, SD = 1.02) than the whole samples group (M =1.21, SD = 1.36), but still represented a true subset as seen by the Wright Map (Figure 1). On the Wright Map, the interviewed students are represented by the squares and the rest of the participants are represented by the triangles. More about the participants and their ASPECT scores can be found in Table 1.

Qualitative Results

Our goal with the qualitative analyses was to both validate the survey responses and provide more explanatory insight for students reported positive or negative experiences. We subdivide these results into two sections: cognitive-focused and participation-focused.

Cognitive-Focused: Understanding and Activity. None of the interviewed students reported any negative impact of the tasks on their cognitive understanding of the content. Five students identified overtly positive distinctions for the project tasks they felt resulted in differences in understanding the material. Students commented on the structured nature of the tasks with Lily further elaborating, “I honestly just really liked the activity. I felt like it really helped my understanding... that was one of the concepts in the class that I felt like, really, like confident about” with Gabi similarly commenting on structure and the role of having a goal: “So, like in a typical group work, you didn’t necessarily have a goal. It was just more like talking.” Two other students commented on the nature of the activity with Alexis noting that the activity, “made me look at proofs differently, and made me understand a little bit more about like what like a professor or other mathematician might be seeing when they are reading a proof,” and George explaining that their groups helped “explain things in a way that made sense” and supported visualizing.

We see these comments as focusing on three elements: the structured and goal-oriented nature of the tasks, the atypical type of activity (e.g., proof comprehension), and the role of peers. We highlight that the students explicitly noted the “structured” nature of the task in supporting understanding and contrasted it with “just talking.” While structuring the task was an initial design element, this is language students spontaneously introduced during the interview.

Finally, we note that not all students had positive reflections about supporting understanding. Several students still preferred lecture over any group work (although this did not impact their understanding of the material.) Joe indicated that he read the material in advance and suggested he did not benefit in the activity to the degree that students who had not prepared may have.

Participating-Focused: Collaboration and Contributions. Nearly all of the students mentioned differences in participation. Many of the students commented on roles and responsibilities supporting more equalized and collaborative involvement where Joy noted, "I think it [participation] was well spread out because we followed the jobs [group roles]. I think they helped with making sure [we were] learning the entire thing and making sure …we all stuck to contributing. I think if there weren't roles, one of us would have definitely wanted... to step up [meaning take over the work] after seeing how lost all of us were at the beginning." Other students commented that the group work was "more collaborative (Marla)" and that the roles led to "everyone getting involved (Karli)." Students again noted how the tasks were structured differently with Lily explaining how in typical group work they just have a set of exercises to finish, but the structure of the [blind tasks] meant they had to "share it with each other and compare, and all of that stuff that made, you know, made me have to share it-- made others have to listen to what I have to say as well."

A few commented on people who tended to share a lot on typical days, but who did not share as much on project task days. Marla described a "leader" who would tell others what to do, they would do it, and he would check their work. She noted that on the project task day, this student was given a non-leader role and when the group members traded out roles he did not want the leader role. It is possible he felt some relief from an unintended role he fell into and then didn't know how to navigate away from on his own.

Some students suggested they liked certain structures more than others. "I really loved the first and the third one a lot, a lot, a lot, a lot. The second one-- I think the structure was confusing, and so I felt like we had to slog through a little more. But I actually don't remember the activity very much. I remember the roles, and that they were confusing (Alexis)." Lily compared "free range" group work to "not as much freedom" in the project tasks due to the roles. She further elaborated that because they each had different information (via their roles) and they had to combine it to find an answer, she "didn't mind" and compared it to solving a mystery.

In contrast, there was one student who voiced a negative reaction to the task structure. George explained, "It was frustrating that I couldn't contribute, because I might have already known the answer." Other students noted that they stepped back during some role activities or wished they had a larger role or a different role (one student said her group switched up roles right away so everyone got what they wanted). However, George was the most direct about feeling the structured task roles held him back. In that interview he commented that he'd hear a groupmate say something wrong and would want to correct them, but didn't feel his role allowed for that. The same student also noted, "Yes, yes, I've never had an issue with respect in the class. I would hope that I properly respected everyone in the class as well. Again. It's hard for me sometimes to tell if I'm being disrespectful. It's not something I'm very good at." He did not elaborate and it's entirely possible he has some differences in interpreting social cues and nuance in how others perceive statements. It also may be helpful for this student to practice restraining from correcting others—however, it is not a task design intent to ban anyone, despite group role, from speaking up or commenting on others' thinking.

Discussion and Conclusion

This study provides initial evidence that structures from K-12 group work can be successfully integrated into undergraduate proof-based contexts. As group work becomes an increasingly common part of advanced mathematics, it is crucial that we consider how we implement it to not amplify status issues that are particularly prevalent in proof-based classes. To address this issue, we developed task templates (stemming from an earlier exploratory abstract algebra context, Melhuish, Dawkins et al., 2022) that disrupted what types of activities students are asked to engage in by moving away from traditional proof construction as the primary task, and integrated intentional structures to support interdependence and personal responsibility. The quantitative results from this study suggest that across four classes, students by-and-large reported positive experiences with the STEP UP tasks. The interviews then shed light on what students perceived as key differences between typical group work days and STEP UP tasks and the ways the STEP UP tasks did or did not support learning and collaboration. In this way, we are contributing to Adiredja and Andrews-Lasron's (2017) call to better understand student experiences in active learning to gain insights into what circumstances may support positive experiences.

All students noted at least one difference between project task groupwork and regular groupwork—almost all had something to do with the structured nature, which they contrasted with "just talking" in typical groupwork. Students who appreciated this structure suggested it led to more collaboration, better understanding, and appreciated having a clear goal in mind. Most students indicated they felt the structures did equalize participation in terms of different student contributions. However, we note that the roles were most divisive and most brought up in the interviews. The students who were explicit about usually being chatty, not having any problem jumping into conversations, or self-identified as strong mathematically commented either an ambivalent relationship to the roles (liked them here; not there) or did not like them (the one student who described them as frustrating). It may be that some students like roles because they have a harder time jumping into discussion and others feel less positive because they did not usually have a hard time. Our theoretical view on status may provide insight into this relationship. We conjecture that the "high status" students may feel more constrained when not left to dominate conversation.

Because the data in this study is all self-reported, we are limited in terms of making conclusions about actual participation rates and nature of collaboration. In future research, we plan to consider empirically the contribution rates in groups to examine the degree that status appears to predict or not predict contributions. Additionally, we are bringing positioning lenses in to explore not just participation rates, but how students are engaging with each other and the mathematics. This initial phase of the research points to several promising avenues for continued work in developing more equitable group work situations in proof-based classes. We suggest other researchers who engage in design of classroom tasks at this level consider not just how to support cognitive and activity goals, but also what structures may support increased involvement and collaboration of all students in small groups.

In this paper, we consider who leads and who follows when a classroom community engages in collective mathematical activity—we describe this as mathematical authority. Building from theoretical writings on authority by Benne and Weber, we advance an activity-based perspective of mathematical authority which we exemplify through vignettes of middle-grades classrooms. Using data from 117 hours of video of 129 math lessons, we employ Loglinear models to identify relationships among the co-occurring authoritative activities of authoring, speaking, and representing. Results extend our understanding of the ways mathematical authority is negotiated during whole-class interaction and the importance of representing and speaking as high-leverage opportunities to foster students' mathematical authority.

Keywords: instructional activities and practices, classroom discourse, middle school education

Social groups and group activity are core to our experiences as learners and teachers, and, sociologists would argue, to making sense of lived experience in general. Social activity almost always involves some form of leading and following. Whether its playing peek-a-boo with a young child, listening to an orchestra perform, children playing a game at the park, or students learning in classrooms, someone is leading, directing, and planning these collective activities. In this paper, we consider who leads and who follows when a classroom community engages in collective mathematical activity—we describe this as mathematical authority. We believe that authority is an ever-present but overlooked feature of mathematics classrooms. In this paper we build from theoretical writings on authority by Benne (1970) and Weber (1947) to advance an activity-based perspective on mathematical authority which we exemplify using vignettes from middle-grades classrooms. Using data from over 117 hours of video of 129 math lessons, we employ Loglinear models to identify significant relationships among co-occurring authoritative activities. These results extend our understanding of the ways mathematical authority is negotiated during whole-class interaction and the importance of representing and speaking as high-leverage opportunities to foster students' mathematical authority.

Theoretical Perspectives & Related Research on Authority

Sociologist Max Weber and educational philosopher Kenneth Benne each framed authority as a feature of social groups that arose from the need for coordinated social action. As a macro-sociologist, Weber focused on broader institutional, historical, and societal structures. Thus, he alluded to social action in a general way as commanding and obeying in service of maintaining group order (the norms, values, behaviors, and roles of the group). For Weber (1947), authority was "the probability that a command with a given specific content will be obeyed by a given group of persons" (p.152), and the action of commanding established a hierarchical relationship between the head and followers. Benne, too, framed authority in terms of directing and obeying:

> [Authority] operates in situations in which a person or group [subjects], fulfilling some purpose, project, or need, requires guidance or direction from a source [bearer] outside himself or itself. The need demarcates a field of conduct or belief in which help is required. The individual or group grants obedience to another person or group … (1970, p. 392).

A key distinction here, one that Benne himself highlighted, was his attention to the field, or context, of authority relations. His explicit identification of the field as a constitutive feature of authority suggests, to us, a more dynamic and transient view of authority wherein the roles of bearer and subjects are fluid and determined by mutually-negotiated purposes that can shift over time and situations. We draw on both Benne's and Weber's work in our conceptualization of authority to further clarify the *field* within which mathematical authority exists. We define *authority* as a dynamic and negotiated relationship within a given field in which one party agrees to lead, while another party agrees to follow that lead. (The words "lead" and "follow" are from Pace & Hemmings, 2007). Further, we suggest that within any field, there is a collection of activities through which a member of the field can hold authority by leading one or more of those activities. *Mathematical authority*, then, is the authority relevant to the field of doers of mathematics that is accessible to all within a classroom and determined by who leads mathematical activities valued by the community.

Much of the authority research consists of classroom studies focused on aspects of instruction related to authority to understand how mathematical authority is constituted in those contexts. For example, in their collaborative body of research Herbel-Eisenmann and Wagner documented how authority was encoded implicitly in our often unconscious linguistic choices in math classrooms (Herbel-Eisenmann & Wagner, 2010; Wagner & Herbel-Eisenmann, 2014a, 2014b.) Their work is part of a growing body of authority research that studies how interactional and discursive routines can constrain or support students as mathematical authorities (Arnensen & Rø, 2022; Engle, et al., 2014; Hamm & Perry, 2002; Kinser-Traut & Turner, 2020; Langer-Osuna, 2016; Langer-Osuna et al., 2020; Solomon et al., 2021). Talk moves such as the types of questions posed, validating activities, wait time, and the appropriation of student ideas can support students to take responsibility, ownership, and authority for classroom mathematics.

In general, we can describe much of this research as linking mathematical authority to certain discursive forms or features of interaction. We agree that authority is indeed at work in the details of micro-level interaction as the extant literature clearly shows, but argue that these interactions are, in part, constituted by and given meaning from the larger activity or goal of a situation. Thus, in this paper we take a different methodological approach and operationalize authority through the lens of leading and directing mathematical activity, drawing from both Benne and Weber's focus on collective social action as a key driver of authority relations. This perspective allows us to describe *who* has authority for *what*; to document how authority changes from one situation to another as participants' roles in different mathematical activities change; and to do so in ways that clearly connect to existing theory.

To operationalize our activity-based perspective of authority, we reviewed the authority literature with a focus on mathematical activities. The majority of research emphasized a specific activity as the primary marker of mathematical authority: the authoring of mathematical ideas

(Arnensen & Rø, 2022; Gerson & Bateman, 2010; Langer-Osuna et al., 2020; Otten et al., 2017; see also Cobb et al.'s [2009] "making mathematical contributions"). That is, who is responsible for generating the mathematical ideas that are taken up in the classroom. We agree that authoring ideas is a core mathematical activity but propose the consideration of other valued mathematical activities. For example, authoring a mathematical idea does not always entail communicating that idea publicly (e.g., Goffman's [1981] distinction between authoring and animating). In fact, this distinction is seen in NCTM's (2000) process standards which differentiate the mathematical activities of communication and problem solving. Communication, for us, is the way in which mathematical ideas are publicly expressed so they are accessible to the group. In many cases authoring and communicating mathematical ideas coincide, but not always. Although the dominant mode of communication in K-12 classrooms is oral, we consider two types of public communication in this study: speaking and representing. *Speaking* is our term for oral communication whereas *representing* is the visual communication of a mathematical idea, including written and gestural forms. Representations include graphs, diagrams, written notation/symbols, as well as physical models that capture "a mathematical concept or relationship in some form" (NCTM, p. 67). We suggest that students' opportunities to produce and engage with various forms of written text, graphs, and models—what we term representing—is a key aspect of learning mathematics and developing proficiency with mathematical discourse in addition to being an important marker of mathematical authority (Arcavi, 1994; Pimm, 1987; Solomon & O'Neill, 1998; Staples, 2007). Thus, in this study, our focus is on who has authority for the mathematical activities of Authoring, Speaking, and Representing during whole-class instruction though we recognize other important mathematical activities are present (e.g., authority for justifying a claim). The research questions we sought to answer are: (1) How is mathematical authority negotiated among teachers and students in middle-grades classrooms?, and (2) How are the different authoritative activities of Authoring, Speaking, and Representing related?

Methods

Setting, Participants, and Data

This study is part of a larger research program investigating productive mathematics discourse in middle-grades classrooms. The participants were 11 grades 5-7 teachers and their students. Participating classrooms were located in four states across the US, and all teachers had at least 6 years of experience. Teachers were recommended by administrators, math coaches, and professional development trainers as good mathematics teachers, but they had different styles of teaching which led to varying instructional routines during whole-class instruction (e.g., some were more lecture-based and others more discussion-based). Data was comprised of video recordings and transcripts of 57 algebra and 72 fractions lessons, comprising a total of 117 hours of instruction. At least 9 lessons per classroom were filmed in a single academic year, with a minimum of 3 lessons filmed in each content area within a classroom. We chose the topics of algebra and fractions because these are common topics across the grade levels in our study and because of their significance in secondary curricula and overall academic success.

Analysis

Unit of analysis. In our definition of authority, the field is more than the setting, group, and group activities; it also incorporates the mathematical focus, participation format, and who has authority for leading each mathematical activity in a given interaction. We account for the field of authority relations in our unit of analysis—a segment. A *segment* is a series of turns of talk with a common focus (e.g., task, strategy) and a consistent form of participation (whole-class, independent work, etc.). Boundary markers for segments were indicated by a change in the problem, task, or topic often indicated by changes in intonation, resources or materials, physical orientation, participants, or the use of particular phrases or linguistic markers. We note that our analysis was restricted to segments of whole-class instruction only. The transcript below illustrating our coding framework is an example of a segment. There were a total of 1688 whole-class, mathematical segments coded across the 129 lessons (an average of 14 per lesson).

Coding. Within each whole-class segment, holistic decisions were made about who led each of the activities of Authoring, Speaking, and Representing which are defined in Table 1. One of the mutually exclusive codes of Teacher, Students, Both (the students and teacher co-lead an activity), or None (the activity did not occur) was assigned on the basis of who led, or had mathematical authority, for *each* activity in a segment. When coding, we considered students' collective mathematical activity rather than individual students' actions because individuals were often not possible to identify from video. We double-coded over half of the 129 lessons (44 algebra and 25 fractions lessons; 954 segments). Coding discrepancies were discussed until coders achieved consensus. Values for Cohen's kappa for Authoring, Speaking and Representing were $\kappa = .71$, .76, and .86, respectively, which indicate substantial agreement.

Table 1: Mathematical Authority Analytic Framework

Mathematical Activity	
Authoring	Generating the mathematical idea that is the focus of the segment.
Speaking	Orally communicating mathematics in a way that is publicly accessible.
Representing	Visually communicating mathematics within a segment in a way that is publicly accessible, visually observable, and mathematically meaningful. Includes writing, gesturing, and modeling.

Exemplifying the analytic framework. To exemplify our analytic framework for authority, we share a segment from a 6th-grade class and explain our coding. The class had been working on writing equations to represent generalized solutions. Students worked independently on the following task: As a contractor, you specialize in outdoor brick stairwells. How many bricks will you need to build a 10-brick-high stairwell? (See Figure 1 below.) Consider how you would code authority for each of the activities of Authoring, Speaking, and Representing.

Teacher: Anybody else have another strategy they want to share? Kelli.
Kelli: (Walks to doc camera.) Mine's kind of like Danica's. So, I found that the, um, tallest part of the brick stairwell is ten (points to the rightmost column), the shortest is one (points to the leftmost column). So I added those together and I got eleven. And the second shortest and the second tallest got eleven. And I kept doing that until I got that (gestures to the five 11s written diagonally in her work). I had five elevens, and I added them together and I got 55.
Student: That's a good one.
Kelli: Oh, you can't really see. I should make it darker.

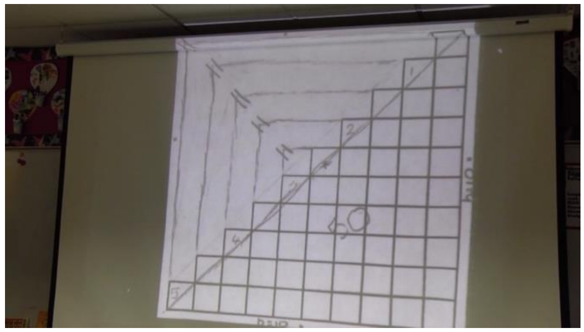

Figure 1: Kelli's written work for the staircase problem

Teacher: Yeah, it's hard to see. Let me zoom in. (Teacher helps with document camera.) Zoom just on your picture. … Alright, one more time now that everybody can see.

Kelli: So I added the shortest one (draws a square around the leftmost column) with the tallest one (draws a square around the rightmost column). And I got eleven (points to the "11" in top left corner). Then I added the second shortest (traces over the second column from the left) and the second tallest (points to the second column from the right) and I got eleven. And then I added the third tallest (points to column) and the third shortest (points to column). ... And I got elevens for all of them (points to the row of "11s" in drawing). Then I added the 11s and got 55.

Teacher: Aah, very cool.… Three claps on three for Kelli.

In this segment, students had authority for Authoring, Speaking, and Representing the mathematics because they led, or directed, these mathematical activities in this situation. Kelli, a student, publicly explained the strategy she authored both verbally and by referring to her written work. She repeatedly gestured to specific columns (i.e., stairs) to connect her written symbols to the problem context and pictorial representation. Her gestures emphasized the pattern she noticed in the representation—that the sum of pairs of 'outer' columns was constant—which she then connected to symbolic notation. Kelli's Representing activity in this vignette, which was primarily gestural but also included some writing, was critical to the clear communication of her ideas. You may wonder why we did not assign the teacher as having authority for any of the mathematical activities despite her verbal contributions: she opened (and closed) the interaction by giving Kelli the conversational floor, acknowledged Kelli's strategy, and supported clarity in Kelli's communication. However, the teacher did not directly communicate or author any mathematics. Thus, the authority Kelli's teacher held was *pedagogical authority*, which we differentiate from *mathematical authority*. *Pedagogical authority* is the authority for directing instructional activities such as selecting topics or tasks, opening and closing tasks, and nominating speakers (Wilson & Lloyd, 2000; see also Oyler's [1996] process authority). Just because a teacher has pedagogical authority does not mean she also has mathematical authority.

Quantitative analyses and loglinear models. While coding segments, we noticed patterns in some codes. For example, when students had authority for Representing in a segment, they also tended to have authority for Authoring. Because we hypothesized that who had authority for different mathematical activities was related, we used a combination of contingency tables, conditional probabilities, and Loglinear models to systematically explore relationships among the mathematical activities in our analytic framework. A Loglinear model is a regression model for non-normal outcomes that represents counts of categories and is appropriate for categorical data. In the Loglinear model, we assume that counts (i.e., cells in a contingency table) follow a Poisson distribution and depend on the categories of variables (i.e., row effects, column effects, and interaction effects for a two-way, or two-variable, model) (Agresti, 2007). We used the Generalized Linear Framework to analyze the multi-factor contingency table created by counting co-occurring codes across the mathematical activities in our authority framework.

Findings

Negotiating Mathematical Authority: Authority Structures

To answer our first research question we share vignettes that illustrate the diverse ways classroom members negotiated mathematical authority for the mathematical activities of Authoring, Speaking, and Representing during whole-class interaction. We introduce the term *authority structure* to describe, in a more general sense, patterns we observed in how authority was distributed across mathematical activities within segments of whole-class interaction. We identified four authority structures in our data—Teacher as Primary Mathematical Authority, Students as Primary Mathematical Authority, Sharing Authority Across Different Mathematical Activities, and Sharing Authority Within the Same Mathematical Activity. These authority structures exemplify common, yet qualitatively different ways authority was negotiated during whole-class interaction. We begin with segments in which one party has authority for the majority of mathematical activities (i.e., two or more activities). We describe the authority structure in these types of segments as a primary authority structure, the difference being *who* is the primary authority—the teacher or students. Consider the segment shared in the methods. This segment exemplifies the authority structure of Students as Primary Mathematical Authority because students had authority for Authoring, Speaking, and Representing (the majority of math activities). Segments in which students were the primary mathematical authority were not the norm but did comprise about 20% of our data. In this authority structure, students are positioned as capable doers of mathematics with the authority to clearly communicate their mathematical thinking. In contrast, consider segments in which the teacher drove the content; we characterize that authority structure as Teacher as Primary Mathematical Authority. Instead of illustrating this authority structure, we ask you to imagine an interaction in which a teacher authors mathematics content and represents it publicly, perhaps giving students opportunities to verbally communicate some parts of the content. In fact, segments in which the teacher had authority for Authoring and Representing, and both the teacher and students had authority for Speaking was the usual way in which Teacher as Primary Mathematical Authority occurred.

For the first two activity structures presented, one party (teacher or students) was the *primary* mathematical authority. Below we present a vignette to illustrate a different type of authority structure in which mathematical authority is *shared*. In this vignette, students in a 5th-grade class solved this problem: How much does each person get if 4 friends share 11 brownies evenly?

Teacher: James, what did you do?
James: I made eleven squares and I divided – and I, um, cut them into fourths.
Teacher: Okay. And those squares represented what?
James: A brownie. (Teacher draws eleven squares on the SMART board.)
Teacher: And then you said you did what to those brownies?
James: I cut them into fourths. (Teacher partitions each square into four equal parts.)

Teacher: Alright. James, after you split each brownie into fourths, then what did you do?
James: I put a number next to each [fourth] so I know that that's one kid.

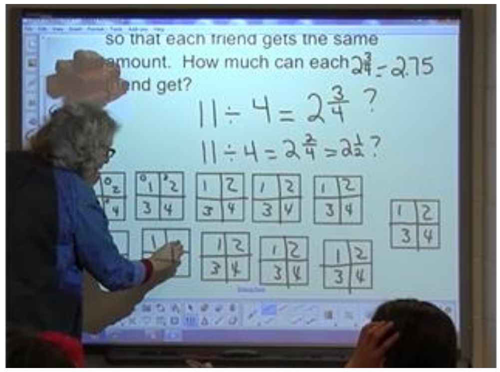

Figure 2. Recording James's solution on the SMART board

Teacher: Okay. So what you're meaning is that piece (points to a fourth) goes to child one? (James nods.) So how did you know from that picture how much each child got?
James: Well, I counted, um. Every child got a fourth of each brownie. So every four squares, that would equal a whole. Each kid gets two wholes and three fourths. ...

In this vignette, the mathematics under consideration was generated by James, but he is not the only person communicating his idea to the class. Because our operationalization of authority goes beyond Authoring to include Representing and Speaking, we can document how the teacher plays an important role in the oral, gestural, and written forms of communication. Although students had authority for Authoring the focal mathematical idea, the teacher had authority for Representing the idea by creating a public visual record of his thinking (and both had authority for Speaking). Thus, we describe the authority structure in this vignette as *Sharing Across Activities*. In this type of shared authority structure, students and teachers simultaneously claim authority for *different* mathematical activities. In other words, each party has sole authority for at least one mathematical activity in a segment. However, at times, teachers and students may share authority for the *same* activity. In fact, we see this in the previous vignette when the students and teacher shared authority for Speaking. But consider if the teacher had also explained how the 11 one-fourths each child received was reflected in the drawing and was equivalent to 2¾. Had this occurred, the students and teacher would have shared authority for Authoring the focal mathematical idea, resulting in codes of both for Authoring, both for Speaking, and teacher for Representing. This hypothetical situation exemplifies our final authority structure of Shared Authority Within the Same Mathematical Activity; this authority structure is characterized by segments in which two or more mathematical activities are coded as both. The Shared Authority Within authority structure was the most common in our data, accounting for 40% of segments.

The four authority structures we shared here provide common yet qualitatively different ways mathematical authority was distributed across the activities of Authoring, Speaking, and Representing in our study. Moreover, our distinctions between the authority structures of Shared Authority Across Different Activities and Shared Authority Within the Same Activity provide clarity to the construct of "shared authority" which is a consistent recommendation across research but with various meanings in the literature (Amit & Fried, 2005; Arnensen & Rø, 2022; Gerson & Bateman, 2010; Langer-Osuna et al., 2020).

Relationships Among Authoring, Speaking, & Representing: Loglinear Models

To answer our second research question, we systematically explored relationships among the activities in our framework using a Loglinear model. We started with a saturated model that included all categorical variables and interactions. Using a backwards selection process, we eliminated interactions in layers to identify the 'smallest' model that fit the data as indicated by model fit statistics (Agresti, 2007). Our final model was: $log(\mu_{ijk}) = \alpha + \beta_i + \gamma_j + \lambda_k + (\beta \times \gamma)_{ij} + (\beta \times \lambda)_{ik}$ where X_{ijk}, the count of the $(i, j, k)^{th}$ cell, is Poisson(μ_{ijk}); each category of Authoring was estimated by β_i, $i = 1, \ldots, 3$ (the three possible authority codes of Students, Both, and Teacher for Authoring); each category of Speaking was estimated by γ_j where $j = 1, \ldots, 4$ (the four possible codes of Students, Both, Teacher, None); and each category of Representing was estimated by λ_k where $k = 1, \ldots, 4$. The final model contains all main effects and pairwise interactions among Authoring and each of Speaking and Representing. Following Agresti (2007), we interpret significant results in terms of odds ratios that compare the relative likelihood of different categories of one authority variable occurring while holding other variables constant. (Due to space, we do not report all coefficients for the final model.)

Our goal with this analysis was to understand which combinations of authority codes co-occurred more frequently than expected—for example, what codes co-occurred when students had authority for Authoring or Representing? We found that when students had authority for Representing ideas, they were 3 times as likely to also have authority for Authoring compared to both or teacher Authoring. [Relevant odds ratio is $\log\left(\frac{\mu_{121}}{\mu_{321}}\right) = 0 - \left(\hat{\beta}_3 + \widehat{(\beta \times \gamma)}_{32}\right) = .72 + .41 = 1.13$, so $e^{1.13} = 3.1$. The 95% family-wise confidence interval for the odds ratio is (2.26, 4.24)]. In contrast, when students had authority for Authoring, the teacher was twice as likely as students to publicly Represent those ideas [$\log\left(\frac{\mu_{123}}{\mu_{121}}\right) = \hat{\lambda}_3 - \hat{\lambda}_1 = .67 - 0 = 0.67$, so $e^{0.67} = 1.95$; the 95% family-wise confidence interval for the odds ratio is (1.58, 2.44)]. Although the authoritative activities of Authoring and Representing were related, that relationship depended on *who* had authority. In general, Representing is a mathematical activity for which the teacher is most likely to have authority, regardless of who has authority for Authoring. But when students did have authority for Representing, it was most likely their own ideas they were communicating. We also found that when students had authority for Speaking, they were more likely to have authority for Authoring, regardless of who had authority for Representing (odds ratios comparing students Authoring to other authorship categories holding students as Speaking constant were all greater than 1). And perhaps not surprisingly, when teachers Authored ideas or shared authority for Authoring with students (both code), the teacher was more likely to be the one Representing those ideas. These findings indicate that when students have authority for the mathematical activities of Representing and Speaking, they are more likely to also have authority for Authoring. Thus, we suggest these two activities may be particularly important opportunities to foster students' mathematical authority.

Discussion & Implications

By incorporating multiple, simultaneous mathematical activities into our activity-based perspective of authority, we expand the field's understanding of how mathematical authority is negotiated in classrooms and provide a useful lens to reflect on practice. We found both consistency and variety in the ways mathematical authority was distributed across the activities of Authoring, Speaking, and Representing which we documented with four authority structures. We suggest that the authority structures of Sharing Within and Across Activities provide specific and productive ways to share mathematical authority in ways that amplify, clarify, and build on students' contributions. Yet despite the prevalence of shared mathematical authority in our data, students rarely had authority for Representing though they often had authority for Authoring. Moreover, authority for Authoring did not imply authority for Representing: the directionality of these relationships was complex. However, the activities of Representing and Speaking seem to be powerful indicators of students' overall mathematical authority and we encourage teachers to seek opportunities for students to communicate mathematical ideas.

In closing, we quote Benne who, over 50 years ago said, "We do not … know the shape of the future society and culture into which we as educators, along with those we are helping to educate, are now moving" (1970, p. 404). He wrote this as part of his argument for an authority that balanced freedom with responsibility in a self-renewing, interdependent community that adapted to the needs of the group, both now and in the future. As we look toward an uncertain future, we believe the activity-based perspective of authority we shared here provides a new and more positive conceptualization of authority that foregrounds the empowerment of students as doers and leaders of mathematical activities in ways that can adapt to accommodate the new activities future mathematics communities deem worthy of learning and learning to lead.

Supporting engagement at the middle school level as well as providing access to high-quality mathematics is crucial. We explore instructional moves that contributed to engagement during an informal geometry summer camp for middle school students, centered around advanced geometry such as braids, symmetries, and platonic solids. We report variation in engagement and explore how instructional moves of open-ended questioning, real-time feedback, and prompting supported positive moments of engagement.

Keywords: Affect, Emotion, Beliefs, and Attitudes; Geometry and Spatial Reasoning; Informal Education; Equity, Inclusion, and Diversity

Middle school is a pivotal time in students' development, and access to opportunities during this age can determine students' confidence in pursuing particular disciplines (Buffum et al., 2016; Shin, 2011). For example, access to high-quality, engaging mathematics during middle school can determine a student's confidence to pursue STEM avenues (Butler-Barnes et al., 2021; Furner, 2017). Unfortunately, many students lack opportunities for high-quality mathematics due to continued inequities in U.S. schools along racial/ethnic and socioeconomic lines (Morgan et al., 2016; Sirin, 2005). Experiential learning that engages students in collaborative and hands-on experiences may work against opportunity gaps (Kolb et al., 2014), while also aligning with community and socially-oriented approaches to learning that are especially important for students from historically marginalized racial/ethnic, cultural, and/or socioeconomic groups (Gray et al., 2020; Xu et al., 2018). We sought to understand middle school students' engagement experiences during a week-long summer geometry camp centered around experiential learning-based activities by addressing the following questions: (1) *What was the variation in students' engagement during the experiential geometry activities, by day and by student?* and (2) *What instructional moves during the experiential learning geometry activities contributed to moments of positive engagement in the camp?*

We focused on geometry to leverage students' daily experiences with space and movement. Up to and through middle school, public school students receive geometry instruction, however, tendencies to provide lecture-style instruction and "teaching to the test" remain prevalent (Close et al., 2020). We sought to provide rich experiential learning opportunities to students so that they may explore abstract geometric concepts that they may not experience in their traditional mathematics classroom: braids, knots, symmetry, etc. Our purpose is to understand how students experience engagement with experiential learning activities centered around geometry and how to support students in order to create positive learning experiences.

Theoretical Framework

Engagement is a multidimensional construct as conceptualized by various researchers that refers to how students connect to learning (Fredricks, 2011; Hospel et al., 2016; Middleton et al., 2017). We used Wang et al.'s (2016) five dimensions of engagement - behavioral, cognitive, affective, social, and agentic - to guide our observation of students during each activity. Our protocol (adapted from Ben-Eliyahu et al., 2018) included columns to document student actions (e.g., "Consider what students are doing: asking, describing…"), level of participation (e.g., "*Active*: takes initiative, *Passive* +: listening, attentive, *Passive* -: unfocused, not on task…"), and affect (e.g., "+: Amazed, joyful…, *Neutral*: calm, relaxed, - : Distressed, angry…").

This study is informed by Kolb et al.'s (2014) experiential learning cycle which consists of a) *concrete experiences* (engaging in an authentic situation), b) *reflective observation* (noticing what has occurred and relating to past experiences), c) *abstract conceptualization* (translating perceptions into abstract understandings), and d) *active experimentation* (honing skills in a new experience). The cycle encourages students to engage in both concrete and abstract thinking through experience and reflection, allowing them to interact with the content and discover connections between ideas. For example, within this study, students engaged in a series of activities centered around identifying the number of mathematical braids that meet a particular characteristic. Following an initial discussion of braids in which students shared their knowledge of what braids are and how they work, the students engaged in a *concrete experience* in which they created braids using pipe cleaners and then attempted to draw the braids using different color markers. Next, the students engaged in *reflective observation* when the instructor asked students how they might draw strings in their illustrations to clearly distinguish which strings were woven in the front versus behind. The students engaged in *abstract conceptualization* as they discovered that leaving a space between the background string and the forward string on both sides of the forward string represented the section of the background string that they could not see. Lastly, students entered into the *active experimentation* phase following this discussion when the instructor posed the question, "How many 3-string braids are there that have just one crossing?" The students used their new understanding to experiment with different possible cases. This cycle was used to engage students in opportunities to develop understanding of a variety of concepts from advanced-level geometry. Instructional moves in each of these phases refer to teacher actions that occurred prior to and during students' engagement in the experiential geometry activities (Bobis et al., 2021; Frey & Fisher, 2010).

Methods

The context for this study was a community-based geometry camp offered on the campus of a large urban university in the Mid-Atlantic. The public school division in which the university is situated is a high-needs school district, serving nearly 23,000 students (75% Black, 13% Latinx, 9% White, and 3% Other) from low-income backgrounds (in the 2017-2018 school year, 100% of students qualified for Free and Reduced Lunch). Priority was given to students from the inner-city school district and portions of surrounding districts known to be low-income areas.

Forty-one students attended the week-long camp; 36 students' data was included in analysis. The students included 18 girls (50%), 17 boys (47%), and one student who identified as non-binary (3%). Eighteen students identified as Black (50%), eight as two or more races (22%), eight as White (22%), and two as Asian (6%). Nineteen students (53%) had completed 6th grade, 10 (28%) students had completed 7th grade, and seven (19%) students had completed 8th grade.

Data sources analyzed were observation protocols, video-recordings of lessons, and surveys. Students took survey items measuring dimensions of student engagement at the end of every day. Video-recordings were transcribed as needed. For the first research question, the second author analyzed survey data by converting responses to a Likert scale of 1 (*strongly disagree*) through 5 (*strongly agree*) and computed averages. For each student, their average scores were calculated for each day of the camp. Using these scores, the students' total averages were calculated to analyze overall engagement per day. Open-ended questions at the end of each survey were analyzed for common key phrases students attributed to their engagement efforts.

For the second research question, the first author watched video to identify cases of "engaged moments" (Yin, 2009) based on the level of students' cognitive (e.g., asking questions, describing their actions) and behavioral engagement (e.g., showing a knot they made). These moments were analyzed using Wang et al.'s (2016) dimensions of engagement, for students' ideas (cognitive), actions (behavioral), participation level (social), and affect (emotional). Instructional moves were inductively coded and analyzed to generate themes in relation to the phase(s) of the experiential learning cycle that was/were demonstrated in the moments.

Results

Quantitative Results

Mean engagement across five days of camp were relatively high: 3.47 (Day 1), 3.53 (Day 2), 3.90 (Day 3), 3.71 (Day 4), and 3.79 (Day 5). Results showed that 0, 14, and 22 students fell into low (< 2.5), average (2.5-3.5), and high (>3.5) engagement groups, respectively. Open-ended survey responses showed that students attributed infrequent breaks to lower engagement, whereas they attributed hands-on activities to higher engagement ratings.

Qualitative Findings

Two cases in which various forms (e.g., cognitive, behavioral) of student engagement were visibly present during the geometry activities were analyzed in-depth to understand the instructional moves that supported students within the experiential learning cycle. One case involved one-on-one interaction between the instructor and a student, while the other case involved interaction between an instructor and three students. Both cases of interaction occurred when students were encouraged to explore a concept individually and/or with their group members, during which the primary and secondary instructors moved around the room to support students' exploration. Overall, findings showed that instructors played an important role in supporting students' engagement in experiential geometry learning. Three major teacher moves that emerged from the analyses are summarized below.

Open-ended questioning. Questions were categorized as open-ended (e.g., "If I were going to try to make yours out of string, what would I do?") or closed (e.g., "It is a type of braid but it is somehow different from this braid, right?"; Chin, 2007). The majority of questions were open-ended: nine out of 10 in the group engagement case and two out of three in the individual engagement case. Use of open-ended questions encouraged students to actively participate by explaining their thoughts regarding what was posed. For example, during the small group case, the instructor posed the question, "What kind of process happened to make this braid that was different from the process that was used to make this one?" Student A responded, "I was folding over and over and over, and he was twisting and twisting." Here, posing open-ended questions created opportunities for reflective observation. Specifically, the student was able to reflect on the differences in braiding techniques which resulted in the production of different braids.

Real-time feedback. Analysis of the engaged moments revealed the instructor's use of real-time feedback which supports students' engagement with and understanding of the concepts (Wisniewski et al., 2020). This was often through the use of positive commentary supporting the students' work, followed by guidance for the students to consider in moving forward. One example of this real-time feedback occurred during the individual engagement case. The student was working to identify the number of braid crossings. The instructor supported the student's thinking and approach by saying, "This is a great way to approach this counting problem. You've broken it into categories where you're going to count what are the possibilities [sic]." Following this positive feedback about the student's moves, the instructor identified an important component to consider within the process, for duplicates and exceptions: "but the things to look for now that are actually technically the same or don't count for some reason [sic]." She then gave an example using cases, which (she explained) is a process mathematicians use. The instructor then encouraged the student to go through his cases and identify whether there are more cases that are equivalent within the cases he had already identified.

Prompting deeper experimentation. Analyses revealed the engagement that occurred following the instructor's use of prompting encouraged students to elaborate on their thinking (Walshaw & Anthony, 2008). Prompting sometimes took the form of encouraging students to consider a particular idea, while other times encouraged physical engagement. For example, in the small group case, the instructor prompted student C to demonstrate how they completed a type of braid. The instructor responded, "Oh okay, you're going full over." As a result of this prompt, student A became involved as well, which led to sensemaking between the two students:

Student A: "Wait, there's an easier way to do that."
Student C: "Huh?"
Student A: "Wait, can I try something? You could have just done… that… just twisting it."
Student C: "Yeah, but that doesn't twist the entire thing like that."
Student A: "Yeah, that's true."

In this example, the instructor's prompting created an opportunity for the two students to engage in active experimentation, where they developed a deeper understanding - together - of a discrepant event: why two braiding processes did not result in the same outcome.

Conclusion

In conclusion, quantitative and qualitative analyses revealed students reported and demonstrated overall high engagement in the camp. The qualitative analysis of two cases involving student engagement during geometry activities provides valuable insights into effective instructional strategies within the experiential learning cycle. The varied instructional moves implemented during these activities support existing literature arguing for intentional instructor actions that support students in engaging with the content (e.g., Chin, 2007; Walshaw & Anthony, 2008). While the geometry camp presents unique contextual considerations that vary from traditional K12 classrooms, the instructional moves presented can be implemented by traditional K12 classroom teachers as a means of supporting students' deeper engagement with geometry concepts and beyond. Our analysis provides a fine-grained look at specific actions making up these instructional moves and student responses, which can provide guidance for instructors looking to implement supportive instructional moves in a variety of learning spaces.

HOW BEGINNING SECONDARY MATHEMATICS TEACHERS RECONCILE COMPETING PROFESSIONAL OBLIGATIONS

Orly Buchbinder	Sophia Brisard	Rebecca Butler

orly.buchbinder@unh.edu	sophia.brisard@unh.edu	rebecca.butler@unh.edu

Building on the theory of practical rationality, we explore how three beginning secondary mathematics teachers reconcile competing professional obligations, namely: disciplinary, individual, and institutional obligations. As these teachers transitioned from supervised teaching to teaching their own classrooms, they reconciled competing obligations and developed their own ideas about mathematics teaching and learning. The analysis revealed that it was only institutional obligation that conflicted with either disciplinary, or individual obligation, or with teachers' own teaching preferences. No other two obligations appeared to clash. The conflict with institutional obligation was reconciled in favor of institutional obligation in less than 30% of instances. In the vast majority of cases, another obligation took precedence.

Keywords: Beginning Secondary Teachers, Teacher Obligations, Practical Rationality

"I thought that my job was to teach math. I was not emotionally prepared for all the other things I need to do in the classroom." These words of a first-year secondary mathematics teacher illustrate the complexity of classroom teaching and the many demands inherent in the profession. Raising the question of "How teachers manage to teach", Lampert (1985) asserts that the work of teaching requires constant management of practical dilemmas caused by competing responsibilities or commitments. For example, a commitment to attend to an individual student's understanding may clash with a commitment to "cover the curriculum;" or a commitment to advance academic achievement may conflict with providing a comfortable learning environment to students. Becoming a mathematics teacher involves, among many other things, learning to manage these types of dilemmas (Herbst & Chazan, 2003; Windschitl, 2002).

Beginning mathematics teachers transitioning from university-based teacher preparation programs to school teaching need support in learning how to recognize and deal with such dilemmas (Bieda et al., 2015). One way to support beginning teachers in this process is through an internship—supervised teaching experience, in which a teacher candidate is placed full-time in the classroom of a mentor-teacher. However, research shows that rather than being supported, interns experience additional competing commitments: toward the university supervisor advocating for ambitious teaching vs. the often-traditional practices of the mentor teacher (Bjerke & Nolan, 2023; Gainsburg, 2012). When entering their first teaching job, novice teachers assume additional classroom responsibilities, some of which have previously been managed by their mentor (e.g., communicating with parents, reporting to administration, coordinating instruction with other teachers). As a result, beginning teachers may feel overwhelmed, and enter a survival mode (Stokking et al., 2003) characterized by rigid, traditional teaching styles. Yet, some novice teachers hold on to the ambitious teaching practices learned in teacher preparation programs (Gomez Marchant et al., 2021; Thompson et al., 2013).

The implied interconnectedness of beginning teachers' early-field experiences and their emerging classroom practices indicates the importance of enhancing our understanding of how beginning teachers learn to reconcile and manage the multiple dilemmas of classroom teaching.

However, research examining this topic, especially longitudinally, has been limited (Cochran-Smith et al., 2008; Gainsburg, 2012). Our study aims to address this research gap.

The study reported herein is part of a larger NSF-funded project that explores the professional growth of beginning secondary mathematics teachers across four years, in multiple settings: from the senior year in their teacher preparation program, into the supervised internship, and their own classrooms. In this paper, we focus on three such beginning teachers: Nancy, Olive, and Diane (pseudonyms) who volunteered to participate in the study. All three teachers excelled in their academic studies as secondary mathematics education majors and demonstrated high buy-in for integrating ambitious teaching practices, as evidenced by the dispositions survey they completed as undergraduates. Moreover, the three participants had some experience with integrating ambitious practices in real classroom settings in their undergraduate preparation (Buchbinder & McCrone, 2023). We examine how these well-prepared beginning teachers coped with the challenges of transitioning from university to school teaching; and, how they reconciled competing commitments and teaching dilemmas.

Theoretical Perspectives

Teacher decision-making draws on many resources, such as teacher knowledge, personality traits, and beliefs. Herbst and Chazan's (2003, 2011) theory of *practical rationality* suggests that beyond individual characteristics, there are certain professional *obligations*, that are common to anyone who holds the position of teacher in the institution of schooling. The authors identify four broad types of professional obligations. The obligation to the *discipline* of mathematics involves authentically representing mathematical concepts, and engaging students with mathematical ideas, values (e.g., accuracy of vocabulary and notation), and practices (e.g., discovery, reasoning, and proving). The obligation to students as *individuals* involves attending to fairness, and consideration of individual student's needs, cognition, and emotions. *Interpersonal* obligation considers the class as a whole, requiring the teacher to manage social dynamics, intergroup relations, and ensure fair sharing of resources, time, and space. The *institutional* obligation requires the teacher to follow school, district, and state policies related to curriculum assessment and standards, and adhere to practices and guidelines shared by members of school mathematics departments.

Becoming a mathematics teacher involves adopting a decision-making framework for managing the work of day-to-day classroom teaching in the institution of schooling. The four professional obligations are an inherent part of this framework, whether explicitly acknowledged by teachers or not. The obligations do not prescribe teacher actions, but rather serve as sources of justification for those actions (Chazan et al., 2016). As pointed out by Bieda et al., (2015) the "obligations can be found in teacher talk as they warrant claims, either explicitly or implicitly, about what should or should not, or might or might not, be done in classroom interaction." Additionally, due to their often-implicit nature, obligations can be captured in situations where they come into conflict with one another. As teachers describe their classroom dilemmas their obligations come to the fore; and by examining the action taken following the decision-making process, we can learn about how the beginning teachers reconcile the competing obligations.

In this paper, we focus on negotiation, managing, and reconciling competing obligations by three beginning secondary mathematics teachers. We examine the following question: *In the discourse of beginning secondary mathematics teachers, what types of obligations surface as* *competing with one another, and how do teachers reconcile competing obligations?*

Methods

Data Collection and Analysis

Three beginning teachers: Nancy, Olive, and Diane volunteered to participate in the study as undergraduates and remained with the project for four years. In this paper, we focus on two time periods: (1) a supervised internship during which each intern taught in their mentor-teacher classroom, and (2) the first year of autonomous teaching. For Nancy, this supervised internship was a traditional length of one year with occasional stretches of autonomous teaching in the second semester. Olive and Diane were promoted to full-time autonomous teaching in their second semester due to the staffing needs of their schools and in light of their exceptional performance. For each participant, we collected multiple video observations, lesson artifacts, and interviews. The data for this paper comes from three interviews conducted with each participant during their first year in classrooms: one at the beginning of the internship and two in the second semester after lessons in which the participants taught autonomously. The fourth interview was conducted in March the following school year by which time they were all novice teachers. All interviews were conducted after one of the researchers observed a lesson taught by the participant. The interview questions probed the instructional decisions involved in the planning and enactment of the lesson.

The interview transcripts were split among three researchers (the authors of the paper), and each interview was coded individually by two researchers. The three researchers met weekly to discuss the coding and reconcile disagreements; such that each code was reviewed by at least two researchers. Teachers' discourse in these transcripts was examined at the utterance level for the presence of an action or decision made by the participant and the justification for that action/decision. These justifications were coded according to the four professional obligations described above (Chazan et al., 2016). In addition, some actions were justified on account of personal resources (i.e., knowledge, beliefs, preferences), when the participants described how they wanted their classrooms to look and feel. For example, consider the quote: "They [students] surprise me every day. I love that every time you do an activity, you're never doing the same thing twice. And every time I try to tweak it a little bit in the right direction." In this quote, Olive's action of "tweaking" an instructional activity is justified on account of her personal enjoyment of the teaching process and breaking the routine ("never doing the same thing twice.")

In this paper, we focus on those instances in our data where two obligations (or an obligation and a personal preference) appeared as conflicting with each other, and the teachers reconciled between them. Although these instances were relatively rare, they illuminate the dilemmas these beginning teachers faced and resolved early on in their professional journey. Hereafter, we refer to these instances as *reconciling obligations*.

Results

Of the total 492 obligation codes, only 35 codes (7%) involved reconciling obligations. For Diane, 8 of 132 obligation codes (6%) were reconciling; for Olive, it was 15 of 156 obligation codes (9%); and for Nancy 12 of 174 obligation codes (7%) involved reconciling. In all instances of reconciling two obligations, one of those obligations was *institutional*. Meaning that either disciplinary or individual obligations or personal teaching preferences conflicted with the institutional obligations. In 28% of all instances, the conflict was reconciled in favor of institutional obligation, but in most cases (72%) it was reconciled in favor of some other obligation (See details in Table 1, below).

Reconciling Institutional and Individual Obligations

In the participants' discourse, institutional obligation most often conflicted with an obligation to students as individuals. This occurred in 18 out of 35 instances (51%).

At the beginning of the internship, some institutional obligations were represented by the need to adhere to the teaching style and the guidance of the mentor teacher. For example, Diane described that her mentor teacher suggested she should show students two ways of solving problems of calculating percentages, but Diane felt it would confuse the students. She said:

> It's like one extra step that they'd [students] have to do that I think would be confusing for them. So, I don't know if I would've even mentioned it, but my cooperating teacher suggested mentioning it.

Here, Diane's desire to avoid confusing students (individual obligation) conflicted with the institutional obligation of following the suggestions of the mentor. Olive experienced a similar tension, although in her case, Olive felt she had to adhere to her mentor teacher's advice to instruct students to solve linear equations by collecting variables on the left side only. Despite her reservations, and because she "didn't want them [students] to do something that the other class didn't do," Olive upheld the institutional obligation and followed her mentor's advice.

As the teachers transitioned to autonomous teaching, the relationships with the mentor were no longer a concern. A different aspect of institutional obligation was now discussed by the teachers but remained in tension with the individual obligation. Specifically, the teachers talked about the tension between the need to "cover the curriculum" while at the same time attending to individual students' needs, prior knowledge, pace of learning, and even moods. Teachers mostly reconciled this tension in favor of the institutional obligation. For example, Diane described her context saying that there are "two students that are completely behind every time and I can't stop and constantly work with them, but I feel bad moving on." Similarly, Olive described the need to move along the curriculum while attending to individual students' learning pace. She shared:

> The reality of the situation is that I cannot give the same work to every kid in this class and expect them all to do well on it. That is just not the case. There are kids who need more than other kids. […] It's definitely taught me a lot about trying to differentiate and trying to make sure I have extra […] resources and things for them to do so that they're not bored.

In this quote, Olive acknowledged that students learn differently; therefore, her solution to managing this diversity was to differentiate her curriculum, ensuring some students were "not bored" while others receive different types of tasks in order "to do well."

Of the three teachers, Nancy was the one to express the tension most explicitly between institutional and individual obligations. She described this as follows:

> I feel like the standards and the things that they want us to teach are taking away from some of the fun stuff that we can do with it. And so, […] I get kind of frustrated because I wanna do fun stuff, but I also know I have other stuff I have to do and it's just kind of trying to find a happy medium, which I don't think I've gotten to yet.

In this quote, Nancy described the tension between the institutional obligation to address the content standards of her curriculum ("things they want us to teach") and her desire to create an engaging learning environment for the students ("fun stuff we want to do"). She described her frustration with the situation admitting that she has not yet found a "happy medium."

Despite the strong influence of institutional obligation, all three teachers described how they resolve, or strive to resolve the conflict in favor of individual obligation. For example, Nancy explained how she worked on revising the curriculum that was handed down to her to make it more engaging and "fun" for the students:

> That's something I've been working on since the beginning because in the beginning of the year it was basically just worksheet review, worksheet, review, worksheet, notes. Like there was no engagement happening. Um, and that's just because those were the resources I was given. But now it's a lot more interactive. There's a lot more fun activities built in.

Diane talked about reconciling the tension between institutional and individual obligations in terms of finding ways to "set them [students] up to be successful without making it too hard, but also without lowering expectations too much." Diane disagreed with some of her colleagues' advice of breaking the problems into isolated skills. She said:

> Talking with some other teachers, they would be like, 'oh, you'll never mix quotient rule with negative exponents.' […] I really want to push them [students] to be able to problem solve through a couple of steps. My goal is trying to find a manageable way to set them up to do that without making the work so difficult that they don't do well.

The institutional obligation in Diane's quote is represented through the community of teacher colleagues, and the advice given to her. Yet the obligation toward individual student thinking and their ability to problem solve takes precedence for Diane in this instance.

Reconciling institutional and individual obligations in favor of the latter sometimes took the form of developing greater sensitivity to students' feelings. Olive explained this as follows:

> I've got a pulse for how the kids change every day. Sometimes they're in a […] good mood. Sometimes […] it's not time to bug that student. […] that kid is in a place today that this math is not the biggest concern right now. […] I can work with that kid tomorrow and that's okay for today because that kid is not having a day.

In this quote, Olive described how she gradually developed "a pulse" for her students' moods, and their ability to act as students in her classroom. Using the word "kids" rather than "students" indicates her obligation to them as individuals, as Olive described prioritizing their well-being over moving on with the curriculum.

Of the 18 instances of conflicts between institutional and individual obligations, the teachers reconciled the dilemma in favor of institutional obligations 5 times and in favor of individual obligations 13 times. While these numbers are small and cannot be generalized in any way, we report on them to provide a sense of data trends.

Reconciling Institutional and Disciplinary Obligations

Institutional obligation competed with disciplinary obligation in 15 out of 35 instances, and in 10 of them the conflict was resolved in favor of disciplinary obligation. The disciplinary obligation was represented by the teachers' commitment to have students learn important mathematical concepts and procedures meaningfully and thoroughly. Additionally, this entails having students learn mathematics in ways aligned with disciplinary values and practices such as exploration, discovery, reasoning, proving, tinkering, and figuring out things for themselves.

Enacting classroom activities that uphold these disciplinary practices may be demanding for novice teachers and may compete with the institutional obligation. For example, as a novice teacher, Nancy received instructional materials from a more experienced colleague. Nancy expressed frustration with the traditional nature of these materials and with an implicit expectation to align her instruction with this mode of teaching. She said:

> We're doing translations and there are so many cool things you can do with translations. […] And I just feel like I need to do the guided notes and practice problems, even though, I don't know, I guess I don't necessarily have to, but it's just like, there are these notes and things that in the past it's been really great for her [another teacher] and it works for her. And I'm just like, I just don't wanna sit there and talk to them for 30 minutes at a time.

This quote shows Nancy's perceived obligation to uphold institutional expectations to coordinate instruction among teachers of the same grade level ("I feel like I need to do the guided notes"). This conflicted with her obligation to disciplinary practices of doing meaningful mathematics ("many cool things you can do with transformations"). Despite Nancy's dissatisfaction, the institutional obligation seems to take precedence in this instance.

Other examples of reconciling in favor of institutional over disciplinary obligation occurred when teachers were pressed for time or struggled to manage classroom discussions. As a result, they cut short an exploratory activity (e.g., "We didn't end up doing this [exploration] because of time. I had to get to the next stuff"); or lowered the conceptual depth of the discussion (e.g., "[If I] try to circulate that room and have a deep conceptual conversation with each of those 28 [students], I don't even think I'd have time in the block to do that").

Nevertheless, in most instances (10 out of 15) the teachers prioritized disciplinary obligation over the institutional. For example, as an intern, Olive modified her mentor's lesson plan about linear inequalities to introduce a short exploration for students to understand why multiplying or dividing an inequality by a negative number changes the sign of the inequality. Olive admitted she had to "push to do that just because in the original lesson plan […] the idea of flipping the inequality sign is not really explored at all." Olive explained that she was "worried that they [students] were going to ask why, and I didn't want to not have an answer to that question." This shows that Olive had to overcome the institutional authority of her mentor and of the prescribed curriculum, to provide a conceptual justification for a mathematical rule. As a novice teacher, she continued to modify her curriculum to make for a more conceptually rich practice. She said:

> If there [is] a worksheet with a ton of problems on it, I will try to deliberately choose three different ones that […] really throw you for a loop, so that they [the students] see different representations of problems where they're doing a similar process, but they're seeing there's something novel about each one.

Similarly, Diane described how she attempted to uphold the institutional goal of having students practice surface area and volume formulas through an exploratory activity where students calculated the surface area and volume of physical objects wrapped in aluminum foil:

> I didn't do much practice with them even using surface area formulas […] and volume formulas. So, they [the students] had the practice of figuring out what the formula means,

plugging the numbers in. […] It was different […] from every day because they [the students] were kind of drawing their own conclusions at the end.

In this quote, Diane almost apologetically admitted that she "didn't do much practice" with the students. This practice was achieved by breaking out from the everyday routine and by upholding the disciplinary obligation of having students "figure out what the formula means, plugging numbers" and "drawing their own conclusions."

The theme of breaking the routine, "doing something different," (Diane) introducing "fun stuff" (Nancy), and "just really hate[ing] the drill and kill idea" (Olive) was common for all three teachers. Sometimes, exploratory activities "did not fit in naturally," in Nancy's words, with the ongoing curriculum topics. For example, Nancy used the pretext of Pi-day (March 14th) to have students explore the value of Pi while teaching linear equations. Despite the tension with the institutional obligation, all three teachers found creative ways to uphold the disciplinary obligation.

Reconciling Institutional Obligation with Personal Preferences

Occasionally, teachers described tensions between institutional obligations and their personal beliefs and preferences about teaching; these tensions were resolved in favor of the latter. Olive discussed her choice to shorten homework assignments, saying that the shorter assignment was more "fair" for students and that this choice was "the first time I had done something that was my idea." Similarly, Nancy described going against her mentor teacher's typical grouping of students into teams of three, saying "I wanted to do groups of four because I feel like groups of four are better". In each case, the institutional obligation (giving homework, grouping students) was overridden by teachers' personal preferences for how they wanted to organize their classrooms (shortening homework and changing group size), which ultimately shaped their actions. Although such conflicts were rare, it was important to these teachers to follow their personal beliefs about teaching, rather than always strictly adhering to institutional norms.

Summary and Discussion

Table 1 summarizes the distribution of codes showing how the three participating teachers reconciled between competing obligations in favor of one of them. For each type of code, the percentage is calculated out of the total N=35 reconciling codes. For each teacher, the total percent of reconciling codes is calculated out of the total number of obligation codes per participant. The results of case studies are not meant to be generalized statistically (Yin, 2017); we report on these frequencies to provide a general sense of data trends.

Table 1: Distribution of Codes for Reconciling Obligations (N=35)

Teacher	**Institutional vs. Individual** Resolved in favor of		**Institutional vs. Disciplinary** Resolved in favor of		**Institutional vs. Personal preferences** Resolved in favor of the latter
	Institutional	**Individual**	**Institutional**	**Disciplinary**	
Diane	2	3	0	3	0
Olive	2	6	2	4	1
Nancy	1	4	3	3	1

Total	5 (14%)	13 (37%)	5 (14%)	10 (29%)	2 (6%)

As mentioned above, reconciling codes constitute only 7% of the total obligation codes; however, they are significant as illuminators of the tensions the beginning teachers encounter as they transition from university to school. Our data show that the main source of conflict for the participants along this journey was their *institutional* obligation. It appeared to clash primarily with either disciplinary or individual obligations and occasionally with participants' beliefs, in our case, their desire to enact ambitious teaching in their classrooms. Similar to the observations in the literature (e.g., Bieda et al., 2015; Smagorinsky et al., 2004), the institutional obligation first surfaced at the beginning of the internship when the participants needed to adhere to the teaching practices and styles of their mentors. This obligation became even more pronounced during autonomous teaching since teachers had to assume additional responsibilities in their classrooms and adhere to the practices of their schools (Lampert, 1985; Windschitl, 2002).

Teachers reconciled in favor of the institutional obligation when they felt pressed for time, either in specific lessons or more broadly, with respect to the pace of the school curriculum and content standards, for example, when there was an expectation to follow the shared curriculum and coordinate instruction amongst multiple teachers and classrooms. Additionally, the class size and the need to manage multiple students or groups inhibited teachers' perceived ability to go into conceptual depth on certain mathematical topics. In these instances, the teachers often had to compromise other obligations to ensure they were in line with the institutional expectations.

However, our data show that in the vast majority of situations (72% of reconciling codes) the conflict with institutional obligation was resolved in favor of some other obligation: disciplinary, individual, or personal preferences. On a side note, we did not encounter cases of institutional obligation clashing with interpersonal obligation. This may be due to the overall low frequency of reconciling codes within the data set; an observation that bears future exploration.

The beginning teachers reconciled in favor of *individual* obligation, in situations in which they felt the curriculum did not support students' classroom engagement. Nancy strived to include more "fun" and "interactive activities" breaking away from the "worksheets and review" routine. Diane devised tasks to make procedures "manageable" and "not too hard" for students, but without compromising problem-solving and "without lowering expectations too much." For Olive, reconciling institutional and individual obligations in favor of the latter was realized in developing heightened sensitivity, "a pulse" in her terms, to students' feelings. She talked empathically about how she can suspend the institutional obligation to the pace of the curriculum to accommodate a student who is stressed or maybe "just not having a day."

Additionally, all three teachers found ways to uphold the *disciplinary* obligation when it conflicted with the institutional obligation. This was apparent in the teachers' expressed desire to enact ambitious teaching practices. This took the form of integrating exploratory activities for discovering mathematical rules and relationships. Olive talked about doing "explorations" to justify the rule of 'flipping the inequality sign," while Nancy integrated an activity about discovering the value of Pi despite its loose connection to the ongoing curriculum topic. The obligation to engage students with disciplinary practices took the form of engaging students with disciplinary mathematical values and practices, like free exploration (Diane), reasoning and justifying (Olive), and allowing students to choose which solution method they want to pursue (Diane). Reconciling the tension in favor of disciplinary obligation did not come easy but took the form of *small* steps like "tweak[ing] things ever so slightly" or doing "little explorations."

Our findings illustrate the strong influence of institutional obligation on the day-to-day work of teaching and the pressure it imposes on beginning mathematics teachers. While the literature suggests that beginning teachers tend to gravitate toward traditional teaching practices in their schools (Gainsburg, 2012; Windschitl, 2002) we are encouraged by our results showing the ability of these beginning teachers to navigate institutional obligation without caving into it.

These findings shed light on the complex situations beginning teachers face as they transition from the idealized setting of their teacher preparation programs into the challenging realities of school teaching. The theory of practical rationality and the four professional obligations (Chazan et al., 2016) help to conceptualize these transition processes as the *socialization* of beginning teachers into the teaching profession during which teachers adopt a particular decision-making framework that makes their classroom practice manageable (Herbst and Chazan, 2011). Teacher educators can build on these conceptual tools, and on the results of the current study, to support future teachers in retaining ambitious teaching practices in the institutions of schooling.

WORKING TOWARDS STRENGTH-BASED PEDAGOGIES IN MATHEMATICS EDUCATION

Kaja Burt-Davies
University of South-Eastern Norway
kaja.burt-davies@usn.no

Annica Andersson
University of South-Eastern Norway
annica.andersson@usn.no

The purpose of this brief research report is to provide insight into Kaja's ongoing doctoral work on storylines and student positionings in mathematics education. Based on a mentorship program in a Norwegian multicultural primary school, where 7th grade mentors collaborate with and mentor 3rd grade mentees during mathematics classes on a weekly basis, this research report explores how storylines can influence the positioning of the mentors. The report presents two storylines that indicates that the mentorship program could have a positive impact on the mentors positionings.

Keywords: Culturally Relevant Pedagogy, Affect, Emotion, Beliefs, and Attitudes

Context: A beautiful transformation of students' positioning

In February 2022, when the first author, Kaja Burt-Davies, started her PhD work, she visited the teachers and classes that had agreed to participate in a larger research project. She immediately understood that one class faced challenges. The teacher apologized for the behavior of the class and explained that it had been a challenging class since they started school. But with a twinkle in her eye, she also said something like, "Well, at least in this class, we have real challenges. It's not the kind of class you read about in textbooks". The classroom was chaotic. At one point, there were 7 adults in the room to manage 18 5th graders. Tired and frustrated after a lesson, the teacher declared: "The only thing that works with this class is to take a bus or be mentors." Kaja noted this in her notebook. A few months later, she saw mentorship in action. The mentees were 1st graders in a classroom across the corridor. At that time, to her, it seemed almost unthinkable that this class would mentor anyone; they couldn't even take care of themselves! However, she was astonished when she saw how the older students embraced the role of mentors. It was as if someone had cast a magic spell over the students. In groups of 2–6 students from both classes (carefully assigned by the teachers), the older students focused and quietly helped the younger ones with mathematics tasks. The older students read problems, counted on their fingers, and demonstrated with pen and paper to the younger students. When she heard one of the most challenging boys say to a younger boy, "You have to read the problem if you don't understand what to do; I'll read it out loud for you," she had to stop. What was happening here?

Objectives and research question

This brief report explores how storylines may impact students' opportunities to assume positions that are beneficial for learning. The aim of the report is to emphasize how mathematics teachers can utilize storylines to establish learning environments where students can position themselves as mathematics learners. To illustrate this research, two storylines are drawn from data collected in the previously mentioned classes, now consisting of 3rd and 7th graders in southern Norway. For three years, the two classes have been meeting weekly through an in-school mentorship program to engage in mathematical activities together. This leads to the following research question: How do mentees' storylines impact the positioning of the mentors?

Towards strength-based pedagogies through the lens of positioning theory and storylines

Kaja's doctoral work is affiliated with the research project *Mathematics Education in Indigenous and Migrational contexts: Storylines, Cultures and Strength-based Pedagogies* (MIM project), where position theory (Davies & Harré, 1990) and the concept of storylines are central. The MIM project explores strength-based pedagogies in mathematics education. We aim to explore how students' strengths and resources (both personal and academic) can be used as a starting point to create learning contexts where students perceive themselves as mathematics learners.

Positioning theory

Herbel-Eisenmann et al. (2015) define positioning as a discursive process involving action and communication to create social structures. In contrast to the static nature of the concept of "role", Davies and Harré (1990) propose that "positioning" directs attention to dynamic aspects, emphasizing how we understand ourselves in dialogues through the terms "positioning" and "subject position" based on existing narratives. Through the MIM project, we aim to promote positioning theory as it brings new perspectives to understanding learners. As most mathematics teachers probably recognize, it is common in mathematics classrooms to have students who desire to learn mathematics as well as those who do not (Andersson et al., 2015).

Through the lens of positioning theory, it is possible to say that students accept or reject positions as mathematics learners. By adopting a positioning theory lens, we assert that teachers can create learning contexts that offer opportunities for students to pivot (Gerbrandt & Wagner, 2023) or change their positions to enhance their engagement when learning mathematics.

Storylines

Based on our experiences as mathematics teachers, we have observed that students' positions often align with one or more narratives that support their views on their position as learners or non-learners. Positioning theory (Davies & Harré, 1990) refers to these types of narratives as storylines. Herbel-Eisenmann et al. (2015) define a storyline as a culturally shared narrative derived from an individual's lived experiences. Interactions among participants contribute to the creation of storylines, which serve as prerequisites for different positions in people's lives. Storylines play a significant role in shaping and influencing the positions individuals are assigned or have access to (Herbel-Eisenmann et al., 2016). During an interview about mathematics, their view on their futures and dedication in mathematics, Farrokh, a 6th grade student, shares one of his dreams:

Farrokh: I want to become a doctor.
Kaja: A doctor?
Farrokh: Yeah, something like that.
Kaja: Why is that?
Farrokh: Because... well, I don't really know what I want to be myself, so my mom wants me to become a doctor. Since I don't know myself, I want to listen to her. And being a doctor is actually a good job.
Kaja: Mmm, why is it a good job?
Farrokh: I don't know much, but I've heard... my mom says it's because, firstly, it has a pretty good salary. And being a doctor or a physician is something you need everywhere you go. So, it's easy to find a job if you're a doctor and have a medical education because

> doctors are needed everywhere. That's why it's easy to get a new job if you move and stuff. That's why it's a good job.

This example illustrates how Farrokh relies on narratives and information he receives at home to construct a narrative for his school life. He positions himself in relation to the future because of the conversations he has with his mother at home. As a result, a storyline such as "becoming a doctor is a good career choice" is supporting Farrokh in his decision to learn mathematics because the effort seems crucial to achieve his goal of becoming a doctor.

Methodology

To understand how the mentor-mentee relationship influenced mentors change of positions, semi-structured group interviews were carried out with both 3rd and 7th grade students, in total 10 students from each class. The 3rd graders were interviewed in pairs, and the 7th grade students individually, in pairs, or in groups of three. For practical reasons, interviews with 3rd graders were conducted first, followed by interviews with the 7th graders.

Thematic analysis

Even though the ongoing analytic process has an inductive framework, the analysis is not free from theoretical or epistemological commitments (Braun & Clarke, 2006). Committed to the [project name], and the context of positioning theory and strength-based pedagogies, the analysis is guided by the search for storylines that can explain "the magic process", described initially—the beautiful transformation of the students' positioning. The analysis process started with manually transcribing all audio recordings, followed by categorizing the text into various themes. These themes were partly derived from the interview questions, which primarily addressed practical aspects like student collaboration and mentor guidance. However, additional themes and sub-themes were also integrated. Notably, *admiration* emerged as a theme in mentee transcripts, while *being a little teacher* was a theme in mentor transcripts. These two themes, later developed into storylines, constitute the foundation of this research report.

Initial results

Storyline 1: "I admire you"

One storyline that emerged most prominently during the analysis of the mentee's interviews was *I admire you.* This storyline was formulated based on many student statements but is rooted in the fact that the mentees look up to the mentors. The reasons for their admiration are many and varied. For instance, Nora explains that *the mentees need the extra little teachers.* Besides acting as *little teachers*, Nora also states that mentors *can be of great help.* Not just with mathematics but also if they *get stuck or something like that*. Jakub og Fariah have other reasons. Jakub talks about the mentors' experiences: *so every day, they had math, that's why they are so good at it,* and Fariah says: *they are getting taller and taller and bigger, and then they almost become adults, and that's when they become better at math every single day.*

Storyline 2: "I like being your little teacher"

In response to storyline 1, "I admire you," storyline 2, "I like being your little teacher," is visible in all interviews. Mentors were asked what they thought about being called a little teacher or almost an adult. The reason behind this question was to find out if mentors' accepted positions made available through storyline 1. Despite facing some challenges, they agree that mentoring younger students positively impacts their self-esteem, with expressions of feeling proud, tough, and skilled. Due to space constraints, we've selected one example of mentor responses:

Kaja: But do you feel grown up? [when working with the mentees]
Madelen: Yes, very much.
Kaja: How is that?
Thea: It's kind of fun.
Madelen: You feel like you're so smart and strong!
Thea: You feel like you're the big, strong, smart, cool one.
Madelen: Not cool?
Thea: No? I feel...tough!
Kaja: But if we removed the whole mentor thing from school? Does it give you something to be mentor?
Madelen: Yes, I feel like I like it because I feel smart. And I'm actually smart in my class too, just saying.
Thea: Yes, you are.
Kaja: But how does it make you feel when others think you're smart?
Madelen: I feel [giggles, laughs] better than the others, I feel a bit egoistic but [giggles].
Kaja: Yeah, but there's something about it, your self-esteem grows. Do you think it helps that you have even better self-esteem because of the mentees?
Madelen: Yes, I feel that.

Discussion

The storylines presented in this report are based on interviews linked to a mentorship program. "The magic process" was chosen because the change of context from their ordinary classroom had a major impact on the mentors' behavior. When the mentors changed their role from student in a challenging learning environment and instead entered the role of mentors where they interacted with different, younger students, they accepted and acted out a position as little teachers. We believe this was because the mentors experienced admiration and as Madelen confirms in the dialogue above, working with the mentees helps her self-esteem. In the MIM project, the goal is to move towards strength-based pedagogies in mathematics education. Through the lens of positioning theory, we are trying to understand how students' strengths and resources (both personal and academic) can be used as a starting point to create learning contexts that offer students positions where they perceive themselves as mathematics learners. We believe that the example highlighted in this report demonstrates how contexts can have a significant impact on students' self-perceptions. This, in turn, may influence their view of themselves as mathematics learners, ultimately leading to a pivot or change in students' positions. In this way, a focus on storylines could potentially serve as a foundational support for transitioning to strength-based pedagogies.

The authors of this article encourage readers to actively participate in contributing their valuable insights and thoughts. Your perspectives are crucial in fostering a collaborative dialogue on the potential applications of positioning theory and storylines as effective tools for the development of strength-based pedagogies. Your contribution will not only enrich the ongoing discussion but also help us better understand how these frameworks can be used to create an empowering and inclusive educational environment. Feel free to share your experiences, reflections, and ideas, both with fellow readers and us.

Keywords: Professional Development, Research Methods, Instructional Activities and Practices

One goal of professional development (PD) is to improve practice by having teachers incorporate what they learn into their existing instruction. We refer to teachers' incorporation of these practices as uptake. Our project seeks to incrementally impact (Star, 2016) teachers' practice through their uptake of instructional nudges, modest instructional suggestions, that are in concert with their existing instructional practices. We designed 16 instructional nudges that varied with regard to whether they were intended to impact curriculum materials (task nudges) or teachers' actions (teacher nudges). For example, Pivot is a teacher nudge that encourages teachers to change the instructional format during their class period (e.g., shifting from whole-class discourse to independent work time) with the goal of increasing student engagement by refocusing the classes' attention. Rate & Review, a task nudge, encourages teachers to provide students with worked examples to rate and review in terms of the quality of the solution in the hopes of growing students' conceptual understanding. The purpose of our study is twofold. First, we seek to understand which of our instructional nudges were high-uptake (Author, 2022. Second, we want to understand what features impact the rate of uptake.

To accomplish our aims, we piloted a PD experience in which we provided instructional nudges to seven algebra teachers. The teachers ranged from novice to veteran and varied in their local context (e.g., school racial and ethnic diversity, location, and socioeconomic status). The main data source for the present study were individual, semi-structured interviews during which each teacher interacted with a heat map activity. The heat map consists of two axes on a continuum of, Hate It to Love It, on the horizontal axis and, Number of Tries, on the vertical axis. Each participant placed each of the 16 instructional nudges on the continuum with respect to their affinity towards the nudge (e.g., hate or love) and the number of times they tried it in their classroom, asking them to think-aloud as they placed each one. Each teacher also completed a survey that aimed to understand their perspectives on their instructional practices, and we conducted three observations across the year to examine teachers' practices both before and after accessing the PD. We coded the interview data for each teacher individually with regard to the factors they considered in using particular nudges and the factors that impacted their view of the nudges. We then looked across the teachers for patterns regarding the factors impacting uptake. We used the survey and observation data to confirm our interview findings.

Our preliminary findings indicate teachers heavily consider the amount of preparation necessary in deciding to take up nudges. In addition, nudges that align with teachers' goals and current practices contribute to their uptake. We will share the results of the heat map interviews. Our findings provide important insights for the design and development of PD and suggest the need for further research into features impacting teachers' uptake of PD in their practice.

TEACHERS' VIEWS OF MATHEMATICS IN DATA VISUALIZATION ACTIVITIES

Elizabeth B. Dyer
University of Illinois Urbana-Champaign
edyer@illinois.edu

George Schafer
Drexel University
gws42@drexel.edu

Keywords: Data Analysis and Statistics; Integrated STEM / STEAM; Informal Education

Data visualization has been proposed as a multidisciplinary topic to integrate mathematical thinking, statistical thinking, critical media literacy, and art or design in ways that highlight critical perspectives (Matuk et al., 2022; Rubel et al., 2021; Woods et al., 2024). While research has focused on students' engagement with data science tasks and curriculum (e.g., Calabrese Barton et al., 2021; Lee & Delaney, 2022; Matuk et al., 2023; Wilkerson & Laina, 2018), less research has focused on how teachers or other educators take up the role of supporting student learning about data. Building on theory from interdisciplinary learning about the importance of teachers' views about the disciplines and their connections (Cohen et al., 2022), we focus on how teachers view the discipline of mathematics in relation to data visualization.

This research aims to explore the following research question: how do novice mathematics teachers view mathematics or mathematical thinking as part of youth's engagement with data visualization activities? We present the preliminary analysis of episodes in an ongoing exploratory case study (Yin, 2009) of the sensemaking of instructors who co-led a 13-week data visualization informal education program for middle and high school grades youth. The team of instructors included an experienced art teacher, an experienced English teacher, and two novice mathematics teachers. The authors identified critical episodes in transcribed video-recorded planning sessions and reflective debriefs by searching for the words math, statistic(s)/stat(s), data, and art in the transcripts. We identified episodes where multiple participants used these words to discuss a similar topic that lasted longer than 1 minute. Both authors identified themes through collaborative analytic memoing and discussing episodes (Saldaña, 2015).

We found that instructors compared math, data, and art as distinct labels for, or types of, activities, youth's interests, and sensemaking. One example comes from an debrief episode about activities that stood out to instructors. Luis, a novice math teacher, commented that in contrast to youth showing interest in art, he wished he "would have seen that kind of spark when we did the math portion…at the very beginning they were, like, already negative…[about] the math part, the mean, median, mode, [and] range." Beth, a novice math teacher, shared that the "dear data" portion was "something so simple and making it math…how many times I took a picture?...It's saying, 'hey, math can be so small, it's what you do every day, you don't know it.'" Sarah, an experienced English teacher, contrasted doing math with making meaning, saying, "A lot of them were just stuck on tallying things and adding them up. 'I'm like. okay, what about as a percentage?'...And so, [our focus is] not even doing math…we're trying to get at like 'is mean meaningful?'" This example shows how the novice math teachers use the label of "math" for activities and youth's experiences in different ways, and suggest potential tensions in disciplinary definitions among teachers that may constrain or expand learning opportunities.

These findings suggest that explicit conversations and sensemaking about what "counts" as mathematics in connection to data science education and data visualization could be important for mathematics teachers, including novice mathematics teachers, to support expansive learning.

AN EXPLORATION OF PRESERVICE TEACHERS' USE OF DISCRETIONARY SPACES AND IMPACT ON STUDENT POSITIONING

Shekira L. Edgar
Western Michigan University
shekira.edgar@wmich.edu

Elisha Hall
Western Michigan University
elisha.d.hall@wmich.edu

As the field of mathematics education research has progressed, scholars and professional associations have contributed to and advocated for an increased focus on equitable teaching practices that are to be adopted and employed by mathematics teachers. This study analyzes how two preservice teachers (PSTs) use discretionary spaces during their first field experience for a secondary methods course. The data consisted of video recordings, transcripts of those recordings, and a reflection paper from both PSTs. To perform the analysis, we used an empirical discourse approach to identify existing themes. Our work suggests that choices made in discretionary spaces came from the preconceived expectations PSTs had of social roles in the classroom. This indicates that an intervention shifting the expectations of classroom roles can promote considerations of equity in the positioning of teachers and students.

Keywords: Instruction Activities and Practices, Classroom Discourse, Preservice Teacher Education, Teacher Beliefs.

Introduction

As the field of mathematics education research has progressed, scholars and professional associations have contributed to and advocated for the increased focus on equitable teaching practices that are to be adopted and employed by mathematics teachers (e.g., Aguirre et al., 2013; Leonard et al., 2010; Crespo et al., 2021; Goffney & Gutiérrez, 2018; National Council of Supervisors of Mathematics [NCSM] and TODOS, 2016; Association of Mathematics Teacher Educators [AMTE], 2017). In this same breath, we as a field, have also looked inward to assess the effectiveness of the ways in which we, as researchers and teacher educators, prepare teachers to effectively enact these practices (McDonald 2005; Hollins, 2011; McDonald et al., 2013; Lyiscott et al., 2018). One potential way of doing so is highlighted in Indicator C.4.2. of the AMTE (2017) *Standards for Preparing Teachers of Mathematics*, which states that "well-prepared beginning teachers of mathematics recognize that their roles are to cultivate positive mathematical identities with their students" (https://amte.net/node/2270). Our work explores the choices preservice teachers make during classroom discussion that either shift or reinforce the positioning of students. These positionings, in turn, prompt a negotiation of roles that have direct impacts on student mathematical identities (Ruef, 2020).

We decided to isolate moments of teachers cultivating mathematical identities within *discretionary spaces* (Ball, 2018; Berry, 2022; Berry, 2023) as these spaces provide focused, in-the-moment insight into teachers' use of discretion in the classroom that is not dictated by policy or curriculum. These "in-the-moment" decisions of facilitating classroom discourse and the corresponding impact on student *positioning* (Herbel-Eisenmann, et al., 2015; Bishop, 2012) contribute to the cultivation of student identities. Previous research provides examples of the impact of communication acts, both verbal and non-verbal, on the mathematical identity of students. For example, Wagner and Herbel-Eisenmann (2008) explain how "just" can be used as an imperative ("just focus on your work") or as an indicator that the answer should be easy ("just subtract five from both sides"). Both cases illustrate how communication acts affect the development of roles within a classroom. When "just" is used as an imperative the teacher takes an authoritative tone creating a sense of hierarchy within the classroom and indicating that the student should blindly follow. On the other hand, "just" as an indicator of simplicity can result in students who don't understand the concept feeling inadequate and as an outsider to the conversation. This assignment of roles and the results thereof has the ability to influence future student contributions and their perceived sense of legitimacy (Wagner and Herbel-Eisenmann, 2008).

To better understand these issues, we investigate this research question: *How do pre-service teachers navigate discretionary spaces in mathematics classrooms, and to what extent does their use of these spaces impact the positioning of students in the learning process?*

Theoretical Framework

We draw on positioning theory (van Langenhove, L., & Harré, R., 1999; Anderson, 2009; Dennen, 2006) as it explains how each participant in a communication act plays a part in negotiating social structure. Within a classroom, teachers often exercise authority as a means of classroom management and control. In this storyline, teachers assume the role of subject matter experts, which leaves students as recipients of information (Wagner & Herbel-Eisenmann, 2015). An alternative is a shared authority structure where students become co-constructors of knowledge, contributing to the general discourse with the teacher as a guide or possibly even on the peripheral as an observer (Harper & Kudaisi, 2023). We are interested in how these negotiated storylines are enacted by preservice mathematics teachers in their early field experiences. Due to the nature of our study, and the complexity and scope of positioning theory, we have narrowed our investigation to only focus on how positioning is used to identify and apply this theory to help better understand how teachers position students during classroom interactions.

Further, positioning is a dynamic action, changing from moment to moment based on moves that either reinforce the established position or shift how participants understand their role with others. For example, in a bulleted list, Bishop (2012) identified moves between two students based on the dialogue they shared, these include the use of an authoritative voice (being critical of the actions of others), face-saving moves (reducing the appearance of a lack of understanding) and the building of solidarity and provision of encouragement. Each of these moves shifted the identities enacted by the students. While we did not limit our analysis to these three movements, they appeared in discretionary spaces within the observation.

Methodology

To conduct this work, we used previously recorded video and audio data from a secondary methods course during the first round of field observations for a group of 14 preservice teachers (PSTs). The course focused on teaching at the middle school level, with an emphasis on analyzing and understanding student thinking and implementing instructional practices in middle school classrooms. The course-embedded field experiences took place in a midwestern public middle school with a majority African American population, located in the heart of a small city that was less diverse. Each PST completed a brief survey at the beginning of the course that was intended to gauge their experience with teaching as well as their beliefs and attitudes of "good teaching" prior to their first field experience. After the experience, they submitted a reflective paper that detailed their impression of the enactments based on an analysis of a video recording of their teaching and the student work associated with that enactment.

As part of the teaching experience, the PSTs were paired and given the same instructional routine of Contemplate then Calculate (Lucenta & Kelemanik, 2022) to teach to a group of 12-15 middle school students during their mathematics period. This allowed PSTs to elicit student thinking strategies by posing complex integer addition and subtraction number expressions that had underlying structures for the students to recognize and use to mentally evaluate the expression.

Of the 14 total PSTs taking the course, seven agreed to participate in the research study. Guided by our research question, we analyzed three video enactments where both PSTs agreed to participate in the study. The video enactment of the seventh PST was analyzed separately because their partner did not consent to participate. The two researchers independently reviewed the videos of the enactments with a focus on identifying episodes of PSTs using language in ways that influenced the positioning of students in the classroom. After this initial round of independent analysis, researchers reconvened to discuss their findings; both identified the same two PSTs for further analysis of the construct, Jaime and Alex (pseudonyms) because although they were presenting similar tasks, their individual approaches to teaching resulted in vastly different responses from students. It is important to note that Jaime and Alex did not perform their enactments as a pair, therefore, the analysis of their use of discretionary spaces was done independently from their partners. We operationally define discretionary spaces to analyze moments during instructional time where teachers make a choice that shifts or directs the learning trajectory of either individual students or the entire classroom. These spaces were identified when PSTs made an instructional move (choice) or used their discretion to facilitate the lesson and ended whenever PSTs shifted their focus away from the initial topic and began a new one.

Once the two PSTs were selected, we transcribed the recordings using an online resource (https://otter.ai) and verified the transcriptions, making minor adaptations as needed. We used an empirical discourse analysis approach (Hodges et al., 2008) that allowed us to identify broad conversational themes contained within discretionary spaces (as defined above) that had the potential to shift or influence student identities in the classroom. We performed a second, more targeted analysis that focused on the two selected PSTs. This second analysis was also performed individually then transitioned to a discussion between researchers. Both researchers identified the same discretionary spaces and labeled them as rich opportunities to examine various ways students are positioned based on the language (verbal and nonverbal) used by the respective PSTs. The identified moments were categorized into *statements* and *interactions*. Statements are uninterrupted utterances by the PSTs, while the interactions include the verbal and non-verbal responses of students. We acknowledge that the positionings discussed in the following sections may vary based on the perceptions of the researcher. Therefore, we do not claim that our positionings listed are the only possible interpretations; they are based on our history and familiarity with the current literature.

Findings

We addressed our research question first by focusing on various discretionary spaces. Initially we looked at individual statements uttered by the PSTs that gave meaningful insight to positioning structures, then at brief interactions. During several moments of the enactment, the two PSTs navigated similar discretionary spaces, which gave an opportunity for comparison

Statements

In Figure 1, similar discretionary spaces between the two PSTs were placed side-by-side for comparison. On either side of observation quotes are possible interpretations of the language used by Alex and Jamie. Notice that there may be alternative positioning interpretations, but based on the perspectives of the researchers, these interpretations seemed most plausible.

Alex		Jamie	
Positioning of Students	Utterance	Utterance	Positioning of Students
Student as an active contributor of knowledge	"Good morning you guys… So we're gonna be going over an instructional routine called contemplate then calculate, [it] will help you practice looking for shortcuts using your own mathematical knowledge…"	"Alright… so today we're going to be working with y'all on contemplate then calculate… we do this to try to get you think like mathematicians…"	Student as a passive receiver of knowledge
Student as voluntary participant	"[C]an I get any volunteers to share what they notice about the problem?"	"We're going to share our noticings out loud"	Student as involuntary participant
Student contribution as part of group	"We have a good observation back here"	"[Y]ou said something really interesting about that"	Student contribution as individual
Student as valuable contributor	"So now I'm going to hand out a piece of paper… you only have to answer one of these… to help you think about how can we use what we know about the problem… and how they relate to one another…"	"Alright, so now we'll move on to reflecting on learning. I'm gonna pass out a paper, if you have a pencil, get them out…just go through, fill in whatever blank you feel like filling in"	Student as neutral contributor
Students as capable	"…using your own mathematical knowledge. Y'all have brilliant brains that y'all can use."	"You don't have to get it right away. Honestly, who expects anyone to? … No one's expecting you to know how to solve it yet."	Students as incapable

Figure 1: Examples of Teacher Language and Impact on Student Positioning

Interactions

From the analysis, we identified three pairs of related episodes of teacher-student interactions that illustrate positioning based on teacher communication acts.

In the following transcript, Alex creates a sense of solidarity and collaboration with the students early in the class, which aligns with Alex's previously stated intention of focusing on the "teaching" aspect of mathematics education.

Alex: "Are y'all ready to think like mathematicians?"
Students: "No"
Alex: "No? Come on, I need some better energy. Come on!"
Students: [chuckling] "Yes"

Conversely, the following interaction in Jaime's class highlights the authoritative structure created by Jaime's desire to be the subject matter expert. During a large-group discussion in response to a question about noticing, a student mentioned there were no variables in the mathematical expression on the board.

Jaime: "Does everyone know what a variable is?"
Student: "ABCDEFG"
Jaime: "Not always. You can also use Greek symbols." [nods to other PST, turns their back to the students and immediately begins talking about another topic]

Here, we see Jaime enforcing this authoritative structure by self-identifying as the subject matter expert, and situating students as mere recipients of information. The physical move of turning their back and beginning to talk about a different topic closes any possibility of question or retort, indicating that Jaime did not expect to be challenged or questioned.

The second episode allowed us to compare similar moments in which we recognized a similar discretionary space treated very differently between the two PSTs. As shown in Figure 2, both PSTs set an expectation that students were to put writing implements away to focus on mental mathematics. However, the way the PST discussed these expectations with the students varied greatly, as did the student response. In the following interactions, Jaime and Alex both set clear expectations; however, the way they address the students in this space is significantly different.

	Alex	Jamie
Interaction 1: The teacher is explaining the task for the day. The teacher made it known to students what they will not be using writing utensils for the beginning of the task.	"The first three steps you do not need a pencil or paper. You'll not need anything to write down. Just use your mind and that's it. Okay? We can do it. All right. Let's put away our pencils. Put away our papers."	"Pens and pencils away. You don't need them for this at all until the very end. We prefer you not to have them out for this because it is supposed to be more mental than verbal."

Impact (Student Response)	Immediately after: Students start putting away things, you can hear shuffling and what sounds like a pencil case or a backpack zipper. Alex: "Y'all ready? Paying attention?"	Immediately after: Students start putting things away, you can hear some shuffling. One pencil remains on the desk (can be seen from camera angle) Jaime moves immediately into expectations for the activity.
Interaction 2: The teacher has completed the task and is moving to the reflective portion of the activity.	"So now I'm gonna hand out a piece of paper. I'm gonna hand out a piece of paper."	"Alright, so now we'll move on to reflecting on learning. I'm gonna pass out a paper, if you have a pencil, get them out"
Impact (Student Response)	[Teacher was walking around handing out paper and pencils after giving students instructions] Alex: [To Student 1] "Do you need a pencil?" Student 1: "Yes" Student 2: "I'd like one" Student 3: "Me too" [Inaudible conversation] Student 4: [In response to another student voicing frustration] "She's [Alex] giving out pencils"	Multiple Students: "Can I go grab my pencil?" Jaime: "We have pencils I believe" Student 1: "Is it mechanical?" Jaime: "No" Student 1: "Can I go grab *my* pencil?" (emphasized) Jaime: "No, we have another group next door also doing the activity." Student 2: "So I can't run and grab my pencil?" Student 1: "Right?" [The class gets a little louder, students start to fuss] Student 3: "Oh my *god*!" [audibly annoyed]

Figure 2: Examples of Teacher-Student Interactions and Impact on Student Positioning

We see here that Jaime set expectations as rules to be followed, which aligns with the previous pattern of Jaime as a rule-setter and subject matter expert, positioning students as rule-followers. Alex, on the other hand, sets the expectation, then follows with encouragement of the students' capability as learners. Alex self-identifies in solidarity with students with the statements "we can do it" and "let's put away our papers".

Within each discretionary space, language shifts the assumed role of teacher and students to fit the narrative storyline that is unintentionally designed by the PST. In Alex's class interaction, the negotiated role of teacher and students were as co-contributors working in solidarity. Jaime's language set expectations more as subject matter expert and receivers of information. Although these are negotiated positions, the inherent power imbalance gives students little influence over these enacted roles.

Discussion & Conclusion

Each PST acted through their previous experience and expressed focus to use discretionary spaces in what they deemed to be meaningful ways. Jamie expressed in the survey that in the phrase "mathematics teacher," the emphasis on mathematics was most important, while Alex emphasized the teacher. As a result, the words and phrases they chose to use reflected their individual focus. Because Jaime emphasized the mathematics, the role she played was as subject matter expert. Conversely, Alex's emphasis on the teacher placed her in the role of encourager and guide, creating a classroom structure of shared authority and established students as co-constructors of classroom knowledge (Ruef, 2021; Langer-Osuna, 2017).

Using the term guide as a metaphor for Alex elicits imagery of a tour guide, giving clear directions of what's to come while walking alongside the students with shared authority. We see this in the use of first-person pronouns of "we", "us", "our" and "ours". Putting herself in the same figurative space as the students builds a sense of solidarity. In stating that students should use their own mathematical knowledge, Alex adds, "Y'all have brilliant brains that y'all can use," identifying the capability of students, setting them as co-contributors to classroom knowledge. She further builds solidarity by asking for volunteers to share their knowledge rather than answers. In addition, with the shared solidarity of the class, students gladly participated in conversation. Each noticing was met with encouragement, and the students were able to build on each other's ideas. The students' participation in the conversation and the unrestrained sharing of ideas confirmed that students took up the position of co-contributors and acted out of this position.

Jaime's focus on being subject matter expert created a hierarchy in which the teachers are the experts and authority. In a pattern of teacher moves, Jaime created an expectation of providing rules for the students to follow, then changing the subject or physically moving in a manner that removed herself from the conversation. The use of first-person pronouns referring to the PST with second-person pronouns such as "you" and "yours" referring to the students creates a division between authoritative voice and submissive voice. In explaining the idea that students would learn to think like mathematician, she stated that "we do this to get you to think like mathematicians." In this statement, "we", Jaime and the other PST, are doing the action to create a result of "getting you to think like mathematicians". This sets the students as passive receivers of information with little agency, which appeared to be a role they were not ready to accept.

In the event of misaligned expectations, students may push back. In Figure 2, we highlight an interaction within a discretionary space where directions were given to students to use pencils for the final activity. Although Jaime acted out her expectations of being a subject matter expert with students as followers, the students challenged this positioning with crosstalk and lack of compliance. It can be noted that this pushback is a method of renegotiating roles in an environment where a power imbalance exists. To counter this imbalance, students band together, all speaking at once and advocating for a common goal. In this case, the goal became about going out of the classroom to get their own pencils, rather than using the pencils given to them. This interaction gives evidence of students' dissatisfaction with the role of passive recipient.

After the field experience, each PST wrote a reflection of their experience with the students. It is interesting to note that Alex mentioned several opportunities for improvement, citing additional ideas that could have helped students connect to strategies of interest. Jaime, on the other hand, used this reflection as an opportunity to synthesize and justify her perception of events that occurred, describing in detail whether the students found the correct answers as a measure of successful teaching.

The difference between these two PSTs is clear in their use of discretionary spaces and the subsequent classroom response. Alex established herself as a guide to the students and worked in solidarity with them, while Jaime attempted to be a subject matter expert in a hierarchical classroom which resulted in pushback from the students. What emerges then is a sense that the choices made in discretionary spaces came from the preconceived expectations PSTs had of social roles in the classroom. The resulting social roles manifested in the ways students were positioned during classroom engagement. When not agreed upon by the other actors (students), the process of positioning has the potential to be divisive, which stifles opportunities for collaboration. On the other hand, communication acts that create a sense of belonging or guide students have the potential to shift positions of the students into co-constructors with shared authority.

Our work suggests that without proper, intentional preparation, PSTs enforce classroom roles that are influenced by their prior experience with mathematics and the teaching of mathematics. Oftentimes, these roles conflict with those shared by the students, as seen in the findings. For mathematics education to shift towards a brighter, more inclusive future, PSTs must engage in explicit shifts of expectations where students' diverse identities, inclusive of cultural and linguistic backgrounds, are leveraged. Student roles must be negotiated rather than dictated and should reflect the brilliance they bring to the classroom. By bringing attention to classroom dynamics that occur within discretionary spaces, we can begin the work where we evolve from simply envisioning to physically creating a future of mathematics education where students are nurtured and positioned in ways that cultivate positive mathematical identities.

In this paper, we describe how mathematics education researchers and mathematicians collaborated to introduce active learning pedagogy into a proof-based linear algebra course. This description highlighted the goals, values, and obligations that mathematicians had for their pedagogical practice, and how challenging it can be to introduce active learning pedagogy into mathematics classrooms that is compatible with these. We also illustrate how mathematics educators' understanding of mathematicians' perspectives allowed mathematics educators to help create instructional techniques that mathematicians are willing to use in their practice.

Keywords: Professional Development, Curriculum, Instructional Activities and Practices, Reasoning and Proof

Introduction

The purpose of this paper is to discuss a recent collaboration project between mathematics education researchers and mathematicians to improve instruction in undergraduate mathematics. In this collaboration, mathematics education researchers and mathematicians worked together to introduce active learning into a proof-based linear algebra course in a manner consistent with the goals and values of the mathematicians who were teaching this course. We illustrate how this collaboration proceeded by describing the challenges and resolution of designing short questions that can be used during lectures that encourage student activity and elicit student thinking. As we describe what transpired, we will discuss mathematicians' values and goals and the importance of attending to them.

Literature review

Most university mathematics courses are taught by lecture (Artameva & Fox, 2011; Melhuish et al., 2022). There is a general consensus amongst researchers in undergraduate mathematics education that this situation is not ideal. Lecturing is largely viewed as an ineffective pedagogy; students who emerge from lecture-based classes in advanced mathematics typically have a poor understanding of central concepts and an inability to write proofs (e.g., Ko & Knuth, 2009; Rasmussen & Wawro, 2017). There is also evidence that students' understanding, performance, and affect improve when active-learning strategies are used (e.g., Freeman et al., 2014; Laursen et al., 2014; Rasmussen & Wawro, 2017). It follows that a key way to improve instruction in undergraduate mathematics is to introduce active learning pedagogy. However, lecture remains the dominate form of instruction across undergraduate mathematics (Johnson, 2019).

This leads to a natural question: Why aren't mathematicians using more student-centered forms of instruction when there is evidence that this pedagogy leads to better learning outcomes than lecturing? We believe that a major reason is because alternative instructional methods frequently do not address mathematicians' most pressing concerns. A primary goal of advanced mathematics courses is to enable students to successfully prove theorems (e.g., Alcock, 2010) and, as Stylianides and Stylianides (2017) observed, there are few research-based interventions that have been shown to improve students' abilities to write proofs that meet mathematicians' standards in undergraduate mathematics education research. Another often cited, but largely unaddressed concern is content coverage.

Braun et al. (2018) argued that the instructional innovations designed and promoted by mathematics educators have designed is not the only way to make university classrooms more active and improve teaching and instead emphasized that there are smaller steps that mathematicians can use to increase student activity in a lecture. For instance, think-pair-share questions and whole class discussions can increase student activity while still enabling lecturing. However, active-learning pedagogy that is compatible with lecturing has not been the subject of much mathematics education research. In this paper, we describe how we worked collaboratively with mathematicians to introduce exactly these types of active learning strategies with their lectures. In doing so, we respond to Artigue's call for projects that are "collaborative projects, building and negotiating, jointly with mathematicians and other university teachers, problématiques that make sense for all those involved, and meet their respective interests and needs" (2016, p. 12).

Theoretical perspective

We use three constructs to categorize teaching. A teacher's *values* correspond to the broad goals they want to achieve in their classroom. Values might include things such as enabling students to prove interesting theorems, preparing students to enter graduate school, of having students regularly engage in authentic mathematical debate. *Strategies* are common adaptable pedagogical techniques that teachers use to achieve their goals. These include things like modeling mathematical reasoning during lectures, asking open-ended questions with adequate wait time, or having students solve problems collaboratively and present their work. *Implementations* are the specific embodiment of a strategy. For instance, the implementation of the strategy of "use a think-pair-share questions" would involve the specific question that was chosen as well as how the question was introduced to the class. We argue that active-learning strategies are most typically strategies while the specific mathematical questions are implementations or tactics.

Broadly speaking, we believe that the lack of uptake of undergraduate mathematics education research is that these are based on strategies that do not align with many mathematicians' values and strategies that are difficult to implement. However, we believe that there are strategies that encourage active learning that are compatible with mathematicians' values. For instance, using think-pair-share questions can be done in a lecture format, or in more inquiry-based classrooms. We drew on Brownlee et al.'s (2017) conceptual description of teacher beliefs and practices as reflexively coevolving. They claimed that as teachers engage in new practices that their beliefs will change, and, as their beliefs change, their valuation of- and engage-in practices will also change.

Methods, Data, and Analysis

During the Fall 2023 semester we formed a collaborative group of mathematics educators and four mathematicians who were teaching different sections of the same proof-based linear algebra course. The research team's progressive goal was to support mathematicians in using more student-centered instructional techniques over time. To do so, we conducted weekly meetings (starting in October) with four mathematicians teaching the course and the five members of the research team. Our study followed a design research framework (Cobb et al., 2003) in which we are simultaneously trying to develop an effective collaborative framework for improving mathematicians' teaching as well as a theory for why our framework is effective and how mathematicians' beliefs and practices evolved.

After the semester, we engaged in retroactive analysis. In instances where mathematicians judged an active learning strategy to be infeasible (either dismissing it before using it, or deciding it did not work for them after using it), they were required to give a rationale for their decision. Using a thematic analysis (Braun & Clark, 2017), we analyzed the mathematicians' rationales to identify what obligations (in the sense of Chazan et al., 2016) that mathematicians had to their institution, discipline, and students that made the active learning strategy infeasible. We then developed a narrative of how our active learnings strategies were ultimately adapted by the mathematicians as feasible given their perceived obligations.

Results and Discussion

In our first meeting with the mathematicians, we initially invited them to use Exit Tickets. The aim here was showing the limited understanding that students had of lectures, as well as helping the mathematicians see the value of attending to student thinking. Our suggested was rejected on the grounds that the mathematicians already knew that the most students did not understand their lectures all that well. As Mathematician D put matters, "I think most of them would say they don't understand yet". To the mathematicians, understanding only came after students had the opportunity to reflect upon the lectures. Our next suggestion was for the mathematicians to give the Exit Tickets for homework problems. Our rationale was that this would give mathematicians the opportunity to see student thinking, but since they were homework, they would not require cutting into any lecture time. This was tried, but mathematicians felt that even these questions took too much time. From our field notes on the implementation of the Exit Tickets, the mathematicians would offer complete answers to the Exit Ticket questions that they asked. Apparently, mathematicians felt an obligation to give a complete and rigorous answer to every question that they proposed.

We proposed a think-pair-share structure for questions. The mathematicians rejected the structure for multiple reasons, including that they did not want to try to force students to talk to each other and it was too late in the semester to introduce the new practice. One noted that the students had established, spatially distanced, seating patterns and asking them to move would be too much.

In general, mathematicians valued the conceptual questions that our team initially generated, as well as the student engagement that they elicited. However open-ended questions, with the nuance and detail that the mathematicians requested, required more time in class than the mathematicians were regularly able to devote to their implementation. This was largely because these questions took students a long time to process and the mathematicians felt obligated to lecture the correct solutions. A structural solution that we found that worked for the mathematicians was to ask clicker-type or voting questions immediately after they introduced a new topic or concept on a topic that they intended to lecture about anyway where the questions had to be ‘understandable’ within about a minute of reading them. This required careful balance between precision in the formulation of the question and the importance of the ideas.

For example, one question that Mathematician B used was, “Do we get equality or inequality in the Cauchy-Schwartz inequality if one of the vectors is a multiple of the other?” This format alleviated the concerns about time in two respects, while maintaining the conceptual focus of the question. First, because the questions were introduced within the context of the lecture, students were already familiar with many of the core ideas of the question so it would take less time to process. Second, because the mathematicians had planned to cover the topic of the questions anyway, no time was “lost” going over the solution to the questions that were asked. We also agreed that students did not necessarily formulate complete answers to the questions that were posed. They could simply make predictions, and discuss with their peers, whether certain statements were likely to be true or not. This could engage the students with thinking about the key theorems that would be covered in the class before seeing their proofs. An innovation that the mathematicians suggested was having all students commit to a yes or no vote on whether statements were likely to be true, so all students had to engage in the task and the mathematicians were able to see the thinking of all students (one even created voting cards that students would hold up).

Overall, mathematicians were satisfied with the format that we created. They liked the conceptual questions that our research team generated—our research team had the time and expertise to generate questions that elicited students thinking about the key linear algebra topics in the course—and they liked the format by which they could use the questions. Mathematician C reflected, “So that’s actually, that’s just like what [Mathematician D] said. It does not take much time and it is actually effective because I can ask everyone someone who would never want to raise their hand. I sort of forced her to raise her hand so that it’s actually useful.” Mathematician D was also enthusiastic about the questions that were used and the collaborative meetings in general:

> Yeah, I thought the suggestions for the questions [generated by the research team] were great. And that's really helpful. Also, just to see the suggestions from other instructors.

Conclusion

In this paper, we illustrated how mathematics educators and mathematicians can collaborate to introduce active learning strategies into the mathematicians’ classrooms. We use our description to suggest three broader points. First, implementing active learning pedagogical techniques that are commonplace in K12 classrooms may not be immediately applicable to advanced mathematics classes. Second, mathematicians had goals and values that of which we were not initially aware that caused problems with implementing our strategies. For instance, mathematicians’ desire to have questions about abstract vector spaces beyond R^n made it challenging to generate conceptual questions that could be answered (or even understood) quickly by the students. Finally, we illustrate how mathematicians and mathematics educators working together is a promising model for generating active learning strategies that mathematicians are willing to use. This supports Artigue’s (2016) contention that changing university instruction may work best if we collaborate with mathematicians to solve problems that are meaningful to them with solutions that they believe are viable.

borowsr@wwu.edu

A classroom study was conducted to understand how to engage in responsive teaching with 18 seventh grade students at three stages of units coordination during a unit on proportional reasoning co-taught by the first author and classroom teacher. We found that teacher-researcher decentering was a mechanism underlying the practice of inquiring responsively in small groups. Decentering involves adopting the perspective of another person by setting one's own perspective to the side and using the other's perspective as a basis for interaction. This paper shows a pattern of decentering actions and a type of question, leveraging questions, supported a student at stage 1 of units coordination to sustain challenges and learn.

Keywords: Instructional Activities and Practices, Communication, Proportional Reasoning

Being able to respond to students' diverse mathematical ways of thinking in a classroom is viewed as essential for supporting student learning—for teaching (e.g., Dyer & Sherin, 2016; Franke et al., 2015). Jacobs and Empson (2016) define responsive teaching as "a type of teaching in which teachers' instructional decisions about what to pursue and how to pursue it are continually adjusted during instruction in response to children's content-specific thinking, instead of being determined in advance" (p. 185). Not surprisingly, this kind of teaching requires considerable skill and expertise (Webel et al., 2021) and is not easy to enact (Empson, 2014).

In our classroom study that took place during a 26-day unit in a 7th grade mathematics class, we aimed to engage in responsive teaching with students who were learning proportional reasoning. We uncovered diversity in students' thinking through assessment of students' units coordination stages (explained later). These stages indicate the multiplicative reasoning that students engage in based on how they conceive of and organize units (Hackenberg & Sevinc, 2024). Since proportional reasoning involves multiplicative reasoning, we used a framework about multiplicative reasoning to track diversity in students' thinking.

In this paper, we look at one teaching practice, inquiring responsively in small groups (Hackenberg et al., 2021), because we found this practice useful in supporting student learning across units coordination stages. As we analyzed our data, we found that decentering, or "taking actions that adopt the perspective of another" (Bas-Ader & Carlson, 2021, p. 2), was a mechanism underlying our practice of inquiring responsively. Researchers who study decentering have argued that it provides a mechanism for understanding teachers' mental actions and behaviors that underlie responsive teaching (Bas-Ader & Carlson, 2021; Teuscher et al., 2016). Our study provides more evidence for this claim from a typical seventh grade classroom.

In our study, 18 students learned to make two cars travel the same speed during a classroom unit on proportional reasoning. Elsewhere we have articulated what three focus students in the class learned, where each focus student was operating at a different stage of units coordination (Hackenberg et al., 2023). In this paper we describe the decentering that supported that learning. Our research question is: How did teacher-researcher decentering in a classroom study with seventh grade students support them to learn to make two cars travel the same speed?

Literature Review: Teachers Interacting in the Moment with Students to Support Learning

How teachers inquire responsively in small groups is part of a larger domain: How teachers interact in the moment with students to support their learning. Researchers have studied this domain from the perspectives of responsive teaching (e.g., Jacobs & Empson, 2016), questioning (e.g., Stein et al., 2008), and decentering (e.g., Bas-Ader & Carlson, 2021). Jacobs and Empson developed a framework that articulated what an experienced elementary teacher did as she monitored—circulated in a class and interacted with groups of students who were working on a story problem. The case study is a valuable documentation of expertise. However, as Bas-Ader & Carlson have pointed out, it does not address what teacher thinking went into making these moves. In addition, Jacobs and Empson do not demonstrate how the teacher's enactment of particular categories of teaching moves supported student learning.

In contrast, Hunt and colleagues (Hunt et al., 2019; Hunt & Silva, 2020) have engaged in responsive teaching in one-on-one teaching experiments with students diagnosed with learning disabilities. In their studies they have linked carefully-crafted teaching moves to specific acts of student learning. However, this work has not been done in full classrooms.

The types of questions teachers ask certainly play a role in responsive teaching: Researchers have studied questions that probe students' responses (Boaler & Brodie, 2004; Stein et al., 2008) or support students to rethink or elaborate on their initial ideas (Franke et al., 2015). For example, Smith and Stein (2018) have proposed two types of questions to ask when teachers are monitoring: assessing questions and advancing questions. The purpose of assessing questions is to find out how students are thinking about a problem or idea. The purpose of advancing questions is to support students to make progress in their thinking about a problem or idea. Smith and Stein encourage teachers to stay with the group to listen to student responses to assessing questions in order to gather information about how students are thinking. In contrast, when the group works on an advancing question, teachers can walk away in order to visit another group.

Bas-Ader and Carlson (2021) used decentering as an approach to study the nature of in-the-moment interactions between graduate student instructors and college students in a precalculus program at a large university. They characterized instruction using five levels of decentering. At the first two levels, instructors primarily tried to get students to adopt teachers' ways of thinking. At the other three levels, instructors exhibited gradations of reflective action. Their study provides "insights into the rationale for the teacher's actions" (p. 17) as they worked to understand their students' thinking and use it in instruction.

Theoretical Frame

Knowledge and Interaction

To understand decentering requires distinguishing between first-order and second-order knowledge. First-order knowledge refers to what a person constructs "to organize, comprehend, and control his or her experience" (Steffe, 2010b, p. 16). Second-order knowledge refers to what a person constructs to describe and explain their observations of another person's experiences (Steffe, 2010b). In decentering, a person sets their own first-order knowledge to the side and tries to build second-order knowledge of the other person's first-order knowledge. Here, knowledge consists of the interactive constructions that people make to organize their experiential worlds.

Piaget and Inhelder (1969) viewed decentering as essential in the construction of knowledge and in socialization because it marks being able to separate one's own viewpoint from that of others, a task that young children cannot yet perform. Indeed, decentering is necessary for the development of mental actions, or operations, because it allows children to move from a state in which all of their operations are centered on themselves to a state in which their operations take their place within a larger world of objects, events, and other people. Other people are especially important in this process, because as children construct others who have their own views, children have to reconcile their views with the views of others, which involves decentering on a social level. Thus, the "decentering of cognitive constructions necessary for the development of operations is inseparable from the decentering of affective and social constructions" (p. 95).

Students' units coordination stages

One way to understand the multiplicative cognitive constructions of students is to use a framework called *units coordination* (Hackenberg & Sevinc, 2024). People create units from "abstracting out the 'one'-ness from some aspect of experience" (Ulrich, 2015, p. 3). With middle school students, a *unit* typically refers to a length or a discrete 1. A *composite unit* is a unit of units, such as conceiving of a package of four yogurt drinks as one item and as four items.

Units coordination refers to how students distribute the units of one composite unit across the units of another (Steffe, 1992). For example, to determine how many yogurt drinks in seven packages, a student might distribute four ones across each of the seven units (packages), for a total of seven fours. A *units coordination stage* is a researcher's generalized model of particular operations and schemes with units that students construct and use to structure problem situations (Hackenberg & Sevinc, 2024). In our study, we had students at all three stages of units coordination typical in middle school. However, in this paper we can only report on one group of students at stage 1. So, here we discuss the units coordination of only students at stage 1.

Students at stage 1 have constructed composite units, and they can track a sequence of these units recursively (Steffe, 1992). To determine the number of yogurt drinks in seven packages of four, students at stage 1 typically count on by 1s past known skip-counting patterns for 4s. These students can also construct *connected number sequences* (Steffe, 2010a). A connected number sequence is made from iterating a length unit to create a set of lengths that are two iterations of that unit, three iterations of that unit, etc. However, students at stage 1 do not construct an a priori multiplicative relationship between a length unit and lengths made from iterating that unit.

Method

Participants

The classroom teacher with whom we conducted the study, Ms. W, was one of 15 middle school teachers who had participated with us in a year-long study group to explore differentiating instruction. We observed Ms. W's only seventh grade mathematics class and invited students to participate. Eighteen out of 20 students submitted consent forms. Before the unit, we sought to develop an initial understanding of students' units coordination stages and to select six focus students, ideally two at each stage. So, we administered written assessments of students' units coordination stages (Norton et al., 2015) and conducted individual interviews prior to the unit.

In the interviews we developed a deeper understanding of students' thinking and sometimes revised our assessment of a student's units coordination stage. Following the interviews, we had five students at stage 1, nine students at stage 2, and four students at stage 3. We selected as focus students two students at stage 1, three students at stage 2, and one student at stage 3. For the analysis for this paper, we included all six focus students, but due to space constraints we present in detail our interactions with one focus student at stage 1, Emily.

Data Collection

All 26 class meetings of the unit were filmed with four cameras: a GoPro that captured the whole classroom, a stationary camera trained on the board, and two roaming cameras. Video from the latter three cameras was inset into the GoPro video for analysis. The classroom was organized into six tables for students to work in groups of three or four. Audio was captured with six microphones fed into a mixer and audio-recorders on each table.

During class meetings, Ms. W and the first author co-led inquiry-oriented instruction with the *Comparing and Scaling* unit of Connected Mathematics Project 3 (Lappan et al., 2014), which addresses proportional reasoning. Research team members operated roaming cameras and interacted with students. Between class meetings the team processed video data, scanned student work, discussed conjectures, and planned for the next class with Ms. W. The first author kept a research journal and wrote a summary of each class session. In the middle and at the end of the unit, we interviewed the six focus students to assess their understanding of topics.

Summary of Speed Investigation

The unit consisted of three investigations: quantifying orangeyness (Days 1-8), quantifying speed (Days 9-18), and understanding percents (Days 19-26). We followed *Comparing and Scaling* for the first and third and designed a replacement for the second based on Lobato's MathTalk project (https://mathtalk.sdsu.edu/wordpress/). We made this replacement because we conjectured that after investigating orangeyness, which is controlled by two continuous quantities, a speed context, also controlled by two continuous quantities, would support students' proportional reasoning. During the orangeyness investigation we found that students at stage 1 were not iterating two quantities as a composed unit to make other mixtures with the same flavor. A composed unit is a correspondence between two composite units (Nabors, 2003). Because we also observed differences among students at stages 2 and 3, we decided to group students by units coordination stage for the start of the speed investigation, Days 9-13.

On Day 10 and 11, students worked on introductory tasks about speed. On Day 12 students worked on the Same Speed Task (Figure 1). We differentiated instruction by giving different numbers to different groups (not relevant to this paper and explained in Hackenberg et al., 2023).

Figure 1. Same Speed Task.

Same Speed Task. The blue car travels ____ miles in ____ minutes.
Find a distance and time for the red car so that it travels the **same speed** as the blue car. Your distance and time must be different than the blue car's distance and time!

When you find a distance-time pair that works, **explain** why it does and **draw a picture**.

Data Analysis

For this paper, analysis occurred in two phases. First, we built second-order models of the focus students. A second-order model is a researcher's constellation of constructs to describe and account for another person's ways of operating (Steffe & Thompson, 2000). Second, we used an existing coding scheme for decentering (Bas-Ader & Carlson, 2021) to analyze individual-environment interactions that were involved in the accommodations. The result of the first phase analysis is reported in Hackenberg et al. (2023). This paper reports on the second phase.

In the second phase, we analyzed the decentering actions of the teachers in interacting with students in small groups during the speed investigation. To do so, we coded all interactions between a teacher and the six focus students during the three days of intensive small group work

(Days 10-12) during which students worked on speed tasks. We used the codes from Bas-Ader and Carlson (2021) to code all utterances of the teacher in each exchange, basing code selection on what the interchange with the student was about. So, even though we were coding the teacher's utterance, codes were contingent on what students said and did in relation to the teacher's comments and questions.

During the coding of data, we had 15 transcripts and videos to code, one for each focus student's small group interactions for each of Days 10-12 (two focus students were in a group together; the other four were in separate groups). Each transcript was coded by at least two authors. The three authors met bimonthly to discuss our code use and what coding revealed about decentering in relation to students' work on speed tasks (e.g., Figure 1). We ran intercoder investigations for each transcript, revising coding until we reached at least 90% agreement. Once we stabilized the coding, we looked for patterns in relation to accommodations students made. That is, we identified instances where specific acts of learning occurred, in 5 of the 15 transcripts, and we examined the nature of the decentering actions for those acts of learning. We compared these patterns to patterns of decentering actions across all 15 transcripts.

Findings

We found two patterns of decentering actions that supported specific acts of student learning. In the first, a challenge to the student (coded PS, *Perturbing the student in a way that extends the student's current way of thinking*) was followed by questions coded LST (*Leveraging the student's thinking to advance the student's thinking*), which we call *leveraging questions*. Then the teacher used follow-up questions and comments to understand students' thinking about their response to the leveraging question (coded FMST, *Following up on response to make sense of students' thinking*). In the second pattern, a challenge (PS) was followed by follow-up questions and comments (FMST), which were followed by a leveraging question (LST). In both patterns, chains of FMST and LST often continued while the students worked to address the challenge.

We found that these two patterns helped us support students to sustain challenges across stages of units coordination. In all cases, sustaining challenges yielded learning, although not always the learning that the teacher was aiming for. We show the first pattern with Emily.

Emily: Constructing Doubled Journeys as Connected Numbers

Student work and decentering analysis. Emily's group worked on making the red car travel the same speed as a blue car traveling 18 mi in 3 min. The group tried 9 mi in 6 min, 18 mi in 6 min, and 18 mi in 2 min. Then Emily's groupmate suggested 36 mi in 6 min. The group found that it worked, and Emily expressed excitement. The first author, known as Ms. H, asked them to explain why doubling produced the same speed and to draw a picture to justify.

Although most students were challenged by the request to draw a picture to show same speeds, Emily seemed especially stymied. Ms. H immediately modified the challenge, asking Emily and groupmates to draw only the 18 mi-3 min journey. Emily said, "I don't really know how to show it. I know how to tell, but I don't know how to show it." When asked how she would tell, Emily said that 18 times 2 was 36 and 3 times 2 was 6, so you could divide each number by 2 or "reduce" it. She did not draw. Thus, modifying the challenge to draw only one journey did not sufficiently support Emily to draw.

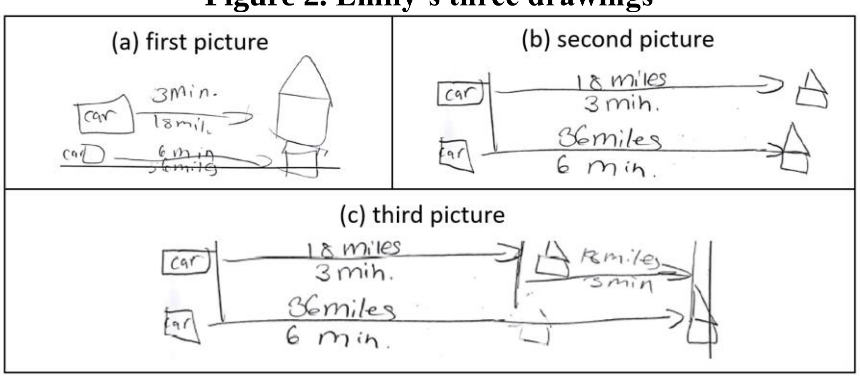
Ms. H then asked Emily to think about the quantities, not just the numbers, because the quantities would give her more power in understanding speed. Ms. H said, "You said something about multiplying by 2. Is there any way to show that in a picture, like... to show 36 miles in 6 minutes is twice 18 miles in 3 minutes?" This question is a leveraging question because Ms. H was asking Emily to think about how to represent her idea of multiplying by 2 in a picture. Emily wrote down numerals to show that 18 x 2 was 36 and 3 x 2 was 6. Ms. H acknowledged her work but said she wanted to know why doubling produced the same speed.

At this point, in a further attempt to support the group Ms. H repeated the modified challenge, asking Emily and groupmates to draw just the 18 mi-3 min journey (Table 1; turn 1). Following this modification, Emily began to draw (Table 1; turn 2).

Table 1. Emily Begins to Draw

Turn	Code	Data
1	Modified PS (repeated, as discussed above)	AH: How could you just draw—you don't have to draw a car—you don't have to draw anything other than something to show 18 miles in 3 minutes. What could show it? [7-s pause] What if you want to show, say, hey somebody, the car went 18 miles and it happened in 3 minutes, what would you draw to show the car's journey?
2		EMILY [draws a car]: That's a bad car. But you have a car. And it's going [draws a segment from the car to a house with "3 min" written over the segment, Figure 2a].
3	LST	AH: Okay, great. I noticed, Emily, you have 3 minutes there. It's kind of like you're saying this is this distance that got covered in 3 minutes. What's the distance again?
4		[Emily writes "18 mil" under the segment.]
5	LST	AH: All right, super. Right here you have this segment, or line, that would show that distance. Now, we also have the other car going 36 miles in 6 minutes. Do you think you could show that one?
6		[Emily draws another segment below the first, Figure 2a.]

Figure 2. Emily's three drawings



Emily's initial drawing (Figure 2a) may have indicated motion from one place to another, not a distance traveled in 3 min. The arrows at the end of her segments suggest this interpretation. However, Ms. H interpreted the segment as a distance covered in 3 min and asked Emily to write in the distance (Table 1; 3). This question is a leveraging question because Ms. H used what Emily had drawn and supported her to develop it so that it might show a distance traveled in a number of minutes. Following this exchange, Emily drew the other car's journey. Ms. H then posed follow-up questions (Table 2; 7, 9, 11, 13) to get a sense of how Emily was viewing her drawing and whether she was thinking about the length of her segments.

Table 2. Emily Revises her First Picture

Turn	Code	Data
7	FMST	AH: Now, would these [segments] be the same length?
8		EMILY: No.
9	FMST	AH: What's the relationship between the length of this one and that one?
10		EMILY: That one's [top] shorter than that one [bottom].
11	FMST	AH: It's shorter, okay. Can you tell me anything more? How much shorter—I mean right now yours is shorter. Do you think it shows well that this is 18 and that's 36?
12		EMILY: Yeah.
13	FMST	AH: How come?
14		EMILY: Because it's labeling them.
15	LST	AH: Do you have the idea of doubling in there though, that you were talking about?
16		[Emily writes "x 2" between the segments.]
17	PS	AH: Okay, well can you show it with the lengths? Emily, can you show the doubling of the lengths? Do you get what I'm asking about?
18		EMILY: It's two times larger.
19	LST	AH: Yeah. Can you draw it that way? Maybe draw it again over here. [Emily draws a second picture, Figure 2b.]

Based on Emily's response that the drawing showed the two journeys well (Table 2; 12), Ms. H posed another leveraging question, "Do you have the idea of doubling in there though, that you were talking about?" (Table 2; 15). Here, Ms. H used Emily's work so far—she had talked about the importance of doubling and drawn a picture where one segment was not double the other in length from our perspective—and asked her to continue to develop it. So, the question was a support for Emily to sustain the challenge of drawing without telling her what to draw.

Emily responded to this leveraging question by writing "x 2" on her picture (Table 2;16). Ms. H then repeated the original challenge about trying to show doubling with the lengths (Table 2; 17). When Emily said, "it's two times larger," Ms. H asked if she could draw it that way (Table 2; 19), a leveraging question that again built on Emily's expressed idea of one journey being two times the other, pressing to see whether she could draw that idea. Emily then drew a second picture (Figure 2b). From our perspective, Emily's second picture shows journeys that are the same size. Ms. H complimented the picture and said to Emily what she saw in it (Table 3; 20).

Table 3. Emily Revises her Second Picture

Turn	Code	Data

20	FMST	AH: That’s a really nice picture. To me, though, when I look at it, it looks like this journey and that journey are the same size. Are they the same size?
21		EMILY: No.
22	LST	AH: Something’s the same about them, the speed. Is there any way to show how the one journey is, as you said, twice as long, twice as big?
23		[Emily extends the 36 mi-6 min segment, but she reaches the edge of the paper and does not make it twice as big as the 18 mi-3 min segment, Figure 2c. AH asks if that shows it exactly. Emily spans the first 18 mi-3 min segment with her fingers, and then she moves her fingers over to make another one, drawing it in.]

When Emily agreed that the journeys in the picture were not the same size, Ms. H posed another leveraging question, “Something’s the same about them, the speed. Is there any way to show how the one journey is, as you said, twice as long, twice as big?” (Table 3; 22) Here Ms. H again used Emily’s idea of “two times larger” (Table 2; 18) and asked Emily to show that relationship in her picture. Following this question, Emily extended the 36 mi-6 min journey, using her hands to indicate fitting two 18 mi-3 min journeys into the 36 mi-6 min journey.

During this interaction, Emily constructed doubled journeys as connected numbers (Hackenberg et al., 2023). The teacher’s decentering actions did not cause Emily to do so, but they opened the possibility for it. We argue that the decentering actions supported Emily to view her segments as lengths and use iteration, an operation she had constructed, on the segment that represented the original journey to create a new journey that consisted of two of the original journeys. Since Emily then spoke of her picture (Figure 2c) as “not drawn to scale,” we have evidence that size was now relevant to her. The next day in the whole class discussion Emily presented to the class how the 18 mi-3 min journey fit two times into the 36 mi-6 min journey, and she explained that her drawing was not accurate, confirming the importance of size to her.

Patterns in Decentering Actions. The pattern we found in these decentering actions is that after a challenge (PS), a leveraging question (LST) often immediately followed. Then the teacher used follow-up questions and comments (FMST) to try to understand Emily’s response to the leveraging question. This understanding then allowed the teacher to pose another leveraging question (LST) based on Emily’s current ideas.

In particular, after Emily first started drawing, the leveraging questions were about helping Emily to expand her drawing or see it in a new way. After her first picture, the leveraging questions (Table 1; 3, 5) asked Emily to expand her drawing to show both journeys and to identify both a time value and distance value for each journey. These questions may have helped Emily to make a correspondence between 18 mi and 3 min, as well as between 36 mi and 6 min, viewing each pair as a composed unit. The follow-up questions and comments (Table 2; 7, 9, 11, 13) were posed to understand how she viewed the changes she had made.

Then the next leveraging questions (Table 2; 15, 19; Table 3; 22) asked Emily if she could follow through (from our perspective) on her ideas to show doubled journeys in her drawing. After Ms. H posed the third of these leveraging questions, Emily changed her drawing to show the larger journey as made of iterating two smaller journeys.

Discussion

In this paper we argue that decentering actions supported to Emily sustain engagement in the challenge of justifying same speeds. Like Jacobs and Empson (2016), we documented responsive teaching moves but with a theoretical grounding of decentering that bases these moves in second-order model building. Like Hunt and Silva (2020), we demonstrated how particular teaching moves supported specific acts of student learning but in a whole classroom.

Our leveraging questions were based on closely observing students' contributions and then asking students to build on that contribution a small amount, toward a large challenge such as drawing a picture or justifying. So, leveraging questions could be seen as a version of advancing questions (Smith & Stein, 2018). Yet they are a quest for a small advance, close to students' work. The judgment of the size of the advance is contingent on the second-order models of students' mathematics that the teacher is building. To determine the efficacy of a leveraging question, a teacher-researcher has to stay to hear the student's response. So, in contrast with advancing questions, leveraging questions require staying put.

We argue that leveraging questions are important for middle school students at stage 1 of units coordination. These students are quite challenged to meet the multiplicatively-heavy demands of topics in typical middle school mathematics curricula and instruction. Leveraging questions may support them to use their abilities to coordinate two levels of units in activity in order to make interpretations of at least some of these topics. In the larger study, we found leveraging questions to be useful with students at all three stages. We view them as a tool for both teacher-researchers and classroom teachers.

PROPOSED FRAMEWORK FOR EXPLORING THE INTERPLAY OF TEACHER INTENT AND STUDENT PERCEPTION IN DISCOURSE

Elisha Hall
Western Michigan University
elisha.d.hall@wmich.edu

Tabitha Mingus
Western Michigan University
tabitha.mingus@wmich.edu

The purpose of this poster is to present a framework that uses discourse and positioning theory as a tool to define relationships in discourse between a teacher and their students and provide a connection between discourse and student perceptions of content accessibility, as well as the student's mathematical identity. Positioning theory evaluates conversations by examining verbal and non-verbal communication patterns (Bishop, 2012), common phrases (Herbel-Eisenmann et al., 2010), or by looking at individual words (Wagner & Herbel-Eisenmann, 2008) for meaning. We use positioning theory as a lens through which we view discourse from classroom observations to describe the apparent negotiation of social roles in that classroom.

Researchers tend to identify roles and positions through their understanding of the social norms of the dominant culture. Students and teachers come from various cultures, shifting how they view social constructs. An aspect missing in positioning theory is identifying teacher intent, driven by their prior beliefs and attitudes, and student perceptions, shaped by the student's previous experiences. Bishop (2012) described a scenario with students where their pre-existing self-identity is enacted through utterances and conversation moves such as interrupting and question-and-answer patterns.

The proposed framework illustrates the interplay between teacher and student, with their outside influences, attitudes, and beliefs. The outcome of the interaction between teacher and student is that students internalize the messages they receive which, in turn, shapes their perceptions of how accessible the content is and their self-identity within the mathematics community. In our future research, we will utilize the framework to combine student perception, teacher intent, and positioning theory to understand how teacher language impacts student beliefs about their position in the classroom and as "doers" of mathematics.

INTRODUCING EULER DIAGRAMS IN AN INTRODUCTORY PROOFS CLASS: A SEMIOTIC ANALYSIS

Lindy Hearne	Corinne Mitchell	Rachel Arnold
Virgina Tech	Virginia Tech	Virginia Tech
lindyh@vt.edu	Cmitchell8@vt.edu	rlongley@vt.edu

Despite calls to make classroom mathematics more accessible to students, research on instructional moves that support accessibility is scarce, particularly at the undergraduate level. We present one teacher's use of Euler diagrams as a pedagogical tool to support students' understanding of logical implication. Through semiotic analysis, we describe how her instructional task sequence may support students' understanding of the semantic, syntactic, and pragmatic features of Euler diagrams and their connections to mathematical logic. Further, we discuss how addressing all three of these features may aid students in forging vital connections between their own intuitive understandings and formal mathematical reasoning. Our framework considers interactions between semiotic features, not just the features themselves—a divergence from the current semantic-syntactic dichotomies used in mathematics education research.

Keywords: Instructional Activities and Practices; Reasoning and Proof; Undergraduate Education; Semiotics; Euler Diagrams

Undergraduate mathematics students' reasoning in proof and proving has become a focal point in recent research. Weber and Alcock (2004) suggested the importance of understanding the semantic and syntactic features of proof production, and Dawkins (2012) highlighted the significance of understanding the underlying structure of students' mathematical activity in proof and proving. However, their use of these semiotic features to investigate teaching and learning of proof does not attend to the ways these features might interact. Furthermore, the pragmatics of a representational system are not addressed in these works, a divergence from the analytic framings in other disciplines, namely applied linguists. This paper explores whether utilizing applied linguists' analytic framing allows us additional insight into student understanding of the biconditional statements within the logical representation system of Euler Diagrams. We analyze the semiotic features (semantics, syntax, and pragmatics) explored in a small group discussion in an introductory proofs class.

Semantics and Syntax in Mathematics Education Research

Semiotic analysis in mathematics education has predominantly attended to semantics and syntactics, focusing attention on the continuum between students' informal and formal understandings which Vinner (1991) called concept images and formal definitions, respectively. Weber and Alcock (2004) described these understandings by identifying features that differentiate the proof production of senior undergraduate students and more seasoned mathematicians. They found the former tended to use "rules" in proof activity, while the latter considered the more intuitive mathematical features when proving. Weber and Alcock (2004) called these two approaches to proof production *semantic* and *syntactic*, respectively.

Hiebert (1985), explains that we understand when we connect new knowledge to our existing knowledge. To develop robust understanding, he argues, we need to connect symbols to their underlying meaning (semantics), connect procedures to their underlying rationale (syntax), and check the reasonableness of the procedures and solutions in the light of other mathematics we know (pragmatics).

Semiotic Features in Linguistics

Hiebert's (1985) approach aligns with applied linguists' analytic framing. According to the American Speech-Hearing Association (ASHA, 2023), *syntax* is the form or structure of language, *semantics* is the content or meaning of language, and *pragmatics* is the use of language in context. For linguists, semantics describes the meaning associated with words and sentences. Words are symbols associated with referent objects or ideas–they have lexical meanings. In discourse, these lexical meanings are semantics but may be subsumed by their pragmatic, or applied situational meanings (Stotts, 2020). Furthermore, the meaning of a word is dynamic, adapting with individual experience and applied context (Assimakopoulos, 2012; Stotts, 2020).

Theoretical Framework

Applied linguistics defines the features of semiotic systems to both assess and remediate language development, considering the interaction of semiotic features. Interactions between semiotic features are seldom considered in mathematics education literature. This paper aims to illuminate these interactions through analysis of students' work using Euler diagrams, a simple representational system: Euler diagrams. We adapt ASHA's semiotic definitions to fit the mathematical context of Euler diagrams in Table 1. Symbols (e.g., words and numbers) are objects used to encode meaning (i.e., mathematical logic). In Euler diagrams, the truth set of a statement is depicted by a region enclosed by a circle, while the universal set is depicted by a rectangle. The spatial relationships between circles within the universal set encode the logical relationships between truth sets (syntax). It is from the interaction of these semantic and syntactic features that students ultimately abstract appropriate logical meaning based on the mathematical context (pragmatics).

Table 1: Semantics, Syntax, and Pragmatics of Mathematical Representation Systems

Semantics	Syntax	Pragmatics
The intuitive meaning of symbols and what they are understood to mean in terms of experience.	Meaning associated with the placement of symbols in relation to one another.	Combinations of semantics and syntax that are mathematically functional or appropriate.

Methods

We were interested in students' interaction with Euler diagrams because they have recently been leveraged in research-based instruction on logical implication (Dawkins & Roh, 2022). Antonides et al. (in press) provide evidence of the spatial elements of this representational system aiding students' understanding of logical structures. The data were video, audio, and students' written work (on iPads) that was collected throughout one instructor's semester-long undergraduate introduction to proofs course. Motivated by the findings of Hub and Dawkins (2018), Euler diagrams are used during instruction to support students' understanding of logical implication. The class included group activities and whole class discussions which refined their understanding. There were many cases where students utilized Euler diagrams spontaneously in groups to support their arguments. The whole classroom dialogue was transcribed, and pertinent portions of the instructor's notes were identified. Screenshots of these are included as figures in the results section. We present one vignette to illustrate how students leveraged their syntactic understanding of Euler diagrams to make sense of the logic underlying their task.

Results

We present an excerpt of a small group discussion demonstrating how students can leverage the syntactic aspect of Euler diagrams to understand biconditional statements. This task arose at the end of a sequence of activities which we conjecture supported students to build an understanding of the semantic and syntactic features of Euler diagrams by utilizing students' pragmatic understandings. Figure 1 depicts an Euler diagram of the true statement ``P implies Q" (P→Q).

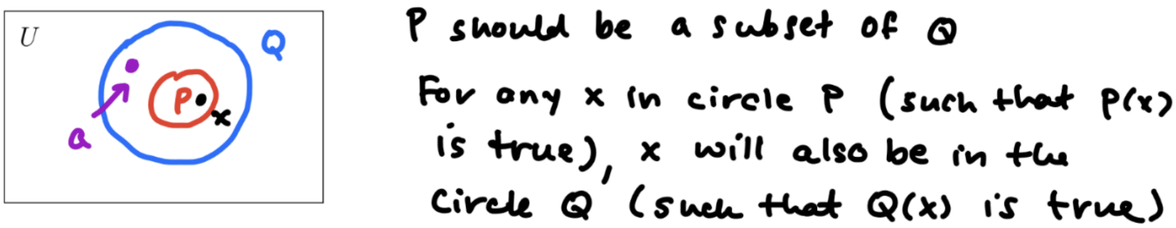

Figure 1: The prototypical Euler diagram for the true implication P→Q

Using the Syntax of Euler Diagrams to Make Sense of Biconditional Statements

Before this vignette, the whole class had discussed whether the converse of the statement, Q→P, must also be true when P→Q is true. They agreed that it was possible to populate an area in Q which was not in P. Thus, Q→P was false. The discussion led one student to wonder what the Euler diagram would be like for the biconditional statement "P if and only if Q" (P↔Q). The instructor encouraged the class to explore this idea in groups.

While not all groups were able to interpret the relationship between the truth sets or successfully generate an Euler diagram representing this case, one group had the following discussion:

Student E: P implies Q. That would just be Q, a giant circle with P in it. So like, something is a multiple of 6, then it's a multiple of three. [Drawing the rectangle]
Student F: You can just draw one circle.
Student G: It's the same circle. [In agreement]
Student E: [Pauses to consider, then drawing a single circle] They have to be the same circle. It's a really direct relationship. They're always both true. (Labeling the circle P, Q)
Student F: It has to go both ways.

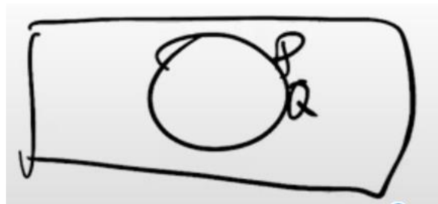

Figure 2: Students' representation of P↔Q

In this interaction, Student E considered the conjecture and the supporting statements of her group. She agreed with her peers, offering a justification for the resulting Euler diagram as she generated it. By attending to the syntactic relationship of the two statements in the Euler diagram, she refined her understanding of biconditional statements.

Student E referenced the initial exploratory task to ground the chosen syntactic structure. This indicated that the syntactic feature itself had become a symbol for her, its own (pragmatic) referent. These more nuanced semantic and syntactic features were used to support the understanding of mathematical inferences that can be made from the diagrammatic interaction of the truth sets. Using features of Euler diagrams to make logical conclusions in this task was mathematically appropriate and functional. The syntactic and semantic features made the implicit logical relationship between the truth sets explicit. This allowed a more flexible and connected use of the representational system, a pragmatic feature of Euler diagrams.

Discussion and Conclusion

This analysis showed how students' understanding of not only the semantic and syntactic features of a mathematical representation but also their interaction empowers them to utilize these features pragmatically. In considering P→Q, Student E supported her abstraction of the meaning of syntactic features by spontaneously connecting the task to a past class example ("So, like, something is a multiple of 6, then it's a multiple of three"). She was able to utilize the relationships between symbols pragmatically. In this way, the syntactic features forged connections between intuitive knowledge and formal mathematical concepts.

Researchers have recognized the importance of connecting procedures, or syntactic processes, to their underlying meaning (see for example Hiebert, 1985). Existing frameworks have described syntax as synonymous with procedural understanding (Bayaga & Bossé, 2018) or instrumental reasoning (Skemp, 1976; Weber & Alcock, 2004). However, these views alone do not capture the importance of the conceptual features encoded in the syntax of the mathematical representation. Adapting ASHA's definitions of semantics, syntax, and pragmatics in our analysis allowed a clearer picture of how students develop competence with mathematical systems of representations. Our reframing of the categories of semiotics is a starting point, elucidating the interaction of semantics and syntax in mathematical sense-making.

While our analysis suggested the utility of Euler diagrams in making explicit the features that are implicit in formal mathematical language and informal conversation, we did not explore this. Future studies should consider an in-depth analysis of students' spontaneous use of Euler diagrams to support reasoning in more complex tasks as a means of developing an intuitive understanding of mathematical statements. In addition, careful analysis of how students develop the semantic and syntactic understandings of these representational systems is needed. The proposed framework could ultimately yield productive insight into which tasks instructors might use to target specific semiotic features of mathematical representations. This insight could then be used as a starting point for unpacking students' difficulties with more complex mathematical representations, including how the order of quantifiers impacts the logical meaning of formal mathematical statements.

ESCAPE ROOMS AS A TOOL FOR ENGAGMENT AND CONFIDENCE-BUILDING IN INTROCUTORY MATH COURSES

J.T. Hird
West Virginia University, Institute of Technology
John.Hird@mail.wvu.edu

Keywords: Instructional Activities and Practices, Classroom Discourse

Issues Facing Students in Introductory Math Courses

This poster attempts to address certain issues faced by students in introductory math courses. We piloted this activity in a course which serves as a prerequisite for *College Algebra*. Many students in the course are first-time first-year and/or first-generation students. Students in such courses frequently struggle with confidence and doubt their own mathematical ability. Many students seem hesitant to seek help from their instructor or tutors on campus when they struggle with the material. The final issue facing students in these courses that we identified is student engagement. Many students see these courses as a requirement they must fulfill but have no interest in the topic of mathematics. Some of these students see the course as a repeat of material already learned and regularly miss class. This leads to poor attendance, so the students miss material that is new or complicated to them.

Escape Room Icebreaker Activity

We implemented an icebreaker activity where students work in groups and apply their mathematical and logical abilities. The activity was an escape room game with a math theme. An escape room is a series of puzzles that participants must complete to "escape" the room/scenario. We used several sets of "Escape Room: The Game ©" by Identity Games. The scenario involves a group of prisoners working together to break out of prison using clues left by a former inmate who was a mathematician and close to escaping. This scenario was perfect for this course since many puzzles were mathematical but only required order of operations, which was an early topic in the course.

To encourage attendance, students were warned that there would be a special activity during the next class period and that successful participants would earn extra credit on the next exam. We worked with the Student Success Center [SSC], which offers free tutoring on campus, to have tutors attend class and join in the escape room activity. Each team included 4-5 students and a tutor. Tutors worked through a similar escape room scenario earlier in the week, so they knew how the game worked and could help guide their teams. Note that this activity does not fit well into common theoretical frameworks, since the goal is to encourage confidence and comfort with tutors, rather than having tutors guide students through course content.

Results and Data

The goal of this activity was to have students use math in a fun way so that they were more engaged with the topic and the course. Tutors were brought in so that students could meet and interact with them in an informal setting and destigmatize seeking help. The class enjoyed the activity, and each group finished the 1-hour activity within a 50-minute class period. The number of SSC visits for students in this course increased from 6 in Fall 2023 to 19 in Spring 2024, despite the SSC seeing fewer visits in the same period. We plan to expand this activity to more introductory math courses next semester.

BEYOND TEACHER NOTICING: DEFINING SECOND ORDER MODELS FOR TEACHERS

Nicola M. Hodkowski
Digital Promise Global
nhodkowski@digitalpromise.org

Amy Smith
Stetson University
asmith92@stetson.edu

In this paper we examine Second Order Models (SOMs) in contrast to teacher noticing, focusing on how SOMs go beyond attending by inferring students' underlying mathematical mental activity, specifically their construction and use of units. Through empirical examples from practicing teachers, we illustrate how SOMs attribute students' mathematical actions to inferred mental activities. By distinguishing between teacher noticing and SOMs, we highlight the importance of developing SOMs for effective mathematics instruction.

Keywords: teacher noticing, elementary school education, number concepts and operations

To imagine the future of mathematics education, it is crucial to draw on past foundational research, using it as a basis to enhance future learning beyond current knowledge. In this paper, we build on recent research (Hodkowski, 2018; Hodkowski et al., under review; Smith & Hodkowski; in press) on teachers' shifts towards instruction that uses Second Order Models (SOMs; Steffe, 2000) to examine how SOMs may go beyond teacher noticing (Jacobs et al., 2010; Mason 1998, 2008), providing empirical examples from existing teachers to present evidence for those differences. Specifically, we asked: What distinguishes SOMs from teacher noticing?

Teacher noticing is an active, proven, pedagogical process where teachers attend to and make sense of their students' work, words, and actions (Mason, 2008; Sherin et al., 2011). Teacher noticing includes teacher attention to students' mathematical strategies and problem-solving, which is more than just noting the type of strategy (e.g., algorithm versus partial product). Rather, the teacher uses their observations to get "a window into children's understanding" (p. 172, Jacobs et al., 2010). The teacher interprets their students' mathematical understandings using evidence from the students' work as the basis for their judgements. Failing to seek understanding of a student's actions and, instead, saying "they just didn't try" would demonstrate unproductive noticing by the teacher (Jacobs et al., 2010). Finally, in teacher noticing, the teacher uses their noticings of student work to guide *potential* instructional decisions. Jacobs and colleagues (2010) noted this as an anticipated intention rather than an enacted one, where the reflection on student reasoning precedes any actual teaching acts. The practice of teacher noticing is considered critical for intentional, effective instruction (Schoenfeld, 2011).

SOM, also referred to as a model of someone else's mathematical reality (Steffe, 2000) is inferences made of a students' thinking (mental operations; Steffe & Thompson, 2000; Thompson, 2000; Ulrich et al., 2014). SOM differs markedly from the observer's (researcher/teacher) own mathematics, which is referred to as one's First Order Model (FOM). When thinking about how the concept of SOM can become a practice useful for teachers, it is important for teachers to make a distinction between their FOM and a student's thinking (SOM). Often, teachers conceive of their students' mathematics through the lens of their own FOM

(Tzur, 2010); that is, the teacher understands a mathematical concept in a particular way and interprets students' mathematics by using their own FOM. Such a teacher likely assumes that, through instruction, students will come to understand mathematical concepts the same way the teacher does (Simon et al., 2000). For example, a teacher may use the "I do, we do, you do" instructional model as a way to teach mathematics however this model teaches mathematics the way the teacher ("I do") understands it. Thus, the teacher uses instructional techniques driven by their FOM understanding of mathematics. The issue is that FOM, while making complete sense for the teacher, may be insufficient for fostering student learning of the intended mathematics (Steffe, 2000).

Developing an SOM has an explicit focus on recognizing not only what the student did, but more importantly, why they did it based on the mental operations inferred from the observer/teacher. This focus on the "why" provides insight into the student's existing conceptions as the starting point for their future learning. In contrast, during noticing, the teacher may work to interpret the student's math but not understand why this math was available to the student. For example, teacher noticing would be considered when a teacher explained that the "student answered the problem 12+5 fairly quickly, however drew 12 circles and then drew 5 more and then counted all the circles. The student understood to add, but needed to draw pictures to solve it." This statement attends to specific mathematical details, but not necessarily why the student made the mathematical decisions they did. On the other hand, SOM for the same student, would be considered if the teacher explained, "The student answered the problem by drawing out all the circles, 12 and then 5, and then counting each one. They understood to add but operated on units of one instead of counting on from the 12 or 5. This indicates the student does not yet recognize and operate with a unit composed of ones just the ones." Teachers with an SOM can describe an intention behind the math action as opposed to just naming the math action (as in noticing) or judging it against their own (FOM).

Instructional shifts from just teacher noticing toward SOM is an essential pedagogical realignment away from the teacher's math as the driver for learning and instead toward student conceptions. Focus on the students' conceptions for learning can pivot instructional shifts from "I do, we do, you do" towards instruction more centered on the students' specific individual needs for advancing conceptual understanding (Hackenberg et al., 2023).

Second Order Models in Research and Instructional Practice

Second order models have been described to be made by researchers and teachers. At the researcher level, SOMs are reliant on a theoretical perspective of learning that requires the core notion of assimilation (Piaget, 1971). Assimilation is a mental process by which a learner's existing understanding organizes and shapes their ongoing learning experience. It is the lens by which we "see" the world around us. Literature has described the different levels that *researchers* make SOMs: Emerging SOM, Developed SOM, and Elaborated SOM (Ulrich et al., 2014). At the Emerging level, researchers have insight into participants'/students' mathematical thinking as separated from their own mathematical understanding, but are not yet able to make instructional adaptations as a result of the SOM – as the model is still being constructed. At the Developed level, a researcher can anticipate and plan interactions with participants/students based on the SOM. Finally, at the Elaborated level, the researcher is able to determine a viable SOM of the participant/student and situate this with other SOMs in a class to create several "like" models of participants/students that drive design and enactment of mathematical instruction for groups.

Teachers’ shifts toward SOM are somewhat parallel to that of researchers', however, at the instructional level the focus for SOM is to create a model of students' existing concepts and acknowledge those concepts’ influence on solutions presented by the student. Specifically, two stages for teachers’ shift toward SOM are cogitation and distinction (Hodkowski, 2018). Cogitation refers to teachers’ increased ability to contemplate and think deeply about what their students’ mathematical mental activity might be. Shifts towards cogitation allow teachers to further separate students’ thinking from their own (FOM), and think more deeply about how students make sense of the mathematics. It is most closely related to the Emerging level of SOM used by researchers and similarly does not necessarily result in instructional adaptations. Distinction is a stage of SOM development where teachers’ ability to distinguish a students’ mathematical reasoning from other students while maintaining a separation of student reasoning from their (the teachers’) own reasoning (FOM). Distinction is likely what researchers may incorporate regularly at all three levels (Emerging, Developed and Elaborated). Particularly in the Elaborated level, researchers use one student’s understanding to attribute similarities to a group of students and organize instruction based on inferences into all students’ available conceptions.

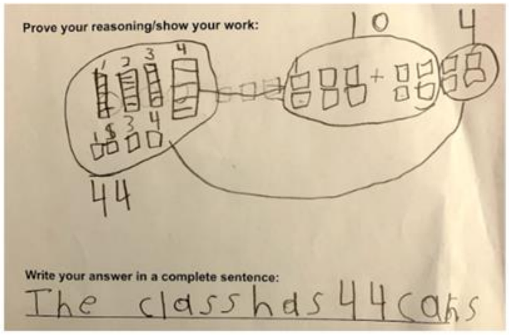
To shift towards cogitation and distinction requires teachers to infer into a student's existing conceptions (what the student can do) and separate these from her (teacher’s) own mathematical knowing (SOM; Hodkowski, 2018; Smith & Hodkowski; in press; Hodkowski et al., under review). Essentially, SOMs enable teachers to infer how students' existing mathematical knowledge shapes their reasoning and mathematical decisions. This shift allows teachers to gain a deeper understanding of why students focus on specific aspects of mathematical problems (Hodkowski, 2018), or make certain errors in reasoning when solving problems (Smith & Hodkowski, in press), or operate on units in ways (Hodkowski et al., under review).

Recognizing what students are attending to (as in teacher noticing) is a crucial initial step for teachers, but transitioning toward SOMs (cogitation and distinction) requires more than mere observation. An SOM encompasses the teacher’s capacity to infer how the student’s existing mathematical knowledge influenced the reasoning presented from the student. Incorporating SOMs involves not only noticing students' abilities but also attributing these abilities to their underlying conceptions. With SOMs, teachers can both observe students' mathematical strategies and delve into the conceptual roots behind them. This pedagogical shift expands the concept of teacher noticing by framing it as a foundation for inferring into students' mental mathematical activities and understanding the conceptual basis of their reasoning through units and how students operate on them. Following we present empirical evidence illustrating that SOM is more than just teacher noticing.

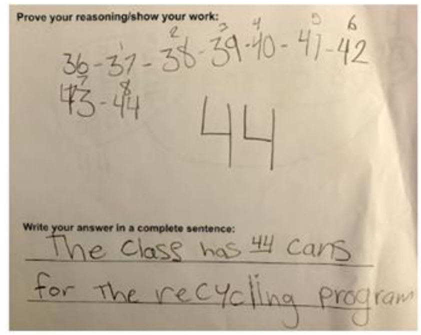
Differentiating Between Teacher Noticing and Second Order Models

We build on recent research (Hodkowski, 2018; Hodkowski et al., under review; Smith & Hodkowski, in press) examining potential indicators toward teachers’ shifts in SOM. Specifically, we present evidence and comparisons between practicing teachers’ noticing as distinct from but related to developing SOMs. To identify evidence of distinctions between teacher noticing and SOM, we asked practicing teachers to reflect on the following scenario and solutions from two students who were not part of the teachers’ current classrooms:

Student A and Student B (work pictured below) were asked to solve the following question: Ms. Smith's class collects 36 cans for the recycling program. Then, Camilla brings in 8 more cans. How many cans does the class have now?



Student A



Student B

Six teachers were sampled from a large, public school district in the Southern United States. Teachers ranged from early career (first year) to veteran (30+ years) across the K-6 spectrum and were anonymously asked five questions based on the pictured work using Google Forms. The questions were: 1) Looking at the work of Student A and Student B, what do you notice? 2) Looking at the work of Student A and Student B, what do you wonder? 3) Looking only at Student A, what can you describe about their thinking and how they solved the problem? 4) Looking only at Student B, what can you describe about their thinking and how they solved the problem? 5) When comparing and contrasting the work of Student A and Student B, what differences can you describe in their reasoning (with evidence). Is this comparison important for their next steps in learning? Why/not?

We used constant comparison analysis (Glaser & Strauss, 1967) to examine teacher responses and distinguish between instances of teacher observation (teacher noticing) and instances of more complex student reasoning descriptions (SOMs). Initially, responses were individually coded by each author for evidence of teacher noticing or indications of cogitation and/or distinction (SOM). The authors then compared their individual coding with each other through multiple conversations to reach consensus between teacher noticing statements versus SOM statements. This collaborative process allowed us to better characterize each teacher's statement and establish how SOM differed from teacher noticing.

Following, we present a sample of teacher responses through our classification of teacher noticing versus indications of SOMs. Our aim is to illustrate that while teacher noticing involves recognizing the students' solutions and strategies, SOMs, particularly cogitation and distinction, describe student thinking based on the construction and operation of units each student might have been using to think about and solve the problem.

Examples of Teacher Noticing

Teacher noticing involves teachers' attention to observing and analyzing how students solved the problems through mathematical strategies and problem-solving approaches. This is exampled from the teacher descriptions seen in Table 1.

Table 1
Examples of Teacher Noticing

Teacher 1	[Student A] found the sum by counting on their fingers. Then proceeded to break the problem up to show the sum of 44 using tens & ones. Then they sort of used arrows to show 4 tens & 4 ones equals 44.
	[Student B] simply counted on.
	Student A is on their way to understanding multiplication.
Teacher 2	[Student A] only have the answer drawn out, so I believe they have a better understanding of the numbers within the problem.
	[Student B] They counted on from the first number, so their thinking shows they have an understanding of the numbers within the problem but may still need some concrete support while working.
	They used different strategies in solving, I think [Student] A may have a better understanding because they did not really have to work out the problem, they just showed the answer. I believe [Student] B has an understanding of the work but may not be quite on the same level of abstract thinking.
Teacher 3	[Student A] likes to group items and numbers to make it easy for them
	[Student B] likes to subtract and can understand the regrouping process.
	Well comparing them they understand regrouping carrying a number but they just go about it in a different way neither of them are wrong. It is not important because they have shown their work and how they got the answer. Next step is give them another strategy.
Teacher 4	I think [Student A] has a solid understanding of how numbers work and has a good understanding of number partners.
	[Student B] was able to count on and also numbered them to show her thinking.
	Student B has a solid understanding of the procedure for counting on, but I am not sure they really understand quantities. Student A seems like they are ready for bigger numbers. It is important because on is ready to fly and the other one still needs support and perhaps more hands on practice.

Teachers’ noticing statements acknowledge that Student A may be on the path to a deeper comprehension of mathematical concepts but conceptual reasons as to why or inferences into how the student operated to arrive at their answer (e.g. counting by ones versus breaking apart to make ten) is not yet accounted for. For example, Teacher 1’s description of Student A's use of finger counting, breaking down the problem into tens and ones, and employing arrows to represent the sum of 44 demonstrated robust noticing and attending to the mathematical details presented. However, in Teacher 1’s description, inferences into the mental operations for how the student thought out and operated on the tens and ones to arrive at 44 seems absent. Similarly, for the teacher noticing group (Table 1), Student B's reliance on counting on is noted which, as suggested by the teachers, is “an understanding of a procedure” (Teacher 4) and “a potential need for additional concrete support” (Teacher 2) but how the student counted on (tracking by ones with each additional count) is not mentioned by the teachers.

Teachers' noticing descriptions recognize the diversity of strategies each student brought, such as Teacher 3's noticing that Student A "used grouping" and that Student B had an "understanding of regrouping". However, why each student would reason this way (inferences into how they operated on tens and/or ones to arrive at the grouping or regrouping) or use such strategies seemed lacking in these teachers' descriptions. From the examples above, teacher noticing statements acknowledge that both students' strategies were valid but do not yet categorize either strategy as being more (or less) conceptually advanced.

Examples of Second Order Models

Teachers' statements which included SOMs, unlike teacher noticing statements, describe inferences made by teachers into students' mental mathematical activities as the conceptual basis of their reasoning through units and how students operated on them, as illustrated in Table 2. These statements suggest the teachers were cogitating and making distinctions about students' mathematical thinking in terms of the units and operations students used; instead of referring to strategies students used to arrive at the correct answers, as seen in the noticing statements (Table 1).

Table 2

Examples of SOM

Teacher 5	First [Student A] broke up the number 36 by tens and ones. Then they add [sic] 8 ones, then had another group of tens. [Student A] then took the left over ones and left them, this is how they got 44.
	[Student B] had to count on and keep track that they counted up 8.
	Student A has a deeper understand[ing] of numbers value and how numbers are formed. Student B does not see numbers the same and sees this more as counting on and not looking at the value of the number. Yes, student A has an understanding of value while student B is still at the surface level of understanding numbers.
Teacher 6	Student A decomposed the 8 more cans into 4 and 4 and decomposed 36 into 3 groups of 10 and 6 ones. She then composed a group of 10 using the 6 and 4. That gave her 4 groups of 10 and 4 extra ones for a total of 44.
	Student B solved the problem by starting with the first quantity and counting on 8 more numbers to add the second quantity.
	I believe Student A has cardinality and is able to subitize with larger numbers. She understands the quantities that are being added and that making a 10 is an efficient way to solve a joining problem. Student B understands the pattern for counting and can count on from a given number. He understands the process for solving a problem by counting on but there is no evidence that he understands the quantities that have been added. (He may understand them, but it is not indicated in his answer.) Both students have used a strategy that works for them to solve a joining problem with result unknown. I believe that Student A's explanation shows a more advanced understanding of the math behind the solution and therefore Student A is ready for other problem types or joining problems with larger

	quantities and that Student B perhaps is not. However, I will admit that I am not really sure about what Student B would need at this point.

There is a distinguishable difference between Teachers 1-4 statements (Table 1) and the statements of Teachers 5 and 6 (Table 2). We attribute this difference to teachers developing SOM as exampled through the cumulation of Teacher 5 and 6's descriptions. For example, when describing Student A's work, both Teacher 5 and 6 noted an approach where the student decomposed 36 into tens and ones (3 groups of ten and 6 ones) and 8 into a group of 4 and a group of 4 and composed numbers, using the 4 to make a ten and then determining 44 with 4 more ones. Teachers 5 and 6's statements explicitly describe distinct units which the student operated, whereas Teachers 1-4 did not provide evidence of this.

Later, when comparing the two students' work, both Teacher 5 and 6 worked to identify why Student A was able to reason as they did (Teacher 5 describing Student A's understanding of "value" while Teacher 6 described it as "cardinality and subitizing"). We attribute this to a developing SOM regardless of the mathematically/ conceptually accurate thinking that a researcher might attribute to these students. The teachers' attention to the "why" Student A was mentally able to work with various, distinct units demonstrated more than teacher noticing. We see Teachers 5 and 6's and statements as attempts to understand what the students were thinking as a result of their solution as well as the "why" (units and how students operated on them). Said differently, for statements in Table 2, teachers seemed to make attempts to infer into what students did know as a way to describe the work that was presented.

Discussion

This paper examined the distinctions between teacher noticing and Second Order Models (SOMs) and presented empirical evidence to illustrate these differences. Teacher noticing, as described in the literature, involves teachers' attention to and interpretation of students' mathematical strategies and problem-solving approaches. In contrast, SOMs involve recognizing not only what the student did but also why they did it based on the mental operations inferred from the observer. This focus on the "why" provides insight into the student's existing conceptions as the starting point for their future learning. While teacher noticing is a crucial initial step, SOMs enable teachers to infer how students' existing mathematical knowledge shapes their reasoning and mathematical decisions.

The empirical evidence presented in this paper illustrates the differences between teacher noticing and SOMs through a comparison of responses from six practicing teachers. The examples of teacher statements provided demonstrate that while teacher noticing involves recognizing the students' solutions and strategies, SOMs, particularly cogitation and distinction, describe student thinking based on the construction and operation of units each student might have been using to think about and solve the problem. An implication of SOMs in instruction is teachers' attention to differences in the way students solve problems based on the units involved. While more research is needed on teachers' development of SOMs and their use of them in instruction, teachers' attention to differences on how students operate can result in more individualized instruction to students who can arrive at the same answer albeit different thinking.

TEACHERS' ENACTMENT OF SOCIAL JUSTICE MATHEMATICS LESSONS

Keywords: Curriculum, Middle School Education, Social Justice

Mathematics class can support students to develop civic dispositions that are foundational to productive citizenship (Education Commission of the States, 2014) and prepare students to see mathematics as relevant and meaningful. Social justice mathematics lessons (SJML; Gutstein, 2003) may provide opportunities for students to consider both mathematics and social issues (Kokka, 2022), yet balancing attention to both is challenging (Bartell, 2013). Citizen Math, one set of SJML, has been documented to engage students in social issues while improving middle school students' mathematics achievement (Jackson & Makarin, 2018). We investigate teachers' enactment of Citizen Math lessons to inform professional learning and further research of SJML.

We utilize Cazden's (2001) two dimensions of interactional routines, *sequential* and *selectional dimensions*. S*equential dimension* refers to routines that are consistent across classrooms and/or lessons. *Selectional dimension* refers to the ways teachers exercise their agency to enact segments of a lesson. Classroom routines are influenced by published materials (Banilower et al., 2018) such as off-the-shelf SJML (e.g., Conway et al., 2023). Yet, even with common resources teachers may enact components differently which is visible in the *selectional dimension*. One difference is in how teachers position mathematics and students, which has implications for teachers' and students' mathematical authority (Herbel-Eisenmann, 2007).

We share our analysis of 22 observed SJML in middle school classrooms to answer the research question: *How do middle school teachers learning to use SJML enact such lessons?* Findings in the *sequential* dimension indicate that teachers enact segments of Citizen Math lessons in a predictable manner consistent with teachers' guides. The timing of each segment was the most variable aspect. In the *selectional* dimension, we found variance among which mathematical concepts were emphasized and how the lesson and mathematics were positioned. For instance, in a 7th grade lesson, students considered the fairness of wages in different professions by analyzing unit rates. Mrs. Amber emphasized that students should consider fairness from their perspectives (e.g., "You're going to determine whether you all think it's fair, whether you think they should be able to make that much…") and throughout the lesson students used mathematics to make sense of the concept of fairness. On the other hand, Mr. Brown's perspective suggested the task was to find a correct answer (e.g., "Is it more valuable to be a football player?") and regularly directed students to use particular procedures. Where Mrs. Amber allowed students to make assumptions, Mr. Brown funneled students' reasoning so that all students performed the same computations. Multiple examples from a variety of these SJMLs illustrate differences across lessons, particularly in the *selectional* dimension. By identifying the various ways that teachers exercise their agency, for example through questioning patterns and constraining authority, we hope to contribute to the discourse about professional development efforts related to SJML. This analysis can support teachers to skillfully implement SJML that advance mathematical goals while also cultivating positive mathematics and civic dispositions.

"I'M STUCK": NAVIGATING CRITICAL JUNCTURES WHEN TEACHING MATHEMATICS THAT IS RESPONSIVE TO STUDENT THINKING

Michael Jarry-Shore
North Carolina State University
majarrys@ncsu.edu

Mary Ramos-Duke
Boise State University
maryramosduke@u.boisestate.edu

In teaching a lesson that is responsive to students' mathematical thinking, teachers urge students to solve problems using whichever strategy they prefer. Prior work has described the difficulties teachers may face in teaching responsively, yet little has sought to characterize the particularly high-stakes moments that may derail a responsive lesson, what we refer to as "critical junctures." We examined 27 prospective elementary teachers' reflections on the challenges they encountered in teaching a responsive lesson in a rehearsal, as well as video of the most common critical junctures. We find that critical junctures involve confusion on the part of the teacher, the students, or both. We also find that many of the challenges teachers described in their reflections did not rise to the level of a critical juncture, suggesting that these may need to be introduced during rehearsals if prospective teachers are to have opportunities to navigate them.

Keywords: instructional activities and practices, preservice teacher education, teacher educators

Imagine the following. A teacher educator (TE) is modeling a Number Talk for a group of prospective elementary teachers (PTs) (Humphreys & Parker, 2015). The TE asks PTs to solve 75 – 29 however they prefer. After a few minutes, a whole-class discussion begins, in which several PTs share their strategies. The first PT describes a strategy the TE anticipated: 29 ➔ 25 and 4; 75 − 25 = 50; 50 – 4 = 46. The second PT describes a compensation strategy the TE had also anticipated: 75 – 30 = 45; 45 + 1 = 46. A third PT then shares: 80 – 30 = 50; 50 – 5 = 45; 45 – 1 = 44. And the TE is stuck, unsure what the PT did, why it did not work, or what to do next.

This scenario took place in a mathematics methods course taught by the first author as he sought to model instruction responsive to students' mathematical thinking (Dyer & Sherin, 2016; Jacobs & Empson, 2016). While difficult to convey in writing, this moment engendered a sense of panic. Such moments, what we call *critical junctures*, can derail a responsive lesson, and even lead a teacher to abandon efforts to teach mathematics in a way that is responsive to students' thinking (Borko et al., 1992). While some work has described what makes responsive teaching challenging (e.g., Ghousseini, 2015; Gibbons et al., 2017), little has characterized particularly high-stakes moments like the one described here. Work characterizing such moments, including what they have in common and how they can be navigated may support TEs in preparing PTs to teach responsively. It may also result in more students experiencing the merits of this approach to instruction for their learning and dispositions (Boaler & Greeno, 2000; Carpenter et al., 1989).

We examined the critical junctures 27 PTs described facing in teaching a responsive lesson in a rehearsal. We answered the following question: What is the nature of the critical junctures PTs encounter when teaching a lesson designed to be responsive to students' mathematical thinking?

Conceptual Framework

Responsive Mathematics Teaching

In teaching responsively, teachers urge students to solve problems using their own preferred strategies rather than a single predetermined strategy shown to them by the teacher (Carpenter et al., 1998). Several of these strategies may then be compared and contrasted in a whole-class discussion devoted to surfacing and developing students' understanding of a key mathematical idea (Sleep, 2012; Stein et al., 2008). Calls to teach responsively are rooted in research showing that such teaching is associated with the development of rich mathematical understandings and productive dispositions towards the subject (Boaler & Greeno, 2000; Fennema et al., 1996).

What Makes Responsive Mathematics Teaching So Challenging?

Despite these benefits, responsive teaching remains somewhat rare (Bishop, 2021; Cobb & Jackson, 2021; Stigler & Hiebert, 1997), due in large part to the many challenges of teaching in this way. In teaching responsively, teachers must necessarily improvise (Borko & Livingston, 1989). Even with substantial prior planning (Stein et al., 2008), teachers are likely to encounter strategies they did not expect or have never seen before, which requires them to comprehend the strategy on-the-spot and decide how to respond to the student who used it (Jacobs et al., 2010). This challenge may be especially salient for prospective teachers, as they tend to be less familiar with the nonstandard strategies students use (Jacobs et al., 2011; Shaughnessy & Boerst, 2018). Even if they follow every strategy, teachers may encounter a challenge in making these strategies the basis of a whole-class discussion (Singer-Gabella et al., 2016) or leveraging them in an effort to surface the lesson's key mathematical point (Ghousseini, 2015; Sleep, 2012).

Such challenges are integral to responsive teaching, yet may not derail a lesson. Critical junctures – the focus of this study – are not only challenging, but threaten to derail a lesson. And while they may share much in common with the challenges described here, they may well differ.

Methods

Participants and Context

Twenty-seven PTs were recruited from an elementary math-methods course. Most presented as white and female, but a range of gender, linguistic, and racial identities were represented. PTs experienced live representations of a Number Talk, Quick Images, Choral Count, and Number String taught by the first author, who also facilitated an unpacking of each representation with the PTs (Lampert et al., 2013). PTs then co-planned a similar lesson to rehearse with a partner.

Data Collection and Analysis

Data consisted of written reflections in which PTs described three challenging moments from their rehearsal, including what occurred, what made it challenging, how they responded, and how things proceeded. Video-recordings of the rehearsals were also gathered with an iPad on a Swivl robot. Analysis began with the creation of a codebook comprised of a priori codes for the types of challenges teachers may face in teaching a responsive mathematics lesson (Ghousseini, 2015; Singer-Gabella et al., 2016; Sleep, 2012). We then read a sample of PTs' reflections to assess the applicability of the codes, which resulted in several emergent codes being added. However, we soon recognized that some codes were unrelated to responsive teaching or described challenges not high stakes enough to comprise a critical juncture. We thus revisited the codes, asking if each challenge: a) was relevant to responsive teaching and b) did or could derail a lesson. Only codes meeting these criteria were kept. We made these decisions by considering our own teaching experience and asking if a given challenge had indeed halted lessons when it occurred. Next, we independently coded a sample of challenges, with those that did not meet our criteria coded NA. We then compared and revised codes as needed. Once codes were stable, we coded additional samples until achieving adequate interrater agreement. The first author then coded all challenges, also applying a code for the lesson phase in which the challenge occurred: a) launch, b) whole-class discussion, or c) lesson closure. We then wrote analytic memos (Maxwell, 2013) in which we described patterns in the codes. To capture what critical junctures entail, we identified instances representative of the most common critical junctures, viewed video of them, and wrote memos describing what occurred therein. We present our analysis of one such instance below.

Results

Table 1 portrays the distribution of codes applied to PTs' descriptions of challenges faced.

Table 1: Critical Junctures

Code	n	Lesson Phase
Unanticipated solution strategy	4	Whole-class discussion
Following a student's thought process	8	Whole-class discussion
Explaining why	1	Whole-class discussion, Closure
Limited range of strategies	4	Whole-class discussion
Partially correct strategy	4	Whole-class discussion
Steering toward the mathematical point	0	Whole-class discussion, Closure
Closing lesson by foregrounding key point	4	Closure
Adjusting in-the-moment	11	Whole-class discussion
NA	45	

Adjusting in-the-moment and following a student's thought process were common critical junctures. Less common junctures were responding to unanticipated strategies, a limited range of strategies, and partially correct strategies, as well as closing a lesson by foregrounding its key point. We had a code for "steering toward the mathematical point," but PTs did not mention this challenge, suggesting that it was not salient for PTs or they perhaps experienced it, but did not write about it as it is less of a "challenging moment" and more of a recurrent challenge woven throughout a lesson. We applied NA codes to 45 challenges. For example, consider the following challenge shared by one PT: "When students answered the questions that we had planned, it was hard to come up with more questions to push them to think deeper." While relevant to responsive teaching, this challenge is unlikely to halt a lesson and thus fell short of being a critical juncture.

A Critical Juncture

We now describe an instance of one of the most common critical junctures PTs faced in their rehearsals: following a student's thought process. For this instance, PTs were teaching a Number String and had already asked students to solve 4×7 and 8×7, which PTs chose as the answer to 8×7 is double that to 4×7. After posing a third problem, 20×7, the following exchange occurred:

Student 1	One-forty [140].
PT 1	And how did you get that?
Student 1	I did it two different ways, actually.
PT 1	Okay.
Student 1	And the first one was, I actually multiplied 28 by five.
PT 1	Perfect. Twenty-eight by five?
Student 1	Yep. Because I knew that four times five is 20, so I just multiplied that by five.
PT 1	Okay, so four times five equals 20 and then you just multiplied that by five?

Student 1	I multiplied the, I knew that the first number string, the four times seven, was 28.
PT 1	Right.
Student 1	And I knew that four times five is 20, so I did the 28 times five, and I got 140.
Student 2	Girl, what?
Student 3	Oh, okay, so she did seven times four to get 28 and then times that by five, to get, I get, I get what she's saying.
PT 1	Okay. So, you did this right here?
Student 3	So, she broke up, she broke…
PT 1	The seven times four to get the 28.
Student 1	Exactly.
PT 1	And then?
Student 1	And I saw that the new equation was 20 times seven, I knew that 20 was four times five, so I just multiplied the 28 by five.
PT 1	Times four, times five? I'm stuck.

The TE then asked Student 1 if she solved 28×5 in one step or solved 20×5 and 8×5, then added the products. Student 1 said that she did the latter and the TE wrote the following on the board:

$$20\times7=$$
$$\wedge$$
$$(4\times5)7=$$
$$4\times7=28$$
$$28\times5=$$
$$\wedge$$
$$(20+8)5=$$

The TE then turned to PT 1 to ask if things were making sense, to which PT 1 responded, "a little bit." PT 1 then asked the class if anybody had a different way of solving the problem, 20×7.

In reflecting on this moment, PT 1 shared: "Student 1 shared a strategy that not only us 'teachers' were confused by, but fellow 'students' were confused by, too. Even after eliciting, I struggled to understand what she did and was unable to revoice or represent her strategy." Thus, PT 1 seemed to concur that this was a critical moment related to following a student's thinking.

Discussion

We contribute to a growing literature seeking to characterize the challenges teachers face in teaching responsively (Ghousseini, 2015; Gibbons et al., 2017; Singer-Gabella et al., 2016). Unlike prior work, we focus not on "challenges," but those particularly high-stakes moments encountered in teaching responsively that either do, or have the potential to, bring a lesson to a halt, what we refer to as *critical junctures*. Critical junctures involve confusion on the part of the teacher, students, or both, which may be expressed overtly (e.g., "I'm stuck," "Girl, what?") or in more subtle ways recognized by a TE, though perhaps not by PTs. Following a student's thought process (Jacobs et al., 2011; Shaughnessy & Boerst, 2018) was a common critical juncture, as was adjusting on-the-spot. At times, the latter was in response to something the TE suggested.

About half of PTs' challenging moments did not rise to the level of a critical juncture. This implies that such junctures may be rare in rehearsals, perhaps because students in rehearsals are adults who are forthcoming with their thinking, thereby limiting confusion. TEs may thus need to introduce critical junctures in rehearsals (Baldinger et al., 2021) if PTs are to have opportunities to navigate them. The lack of critical junctures may also have been due to PTs not recognizing junctures when they arose or junctures being resolved by a TE before becoming critical for PTs.

An objective of ours moving forward is to develop even greater clarity regarding what makes a critical juncture a critical juncture. As we describe above, the critical junctures in this study either derailed, or had the potential to derail, a responsive mathematics lesson. They were also characterized by notable confusion. However, in our analysis, we recognized that some of the critical junctures that fulfilled these criteria (e.g., following a student's thought process) seemed more critical than others (e.g., limited range of strategies). In future work, we plan to specify such distinctions and may even create tiers in terms of a critical juncture's criticality.

AN EXPLORATORY STUDY INVESTIGATING RESEARCHERS' PRODUCTIVE STRUGGLE CONCEPTUALIZATIONS IN TWO DISTINCT CONTEXTS

Nitchada Kamlue
Western Michigan University
nitchada.kamlue@wmich.edu

Keywords: Instructional Activities and Practices, Problem-Solving.

Identifying key features of *productive struggle* helps build a common language and shared understanding of this term across conducting research and enacting the National Council of Teachers of Mathematics' (NCTM, 2014) teaching practice "[supporting] productive struggle in learning mathematics" (p. 10). However, productive struggle is a complex phenomenon. One way to better understand this phenomenon is by investigating how different researchers conceptualize productive struggle, such as by depicting it through the figures in their published papers. Thus I investigated the research question: *What do researchers' conceptualizations of productive struggle in distinct contexts reveal about key features of productive struggle?*

This exploratory study emerged from a larger ongoing study that investigates the definitions of productive struggle (e.g., Kamlue & Van Zoest, in press). As I analyzed studies that investigated productive struggle, I noticed that Warshauer's (2015) study [W15] and Granberg's (2016) study [G16] had several key differences, including interaction opportunities, mathematics content, and study foci. For example, in W15, students had opportunities to work individually, in a small group, or as a whole class, and the students received support from their teachers. In contrast, students in G16 worked in pairs and received automatic feedback from GeoGebra software. Moreover, while G16 used linear function problems for upper secondary school students in her study, W15 used proportional reasoning for middle school students. I also noticed that while G16 focused on the problem-solving process (e.g., correcting prior knowledge), W15 focused on classroom interactions (e.g., teacher-student interactions).

Since these two authors investigated the productive struggle construct through different lenses (e.g., different study foci), I analyzed these two articles, particularly focusing on the depictions in their figures as a proxy of their conceptualizations, to identify commonalities in their approaches. I analyzed the two articles using the four dimensions (*tasks*, *student struggles*, *teacher responses*, and *outcomes*) that were identified in W15's *productive struggle framework* (p. 391) as a starting point to investigate how G16 aligned with or differed on those four dimensions. Then, I discussed the initial findings with other researchers to confirm or disconfirm the findings.

The initial results indicated at least three commonalities between how W15 and G16 conceptualized productive struggle in learning mathematics that can inform future work on productive struggle. First, tasks that are unfamiliar to the students promote productive struggle. Second, struggles that tended to be productive concerned important mathematics (e.g., *error concerning prior knowledge* (Granberg, 2016, p. 39), not *error due to carelessness* (Warshauer, 2015, p. 386)). Finally, student responses to the feedback they receive emerged as important, regardless of the form of the feedback (e.g., teacher responses, automatic feedback from GeoGebra, peer responses). This poster will illustrate my analysis of these studies and elaborate on how my results can inform future research into productive struggle.

'YOU DO NOT LEARN MATHEMATICS; YOU GET USED TO IT': AN INVESTIGATION INTO GRADUATE MATHEMATICS

Peter Karanevich
University of Colorado Boulder
peter.karanevich@colorad.edu

Keywords: Tertiary Mathematics, Teaching Practice and Classroom Activity, Systemic Change

Efforts to make mathematics more equitable and inclusive for anyone who wishes to pursue it have been happening for the past 40+ years in K-12 grades. More recently, efforts to reform undergraduate mathematics -- in particular, the calculus sequence (Smith et al., 2022) -- have been underway as well. Mathematics education in proof-based courses, like those taught in graduate classes, and teacher pedagogy and practice in college mathematics are both understudied fields in education (Weber, 2012; Melhuish et al., 2022; Speer et al., 2010). Conversations regarding graduate-level mathematics instruction could open up communication between researchers in mathematics education and research mathematicians, which could benefit students enrolled in graduate courses, professors who teach these courses, and students who aspire to pursue mathematics at any level.

This project aims to bridge the mathematics and education departments within a university in the Rocky Mountains in an ethnographic endeavor to study teaching and learning practices in a graduate mathematics course. Graduate courses are prime candidates for studying learning based on the motivation of the students that participate in them and given the similarity between modern mathematics teaching methods and the goals and methods of mathematics research. The type of work accomplished in graduate mathematics courses includes developing intuition about how ideas are connected and the validity behind statements, developed through exploring patterns, formulating conjecture, and seeking solutions to them (Schoenfeld, 1992). While performing mathematics research, one must enact these practices and understand the material that forms the foundation, which is typically what graduate courses are for. So, understanding how mathematics is taught in graduate courses and relating it back to the work of a mathematics researcher can open up possibilities for creating classrooms where learning mirrors research more closely.

This study inquires into how graduate mathematics content is learned and taught in university classrooms. To gain understanding about the teaching and learning process, the researcher has conducted interviews with 15 students enrolled in graduate mathematics courses (graduate, undergraduate and from schools outside of math), six instructors of graduate mathematics courses and one postdoctoral scholar. Classroom observation data was also collected using a modified P2C2 protocol from the SEMINAL project (Smith et al 2022). These observations focused on student interactions and teacher moves.

I perceive teaching and learning as social activities. Prior research has shown enhanced student understanding of mathematical concepts and desire to pursue mathematics further (Boaler and Greeno 2000). Looking at what strategies students are using to learn content and what professors do in class to motivate student learning can begin conversations about what strategies are currently happening as well as envision futures where more students are drawn to learning mathematics and have enhanced opportunities to do so at this level.

We report on undergraduate students' experiences of different group formation methods used by eight instructors of an introduction to proof course. We offer themes of student experience of three group formation methods: random selection, student selection, and instructor selection.

Keywords: instructional activities and practices, undergraduate education, reasoning and proof

Group work implementations vary across many dimension, such as the frequency of the group work, the content worked on, and the instructor assistance offered (Smith et al., 2020). In this report, we focus on one such dimension: *group formation*, that is, how groups are formed. In particular, we are interested in undergraduate students' experiences of different group formation methods and seek to learn:

- How do undergraduate students experience different group formation methods?

To this end, we report on the experiences of 29 undergraduates from eight sections of an introduction to proof course where about two-thirds of class time was dedicated to group work. Although group work has been extensively studied in the K–12 context, it has received less attention at the undergraduate level. Due to the contextual differences, research results from the K–12 context may not map directly onto the collegiate context.

Literature Review

Below, we briefly review existing literature on group formation using Hagelgans et al.'s (2001) four-part classification of group formation methods, which will also frame our results.

Random Selection

Groups can be organized by random assignment, a method argued for by Liljedahl (2021). He noted that groups should be randomized every hour or so to avoid students settling into active or passive positions, and he observed that groups needed to be *visibly* randomized, for otherwise students doubted that groups were random and returned to fixed positions. Yet, random selection can also lead to unfortunate groupings, such as minoritized students being isolated in their groups (Reinholz, 2023). For example, Hwang et al. (2022) documented two undergraduate students' experiences of being linguistically isolated in randomly formed groups.

Pseudo-Random Selection

Hagelgans et al. (2001) used the term pseudo-random selection to refer to "[t]he instructor mak[ing] a few adjustments to randomly selected groups" (p. 19). They suggested that any such adjustments should be made before the class so that students do not see the adjustments. This stands in contrast to Cohen and Lotan's (2014) suggestion to make adjustments openly. Reasons for making these adjustments could be to pair newly arrived students with translators or to separate unproductive friends/enemies. Further, paying attention to race, gender, and individual needs and making adjustments accordingly can serve to counter known issues such as white men dominating participation (Reinholz, 2018, 2023).

Instructor Selection

By determining groups themselves, instructors can ensure heterogeneous groups, paying attention to race, gender, and individual needs (Reinholz, 2018). Instructors can also utilize student input. A concern raised by Cohen and Lotan (2014) is that some instructor choices, for example with respect to gender and race, can be easily noticeable and lead students to viewing other students as stereotypical representatives rather than as individuals.

Student Selection

Instructors can also permit students to form groups on their own. Cohen and Lotan (2014) raised several concerns about this method: (a) friends will typically choose to work together and be focused on play rather than work, (b) socially isolated students may be isolated even further by not being selected, and (c) some students who need extra support may be less likely to receive it. Reinholz (2018) added that student selection may also lead to excessively homogeneous groups, which can also lead to the exclusion of students.

Methods

This study's data set is a subset of a larger data set that was collected to understand students' experiences in university mathematics classes across multiple years. Data collection began when students took a group work-based introduction to proof (ITP) course at a large public university in the Midwestern United States and continued into subsequent proof-based courses.

ITP Context

The ITP course was a multi-section course, where each section was typically taught by two graduate students, one serving as the instructor, the other as a teaching assistant. The course was coordinated by a faculty member, who asked instructors to use group work with groups of three to four students. No further group work implementation instructions were provided to the instructors. Around two-thirds of all class time was dedicated to group work.

Data Sources

We drew on two data sources in this study: (a) classroom observations, and (b) semi-structured interviews. The classroom observations were of eight sections, split across two semesters, each observed by one or two researchers. We tried to observe classes at least once a week and thus have a total of 116 observations, of which 83 included group work.

In each of these eight sections, we recruited between two to five participants for a total of 29 participants. In our recruitment, we attended to gender, race, ethnicity, and major in the hope of accurately representing the diverse set of experiences of the ITP student body. All but one of the 29 participants took part in two semi-structured interviews: an early-semester interview (ESI) several weeks into the semester, and a late-semester interview (LSI) towards the end of the semesters. (The 29th participant only completed the ESI.) In the interviews, we sought to learn about students' course experiences more broadly, and although group work was an important experiential component addressed by all participants, it was not the sole focus of the interviews.

Data Analysis

First, we used a bottom-up approach to classify the group work formation methods we witnessed instructional teams implement. This approach resulted in seven group work profiles. Comparing our profiles to Hagelgans et al.'s (2001) taxonomy, we were able to recognize our group work profiles as subcategories of the taxonomy. For example, we identified two different types of random selection: one in which the groups were randomized in public (i.e., in front of the class) and one in which the groups were privately randomized by the instructional team. Yet, our refinement of Hagelgans et al.'s (2001) taxonomy is not the focus of this report: We view the classifying of the classroom observations as context for students' reported experiences.

To learn about students' experiences, we used a series of coding methods to identify themes. The first author began by using two rounds of structural coding (Saldaña, 2009): first, to identify interview segments that addressed group work, and, second, to narrow the group work segments to those subsegments pertaining to students' experiences of the group formation method. The group formation subsegments were then themed (Saldaña, 2009) by the first author, that is, each subsegment was summarized by a several sentence-long thematic statement. Last, the first two authors used pattern coding (Saldaña, 2009) on the thematic statements to identify central themes of student experience. For each theme, we wrote an extended description. We include an example thereof in the Results.

Results

In the 83 observations that included group work, we observed student selection methods 42 times, random selection methods 26 times, instructor selection methods 12 times, and pseudo-random selection 3 times. Accordingly, participants' comments about their experience mainly focused on random selection and student selection, with a smaller number of comments about instructor selection. Furthermore, mirroring participants' experience in the classroom, participants' discourse on random selection was entirely about *weekly* random selection and their discourse on instructor selection was almost entirely about instructor selection *with student input*. In Table 1, we present the themes identified for the three broad types of group formation methods discussed by the participants. Thereafter, we offer our description of Random Selection Theme #2 as an example of one of our theme descriptions.

Table 1: Students' Experiences of Group Formation Methods Themes

Group Formation Method	Student Experience Themes
Random Selection (Each Week)	1. Participants' overall experience in randomized groups was positive or neutral 2. By working in multiple randomly formed groups, participants met many of their peers, which had several positive consequences 3. Participants also identified downsides of random selection 4. Participants identified advantages and disadvantages of randomizing groups *each week* 5. New interactions and positions in new randomized groups
Student Selection	1. Participants offered a mixed picture of group work experiences in student-selected groups 2. Student selection typically led to participants working "with" their neighbors for the semester (subject to minor adjustments) 3. When given the option, some participants chose to work alone

	4. Fixed interactions and positions in student-selected groups
Instructor Selection (With Student Input)	1. Not all participants submitted group preferences, but those who did asked to work with peers they were comfortable with 2. Being in a permanent group created by the instructor with student input made many, but not all, participants happy

Example Theme Description of Random Selection Theme #2: By Working in Multiple Randomly Formed Groups, Participants Met Many of Their Peers, Which Had Several Positive Consequences

Since instructor 1 randomized groups every week of the semester and instructors 6 and 7 randomized groups for a large part of the semester, students who experienced random selection worked with many of their peers. The participants reported multiple positive outcomes, including *getting to know their classmates*. Even though this may seem natural or even trivial, five participants (O, M, G, F2, E2) shared that they had not gotten to know their peers in past classes—even in small classes and classes with group work. Consider G's story:

G:	[...] I work with my friend. [...]
Interviewer:	Did you meet when you came to class, or did you know each other before?
G:	Not known [*sic*] very well, but I was seeing him in my Calculus 2. First semester I remember him, and Calculus 3 I think I've seen him in the class, but I haven't talked to him until I came to this class. And I saw him in class, and I remember him, I remember his face, but I never know [*sic*] him before. (ESI)

Aside from G, multiple other participants (K, C2, F2, N2, E2) reported *being able to make friends* in the class. More broadly, M shared in her ESI that "[in] high school I felt like I definitely had a bond with my other math kids that I feel a similar bond to the math kids in [this course]." Aside from getting to know their peers and forming friendships, three participants (M, H2, N2) described *benefiting from hearing different perspectives*.

Interviewer:	Do you feel like you've learned directly from anybody in class?
M:	Yes [...] I know that [NAME 1] usually uses contradiction work and I use direct proofs. His way of doing it is always different. Then [NAME 2], like I said, just has a completely different way where he brings in other variables if he needs them [...] (LSI)

Last, participants highlighted that changing groups provided them with two valuable insights: (a) *understanding one's speed in relation to one's peers'* (i.e., "know[ing] how fast, or how slow I am compared to a part of the class" [H2, ESI]), and (b) *determining whom one works with productively* (i.e., "who I work with better or who I found to be more productive" [N2, LSI]).

Discussion

In this study, we explored students' experiences of group formation methods by identifying 11 themes across three group formation (sub)methods. The themes paint a generally positive picture of weekly random selection and raise concerns about student selection. From the two themes about instructor selection (with student input), we learned that letting students provide instructors with their group preferences may be useful but not a cure-all.

We acknowledge the importance of the ITP context for this study. Several participants identified key aspects of the ITP context that made their group work experience (positively) different from past group work: (a) the utility of group work in an ITP course, unlike calculation-heavy courses like Calculus, (b) their peers' motivation and seriousness about the work, and (c) the emphasis on understanding and not receiving a grade for group work. Particularly the first two appear to us a dividing line of typical early and later undergraduate students' experience. We are left wondering to what extent the line can be (re)moved via active learning implementations of early undergraduate courses, like Calculus.

In this theoretical paper, we present the results of an analysis of literature on equitable mathematics teaching. We bound our review to research published in Educational Studies in Mathematics *between 2010 and 2023. In our review, we considered how authors conceptualized equity, the recommendations they made to teachers, and how they positioned students.*

Keywords: Equity, Inclusion, and Diversity; Systemic Change; Teacher Educators

This year's theme asks that we envision the future of mathematics education in uncertain times. In order to envision the future, we first turn to the past. In particular we trace the recommendations made as to how classroom teachers should create more equitable mathematics classrooms. Given the large body of work now addressing equity in mathematics education, we are interested in what it is that mathematics education researchers are saying about equity and how the work of addressing equity is transferable to actions that teachers could take in K12 classrooms. We conducted a literature review of *Educational Studies in Mathematics* (*ESM*). *ESM* was chosen for three reasons: (1) It is considered "top-tier" journal in mathematics education (Nivens & Otten, 2017; Williams & Leatham, 2017); (2) In our initial search which included *Journal for Research in Mathematics Education* and *For the Learning of Mathematics*, *ESM* returned the highest number of articles that met our criteria; (3) the journal aims indicate that it is, "open to all research approaches and research foci, including cognitive, socio-cultural, socio-political, and language-related aspects of mathematics education" (*ESM,* 2024). Given this aim of the journal, we expected that *ESM* might provide the most diverse representation of views on equity. The research questions that guide our review are:

1. What is the scope of research on equitable mathematics education?
2. How are authors framing equity and who do they position as *needing* equity-focused pedagogies?
3. What actions has the research on equity in mathematics education suggested for classroom teachers?

Phrases such as 'equitable mathematics teaching', 'equity-focused pedagogies', and 'equity in mathematics education' convey distinct nuances, our purpose is to engage with the way mathematics education researchers have employed their use in explorations of equity-related issues in mathematics education.

Perspectives and Theoretical Framework

There is no single set of directions or procedures that can be followed to create an equitable classroom environment, and we have found in our research that enacting equitable pedagogies takes substantial time (Castanheira et al., 2024). We begin by stating that equitable teaching is an ongoing, elusive, never finished endeavor. Due to the disciplinary and societal positioning of mathematics in K12 environments, we, and others (Martin, 2015, 2019; Stinson, 2004), argue that creating equitable *mathematics* classrooms requires working against the grain. All change in schools requires recognizing and then challenging the taken-for-granted (Britzman, 2003), in this paper, we analyze the ways the mathematics education researchers are framing equitable practice and the actions necessary to create equitable mathematics classrooms. An underlying assumption to the calls for more equitable teaching practices is that the inequities present in schools can be addressed and remedied by teacher actions. Some question whether teachers can effect substantial and sufficient change within the current structures (Bullock, 2023; Martin et al., 2019), we honor these perspectives; however, in this project, we are curious about the scope of recommendations and how they position teachers. Therefore, we traced how equity was conceptualized within a subset of Mathematics Education Research (MER). and further consider how teachers are positioned in terms of their agency to address inequities.

Modes of Inquiry

In 2010, Katherine, Heid, asked "Where's the math (in mathematics education research)?" Given this push to recenter and prioritize mathematics content, we were curious as to patterns we might find in the MER related to equity from that point until the present. Thus, we searched articles from 2010 to 2023 in *ESM*. We identified 190 total records. Of the initial search we excluded 98 duplicates, book reviews, and editorials. Then, the team reviewed the abstracts of the remaining 92 identified articles retaining any article that met the following criteria:

1. Audience is K12 mathematics education researchers or mathematics teacher educators
2. Equity is a central focus of the article
3. Manuscript suggested recommendation(s) to support equitable mathematics teaching and learning

After these criteria were applied, there were 22 manuscripts to review (see Figure 1). We reviewed each article and considered the following. What, if stated, was the author's stated purpose? To whom were equitable teaching recommendations or interventions directed?; How, if at all, did the authors conceptualize or describe equity?; What recommendations were made for actions that K12 teachers should take to teach mathematics more equitably? How do the stated recommendations position teachers in terms of their agency within the classroom? And, how, if at all, did the authors acknowledge structural and systemic influences on classroom instruction?

Figure 1: Literature Review Process

Results

In this report, we share our analysis of three areas, conceptualizations of equity, recommendations for and positioning of teachers, and positioning of students. We begin by considering the *conceptualizations of equity*. Across the articles 11 of 22 articles did not directly define equity, or a form of equity. In these cases, we acknowledge that all authors did not omit a definition, but that some focused heavily on social justice or equity adjacent ideas. Of the articles that did provide conceptualizations of equity, there were ten which were borrowed from other authors. There were two main themes. Equity as *taking up space or making room*. Lui (2022), Hand (2012), and Ruef et al. (2020) take the view of equity as taking up space or allowing student ownership of classroom space or mathematics. This definition within a classroom space aligns with NCTM's Access and Equity Position Statement (NCTM, 2014), which is drawn upon by Yilmaz et al. (2021). Matthews et al. (2021) and Xie et al. (2021) use a similar conception of taking up space, but with the space being within larger society. For example: "the creation of liberatory spaces that disrupt dehumanizing conditions and provide avenues for hope" (Matthews et al., 2021, p. 336). Equity as *societal fairness*. Valoves-Chavez (2018) and Roos (2023) conceptualize equity as fair chances, or fair distribution of opportunities, for advancement of the self or mathematics knowledge. Neither identify where, or with whom, the responsibility of distribution of fairness rests. Whereas Bollock (2023) and Chen (2023) explicitly and critically situate fairness and opportunity within societal structures and acknowledge that teachers do not have control nor individual responsibility to overturn systems of oppression.

Next, we analyze the *recommendations for action and positioning of teachers.* We analyzed the way in which definitions of equity position the teacher, students, classroom space, and society and who has the ability to enact change. Within equity definitions, some position the choices of the teacher as the creator/driver of equitable space (specifically Boylan, 2016). With Hand (2012), Ruef et al. (2020), Yilmaz et al. (2021) picking up definitions which see the teacher's choices as providing agency to students. Chen (2023) acknowledges that while teachers make equitable instructional actions, these actions do not solely promote necessary change to dismantle inequitable systems.

Discussion

Across suggestions for teacher practice, we found a continuum from practical and observable actions to overarching ways of being in mathematics classrooms. Several authors described planned recommendations for teacher practice that could lead to more equitable mathematics teaching and learning. Hand (2012) suggested ways of noticing and responding to classroom life that teachers could enact to create a trusting environment. Bonner (2014) recommended ways for teachers to develop knowledge of students and their community to build relationships and trust. They recommend relationship building as providing a "more practical place from which to work" (p. 397), thus allowing classroom change responsive to a student's community. Conversely, Yilmaz et al. (2021) suggested overarching professional development on implementation and utilization of mechanisms to support student needs. These recommendations are non-specific but identify teachers as the decision-makers and enactors of change within the classroom space.

A subset of articles included conceptualizations of equitable teaching practice that are made-in-the-moment. These conceptualizations primarily draw on post-structural and new materialist theoretical frameworks. They present equitable or ethical classrooms as being made by teachers in ongoing and inter-acting relations between students, curriculum, and discursive elements. Boylan (2016) upholds this perspective in their discussion of ethical practice drawing on Levinas. Liu and Takeuchi (2023), drawing on feminist new materialist theory, acknowledged "spatial and temporal configurations of pedagogy that enable or hinder racialized multilingual learners" (p. 270). And further discussed student agency as being fostered through the use of space, discourse, and the decentralization of the teachers. While many of these authors also acknowledge the impact of societal and school structures, these statements and guidance imply agency within the teacher to fix inequities within classroom spaces. We found few examples of explicit acknowledgement of systemic inequities (e.g., Bulluck, 2023; Chen, 2023; Louie, 2017)

Some studies focused on making changes to the classroom environment to better serve specific student populations. For instance, Hand (2012), Liu and Takeuchi (2023), and Bonner (2014) directed their research towards reconceptualizing mathematics pedagogical spaces to better include and serve traditionally minoritized students. These studies acknowledged the inherent deficiencies in the teaching and learning of mathematics and aimed to reposition "learners from nondominant ethnic, racial, and linguistic backgrounds" (Hand, 2012, p. 233) and "racially and linguistically minoritized students" (Liu & Takeuchi, 2023, p. 268) from being seen as learners of deficiency to being recognized for their potentials and what they can contribute.

Across other studies, there seems to be a preference for an asset-based approach to describing students by focusing on the strengths, potentials, and rich cultural values they bring into the classroom. This is evident in the way these populations are framed as not merely recipients of mathematics education but as contributors who can be active in the learning process. For instance, Matthews et al. (2021) emphasized reimagining work highlighting the need for a shift towards recognizing and harnessing the culture and excellence of black learners. Also, Takeuchi (2017) focused on the mathematical resources students of immigrant parents access at home, which suggests that we should recognize the valuable and often overlooked assets these students come into their various mathematics classrooms with as learners. Despite the intentions of some research studies to position students from an asset-based lens (e.g. Hand, 2012; Liu & Takeuchi, 2023; Matthews et al., 2021; Takeuchi, 2017), which emphasizes the strengths and potentials, some findings from our review suggested a contrasting perspective at the classroom level. Notably, Darraugh and Valoyes-Chávez (2019) drew attention to how their data showed that "students in general were viewed as being a problem." and that "teachers spoke more about the students than any other factor as being one of these challenges" (p. 431).

Conclusion

Given the history of reform practices, we analyzed the recommendations by the level of control they attributed to the teacher in enacting the recommendations and whether they accounted for any external factors. We identified two continuums of conceptualizations of the teacher in relation to equitable practice. The first continuum moves from conceptions of the teachers as an independent actor able to perform new practices to create a more equitable learning environment to a conception of teacher as in ongoing relation to the students, discourses, material environment with some level of agency. The second continuum moves from articles that largely ignored systemic and structural conditions to those that explicitly acknowledged and named systemic and structural influences and interactions. By considering the ways that MER conceptualizes equity, who it is for, and how it might be enacted, we are left to wrestle with the ambiguities within this body of research. Leaning too far toward a conception that positions teachers as in complete control creates the possibility for teachers to serve as scapegoats. Likewise, giving too much power to systemic influences can create apathy. As mathematics teacher educators envisioning a different future for students and teachers in K12 environments, questioning the taken-for-granted has propelled us to consider the multiple levels of work, and we reiterate for ourselves and the field that "equity" is a target that is always on the move in relation to our communities, commitments, and expressed and unexpressed values.

RESEARCHERS LEARNING FROM TEACHER NOTICING: THE CASE OF MR. THOMPSON

Keith R. Leatham	Shari L. Stockero	Blake E. Peterson
Brigham Young University	Michigan Tech University	Brigham Young University
kleatham@mathed.byu.edu	stockero@mtu.edu	peterson@mathed.byu.edu

In this exploratory study, we analyzed one mathematics teacher's annotations of a transcript of their teaching. The teacher was prompted to annotate the transcript for actions that contributed to or hindered their enactment of a complex teaching practice. We analyzed these noticings to explore what we could learn about the teacher's understanding of the practice, and then what these understandings revealed about our own conceptualization and communication of the practice. Our approach to analyzing teacher noticing illustrates how the study of noticing can contribute to advancing researchers' understanding not just of teachers' noticing but also of the phenomena they are noticing.

Keywords: Classroom Discourse, Instructional Activities and Practices, Research Methods, Teacher Noticing

Research on teacher noticing has typically centered around how to best support teachers in learning to notice salient features of the classroom. The majority of this work has focused on understanding the effectiveness of specific noticing interventions (Jacobs et al., 2010; McDuffie et al., 2014; Santagata et al., 2021; Schack et al., 2013; Stockero et al., 2017), but studies have also focused on comparing different methods of documenting noticing (e.g., Lee, 2021) and understanding how noticing develops (e.g., Bragelman et al., 2021; Simpson & Haltiwanger, 2017). Other studies have focused on understanding how teacher noticing interacts with factors such as teaching experience (Yang et al., 2021), mathematical knowledge, and affect (Jong et al., 2021), which allows the field to consider how such factors might need to be accounted for when supporting teachers in learning to notice. Still other research has examined the long-term outcomes of noticing interventions by focusing on the extent to which noticing skills developed in a teacher education intervention transfer to classroom teaching practice (Sherin & van Es, 2009; Stockero, 2021). In all of this work, the intent was to examine teachers' noticing in order to understand how to better support that noticing.

We encourage the field to consider, however, how the study of teacher noticing can contribute to advancing researchers' understanding not just of teachers' noticing itself but also of the phenomena they are noticing. One example of this approach is Louie et al.'s (2021) work focused on understanding anti-deficit noticing. In their work, they used a noticing interview to analyze how one teacher's noticing aligned with and differed from deficit and equitable frames from the literature. The outcome of their analysis was a conceptualization of anti-deficit noticing and what it might look like in practice. We contend that the study of teacher noticing could also help us understand other aspects of teaching. In this exploratory study, we examine how studying a teacher's noticing around his enactment of a complex teaching practice can help us better understand our own conceptualization and communication of that practice.

Theoretical Framework

Broadly speaking, our work aligns with the cognitive-psychological perspective on noticing in that we "recogni[ze] that human perception is limited and that teachers must learn to pay attention to certain instructional aspects while disregarding other aspects" (König et al., 2022, p. 3). In particular, our research has focused on supporting teachers to notice student contributions that have high potential to advance students' learning of mathematics if taken up during a lesson. We have also focused on understanding how teachers might subsequently keep students focused on jointly making sense of those contributions during a whole-class discussion by noticing and taking up ideas that support such sense-making and putting aside those that do not.

Mathematical Opportunities in Student Thinking (MOSTs) (Leatham et al., 2015) are high-leverage student contributions that are important for teachers to notice because they create an opportunity to engage the class in making sense of the significant mathematics embedded in the instance. Building on a MOST (hereafter referred to as building) is the teaching practice that takes advantage of the opportunity a MOST provides by engaging the whole class in a joint sense-making discussion focused on understanding the mathematics at the heart of a MOST. Building is "comprised of four elements: (1) Establish the student mathematics of the MOST so that the object to be discussed is clear; (2) Grapple Toss that object in a way that positions the class to make sense of it; (3) Conduct a whole-class discussion that supports the students in making sense of the student mathematics of the MOST; and (4) Make Explicit the important mathematical idea from the discussion" (Leatham et al., 2021, p. 1393).

In this exploratory study, rather than considering how to support teacher noticing, we consider what we as researchers can learn from a teacher's noticing as they reflect on their enactment of building. That is, we theorized that examining the instances a teacher identified as important in their enactment of building and how they discussed those instances in relation to a conceptualization of building that had been shared with them could advance our own understanding—both about the practice of building and how we communicate that practice to teachers. In a sense, we extend van Es and Sherin's (2002) notion that noticing entails "making connections between the specific of classroom interactions and the broader principles of teaching and learning they represent" (p. 573) to consider how researchers can use the connections a teacher makes in their noticing as a venue for advancing their own understanding.

Methods

As part of a larger research project, twelve teacher-researchers (TRs) worked with the authors as they conceptualized the teaching practice of building by enacting the practice in their classrooms and then allowing the authors to analyze those enactments. Mr. Thompson, the subject of this case study, was one of the twelve TRs. At the time of the study, he had been teaching junior high school mathematics for about 20 years, had been recognized for his excellent teaching, and worked part-time as an instructional coach for his school district. Following the final two enactments of the mini-tasks, Mr. Thompson was provided a transcript of each enactment and asked to annotate instances where his actions either contributed to or got in the way of enacting an element of building.

Mr. Thompson provided 24 annotations across two different enactments of building. Given the prompts for the annotations, we viewed them as instances of noticing with respect to the practice of building and used them as the unit of analysis to answer the research question: *How can teachers' noticing help researchers refine both their theorization of a teaching practice and how the practice is communicated to teachers?* Looking at each annotation in the context of what happened during the enactment, the researchers determined whether what Mr. Thompson noticed provided evidence of understanding, partial understanding, or lack of understanding of building. After deciding what a given “noticing” told us about Mr. Thompson’s level of understanding, we identified what contributed to this level of understanding.

Results

There were two primary categories of what we as researchers gained from our analysis of Mr. Thompson’s noticings: (a) an expanded conceptualization of building, and (b) an expanded understanding of how to develop teachers’ understanding of building. We use examples of Mr. Thompson’s noticings to illustrate each of these categories.

Expanded Conceptualization of Building

At times our analysis of Mr. Thompson’s noticings with respect to building prompted us to consider aspects of the practice that we had never considered. At other times our analysis helped us to better understand aspects of the practice of which we were aware, but about which we still had uncertainties. In such situations, the TRs were using their classroom expertise to try to enact a broad vision of the practice and their attempts allowed us to further conceptualize what it would take to enact moves that would align with our own vision of the practice. For example, at one point during Make Explicit Mr. Thompson asked the class, “Now we’ve talked about this year, what we call the value that you plug in for x, it has a name. Do you remember, what’s it called? What do we—what do we call the possible things you can plug in for x?” He attached the following comment to his transcript: “Not contributing very well (Make Global): As soon as I attempted to have students consider the understanding about this specific problem that has now been shared things went awry.” We still had many questions at this point about the kinds of moves a teacher might make when trying to scaffold the class toward articulating the mathematical point that could be gleaned from their prior sense making about the MOST. Mr. Thompson’s attempt to provide such scaffolding, the difficulties that ensued, and his own noticing of those difficulties, allowed us to better understand the nature of the teachers’ scaffolding at this point in building. In particular, we realized the complexity of determining the extent to which students themselves might be positioned to articulate the mathematics and the extent to which the teacher might need to do some of that work.

Expanded Understanding of How to Develop Teachers’ Understanding of Building

At times our analysis of Mr. Thompson’s noticings with respect to building confirmed our conceptualization of the practice. In such instances we often gained insights into our own efforts to develop Mr. Thompson and his fellow TRs’ understanding of building in preparation for their enactments. There were times when we had been explicit in our work with the TRs about a given aspect of building and yet Mr. Thompson’s noticing seemed to provide evidence of incomplete understanding of that aspect. There were other times when his incomplete understanding was likely due to a critical oversight on our part. That is, while the aspect of building was mutually understood by the research team, it had remained implicit in our work with the TRs. Finally, several of Mr. Thompson’s noticings with respect to building revealed how some important routines from his typical task-based teaching hindered his ability to enact our conceptualization of the practice. For example, at the beginning of the Conduct element of one enactment, Mr. Thompson elicited a contribution that was clearly related to making sense of the established MOST. The protocol in these situations was to invite the class to consider how this contribution might help them to further make sense of the MOST. Instead, Mr. Thompson set aside the contribution and collected contributions from five additional students. He attached the following comment to the section of the transcript where he elicited this collection of contributions:

> I'm not sure that this is a real nice fit with the framework for MOSTs. The closest fit might be Conduct? Anyway, I do think it is helpful for there to be a bit of sharing like this to occur….a chance for some initial thoughts and rough draft thinking to get out there.

We see here an awareness that this collecting rather than connecting a contribution to the MOST at the beginning of Conduct likely did not fit the conceptualization of building Mr. Thompson was enacting. Nevertheless, he felt it was important to deviate in this way. We realized in analyzing this noticing (and others that were similar) that we needed to pay more attention to teachers' typical teaching routines, considering which aspects of those routines might be valuable to activate during building and which might need to be "deactivated" for the sake of building. In this case, Mr. Thompson seems to have assimilated building into his prior practice rather than accommodating that practice to create new space for the building practice.

Discussion and Conclusion

In this exploratory study, we focused on analyzing the noticings from a single teacher. Data from the larger project will allow us to analyze noticings from a dozen teachers. We suspect that analysis of the larger data set will provide additional ways teacher noticings can be used to develop researchers' conceptualization and communication of a teaching practice. In addition, we might learn which of these ways are more common or more useful for these purposes.

The noticing literature has tended to focus on whether teachers are noticing what we, as researchers or teacher educators, want teachers to notice. And for good reason. It is important that teachers develop the skills for noticing certain things over others (e.g., the substance of students' mathematical ideas over students abilities to articulate those ideas). The goal of such research is to better understand how to help teachers develop those noticing skills. The results of this exploratory study demonstrate how teachers' noticings can provide insight into their understanding of the phenomenon they are noticing which, in turn, can provide insights into the phenomenon itself. Mr. Thompson is an experienced teacher with substantial noticing skills. As researchers we were able to leverage that noticing to help further our understanding of building.

Although it is certainly important that the field of mathematics teacher education continue to seek ways to help teachers improve their noticing skills, it also seems important, particularly when working with inservice teachers, to position them as important resources from whom we as researchers and teacher educators can learn (Freeburn et al., 2024). Mr. Thompson is a skilled and accomplished teacher who engaged enthusiastically in our research and demonstrated a desire to learn from the experience as well as help us to learn. In fact, he expressed on numerous occasions that his work with us was one of the best professional development experiences he had had. Thus, when his noticings revealed a mismatch in understandings of the practice of building it in no way reflected poorly on him as a teacher or learner. When his noticings revealed a difference, we were able to hone in on that difference and consider whether and to what extent the difference might matter. His noticings also provided ample opportunities for us to reconsider how we communicate the building practice to others. Perhaps there is a lesson in this work for all of us as mathematics teacher educators and mathematics education researchers: Let us use the expertise of the students and teachers with whom we work to shine the light on ways we can improve, to evaluate our own work more so than theirs.

Acknowledgments

This research report is based on work supported by the U.S. National Science Foundation (NSF) under Grant Nos. DRL-1720410, DRL-1720566, and DRL-1720613. UNDERSTANDING ONE MIDDLE SCHOOL'S MATHEMATICS INTERVENTION CONTEXT

Erica N. Mason
University of Illinois Urbana-Champaign
enmason@illinois.edu

Camille Griffin
University of Illinois Urbana-Champaign
cgriffi5@illinois.edu

Keywords: Curriculum, Middle School Education, Teacher Beliefs

Mathematics intervention is an often under-investigated aspect of mathematics instruction. Mathematics intervention is generally understood to be supplemental instruction for students who require "increasingly intensive instruction matched to [students'] needs" (RTI Action Network, n.d.) and is often conceptualized through the lens of special education (e.g., National Center on Intensive Intervention, n.d.). When general education teachers are responsible for mathematics intervention instruction, they may especially lack guidance about how to support a range of learners in supplemental instructional contexts (e.g., Perry et al., 2015). The purpose of this study was to understand how general education teachers at one middle school thought about and enacted mathematics intervention curriculum and instruction.

Context, Participations, and Data Collection

Unity Middle School (a pseudonym) is in a small Midwestern city. In 2021–2022, the state designated Unity as an "on watch" school since it was in the lowest-performing 5% of all schools in the state. The school has almost 900 students, the majority of whom are Black or Hispanic (59.9%); 19% of Unity students receive special education services.

This research team has been co-designing research activities with Unity since the 2021–2022 school year. In spring 2022, the mathematics instructional coach and the two authors of this paper, co-designed this investigation. Driven by the instructional coach's interest in reimagining the intervention space, we decided to first collect data about the current landscape of intervention instruction—what was happening in classrooms and how teachers talked about mathematics intervention itself and in relation to core instruction.

There were six voluntary participants—four mathematics teachers and two science teachers; five participants taught one section of mathematics intervention and one participant was the school's mathematics interventionist. Using a co-designed observation tool, each team member conducted three, 50-min classroom observations in each teacher's classroom. Each teacher also participated in one, 60-min semi-structured audio-recorded interview. The instructional coach collected one-third of the classroom observation data; the first author conducted all interviews.

Preliminary Findings and Possible Implications

As part of our research team, the instructional coach has been coding and analyzing data with the paper authors. Preliminary findings reveal that the majority of teachers in this study viewed remediating basic skills as the purpose of intervention and believed that core instruction and intervention should be more different than similar. These articulated beliefs were consistent with observational data, which revealed intervention curriculum and instruction aimed at below-grade-level content and focused on "procedures without connections" (Smith & Stein, 1998, p. 346). Our co-analysis will conclude in the summer of 2024. Findings from this project can inform how schools and districts conceptualize mathematics intervention and at what efforts they might aim for resources.

DEPRIVITIZING INSTRUCTIONAL PRACTICE USING INSTRUCTIONAL CIRCLES

Matthew Melville
Purdue University Fort Wayne
Mdmelvil@pfw.edu

Betsy Berry
Purdue University Fort Wayne
Berrys@pfw.edu

Keywords: Professional Development, Mathematical Knowledge for Teaching, Teacher Knowledge.

Background

The effectiveness of professional learning opportunities depends on their content and how the content is facilitated, *what* teachers' study, and *how* they study it (Van Es et al., 2014; Kazemi et al., 2008; Kennedy, 2016). In my study, I focus on the way in which professional learning opportunities are facilitated, on how teachers are engaged in studying teaching.

Instructional circles are somewhat informal gatherings of small groups of teachers to discuss instructional practices (Melville, 2022). These circles seem oriented to analyzing specific practices and sharing advice rather than collectively designing a lesson or learning about a specific instructional method. Some local teachers and educators voluntarily attend instructional circle sessions that usually meet once every few months. Japanese teachers have described them as important professional learning activities that serve an essential function quite different from lesson study. This session will look at how instructional circles support the development of teachers' ability to critically discuss improvements to instructional practices enabled through the deprivitization of their practice.

U.S. teachers often have a difficult time deprivitizing their practice among other professionals (de Jong et al., 2019). Often when teachers do deprivitize their practice, three main types of interactions occur: giving praise, giving advice, and (uncommonly) engaging as challenging colleagues (Males, 2009). Engaging as challenging colleagues is less about critiquing the professionalism of the teacher but working together to improve the instructional practices found within a lesson. Thus, taking the focus from the teacher and put onto *teaching* (Hiebert & Grouws, 2007). This session will present how instructional circles are able to help teachers deprivitize their practice and engage as challenging colleagues to improve their instructional approaches to teaching.

Methods and Results

An ethnographic approach was taken to learn about how instructional circles engage U.S. teachers in deprivitizing their practice in a community of learners. We focused specifically on what teachers brought to the instructional circle, what they taught, and then how they felt the process beneficial for their learning. We did participant observations, interviews, artifact collection, and journaling.

So far, we have found that instructional circles addressed the need for a safe place for teachers to share their practice with others. In other words, teachers felt comfortable deprivitizing their practice to allow for high-quality discussions about the improvement of instructional practices as identified by the teachers themselves. Teachers were able to develop a community of learners through their focus on improving a specific aspect of the lesson plan. For example, one teacher was trying to increase student engagement and asked the other teachers for their input. Teachers offered advice, but the focus was more detailed through the lens of trying to accomplish the learning goals.

CONFERRING TO ELICIT AND ADDRESS EPISTEMOLOGICAL OBSTACLES

Corinne Mitchell
Virginia Tech
cmitchell8@vt.edu

Ben Bruncati
Virginia Tech
bbruncati23@vt.edu

Rachel Arnold
Virginia Tech
rlongley@vt.edu

Epistemological obstacles (EOs) are cognitive challenges students experience that persist despite research-based instruction (Brousseau, 2002; Sierpińska, 1987). Informed by prior research, The Proofs Project (NSF DUE-2141626) designed and implemented instructional materials that elicit and address these obstacles in transition to proof (TTP) courses through cycles of small group exploration and whole-class discussion. We investigate the discursive routines of one teacher as she elicited and addressed EOs around transforming conditional statements and we discuss implications for teaching with this theory.

Keywords: Instructional Activities and Practices; Classroom Discourse; Reasoning and Proof

Teaching in ways that elicit meaningful participation in classroom mathematical discourse has become a primary objective of modern mathematics education (NCTM, 2014; Speer & Wagner, 2009), but developing these practices is known to be challenging for teachers (Andrews-Larson et al. 2019, Bishop et al., 2020, Henderson et al., 2011). In K-12 education, researchers who have investigated these practices in whole-class discussions have found that features like responsiveness and intellectual demand can support students' learning (Bishop, 2021) as well as their mathematical attitudes and identities (Boaler & Greeno, 2000; Wagner & Herbel-Eisenmann, 2008). At the undergraduate level, Mesa & Cheng (2010) illuminated some of the ways instructors' discursive moves shaped students' agency in calculus and introductory courses like college algebra. Building on this work, we wondered how teachers in transition-to-proof (TTP) courses might use student-thinking to drive mathematical discussions, given the "didactical gap" between the mathematics of K-12 education and proof-based mathematics (Balachef, 2010).

To bridge this gap, students must take up the rigorous logical reasoning and communication practices of mathematicians in a context with distinct epistemic and heuristic commitments from computation-based courses, like formality and abstraction (Melhuish et al., 2022; Lew & Mejía-Ramos, 2019; Sfard, 2014). They must also adapt to higher demands for conceptual understanding and autonomous problem-solving as compared to prior math courses (Selden, 2012; Tallman et al., 2021). In addition to these difficult shifts in mathematical practice, there are unique cognitive challenges students encounter in TTP (Dubinsky, 1990; Harel, 2002; Stylianides et al., 2007). Working with logical implications (LIs), or conditional statements, is one such challenge (Arnold et al., in press, Antonides et al., in press). Students may erroneously interpret conditional statements as biconditional (Girotto, 1991) and conflate implications with their converse (Duran-Guerrier, 2003) or inverse (Knuth, 2002). Further, students struggle to utilize the equivalence of a LI with its contrapositive (Dawkins & Hub, 2017) and its disjunction (Hawthorne & Rasmussen, 2015). Brousseau and Sierpińska (1987) conceptualized these necessary challenges as *epistemological obstacles* (EOs): "cognitive challenges that persist even in response to research-based instruction," perhaps due to teachers circumventing them, rather than addressing them (Kokushkin et al., 2023, p. 1).

Considering the challenges students face in TTP from both a discursive and cognitive perspective, it would be edifying to understand how teachers might elicit students' thinking around these EOs and address them during whole-class discussion. We investigate one teacher's routines in the context of eliciting and addressing EOs around logical implication in an undergraduate TTP class.

Theory and Methods

The theory of epistemological obstacles emphasizes the importance of eliciting and exploring students' thinking through questioning, probing, and challenging tactics aimed to bridge students' informal ideas with formal reasoning, or, as Bishop (2021) framed it, teaching in ways that are *responsive* to students' thinking and require *intellectual work* from both teacher and students. These discursive routines enacted in classroom interactions are related to Munson's (2019) *conferring* interactions in which the teacher elicits and probes student thinking and then responds to what has been uncovered (Munson, 2019, p. 2). We investigate the ways these discursive modes arise in a TTP class with attention to specific EOs entailed in the lesson, especially because the research-based instruction we study aims to "elicit and address students' experience of epistemological obstacles head-on" (Arnold & Norton, 2022). Reasoning about hidden quantification (Qh) is one EO from prior investigations particularly relevant to this study (Norton et al., 2023).

The data in this study were collected as part of a larger project focused on addressing cognitive and instructional challenges in TTP. The data consist of one 50-minute class video of a TTP course taught at a large, land-grant university in the eastern United States by the third author, Dr. A. To begin data analysis, the first author created an initial transcript from the class video using Otter.ai, then edited the transcript by hand for accuracy. Episodes of whole-class mathematical discussion were identified for analysis; discussions that were not mathematical in nature (i.e., about assignment due dates) were not analyzed. Within each episode, several related verbal exchanges between teacher and students occurred. Here, an exchange is comprised of a corresponding initiation, response, and follow-up. We coded each of the teacher's follow-ups for intellectual work and responsiveness, using the following coding scheme from Bishop (2021). Intellectual work determined whether the teacher's move requested information from students (demand) or provided information (give). For both types, low-level and high-level moves are distinguished. Several additions to categories were developed to accommodate the mathematical activity in TTP classes. For instance, Bishop's (2021) framework did not account for requests to evaluate logical statements at a particular value in the universal set because the subjects of her study were not TTP students. However, students at this point in the course could be expected to make this calculation routinely, so responses of this type were coded as Low demand. Similarly, connecting an idea to formal notation or logical structures entails high intellectual work for students, so responses of this type were coded as either High give or High demand depending on the response type.

Bishop's (2021) responsiveness moved beyond conceptualizations of responsiveness as binary—i.e., teacher interactions as either responsive or not (see Munson, 2019)—to investigate responsiveness as a continuum describing "the *extent* to which student ideas are elicited, incorporated, and built on" in class conversation (p. 12), like Jacobs and Empson (2016). Responsiveness has three levels: Low or No responsiveness, Medium, and High, depending on whose idea became the focus of the response. Low or No responsiveness follow-ups include evaluating, revoicing, acknowledging, or making a related statement or question to a student's idea. Medium-level follow-ups involve corrective moves, co-opting student responses to make a point, or incorporating basic information provided by students to supplement the teacher's response. The last level is subdivided into levels High I and High II depending on whose reasoning was displayed in the follow-up: the teacher's or the students', respectively (Bishop, 2021, p. 478-79).

Because our curiosity lies at the nexus of Dr. A's eliciting and addressing moves around EOs and their function as responsive or intellectually demanding speech, we attended to shifts in responsiveness and intellectual demand within Dr. A's follow-ups. We expected Dr. A's responses to shift while eliciting and addressing an EO because eliciting students' thinking around EOs necessarily makes demands of students whereas addressing EOs requires both responsiveness to students' thinking and intellectual work from the teacher.

To identify these shifts, we collected the codes for all exchanges in class discussion and looked for when one or more codes changed across exchanges. For instance, we noted shifts from Medium responsiveness to High I or from High demand to Low demand. We also identified, and member-checked with Dr. A, the EOs underlying the mathematical content discussed within each segment to note their possible connections to these shifts. A shift across exchanges became a routine if a) it was repeatedly enacted across the lesson and b) a feature of an EO (e.g., quantification, or Qh) was being discussed. Note that we do not view these shifts as entailing a change in the quality of a response; a decrease in responsiveness or intellectual work does not necessarily imply a lowered quality of teaching. In contrast, a shift from High II to High I responsiveness meant the follow-up was (neutrally) less responsive because the teacher's thinking, rather than the students', drove the response—an essential move for refining and formalizing students' thinking.

Results

We present a discursive routine found in Dr. A's class that is characterized by tandem shifts in the intellectual give and demand of Dr. A's responses to students: as intellectual give increases, intellectual demand decreases. We refer to this routine as C*onferring to Elicit and Address*, adopting the terminology of Munson, (2019). This routine arises in 12 out of the 25 exchange pairs we analyzed. The remaining exchange pairs either did not exhibit shifts that were repeated multiple times (failing our first criterion) or did not address an EO (failing our second criterion). We present a vignette displaying this routine and discuss Dr. A's moves below.

Vignette: Truth sets are subsets

Prior to this vignette, students had been working together in small groups to create an Euler diagram depicting the true statement P implies Q, denoted P → Q.

Dr. A: Alright, let's come back together. What should the relationship between the truth sets P and Q be, in the event that the implication P implies Q is actually true? [calls on Alex] Yeah?

Alex: P should be the smallest circle within a larger circle, Q.

Dr. A: P should be inside - the circle for P should be inside the circle for Q, what do you all think? What's another way that we could describe that relationship? [calls on Joe] Yeah?

Joe: P is a subset of Q.

Dr. A: Yeah, P is a subset of Q, so we want to make sure that we're seeing that in our picture. [drawing the Euler diagram] So this one should be Q and then the one on the inside should be P. And we said that means that P should be a subset of Q.

There was a notable shift in Dr. A's intellectual work across her responses to Alex and Joe. After Alex described her group's diagram, Dr. A revoiced the contribution and asked, "what do you all think? What's another way that we could describe that relationship?" This was a High intellectual demand response, requesting that the class make sense of Alex's statement and then probing to elicit a more formal version of it. This was also High II responsiveness because it placed Alex's contribution at the center of discussion.

When Joe articulated the correct subset relationship, Dr. A's response shifted from High to No demand, instead giving information to students in the form of a summary of the discussion. The shift in intellectual work occurred precisely when a student had attended to the subset relationship between the truth set of P and the truth set of Q. This centered on the Qh EO because it attended to the sets of values for which each statement is true and the relations between them. Rather than pressing Joe for further explanation or requesting other students to make sense of his thinking, Dr. A connected the two contributions herself to summarize the main ideas and drive the discussion toward the next topic. This move also contained a shift in responsiveness, from High II to Medium because Dr. A was revoicing Joe and Alex's statements.

Discussion and Conclusion

In analyzing Dr. A's implementation of curriculum materials designed to elicit and address EOs in her TTP class, we characterized the ways instructors might elicit and support high quality student thinking in classroom discourse while maintaining mathematical rigor. By attending to Dr. A's intellectual work and responsiveness, we identified a clear discursive pattern, called Conferring to Elicit and Address, in which Dr. A used high-demand responses to elicit students' thinking about a particular EO and then address it using high-give moves. This routine aligns with the theory of EOs that informed the larger project as it ostensibly elicited students' initial understandings and ways of reasoning about the task, creating the need to address the EOs they experienced. In turn, Dr. A's intellectually giving moves appeared to refine students' ideas into more formal mathematical notation and reasoning. By hinging on key aspects of students' experience with EOs, this routine emphasizes the production of intellectual need (Harel, 2013) in discourse, so that the teacher's giving moves organically impart mathematical disciplinary practices as useful tools that empower students to formalize their own ideas.

EOs are not limited to the context of TTP; practitioners are aware of a wealth of cognitive challenges in mathematics that persist despite best practices. To orchestrate mathematically rich class discussions on all grade levels, teachers can design in advance their Conferring to Elicit and Address routines by drawing explicit connections between features of the task, possible student contributions, and the EO(s) they've identified in their lesson. This supports the effective enactment of the intellectually giving and demanding responses necessary to address EOs when Conferring to Elicit and Address. Finally, because responsiveness and intellectual work are about whose thinking is on display and whose ideas drive mathematical discussions, great care must be taken in utilizing these discursive structures in ways that support equitable participation for students who have been historically marginalized in mathematics. Although we have identified one discursive routine to address cognitive challenges, more work is needed to understand the ways such discursive routines might support students in terms of equitable participation, access, and affect. Additionally, future research should investigate the discourse of a variety of teachers in TTP courses to further explore the consistency of this routine across contexts.

ELEMENTARY MATHEMATICS SPECIALIST COACHES' STRATEGIES FOR GROUPING STUDENTS FOR INSTRUCTION BASED ON EVIDENCE IN ARTIFACTS

Kimberly Morrow-Leong
George Mason University
morrowmath@gmail.org

When elementary mathematics specialist coaches observed written artifacts of student thinking, they organically created groupings and pairings of students. Their interpretations of student work reveal two broad categories for meaningfully grouping students for instruction. One grouping strategy subjectified students, rendering a global evaluation of their performance. Mathematizing strategies were based on the evidence of mathematical thinking shown in students' work. Both strategies have the potential to inform instruction, but the mathematizing grouping strategies may have more potential to support mathematical instruction, while subjectifying strategies may pose threats to student identities as learners of mathematics. The noticings and spontaneous groupings described in this study illustrate different approaches to forming working groups that may serve a broader variety of instructional goals.

Keywords: Teacher Knowledge, Assessment and Evaluation, Instructional activities and practice, Elementary Mathematics Specialists

The formation of student groups is essential for promoting productive classroom discourse and allowing students opportunities to learn from each other's mathematical thinking. This report focuses on coaches' observations, specifically related to their strategies for grouping students for instructional purposes. The results suggest that a binary choice (success or non-success) for grouping students is simplistic.

What coaches noticed in student work (Sherin, Jacobs, & Philipps, 2011), how they interpreted it, and then responded raised issues of mathematical identity, reflected in the participants' utterances (Haye, et al., 2011) as they described students' work. In order to make sense of the utterances participants used to talk about students and their work, the identity perspective shared by Heyd-Metzuyanim and Sfard (2012) was invoked. *Mathematizing* describes the utterances about objects of mathematics– the symbols, the representations, etc. Utterances that address the doer of mathematics are referred to as *subjectifying* language and threaten to fix students' identity in mathematics (Aguirre, Mayfield-Ingram, & Martin, 2013).

Four licensed teachers serving as coaches were invited to observe and reflect on 13 written student work samples on a task. The elementary mathematics specialist coaches all independently and spontaneously used their investigation of the student work samples to plan for instructional groups. Using Heyd-Metzuyanim and Sfard's (2012) framework, their utterances were coded as *mathematizing* or *subjectifying.* Two broad categories emerged. In one category, the coaches generalized student performance and formed groups based on global performance. For the second category, the coaches' utterances reflected the mathematizing category, referring to the mathematics present in the student work. Coach utterances that focused attention on details of mathematical thinking fore-fronted student thinking to steer instructional group creation.

A coach can leverage language cues to draw attention to grouping strategies, either by attending to their own language or noting the language of their client teachers. The coach can then use this information to constructively guide the teacher client to create working groups, remedial groups, or other groups designed to maximize students' opportunities to learn. Future study might examine the noticings of novice and experienced teachers

REIMAGINING MATHEMATICS CLASSROOM DYNAMICS: EXPLORING PLACE AND SPACE AS CONTEXTUAL VARIABLES THROUGH THE LENS OF MATHEMATICS TEACHER EDUCATION (MTES)

Hillary Omoze Ongoyo
Purdue University
homoze@purdue.edu

Abigail Erskine
Purdue University
aerskin@purdue.edu

This study explores how place and space influence mathematics classroom interactions, focusing on insights from Mathematics Teacher Educators (MTEs). Through geospatial lenses, we investigate how teachers' and students' accessible identities and positioning shape teaching practices, student mathematics learning, and specific aspects of knowledge generation and flow within the mathematics classroom. Employing semi-structured interviews with MTEs, we unveil the influence of geographic and non-geographic factors on mathematics classroom dynamics. Our findings offer practical insights for educators striving to create inclusive learning environments. Aligned with the conference theme of envisioning the future of mathematics education, this research provides a fresh perspective on the crucial role of place and space in shaping the dynamics of mathematics education.

Keywords: Place, Space, Student Mathematics Learning, Mathematics Teacher Educators

In this research, we employ dialogic lenses to illuminate the complex dynamics shaping interactions within mathematics classrooms. Our focus is unraveling the positionalities and identities available to teachers and students during mathematical lessons. Specifically, we delve into the influence of place (the origins of students and teachers) and space (the characteristics of the learning environment) on the identities accessible to individuals in their mathematics classes (Butler & Sinclair, 2020; Tate, 2008). Drawing on the works of Tate (2008), Masingila (1993), and Rubin (2007), we acknowledge the significant influence of students' out-of-school experiences and discourses on their prior knowledge, engagement, and experiences with the conventional mathematics classroom. Furthermore, Leyva (2021) underscores how institutional ideology, culture, and beliefs shape students' mathematical experiences within diverse classrooms, varying across institutions, school districts, and geographical contexts. (Anderson, 2014; Hogrebe & Tate, 2012).

Central to this argument is the assertion that a teacher's proficiency in teaching practices is linked to the identities they embody and the identities accessible within the classroom setting (Darragh, 2006; Omoze et al., 2024; Simon, 2012). Simultaneously, student learning, classroom interactions, and the generation and sharing of knowledge are profoundly influenced by student identities, positioning, and discourses permitted or restricted by the teacher during lesson exploration (Andersson & Wagner, 2019; Robin, 2007). However, these dynamics operate within the constraints and influences of place and space factors, delineating the geographic and non-geographic realms of the learning institution, as well as the diverse backgrounds of teachers and students (Leyva, 2021).

The primary aim of this study is to reposition Mathematics Teacher Educators (MTEs) within the context of mathematics classroom interactions. By eliciting reflections on their past experiences, MTEs offer valuable insights into how place and space as contextual variables can be effectively addressed to enrich students' mathematical conceptualization. This study focuses on the strategies and approaches that can mediate the influence of place and space, ultimately enhancing students' learning experiences. Through in-depth interviews and leveraging the expertise of MTEs, this research endeavors to illuminate the significance of space and place in the mathematics classroom, contributing to the existing body of knowledge in mathematics education and offering practical implications for educators striving to create inclusive and supportive learning environments. The central research question guiding this investigation is: How do Mathematics Teacher Educators (MTEs) perceive place and space as contextual variables in mathematics classroom interactions?

Conceptual Framework

In recent decades, there has been a notable shift in research toward employing geospatial lenses to analyze and critique mathematical learning outcomes, diversity, equity, and inclusion in mathematics education (Larnell & Bullock, 2018; Rubel & Nicol, 2020). Many researchers in the field of geospatial analysis assert that place and space significantly influence students' mathematics classroom experiences and, consequently, their learning outcomes, highlighting the growing recognition of their impact on educational dynamics (Hogrebe & Tate, 2013; Holland et al., 1998; Tate, 2008). Understanding the complex relationship between geospatial factors and students' identities is paramount for fostering a holistic educational approach (Andersson & Wagner, 2019; Bishop, 2012; NCTM, 2000).

Socio-spatial Framework

Larnell and Bullock's (2018) Socio-spatial Framework (SSF) provides a comprehensive perspective that outlines the geographical, social, and temporal dimensions of the mathematics learning environment. Although Larnell and Bullock originally intended to develop theoretical lenses for understanding urban mathematics education, we focus on the human and critical geography aspects of their framework to examine how mathematics teacher educators (MTEs) perceive place and space in their practices. Specifically, we are using the SSF to interpret learning environments, including the planning and organization of mathematics classrooms. For example, they explain that "by socio-spatial dialectic, we mean that the social significations and spatial considerations necessarily interact to determine meaning for urban contexts" (p. 48). Suggesting that the geographical characteristics of a small town or city, combined with a particular community's cultural beliefs and practices, create a meaningful place. This meaningful place then contributes to shaping and defining local discourses, language, out-of-school mathematical experiences, and embodied identities for students and educators.

The SSF highlights the complex relationship between geographical factors, social influences, and temporal dynamics within mathematics classroom settings. The spatial dimension underscores the importance of understanding the spatial context of mathematics learning, including geographical contexts, classroom arrangement, resource accessibility, and organizational layout (Hogrebe & Tate, 2013; Tate, 2008). The social dimension acknowledges the profound impact of sociocultural contexts on students' engagement with mathematical concepts, emphasizing culturally responsive teaching strategies and diverse perspectives within the learning environment (Ladson-Billings, 1995; Gay, 2018; Wachira & Mburu, 2019). Finally, the temporal dimension delves into the dynamic nature of learning experiences over time, highlighting the continuous process of knowledge construction and the enduring influence of past experiences on student learning outcomes (Larnell & Bullock, 2018).

Place as a Contextual Variable

Place, as a contextual variable in education, refers to the geographical location endowed with unique non-geographical characteristics that shape individuals' experiences, perspectives, and interactions within a specific setting (Butler & Sinclair, 2020). It encompasses the physical aspects of a particular location, including its geographical coordinates, geopolitical demarcations, and imaginary boundaries (Angweh, 1987; Massy, 2009; Tate, 2008). The geopolitical and imaginary boundaries can include school districts, urban, suburban, rural areas, states, countries, or even continents, each with distinct landmarks, physical features, and cultural attributes.

The meaning attached to a place goes beyond its geographical coordinates and is derived from factors such as the historical, cultural, or social attributes associated with that place (Angweh, 1987). The place is not solely defined by its physical characteristics, but also by the unique characteristics that shape individuals' perceptions and understanding of the world (Butler & Sinclair, 2020; Holland et al., 1998; Weiland & Poling, 2022). For example, a person living in Greenland, where snow is prevalent, may have developed specific ways of interacting with and understanding the world in terms of snow, while someone living in the Sahara Desert, experiencing consistently high temperatures, may perceive the world in terms of sand dunes. These different environmental contexts significantly influence individuals' experiences, perspectives, and knowledge construction.

Space as a Contextual Variable

Space extends beyond the physical boundaries of a classroom to encompass the broader educational landscape. The spatial distribution of schools, educational resources, and infrastructure within a community or district can significantly influence students' access to quality education (Hogrebe & Tate, 2012). Disparities in spatial distribution and resource allocation can create inequalities in educational opportunities, affecting students' learning outcomes and academic achievement (Lee & Ready, 2009). Therefore, understanding the spatial dimensions of educational environments is crucial for addressing educational inequalities and promoting equitable access to education.

Place and space contextual variables play distinct roles in shaping and influencing students' mathematics learning experiences (Butler & Sinclair, 2020). Understanding these differences is essential, as they highlight unique contextual variables within the educational discourse. Recognizing these distinctions helps educators navigate the specific variables of the mathematics classroom, thereby enhancing their teaching practices and fostering inclusive learning environments

Methods

Context and Setting

MTEs' extensive knowledge and insights, gained from teaching mathematics across diverse educational environments, provide valuable context for understanding the spatial and situational dimensions of mathematics education. Their varied experiences navigating different classroom settings and encountering diverse student populations enrich the exploration of how space and place shape instructional practices and student learning outcomes. Moreover, MTEs are uniquely positioned to interact with both preservice and in-service educators, contributing to the study's depth. The research captures the diverse range of MTEs' conceptualizations of space and place through semi-structured interviews, shedding light on the factors influencing instructional decisions and student engagement (Jacobs et al., 2010).

Data Collection and Analysis

The study involved semi-structured Zoom interviews with Mathematics Teacher Educators (MTEs) from a mid-western US university. Purposeful sampling ensured diverse faculty and graduate student perspectives. Interviews explored MTEs' views on place and space in mathematics classrooms and their impact on teaching. Audio recordings were transcribed, deidentified, and securely stored. Data analysis used Saldaña's (2014) dual-engagement strategy and Braun and Clark's (2008) thematic analysis, identifying themes through narrative inquiry. Descriptive coding highlighted key elements, addressing challenges in interpreting distinctions between "place" and "space" with insights from Poland and Pederson (1998).

Findings and Discussion

In response to our research question, MTEs perceive place and space as integral components shaping mathematics classroom interactions, and their beliefs underscore the transformative influence of these perceptions on instructional practices (Rubel & Nicol, 2020).

For instance, one MTE participant illuminates the distinction between "place" and "space," defining "place" as the physical environment encompassing geographical factors, student backgrounds, and the educational setting. In contrast, "space" is viewed as the classroom's physical layout, including seating arrangements, technology, and teaching tools. This definition aligns with Larnell and Bullock's (2018) socio-spatial framework's spatial dimension, focusing on physical location and background, a notion supported by Gravemeijar (1994) and Masingila (1993). It also resonates with Hogrebe and Tate's (2012) concept of geographical locations. However, their vision of space is confined to classroom design, including desk arrangements and teaching tools (Rubin, 2007).

> "Place to me is all about where you're located, where you're teaching, where your kids are coming from, and where they're at. Space, on the other hand, is the actual layout of the classroom, how you set up your desks or tables, how you use technology and various teaching tools."

Another perspective offered by participants defines space as the environment, which could be sociocultural, sociopolitical, or intellectual. According to one participant, "Space is more about kind of the social and intellectual environment that you're in." This broader conceptualization emphasizes the influence of the sociocultural and intellectual atmosphere on the learning environment, aligning with Larnell and Bullock's (2018) social signification dimension (Leyva, 2021; Rubin, 2007).

> "Space is more about kind of the social and intellectual environment that you're in."

The significance of cultivating an environment that allows students to personally connect with mathematics is underscored by MTEs, echoing Gravemeijer's (1994), Masingila's (1993), and Omoze et al. (2024) observations that student backgrounds impact how they interpret mathematical problems. They stress the importance of allocating time for individual or group work, enabling students to share insights with their peers (Yackel & Cobb, 1996).

Conclusion and Implication

MTEs play a pivotal role in advocating for pedagogical practices that foster inclusive and effective learning environments grounded in the understanding of place and space variables. Their insights highlight the need to address the challenges posed by fixed classroom layouts and promote flexibility to enhance student engagement and collaboration. As MTEs continue to navigate the complexities of mathematics classroom interactions, their contributions serve as guiding beacons for creating dynamic and equitable learning spaces. This study highlights the critical role of MTEs in shaping diverse, equitable, inclusive, and effective learning environments. The findings underscore the need to address challenges posed by fixed classroom layouts, promoting flexibility to enhance student engagement and collaboration.

EXPLORING HOW EARLY-CAREER MATHEMATICS TEACHERS USE AN INTERACTIVE/DIALOGIC APPROACH TO COMMUNICATION

Annika Perlander
University of South-Eastern Norway
annika.perlander@usn.no

Annica Andersson
University of South-Eastern Norway
annica.andersson@usn.no

Dave Wagner
University of New Brunswick
dwagner@unb.ca

Inviting students to participate in mathematical dialogues could help them develop a better conceptual understanding. For classroom dialogues to be effective, teachers' communicative approaches must be consistent with the activity's purpose and create support for students to participate in joint meaning making. This paper gives examples of how two early-career teachers use an interactive/dialogic communicative approach to invite and engage students in dialogues. We describe how teachers invite students to participate in meaning-making processes of mathematical content in three different situations over a series of mathematics lessons—to activate previous knowledge, to contrast students' solutions and to work on problem-solving tasks. In the ongoing analysis, we ask how these types of situations can be related to teaching purposes and the progression of students' understanding of the mathematical content.

Keywords: Communication, Classroom Discourse, Instructional Activities and Practices

Research show that participating in conversations about mathematics promotes students' understanding of mathematical concepts and the development of a formal mathematical language (e.g. Barwell, 2016; Schleppegrell, 2007). For such conversations to be successful, the teacher must balance between focusing on the process of students sharing their ideas and focusing on the learning of the specific mathematical content (Sherin, 2002). In practice, classroom talk varies in the level of student participation and the possibilities for them to share ideas or perspectives (Mercer & Howe, 2012; Mortimer & Scott, 2003; Warwick & Cook, 2019). To activate the learning potential in classroom talk, the teacher must not only invite students to participate in dialogues but also support their meaning-making processes toward a scientific view of the subject (Scott et al., 2011; Walshaw & Anthony, 2008). How the mathematical content is presented will also influence students' engagement and understanding (Dietiker et al., 2023).

Although the teacher's approach to communication can set frames for meaning-making processes in the classroom (Scott et al., 2006), students' reactions, questions and expectations all influence classroom interactions. The exchange of initiatives and responses in interactions between teachers and students adds a dynamic aspect to teaching, requiring teachers and students to be prepared to respond to one another in meaning-making processes. Then, teachers' planned actions in each moment may change, resulting in improvisation (Bishop, 2008). The teacher must make new decisions for how to respond or what of the students' input to include further in teaching, maintaining the conversation's mathematical productivity. However, inexperienced teachers may struggle with dynamic aspects such as instantaneously enacting strategies that encourage students to share their ideas or building on students' contributions in a whole class setting (Alexander, 2020; Lewis, 2014).

In this paper, we focus on how early-career teachers implement an interactive/dialogic communicative approach to engage students in classroom talk and negotiate the meaning of mathematics. Our guiding research questions are: How are students invited to participate in the negotiation of the meaning of the mathematical content within an interactive/dialogic communicative approach? How are the teachers building on the students' contributions?

Theoretical approach

We take a dialogical approach to this research on classroom interactions to highlight "the role of interaction and contexts, as well as language and the contribution of 'the other'" (Linell, 2009, p. 7). Dialogic theories describe meaning making as multi-voiced and interactive with others or oneself. The meaning of actions and knowledge is created in dialogue with others when trying to make sense of the world in a specific context. The others are not only the physical people we communicate with but also people present in traditions, expectations, previous knowledge, or ideas brought into a conversation by the participants. When using a dialogical research approach to explore interactions in mathematics classrooms, all the participants are positioned as contributors to the meaning of mathematics (Barwell, 2016). Such meaning-making processes could be about understanding representations of a mathematical concept or what counts as an acceptable mathematical explanation/justification in the classroom (Cobb, 1999).

Mortimer and Scott (2003) have identified four classes of communicative approaches used by science teachers to support meaning making in classroom talks. These approaches address aspects of classroom talk that are also relevant to mathematics teaching and learning.

- *Interactive/authoritative approach*: One perspective/idea is explored (authoritative). Students are invited to contribute (interactive), but the teacher evaluates their ideas to support the scientific view.
- *Interactive/dialogic approach*: All participants are invited to take part in the talk (interactive) and to contribute with perspectives/ideas on the subject (dialogic).
- *Non-interactive/authoritative approach:* The teacher alone stands for the content and perspective/ideas (authoritative), and students are not invited to contribute with responses or new initiatives (non-interactive).
- *Non-interactive/dialogic approach*: The teacher makes different perspectives/ideas accessible to the students (dialogic), but the teacher presents them rather than the students (non-interactive).

The approaches provide different opportunities to participate in classroom talk and contrast everyday views on a subject with the scientific view (Scott et al., 2006). So, depending on the content and the teaching purpose, the teacher can use shifts between these approaches to support students' understanding of mathematical content. Scott and Ametller (2007) associated a dialogic communicative approach with a teacher opening up classroom talks by, for example, inviting students to compare several ideas. In contrast, an authoritative communicative approach, such as the teacher reviewing presented ideas, was used to close down classroom talks. The study by Mortimer and Machado (2000) demonstrated a correlation between different approaches and talk patterns. For example, an interactive/authoritative approach was characterized by talk patterns of teacher initiation, student response and teacher evaluation (IRE-patterns). In an interactive/dialogic approach, the third turn (teacher evaluation) in such patterns instead consisted of teacher feedback or a new invitation for others to participate.

This paper focuses on teaching episodes in which the teacher shifts to and from an interactive/dialogic communicative approach to explore how teachers balance incorporating students' contributions in teaching and supporting students in making sense of mathematical content. We note that although teachers may choose or indicate a specific communicative approach to interactions, other participants may respond differently to what the teacher expects. Moving forward, we use dialogues to describe classroom talks where several participants contribute to the content.

Methodology

This classroom study was conducted in two Scandinavian upper secondary schools. Two early-career mathematics teachers were observed during a sequence of lessons covering a mathematical curricular unit (quadratic equations and vectors, respectively). The teachers themselves planned all the teaching. Both participating teachers had a master's degree in engineering and retrained as mathematics teachers for upper secondary school. At the time of classroom observations, Teacher 1 had taught for less than two years, and Teacher 2 had around five years of teaching experience. All observations were video recorded (approximately 14 hours per teacher) by the first author. Microphones worn by the teachers captured dialogues during group and whole-class activities. The students were 16–18 years old and **took a mathematics course for further science studies**. All participation in this research was voluntary, and the researchers had no prior connections to the participants. The participants were informed of the fundamental ethical principles of integrity, confidentiality, and anonymity (Clark et al., 2021; Forskningsetiske komiteene, 2018). Students who did not consent to video recording were seated outside the camera view, and their conversations and interactions with the teacher were not included in the data material.

In the analysis, we concentrated on episodes that involved dialogues with the whole class or with students during group or peer discussions. Teacher's communicative approaches were identified based on the level of interaction with students (interactive to non-interactive) and the extent to which students' ideas were allowed to influence the progression of a lesson (dialogic to authoritative) (Mortimer & Scott, 2003). Patterns in the teachers' and students' turn taking were explored through the type of questions, amount of talk time, and presence of evaluation and feedback in teacher responses. The approaches were first identified by the first author. In a validity process, the coding was then discussed collectively in a research group. Consensus on the features behind the coding was reached after reviewing video material and transcripts from various episodes from both teachers. At the PME-NA conference, we will share examples of transcripts to explain how the approaches were identified, teachers' prompts for inviting students to participate and their responses to students' contributions. Here, we focus on results from the analysis of when the teachers used an interactive/dialogic communicative approach.

Results

Three types of situations in which the teachers were more likely to apply a dialogic communicative approach were identified in both teachers' classrooms: 1) to activate or make visible students' previous knowledge, 2) to contrast students' solutions, and 3) to guide students' group discussions during problem-solving tasks. The situations could be linked to specific teaching purposes expressed by the teacher either in the introduction of an activity or as part of an evaluation at the end of a lesson. The first two types of situations occurred as part of teaching episodes, which started with a group activity and were followed by a whole class discussion. The third type occurred during students' group work with problem-solving tasks as the teacher moved between group dialogues.

The first type of situation was used by the teachers to make visible students' previous knowledge of mathematical content. The teachers used them as transitions between activities during a lesson or as a start of a lesson, often before introducing a new mathematical concept or using a familiar concept in a new setting. In these situations, the teacher invited students to engage in collaborative discussions in pairs or groups, prompting them to recall prior knowledge. The purpose was to activate the students' knowledge and to find ideas to build on or address during upcoming activities. For example, Teacher 1 asked the students to remember the characteristics of a quadratic function before introducing them to a zero-product procedure. Teacher 2 asked the students, before presenting the mathematical definition of a vector, to think about when it could be helpful to know both the size and direction of a physical quantity. In the whole-class discussion that followed the peer discussion, the teacher invited multiple students to share their ideas and asked them to explain or develop their answers. This first type of situation often ended with the teacher shifting to a more non-interactive approach, summarizing contributions, or providing examples of correct procedures. In the follow-up phase, the teacher stayed in an interactive/dialogic approach if the students agreed with the invitation to share their ideas. However, if there were no responses or just a single student answered, the teacher shifted to a non-interactive approach rather than attempting a new strategy to encourage participation.

The second type of situation occurred when students were given the opportunity to contrast different solutions to mathematical tasks. As in the first situation, these situations involved shifts between work in groups or pairs and whole-class discussions. The teaching purposes were to support students' conceptual understanding of rules/procedures and to provide opportunities to reflect on correct notations and mathematical language in their communication. For example, both teachers created discussion tasks around students' errors in their solutions on a previous test. Teacher 1 handed out premade solutions for the students to correct, and Teacher 2 presented solutions on the whiteboard and asked the students to evaluate them. In the follow-up phase, different groups were asked to share reflections, show their solutions, or elaborate on someone's explanation. The teachers asked questions to clarify mathematical language use or highlight what mathematical rules were being used (or misunderstood). These situations ended with the teacher repeating the correct solution or reminding the students of the correct mathematical rule in a non-interactive/authoritative communicative approach. If there were aspects of the mathematical content that the students did not bring up, the teacher presented them at the end.

The third type of situation where the teacher used an interactive-dialogic approach occurred during more extended group activities with problem-solving tasks. Positive feedback such as "You are well on the way! Nice opening! Clearly described!" was a typical start to these dialogues. To include students in the dialogue, the teacher could ask questions such as "How have you started? What strategies have you tried? Do you see any patterns?" These questions aimed to get ahold of students' starting points and guide (or challenge) them toward a solution or understanding without showing them how to do it.

Discussion

In all three types of situations, students were invited to share their ideas without the teacher knowing precisely what contribution the students would have. However, how students' ideas were incorporated further in teaching varied in our material. In exploring how students are invited to negotiate mathematical content within an interactive/dialogic communicative approach, we will continue our analysis by comparing the results with previous research (e.g., purposes identified by Mortimer and Scott, 2003). Additionally, we will compare the three types of situations to search for additional characteristics. In this work, we ask a couple of questions to distinguish or find similarities between the situations: What is the mathematical focus of the meaning-making processes? What positions are made available for the students when the teacher invites them to think and share their ideas? How are the students responding to the invitations to participate in meaning making? In what ways can an invitation to participate be linked to where in the sequence of lessons/activities the situation appears? We intend to share some of our answers and insights into these questions at the PME-NA conference to contribute to research on how early-career teachers handle dynamic aspects of teaching during classroom dialogues.

Classroom discussions are important for students' mathematical learning, but often, who and how students participate illuminates persistent issues of gendered and racialized bias. Teachers can disrupt potential issues of inequity by providing varied opportunities for students to participate in discussions. In this paper, we consider an observation tool to make sense of the nuanced features of interactions between a teacher and students during mathematics classroom discussions. When examining the lesson with attention to student race, new understandings are illuminated in the interactions between teacher and students.

Keywords: Classroom Discourse; Equity, Inclusion, and Diversity; Instructional Activities and Practices

Classroom discussion has long been shown to support students' broad learning and engagement across content areas (Khong et al., 2019; Mercer et al., 1999; Reznitskaya et al., 2009) and specifically in mathematics (Kazemi & Stipek, 2001; O'Connor & Snow, 2017). Teachers, then, are asked to create meaningful opportunities for discussion in their instruction (O'Connor & Michaels, 2019; van der Veen et al., 2017). However, research has found that some students from historically marginalized groups can be further marginalized within classroom discussions (Chen & Horn, 2022), which in turn influences these students' opportunities to participate (e.g., Grøver Aukrust, 2008; Reinholz & Shah, 2018).

The benefits of classroom discussion for students' mathematical learning combined with the challenges of making such discussions inclusive spaces for diverse groups of students require more attention to how mathematics classroom discussions unfold. This includes attending to what teachers and students do. To address this concern, we build on our prior work in which we analyzed how the teacher and students participated as well as differences between how boys and girls participated for a focal subset of students. In this analysis, we ask: How does fine-grained coding of teacher and student participation, combined with student demographic data, reveal differences in patterns of participation by race? Our intent in examining this question is not to evaluate a teacher on her practice in one lesson but to focus on what our analysis tool may reveal about patterns of participation with respect to race that may then be used to support future teacher professional development.

Theoretical Framing

Our conceptualization of classroom discussion is rooted in sociocultural views of learning (Mercer, 2000; Vygotsky, 1978) and Bakhtin's (1981) theories of the dialogic. As such, we see classroom discussions as spaces where interactive (i.e., dialogic) student talk supports understanding. This talk supports the co-construction of knowledge as it influences learning in classrooms (John-Steiner & Mahn, 1996). In other words, how people think and talk with one another supports shared learning.

Such conceptions of learning include the interaction of talk between people and the context of their lived experiences (Bakhtin, 1981; Wells & Arauz, 2006). Given the interplay between talk and context, we analyze classroom discussion, attending to the teacher's and students' contributions, with particular attention to patterns of student participation for different demographic subgroups. How these three elements interact with one another creates a clearer picture of the events of a classroom discussion, where teachers solicit student ideas, students share their own thinking or add to the thinking of others, and teachers take up or extend those students' ideas in some way (Bishop, 2021; Michaels & O'Connor, 2015; Webb et al., 2014).

Student participation plays a central role within the combined frameworks of dialogic talk and sociocultural perspectives of learning. Research has examined the influence of social demands in classrooms on how students may be enabled or constrained to participate (Kovalainen & Kumpulainen, 2007; Ng et al., 2021). Dialogic and sociocultural perspectives provide lenses for making sense of what happens in classroom discussions. Using this perspective, we attend to teachers' actions and the participation of the students in relation to the teacher's actions within a dialogic conversation. We also examine the role that race may play in student participation during classroom discussions as an aspect of the sociocultural nature of their learning environment, particularly given the research on how whiteness has influenced who has power and is valued in education spaces (Battey, 2013; Haviland, 2008).

Methods

This analysis takes place in the context of a partnership with elementary schools aimed at supporting teachers to engage in dialogic discussion across content areas. To better understand teachers' ongoing learning and facilitation choices, we observed whole-class discussions in mathematics, ELA, and science for each teacher in each year of the study. This analysis focuses on video-recorded observations of mathematics classroom discussions for nine teachers (grades K - 5) at Rivers Elementary, focusing on one teacher (Allison). First, we explain the analytical approach, the results from our prior analysis, and then explain the subsequent layer of analysis.

Analytical Approach

To best make sense of the dialogic aspects of classroom discussions and who gets to participate in this discussion, we combined aspects of two previously used observation tools: (1) the Equity Quantified in Participation (EQUIP) framework (Reinholz & Shah, 2018) and, (2) the Low Inference Discourse Observation (LIDO) instrument (LaRusso et al., 2023; O'Connor et al., 2016). The EQUIP framework was designed to focus on student participation, while the LIDO instrument was designed to assess the dialogic nature of teachers' and students' talk. We coded classroom observation videos by individual student contributions. For each contribution, we documented the teachers' original question (teacher solicitation), how a student was asked to share (solicitation method), what the student said (student contribution), and how the teacher took up what the student said (uptake type). Table 1 shows these four dimensions coded and the different coding options.

Table 1: Coding Schemes and Descriptions

Teacher Solicitation	Solicitation Method	Student Contribution	Teacher Uptake Type
(S2S) Encouraging students to respond to students	(Called On - by teacher) Teacher selects a student to share	(S2S) Student to student talk	(Follow-up) Teacher asks a question with a connection to the student contribution
(Explain) Teacher asks students to explain, clarify, give evidence	(Called On - by student) Student selects another student to share	(S ref S) Student referring to another student's ideas	(Elaborated) Teachers adds detail or clarity to a student idea
(Continue) Encourages students to continue	(Student Called Out) Student shares without being called on	(Because) Student provides reasoning	(Revoiced) Teacher repeats or paraphrases what a student said
(Open) Open question	(Choral Response) Multiple students respond together	(Q4T) Student asks Teacher a question	(Acknowledged) Teacher acknowledges student idea
(Semi-open) Between closed and open	(Turn and Talk) Students are directed to discuss the question with a partner or small group	(Extended) Student response longer than a simple clause	(Redirected) Teacher redirects student idea
(Closed) One expected answer		(Simple) Minimal student turn, brief	(Evaluated) Teacher makes a judgment about student contribution
(None) No solicitation		(Unrelated) Not connected to discussion	(None) No uptake by the teacher

Videos were coded with four raters, who were trained on the coding scheme and engaged in practice and consensus coding across multiple rounds. Inter-rater reliability was assessed by comparing codes from all raters after training and by comparing codes from pairs of raters in an ongoing manner. Our Krippendorf's alpha scores for training ranged from .68 to .96 and ranged from .57 to .81 for independent coding. Since the independent reliability tests were conducted in pairs, there were fewer comparisons than the training reliability across four coders, which likely contributed to the reduced alpha statistics.

Our prior analysis (Wilhelm et al., 2024) examined the nature of the mathematics discussion and how student participation differed by gender for a focal subset of students (n=8) in one teacher, Allison's, classroom. That subset consisted of all students in Allison's class for whom we had parental consent to participate in the study. This sample of students consisted of four girls[1] and four boys (Alma, Samika, Lucy, Casey, Jaden, Kai, Derrick, and Robert, all pseudonyms).

[1]While we recognize that gender is more expansive than the categories of girl and boy for students, we report on only these categories as the listed options in the school's demographic data.

The girls within the sample identified racially as white[2] (n=2), Hispanic (n=1), and Asian (n=1). The boys within the sample identified racially as white (n=2), Black (n=1), and Black and white (n=1). Given our attention to participation by race and the role of whiteness (Haviland, 2008; Taylor-Heine et al., 2022), we focus on the six students from this set who identified as white or Black. Students who identify as only white are categorized as white, and students who identify all or in part as Black are categorized as Black for this analysis. We share the results and statistical comparisons of Allison's lesson. Given that the focal sample is small, with just one lesson's worth of information about their participation, we also aggregated the participation patterns of Black and white students in the observations of the teachers across Rivers Elementary in order to see if some of the emergent patterns from Allison's discussion were true across a larger population of classrooms and students. We provide descriptive information about the four categories described in Table 1: Teacher Solicitation, Solicitation Method, Student Contribution, and Uptake Type. For the aggregated sample, we use Chi-squared tests to compare the distributions and report statistically significant differences.

Prior Analyses

Before answering our research question about how patterns of participation varied by student race, we describe Allison's lesson and summarize results from our prior analysis of Allison's mathematics lesson (see Wilhelm et al., 2024 for more detail). The classroom discussion we analyzed focused on supporting students in representing three-digit numbers (e.g., expanded form, word form, standard form). During the discussion, Allison specifically introduced students to the expanded form with input from students into the definitions of key terms like sum, value, and digit. Looking at the data in the aggregate, we saw evidence of a lesson where students were encouraged to share their ideas, often in response to questions with one expected answer, one after the other. Frequently, this looked like Allison listening to what a student said and then calling on a new student to support the flow of discussion without asking a new question. While it was most common for Allison to invite students to participate by calling on a new student to share their idea (49.3%), we noticed her intentional use of choral response (16.0%) and turn and talk (9.3%) that supported more students talking and getting students to talk directly with one another as these moves allow everyone to share an idea. Likely tied to the prevalence of Allison posing questions with one expected answer, the most common type of student response in the discussion was simple, one-word or brief answers (64.8%). Finally, the most common approach Allison had in responding to a student's idea was to allow or encourage other students to engage (no uptake, 37.3%), offering no further questions or rephrasing of her own.

Results

When looking at the subset of students in Allison's classroom by their racial demographics (see Table 2 below), some other differences emerge in how their ideas were solicited, shared, and taken up, particularly between the Black and white students. The patterns of questions (teacher solicitation) students received were fairly similar. However, white students tended to receive more questions asking them to explain their thinking (5% Black, 30% white). For example, after stating, "sum is the value of an addition problem," Allison asks one of the white students to

[2]We make an intentional choice to leave white uncapitalized and to capitalize instances of Black to describe race where other scholars have documented white as a social construct and Black a "self-determined name" (Dumas, 2016, p. 12).

explain what value means in that statement. Related to what students said in the discussion (student contribution), 80% of the responses from Black students and 60% of responses from white students were classified as simple. Additionally, most responses from white students included longer answers (extended; 30%). Finally, concerning how Allison responded to student contributions (teacher uptake type), Black students were most likely to be asked follow-up questions from the teacher following their responses (40% vs. 30%), and white students were more likely to have their responses repeated (revoiced) by the teacher (30% vs. 10% revoiced).

Note. This table compares discourse elements for a mathematics lesson in Allison's 2nd-grade classroom, comparing the participation of 6 focal students by race. The number of students here is too small to determine statistically significant differences. Italicized values point out a difference but not at a significant level ($^{+}$ qualitative difference visible).

The differences in teacher questions and student responses between Black and white students are illuminated in an excerpt from the lesson below. Allison asks the class if the equation 156 = 50 + 100 + 6 is true or false. In what follows, Jaden (the only Black student in the exchange) is prompted with multiple closed-ended questions with simple responses compared to the other peers (Alma and Casey) who share here:

Allison — Alma, can you tell us why you think it's false? Then we'll come to you [Jaden] if it's different. [To Alma] what made you say it was false?

Alma — There's 50, then 100, then 6. It's the order

Allison — Because there's 50, then 100, and then 6? Ok. Their order? 5 1 6? Ok, she's saying it's because of the order…Jaden, tell me what you think.

Jaden	What I think is, so when there's 50 and 100 that gets 100 and then we have the 6 and I think that's 106.
Allison	So you think it's 106. Someone who thinks true, Casey, you said true. Now I want Jaden to listen because if you want to revise your thinking you can. Casey, why did you think it was true?
Casey	I said it was true because I saw that there was the same numbers up on the board but they were just flipped flopped. So I still saw a 100, I still saw 50, and I still saw 6.
Allison	So you saw all the components but you knew they were flipped flopped, or mixed up.

[Allison walks through recording the place value before turning back to Jaden]

Allison	Do you want to revise your thinking now?
Jaden	Yeah
Allison	Ok, on your board do you see a 50?
Jaden	Yeah
Allison	On your board do you see a 100?
Jaden	Yeah
Allison	On your board do you see a 6?
Jaden	Yeah
Allison	Ok, what is that number? What does 100 and 50 and 6 equal?
Jaden	One hundred fifty six.
Allison	One hundred fifty six.

In this exchange, we see some misconceptions from the students Alma and Jaden. Notice how Alma and Casey are prompted with questions to explain their thinking in this exchange (e.g., "why did you think it was true?"). However, Jaden (who identifies as Black) is posed a series of closed, test-like questions to attend to the revisions in his thinking.

This pattern in uptake type for white students was similar to the pattern in uptake for girls we saw in our previous analysis, with girls receiving more revoicing of their ideas (see Wilhelm et al., 2024). Additionally, the pattern in uptake type for Black students may be explained by one of the students in the subset, a Black boy, who had the majority of responses across the group that included a follow-up from the teacher. The intersectional identities of these students are important to this analysis of their discussion participation. For example, both Black students in our focal sample identify as boys. The teacher questioning frequencies by race showed more use of closed-ended questions by the teacher and simple answers from the students. However, these frequencies are more aligned with how girls participated in the discussion (i.e., asked more closed-ended questions and answered with more simple responses).

Table 3: Aggregated Classroom Discussion Participation of White Students (N=35) vs. Black Students (N=14)

Teacher Solicitation	White	Black	Solicitation Method	White	Black
S2S	2.80%	3.30%	Called On (by teacher)	93.80%	93.30%
Explain	17.2%	10.00%	Called On (by student)	0.70%	0.00%
Continue	12.40%	16.70%	S Called Out	5.50%	6.70%

Note. This table compares discourse elements for all observed mathematics lessons of teachers in Y1 of the study with consented students who identified as Black or white. Values that are bolded point out a statistically significant difference.

We were curious if we would see similar participation patterns when we looked across more lessons. Table 3 shows the aggregated analysis of participation patterns of consented Black and white students at Rivers Elementary across grades K - 5 classrooms. Some of the differences in Allison's classroom discussion are not apparent in the aggregated set, such as how students were called on (solicitation method) and how teachers took up students' responses (uptake type). Some of the same differences we saw in Allison's lesson were present, but to a lesser degree, such as the types of questions the teachers ask (more explain your thinking questions for white students, more continue your thinking questions for Black students). What is interesting is the continued differences in student contributions, where white students were more likely to provide an extended answer than Black students (25% white, 1.7% Black), and Black students were more likely to provide a brief answer ("simple," 60.5% white, 82.8% Black). These differences in how students responded were statistically significant.

This fine-grained analysis of the mathematics lesson suggests differences in how students participated based on race, which exemplifies the potential of analyzing data at the individual level. With an even larger sample of student contributions, it would be worthwhile to analyze this data by intersectional subgroups as done in other literature (e.g., Reinholz & Wilhelm, 2022). The use of the observation tool helps make visible the moves of the teacher and students in a classroom discussion, with the opportunity to pay attention to participation related to student demographics.

Conclusions

We began this deeper analysis of Allison's mathematics classroom discussion to understand the details of a teacher's facilitation and student participation and what would be visible when specifically paying attention to student race. Our sociocultural and dialogic framework thus centers how these features of facilitation and participation interact with one another (Bakhtin, 1981; Wells & Arauz, 2006). Attending to issues of equity within dialogic talk is important because of the numerous ways that mathematics classroom discussion can constrain student participation (Black & Radovic, 2018; Ng et al., 2021). The intent of this analysis is not to draw generalizable conclusions about Allison's specific practice but to provide an image of what such an observation tool allows mathematics educators to see and track in future classroom discussions to understand if such findings become larger patterns pertaining to student participation, such as the emerging results of the aggregate data for Rivers Elementary. Analyzing the nuances of what happens in classroom discussions thus illuminates who is potentially marginalized in their participation (Chen & Horn, 2022).

In our focal set of students from Allison's classroom, we found that Black and white students participated differently. For example, we found that despite the fact that both Black students were boys, who generally tended to be asked more semi-open questions, the Black students were more likely to be asked closed questions, while white students were more frequently asked to explain their thinking. With just six focal students, it was not possible to meaningfully disaggregate the data by intersectional subgroups (e.g., Black boys), but that intersectionality is critical and likely contributes to explanations of participation patterns. Other studies have shown significant differences between intersectional subgroups, with a large body of qualitative evidence demonstrating differences in classroom experiences (e.g., Gholson & Martin, 2014; Joseph et al., 2019; Morris, 2007).

We want to reiterate that Allison's classroom discussion results are based on a single observation in one content area with a small sample of focal students. Although some emergent patterns were not present or not as prevalent in the larger set of Rivers' classroom discussion data, we do see patterns in how white vs. Black students are entitled to contribute their ideas to a discussion. We specifically consider how students may have been entitled to participate, recognizing the interrelated role of interactions between teachers and students that can inform how students are "entitled or constrained" to participate (Black & Radovic, 2018, p. 274). In our data, we see that white students were more likely to provide extended responses, whereas Black students were more likely to provide simple, brief responses. These differences suggest continued examination of why these students participated in this way. In drawing attention to these patterns of participation, we aim to demonstrate that by disaggregating the data by particular social demographics, it is possible to ask questions about whether participation is equitable (Lavigne & Good, 2021; Reinholz & Shah, 2018).

Details about the nuances of student participation in a mathematics classroom discussion were illuminated through the use of our observation tool. Originally, LIDO was designed to assess students' and teachers' dialogic talk, while EQUIP was designed to focus on the equity of student participation. By combining aspects of the LIDO instrument (LaRusso et al., 2023; O'Connor et al., 2016) and the EQUIP framework (Reinholz & Shah, 2018), we were able to attend more carefully to student participation through the interplay of a teacher's solicitation and student contribution of ideas during a classroom discussion.

Investigating mathematics classroom discussions through a combined tool to track dialogic talk and student participation supports the future of mathematics education in such uncertain times. The tool provides two ways to attend to the challenges of the educational and political landscape. Related to educational needs, teachers are being asked to demonstrate disciplinary expertise across content areas, including cross-content classroom discussions (Fitzgerald & Palincsar, 2019). Such a tool, then, could support analysis of classroom discussion across disciplines to leverage features of similarity for facilitating quality instructional practices. For example, from the current study, this observation data was collected at the beginning of our work together, where teachers participated in a 3-year long professional learning program to support and reflect on their classroom discussion practices. Related to the current political landscape, we see a voice of doubt that argues such issues of race and gender are even present, and thus, ways that such activity to support equitable classroom practices are limited (Lopez et al., 2021; Wuest, 2018). A tool that looks at teacher and student engagement in discussion examined by factors such as race and gender can provide empirical evidence for particular inequities that cannot be as easily dismissed. Mathematics education could thus benefit from purposeful attention to instructional practices to identify potential patterns of inequity. Analyzing how these practices unfold in classroom discussions provides a first step to articulating their presence empirically.

GETTING COMFORTABLE: DELEGATING AUTHORITY WHILE POSITIONING STUDENTS WITH AGENCY

Mary Ramos-Duke
Boise State University
maryramosduke@u.boisestate.edu

This multiple case study explores how two elementary mathematics teachers made themselves and their students comfortable with the teacher delegating authority to students while also positioning students with agency. I conducted three Video Stimulated Recall (VSR) interviews and pre- and post-semi-structured interviews with each teacher to understand their practices and thoughts about moments from prior lessons related to authority and agency. The results indicate that, while one teacher expressed being quite comfortable delegating authority to students and positioning them with agency, the other expressed reservations. Results also indicate that teachers make students and themselves comfortable delegating authority and positioning students with agency by creating time to understand students' solutions, getting to know students' assets outside of the classroom, and employing Social Emotional Learning (SEL) strategies.

Keywords: elementary school education, teaching practice and classroom activity

Implementing an ambitious approach to teaching elementary mathematics is complex work that requires teachers to delegate authority to students while positioning them with agency (Aguirre et al., 2013; Amit & Fried, 2005; Dunleavy, 2015). Existing literature demonstrates the benefits of providing opportunities for students to engage in such a vision of ambitious mathematics instruction (Ball, 1993; Carpenter et al., 1989; Jackson et al., 2017). Teachers in the United States may experience discomfort and tension, however, when they shift from traditional mathematics instruction – in which students typically lack authority and agency (Stigler & Hiebert, 1997) – to an ambitious instructional approach, in which students have more say about the validity of mathematical ideas (i.e., authority) and freedom to solve problems as they choose (i.e., agency) (Ball, 1993; Langur-Osuna et al., 2020). To understand how teachers combat this tension, this multiple case study (Creswell & Poth, 2016) explored how teachers delegated authority while positioning students with agency (Hicks et al., 2023; Turner, 2013). I answered the following research questions: (1) What practices and activities do teachers engage in to help make themselves feel comfortable with teachers delegating authority to students while also positioning them with agency in elementary mathematics classrooms? (2) What practices and activities do teachers engage in to help make students feel comfortable with teachers delegating authority to students while also positioning them with agency in elementary mathematics classrooms?

Theoretical Framework

Authority

Authority in mathematics resides with whoever is regarded as mathematically legitimate (Amit & Fried, 2005; Dunleavy, 2015). An ambitious vision of mathematics instruction (Jackson et al., 2017) requires teachers to delegate authority to students so that they play a role in deciding which contributions are mathematically sound and valid, and why (Gresalfi & Cobb, 2006; Hicks et al., 2023), thereby contributing to students feeling mathematically legitimate.

Agency

Agency is having the freedom to solve problems as one sees fit (Dyer et al., 2023). In the context of the mathematics classroom, agency necessitates day-to-day attendance (Aguirre et al., 2013; Turner, 2003). Therefore, in an elementary mathematics classroom, teachers must routinely position students with agency for them to develop a sense of agency (Ball, 1993; Boaler, 2002; Lampert & Ghousseini, 2012).

Delegating Authority and Positioning Students with Agency is Difficult

Teachers may be uncomfortable delegating authority and positioning students with agency. (Dunleavy, 2015; Turner, 2003). Societal metanarratives and prior knowledge of what elementary mathematics classrooms should look like might impact teachers' beliefs of who holds mathematical authority (Aguirre et al., 2013; Bartell, 2016). Moreover, when teachers delegate authority to students while positioning them with agency, it can create an unpredictable learning environment where a lesson can take unanticipated turns (Kazemi et al., 2009; Stein et al., 2008). Students might be uncomfortable as well. All students come to school with a set of beliefs, cultural and community norms, and an idea of "what to do" in order to learn (Delpit, 1995; Lampert et al., 1998). These factors might be at odds with ambitious mathematics instruction (Lubienski, 2000); therefore, students might not be used to being delegated authority or positioned with agency (Aguirre et al., 2013). However, the teacher is responsible for helping students transition into this environment and has the power to develop students' comfort with being delegated authority and positioned with agency in the mathematics classroom (Jackson et al., 2017; Langer-Osuna et al., 2021).

Methods

This multiple case study (Creswell & Poth, 2016), inspired by Gutiérrez's statement, "I have always believed we learn best from understanding 'success' cases" (Gutiérrez, 2011, p. 21), explored how teachers made themselves and students comfortable with delegating students authority while positioning them with agency in elementary mathematics classrooms.

Positionality

My previous professional roles, such as an elementary classroom teacher, mathematics instructional coach in Title I schools, and teacher educator supporting pre-service teachers, contribute to my background knowledge, biases, and interpretations of data.

Participants and Context

This study, which took place at the beginning of the school year, included two participants, each teaching at elementary schools in the same district in the Pacific Northwest. Though unknown at the time of data collection, the district participates in a social-emotional program, *Everyday Speech*. Participant A, who was in their 16th year of teaching at the time of the study, teaches third grade at a school that has Title I status, participates in the Advancement Via Individual Determination (AVID) program (AVID, 2012), and serves a diverse population. Participant B, who was in their eighth year of teaching, teaches first grade at a school in the same city that does not qualify for Title I status. The participants in the study met the following criteria: (a) the participant was seeking to delegate authority to students and position them with agency during mathematics instruction, (b) the participant taught first, second, or third grade, and (c) the participant taught in a public elementary school setting.

Data Collection

I used Video-Stimulated Recall (VSR) to allow teachers to articulate their thoughts and feelings related to interactions in their teaching (Martinelle, 2020; Muir, 2010; Nguyen et al., 2013). The data collection protocol was as follows: (a) lessons were video-recorded using a SONY™ EV-10 camera and audio-recorded with a Lavalier microphone or ZOOM H1 exterior microphone, (b) after the lesson, I selected moments from the lessons that exhibited interactions related to mathematical authority or student agency, (c) occurring the same day, and as soon as possible, the teacher and I met for an interview, in which the teacher watched and reflected on selected moments (Calderhead, 1981; Nguyen et al., 2013).

Additionally, pre- and post-semi-structured interviews were conducted with each participant via Zoom (Creswell & Poth, 2016). As Calderhead (1981) states, VSR alone cannot completely capture teachers' thoughts. Therefore, interviews were conducted before and after the VSR process to add context, confirm or disconfirm findings from the VSR data, and access additional insight regarding teachers' practice with respect to delegating authority and positioning students with agency (Calderhead, 1981; Creswell & Poth, 2016; Lincoln & Gruba, 1985).

Data Analysis

Data was analyzed using the process of thematic analysis (Braun & Clarke, 2021). A codebook was developed that consisted of a priori codes connected to relevant literature (Carpenter et al., 1989; CASEL, 2022; Moll, 2019) while allowing for unanticipated codes to emerge (Saldaña, 2021). Multiple iterations of the codebook were developed throughout the data familiarization process (Braun & Clarke, 2006). An external audit process took place with another researcher familiar with the project to stabilize code descriptions and examples. Additionally, the audit process enhanced the accuracy of my interpretations (e.g., distinctions between authority and agency were discussed during the coding process) and conclusions for this research project. The themes were derived from the coded data (Table 1) by analyzing frequency, co-occurrences, and triangulation (Creswell & Poth, 2016; Lincoln & Guba, 1985).

Results

Through thematic analysis of the VSR interviews, I identified the following themes: (a) Tension, (b) Time to think for teachers and students, (c) Getting to know students' knowledge and culture, (d) Tending to students' emotions, and (e) Being or becoming comfortable. Below, I share examples of reflections from Participant B demonstrating the themes of *Time to think* and *Tending to students' emotions*.

Table 1: Topics Discussed by Teachers in VSR Reflections

Teacher Discusses		Teacher A	Teacher B	Total
Authority	Teacher Delegating Authority	13	7	20
	Student Initiating Authority	4	5	9
	Teacher Withholding Authority	0	0	0
Agency	Teacher Positioning Students with Agency	9	8	17
	Student Assuming Agency	5	3	8
	Teacher Withholding Agency	0	1	1
Comfort	Teacher Comfort	1	2	3
	Student Comfort	5	2	7
	Teacher's Lack of Comfort (Tension)	0	5	5
	Student's Lack of Comfort (Tension)	0	0	0

Time to Think	Time to Think to Make Themselves Comfortable	1	4	5
	Time for Student Thinking to Make Students Comfortable	3	2	5
Knowledge, Culture, and Language	Student Knowledge, Culture, and Language to Make Themselves Comfortable	0	0	0
	Student Knowledge, Culture, and Language to Make Students Comfortable	4	0	4
Emotions	Social Emotional Learning to Support Delegating Authority and Agency	7	8	15

Time to Think

Both teachers spoke of the importance of *time to think* in order to understand students' thinking, thus, fostering students' mathematical legitimacy (authority) and freedom to solve problems as they see fit (agency). As an example, Participant B reflected on a moment when a student posed a subtraction representation (whole-part=part; 9-1= 8) for a part-part-whole activity (the whole was 9), stating, "I felt frantic in the moment." When looking for the intended representation, the teacher asked the student "Oh, but what is our whole number?", then went on to discuss the following:

> …because I saw 8 at the end of her equation. and then she said, "But it is subtraction." And I said, "Oh, we just haven't talked about subtraction," I called out that she did not have the 9 that I was looking for. But then she, I don't want to say called me out, but said, "But it is subtraction, I did 9-1."

Participant B went on to share that they felt relieved that they had time to make sense of the student's representation while conferring one-on-one before the whole-group discussion, stating, "If I was teaching whole group, they [students] are all staring at you. It gave me some time, and I feel like that is what they need, too."

Tending to Students' Emotions

Participant B discussed *tending to students' emotions* to create a comfortable environment for students to exercise their mathematical authority. In the following example, Participant B discussed how they sought to delegate authority by promoting students' ability to give feedback on their peers' mathematical solutions while also receiving feedback from their peers ("glows and grows"):

> It's a process, I've only started the 'glows and grows' last year. It's nerve-wracking…we are also trying to teach them social-emotional [skills] and how to make their peers- I don't want to say better versions of themselves- but to help them, without hurting their feelings…I don't want to say back in the day, but when you call someone out, it's embarrassing or makes you feel super sad, or I am just not good at this. Before we even get here, we go over 'growth mindset' and how we can't do things yet, the power of yet.

Participant B continued to stress the need to *tend to students' emotions* to create a classroom environment in which students are not embarrassed or hurt by feedback (peers exercising mathematical authority), saying, "So, there is a whole social-emotional piece before we dive into academics, specifically math…It's social-emotional…It's a work in progress."

Discussion

This study contributes to the field by illuminating the ways teachers make themselves and students comfortable with the teacher delegating students authority while positioning them with agency. Results indicated that teachers make students and themselves comfortable by creating time to understand students' solutions (Carpenter et al., 1989), getting to know students' assets outside of the classroom (Moll, 2019), and employing Social-Emotional Learning (SEL) strategies (CASEL, 2022).

Time was limited for this study. The next steps might be to use similar methods to explore the longitudinal development of teachers' practice in this realm.

JUXTAPOSITIONING CASES OF DELEGATED MATHEMATICAL AUTHORITY TO ELEMENTARY STUDENTS IN THE CONTEXT OF COORDINATE GRAPHING

Ingrid Ristroph
Boston University
iristro@bu.edu

Keywords: Algebra and Algebraic Thinking; Classroom Discourse: Elementary School Education; Equity, Inclusion and Diversity

This poster focuses on how two 3rd grade teachers taught conventions associated with coordinate graphing with a goal of developing a method for capturing the degree a teacher delegates mathematical authority. This study came from a larger study of an analysis of a common set of early algebra lessons enacted in 78 classrooms guided by the question, "How are mathematical conventions introduced and treated by teachers in elementary classrooms?" (Ristroph, 2024). Those findings revealed those teachers rarely explicitly addressed conventions as such, most frequently introduced mathematical conventions in a manner of direct instruction, and when spoken of they were often attributed to external agents (e.g., "they", "people", "mathematicians"). The few episodes in which teachers delegated authority to their students to explore alternatives to conventions gave motivation for this work.

The ways in which elementary teachers of mathematics confer mathematical authority are explored by asking the following:

How is the power to form and justify mathematical ideas either withheld by the teacher or delegated to students? How does the teacher's talk moves, uptake of student's ideas, and participation structures constitute a delegation or withholding of mathematical authority?

Perspective

Mathematical authority is the view of another subject (i.e. person, community, object) as a legitimate source of mathematical knowledge or mathematical reasoning and, thus, able to make meaningful mathematical contributions (Gresalfi & Cobb, 2006; Hamilton, 2022). The delegation of mathematical authority in the classroom can be construed as the set of teacher moves that position students as having the power to rely upon mathematical authority situated internally or within the community of peers' "taken-as-shared" knowledge (Dunleavy, 2015; Wood et al., 1991).

Development of Methods

A lesson introducing coordinate graphing was taught and video recorded in 26 third-grade classrooms. Instances were flagged in which the power to form mathematical decisions was largely positioned either within the teacher or students'—this pass yielded the resulting two seemingly diametrically opposing episodes which became the focus of this poster. Teachers' talk moves, uptake of student ideas, and participation structures are currently being operationalize for qualitative analysis.

A coding framework and preliminary findings will be shared.

TEACHERS' PERSPECTIVE ON USING STORYTELLING TO TEACH MATHEMATICS

Jessie C. Store
Alma College
storejc@alma.edu

Emily McDonald
Coleman Schools
emcdonald@colemanschools.net

Storytelling is a versatile and inclusive pedagogical tool that accommodates for different ways of mathematical thinking and contexts including cultural and linguistic. This study sought to understand factors for realizing the power of storytelling as a pedagogical tool for mathematics namely teachers' perspectives of the role of storytelling, and how well the curriculum supports incorporating storytelling. Using qualitative research methodology, the results show the need for teacher training and curriculum materials that support story-based pedagogies.

Keywords: Teaching Practice and Classroom Activity

Research demonstrates that storytelling is an effective teaching tool shown to increase achievement and facilitate authentic learning through motivation, engagement, and contextualization of information (Doğan, 2021; Wilkerson & Laina, 2018). This aligns with the goals of the U.S. Department of Education for "creating authentic learning experiences that encourage and prepare learners" (National Science and Technology Council, 2018, p. 5). Storytelling has also been shown to be a versatile and inclusive teaching style that accommodates different ways of thinking and contexts including cultural, linguistic, identity, subject, and age (Doğan 2021; Posey & Lavik, 2021). The narrative paradigm (Fisher, 1984; Roberts, 2004) posits that through narratives, we develop a deeper understanding of our own and others' knowledge of culture. It can address the opportunity gap expressed by Harvard-sponsored Panelists as reported by The Harvard Gazette on the need for more inclusive STEM education (O'Rourke, 2021). It makes math topics accessible to a diverse group of students when the student identities are intentionally taken into consideration.

Storytelling is a practice that contextualizes math to create a more authentic learning experience rather than focusing on rote memorization (Lemonidis & Kaiafa, 2019; Doğan, 2021). Lemonidis and Kaiafa 's study with experimental and control groups showed that "the use of storytelling had a positive effect on students' achievement in fractions, as the experimental group performed significantly better than the control group" (p. 165). Gould and Schmidt (2010), describe how storytelling was able to increase motivation in trigonometry. Furthermore, it can be identified as a form of student-centered learning (Doğan, 2021; Büyükkarci & Müldür, 2022). Thus, storytelling in math is more than just a motivator, it's also an effective tool for increasing achievement.

Objective

Low performance and achievement gaps in math persist while improving the teaching and learning of mathematics continues to be of national importance. Empirical studies provide evidence that storytelling can be one of the effective tools for addressing challenges facing STEM education. Critical factors in the effectiveness of storytelling include teachers' pedagogical content knowledge, beliefs about the role of storytelling, teaching practices, and their perception of the place of storytelling in the curriculum. Studies on these critical factors are scarce in the literature. Therefore, this study sought to study storytelling in math through these research questions:

a. How do math curriculum materials support teachers' use of storytelling for teaching?
b. How do teachers incorporate storytelling as a tool for math teaching and learning?
c. What are teachers' perceptions about the role of storytelling in mathematics?

Methodology

This research utilizes a qualitative research design as it seeks to understand through descriptions and experiences. Fossey et al describes qualitative research as "a broad umbrella term for research methodologies that describe and explain persons' experiences, behaviors, interactions and social contexts without the use of statistical procedures or quantification." (Fossey et. al, 2002, p. 1). Eleven teachers participated in this study. All participants were elementary (10 teachers) or middle school teachers from schools in one of the states from the Midwest. The participants' teaching experience ranged between fifteen and 30 years. Ten participants self-identified as female and one as male. Data were collected through semi-structured interviews. All interviews were audio recorded.

Data were transcribed using computer software: Nvivo and Microsoft. The transcriptions were further checked by researchers to ensure accuracy. Using both software services and human transcription is important because "While AI may offer a cheaper and quicker alternative to human transcription, these transcripts will need to be meticulously checked by the researcher to ensure accuracy, fill in missing details or edit for context and readability" (McMullin, 2021, p.3). The steps for thematic data analysis begun with getting familiar with the data, then generating initial codes based on the literature and participants' own words, then lastly revising codes based on responses. Transcriptions were coded using line by line coding which involved naming each data which allowed the researchers to "remain open to the data and to see nuances in it" (Charmaz, 2006, p.50). Identifying themes involved identifying repeated patterns in the line-by-line codes to "summarize, highlight key features of, and interpret a wide range of data sets" (Kiger & Varpio, 2020, p. 8). Data analysis was conducted by multiple coders to "improve both the internal quality and external reception of qualitative studies" (O'Connor & Joffe, 2020). All the data were coded by two researchers.

Results

Math Curriculum Materials

Almost all teachers said they think their curriculum materials incorporated storytelling but with some sort of caveat. Excerpts 1 through 4 were responses when participants were asked how well their math curriculum included storytelling. As the excerpts show, the caveats included grade level as a factor, story readability, school context, and relatability of story problems. The participants wished the "curriculum was very intentional in including stories that went along with what was being taught in that unit" but did not perceive their curriculum as doing this well.

Interview excerpt 1.

"I think in the younger grades probably more so, but in the 6th grade we're moving at such a fast pace. I mean, we really don't have the number talks and we don't go through what some of the younger grades do. So, I really think at my grade level, it doesn't lend itself as much."

Interview excerpt 2.

I do think the curriculum incorporates math storytelling as a tool for teaching math. One of the only problems I am finding though is that the students who cannot read well have a big aversion to that section and are completely put off by it. This makes it very hard for me since I need to walk them through every problem and sometimes feel like if the curriculum had used simpler language this wouldn't be such a big deal. Being in a such a small, rural area also poses a problem with the students' comprehension of multicultural names or activities that cannot be sounded out to pronounce.

Interview excerpt 3.

Our curriculum already has many story problems throughout the lessons, but many are hard to relate to. At times I will change them up and use my own students as examples and insert their names and friends so they can understand it better.

Interview excerpt 4.

We have even just some books that we could get and read, but even the way that those are done, they're still so disconnected to what we're actually teaching, and it's not like they're even any have high interest stories that the kids really want to hear. It's just so disconnected, so our curriculum does a horrible job of having anything extra like that involved in it.

Storytelling in Math Instruction

Most of the participants said they always or almost always use storytelling in lesson delivery. The most common way storytelling is incorporated is for the application of math concepts such as for problem-based learning. Storytelling is also used for lesson introduction as one teacher explained "Starting a lesson, you always want to do some type of spark, so you are really striving to relate it to the current culture or what you're currently studying." Eight of the ten participating teachers said they do not have students tell stories in math learning. When teachers reported that their students tell stories in math, it was unintentional and was because students were telling personal stories. Only two participants identified having students tell stories intentionally. The justification for not intentionally using storytelling included that students "see stories as part of literacy, and not as part of math." Another teacher explained that it is because students "solve the problem and just focus on numbers that they forget how much language is involved in the math."

The Role of Storytelling in Math

Multiple themes emerged when teachers were questioned on how they perceive the role of storytelling in math classrooms. The themes included engagement, personal connection, application, retention, and perseverance.

Engagement. The most robust theme for the role of storytelling in math was engagement. Participants believed that storytelling is necessary "so that the math sticks, is interesting, alive and it's applicable." The engagement theme also focused on personal connections, as explained in Excerpt 5. They view personal connections as support for engagement, information retention, and application. One teacher said, "I think it is important that students relate math to the real world. I think if your students hear short stories or scenarios that relate to them, they will be more engaged in the learning." Other teachers thought many elementary students are not able to make personal connections with the math they learn without storytelling.

Interview excerpt 5.

I think it's a piece of engagement and sometimes with these stories that you share from your own experiences it gives students a better idea of who you are. . . I think in teaching you're not just the so-called sage on stage and if you want to do a good job you need to know a little bit about your students. But that also means at times to give a little bit of yourself, so they know a little bit more about you as well.

Application. As may be noted, the referral for real-world applications of math through storytelling is not suggested only in the sense of supporting content connections of how to apply mathematical content in real-world situations. The theme of application is also focused on how the mathematical content can be applied to the students and make those personal connections.

Information retention. The role of storytelling for information retention emerged from the data in the context of mathematics learning. A teacher explained, "I think it is very important because wherever you can insert real-world applications to what the students are learning, they tend to retain more information."

Perseverance. Storytelling in math was also perceived to aid in perseverance. Many responses echoed that teachers share their previous struggles with math and how they worked hard and sought support as students to be successful. The teachers identified value in using personal experiences with mathematics to engage students in the "if I can do it so can you" mentality to motivate students to persevere.

Intentionality and Readiness to Teach with Storytelling

Teachers explained that their storytelling is intentional if their curriculums have adopted it. These curriculums that teachers viewed as having adopted storytelling were Amplify, MyMath, and Big Ideas Math. When discussing students sharing stories, this was also done unintentionally and often not purposefully. Furthermore, 10 out of 11 participants reported that they have never had any professional development or training related to story-based pedagogies math. The one participant who had reported having professional development was an educator in a Montessori school. The participant's Montessori curriculums are designed with stories and base their curriculum on 5 main stories. This participant has three professional development days per year to learn about the story-based curriculum. Additionally, participant's Montessori School hold weekly meetings with spaces for learning about how to teach using storytelling.

Discussion and Conclusion

Some of the study's results align with the existing literature. For example, teachers perceive storytelling as a tool for engagement, motivation, and improving achievement as reported in the literature (Doğan, 2021; Wilkerson & Laina, 2018). Unlike literature that identifies storytelling as a tool for inclusion pedagogy (Piipponen & Karlsson, 2019; Mahmood et al., 2020), inclusion was not a robust theme in these data. The study also adds to the literature the finding that although storytelling is a valuable tool in math classrooms, lack of intentional incorporation and training are persistent problems.

The implications of this paper are that schools should provide more professional development around the intentional use of storytelling in the classroom and be more intentional about incorporating story-based pedagogies in teacher education. Schools and curriculum specialists should consider developing and selecting curriculums that motivate story-based pedagogies. Teachers themselves should take the storytelling they utilize in the classroom and make its incorporation more purposeful.

This study examines the impact of teachers' beliefs on the implementation of Mathematical Knowledge for Teaching (MKT) slope, focusing on an in-depth case study of an in-service teacher, Ms. R. Through classroom observations and interviews, we explore how Ms. R's beliefs about her students' abilities and backgrounds influence her teaching of slope. Findings reveal that deficit beliefs significantly mediated the implementation of MKT slope, affecting instructional decisions and practices.

Keywords: Teacher Beliefs, Mathematical Knowledge for Teaching.

Teachers' beliefs affect their instructional strategies and shape their classroom practices, and one particularly influential aspect of teachers' beliefs is their asset or deficit thinking about students. This study narrows its focus to Mathematical Knowledge for Teaching slope (MKT_{slope}), investigating how one teacher's beliefs about students' mathematical abilities, behavior, and potential career paths affected the enactment of her MKT_{slope}. We conducted a series of classroom observations with an in-service teacher and then, in response to one classroom incident, which we introduce below, we collected a sequence of follow-up interviews to understand the dynamic between the teacher's MKT_{slope} and her beliefs about her students. In this paper we examine how a teacher's beliefs influenced her actions to constrain student engagement with the mathematical concept of slope. In doing so, we address the following research question: How does one teacher's beliefs about student groups affect the implementation of MKT_{slope} in a classroom setting?

Literature Review and Background

Teachers' Beliefs and Expectations in Mathematics Education

Teachers' beliefs significantly influence their instructional actions in mathematics education. Beliefs about mathematics, teaching, and learning are pivotal in shaping classroom practices (e.g. Conner et al., 2011; Liljedahl, 2009; Thompson, 1984). A number of researchers have also studied more specific or nuanced teacher beliefs. In particular, studies have shown that teachers' beliefs about their students, including their needs and backgrounds, play a critical role in determining their teaching approaches (Sztajn, 2003; Skott, 2001). This study addresses how one teacher's deficit beliefs about her students affected her instruction.

Deficit thinking involves attributing academic challenges to perceived deficiencies in students (Valencia, 2010), often linked to their racial or cultural backgrounds (e.g., Diamond et al., 2004; Bol & Berry, 2005), socio-economic status (e.g., Rubie-Davies, 2016), or language (e.g., De Araujo, 2017). This perspective tends to overlook students' existing skills, focusing instead on their weaknesses. Deficit thinking is not only a personal bias but is also entrenched in educational systems and societal structures (Parks, 2010). It leads to biased expectations and inequitable treatment in educational settings (Martin, 2009; Irvine & York, 1993; Townsend, 2000). For instance, academic failures among marginalized students are often linked to inherent deficiencies, overlooking the role of teaching methods and educational practices (Delpit, 1992).

More recently, researchers have increased the amount of attention given to deficit-based beliefs because these beliefs influence teachers' choice of tasks and instructional strategies, often limiting mathematical opportunities for those to whom they attribute deficiencies (Jackson et al., 2017; Peck, 2021). Marginalized and lower-achieving students frequently encounter tasks emphasizing procedural skills rather than conceptual understanding (Ferguson, 1998). These beliefs can result in simplified language and less challenging mathematical tasks (De Araujo, 2017), lower cognitive demands in activities (Jackson et al., 2017), and a diminished sense of responsibility for student learning, ultimately leading to lower expectations and fewer opportunities for students (Diamond et al., 2004; Flores, 2007). This creates a negative feedback cycle that only exasperates the issue. In attributing deficiencies to particular student groups, teachers may then lower the cognitive demand of the tasks they implement, which then limits students' reasoning opportunities and prevents them from building the competencies teachers would like to see, thus leading to a self-perpetuating cycle of lowered expectations.

This study explores how a teacher's deficit thinking about her students' mathematical abilities, behavior, and career paths affected her teaching of slope. Unlike previous research that has drawn on surveys, NAEP data, or simulations (e.g., Bol & Berry, 2005; Battey et al. 2021; Irvine & York, 1993; Lubienski, 2002), we examine a specific classroom-based incident in which a teacher's beliefs influenced her in-the-moment decision making in a manner that reduced opportunities to reason meaningfully about slope as a ratio of change.

Mathematical Knowledge for Teaching (MKT)

Teachers' MKT is crucial for effective teaching (e.g., Ball et al., 2008; Harel, 2008; Kahan et al., 2003.; Rowland et al., 2005). We use Silverman and Thompson's framework (2008), which is rooted in the concept of key developmental understandings (KDUs), which are essential for developing a teacher's MKT. Initially, a teacher must identify and develop their own KDU for a specific mathematical topic, which equips them with knowledge that has the potential for pedagogical application. This knowledge must then undergo a process of reflective abstraction to transform into pedagogically powerful MKT. The framework further requires a teacher to adopt students' perspectives ("decentering," p. 508), envision how students might grasp mathematical concepts similarly to themselves, and devise supportive activities and discussions.

Researchers have identified various meanings of slope among teachers (see e.g., Nagle & Moore-Russo, 2013; Byerley & Thompson, 2017). Three prevalent meanings include slope as steepness, in which slope is seen as a physical property with visual steepness; slope as rise over run, in which slope is understood as a geometric or algebraic ratio often focused on procedural movement (i.e., "rise" and "run") on a Cartesian plane but lacking in multiplicative reasoning (Byerley & Thompson, 2017); and slope as a ratio, in which one compares changes in two quantities to multiplicatively form a new quantity, which is an interpretation applicable across various contexts and related to the mathematical property of constant rate of change (Diamond, 2020; DeJarnette et al., 2020). This last interpretation, though less common, is essential for a comprehensive understanding of slope and its applications in mathematical concepts and real-world scenarios.

Diamond (2020) defined MKT_{slope} as teachers' personal understanding of slope, teachers' understanding of students' developed meanings for slope (e.g., slope as steepness, slope as formula, slope as ratio, etc.), and how the teachers use classroom activities and discussions to support the development of these meanings. We examine a teacher's MKT_{slope}, particularly her focus on the slope-as-formula meaning, and how it is mediated by her beliefs about students.

Interaction Between Teachers' Mathematical Knowledge and Beliefs

Research indicates a complex interplay between teachers' mathematical knowledge and their beliefs, which affects their instructional practices (Bray, 2011; Campbell et al., 2014; Wilkins, 2008). Teachers' beliefs mediate their instructional decisions, and these beliefs are, in turn, influenced by their mathematical knowledge (Fennema & Franke, 1992; Zhang & Wong, 2015). Studies have shown that although strong knowledge is essential, beliefs play a critical role in how teachers engage with instructional practices (Charalambous, 2015; Copur-Gencturk, 2012). However, the specifics of this interaction, especially instructional decisions in the moment, remain underexplored (Philipp, 2007; Wilkins, 2008; Yang et al., 2020). Most research addresses beliefs about mathematics and its teaching and learning, with limited studies on how teachers' beliefs about students might mediate their knowledge to influence instruction. Our study bridges this gap by examining how a teacher's deficit beliefs about students affected her use of MKT_{slope}, revealing how such beliefs constrain student engagement with complex mathematical concepts.

Methods

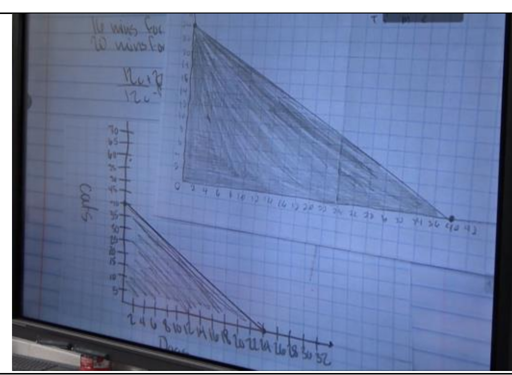
This study is part of a larger project focused on understanding how teachers support students engaging in mathematical generalization (see Ellis et al., 2024). We conducted a series of classroom observations and interviews with several teachers to observe what happened in practice and to understand their beliefs about generalization and their perspectives on the lessons. Within this broader project, we identified Ms. R, a sixth-year high-school algebra teacher from a rural district, for an in-depth case study (Merriam, 1998; Yin, 2009) due to her insights into the teaching and understanding of slope. While teaching her lesson on Systems of Equations and Inequalities, Ms. R used the Pet Sitter Task (Figure 1a). She asked students to collaborate and represent the constraints algebraically and graphically. As she facilitated the discussion, Ms. R make some choices about which she later expressed regret, and the details of the situation are discussed in the next section.

Carlos and Clarita have been worried about space and start-up costs for their pet sitters business, but they realize they also have a limit on the amount of time they have for taking care of animals they board. To keep things fair, they have agreed on the following time constraints.

<u>Feeding Time:</u> Cats will require 12 minutes to eat per day. Dogs will require 20 minutes to eat per day. Carlos can spend up to 8 hours each day to feed the animals.

<u>Playing Time:</u> Cats need 16 minutes each day to be brushed. Dogs will need 20 minutes each day playing with the ball. Clarita can spend up to 8 hours to play with the animals.

Write inequalities for each of these additional time constraints. Shade the solution set for each constraint on



separate coordinate grids.	

(a) (b)

Figure 1: (a) The Pet Sitter Task and (b) Two differently oriented graphs from two different students for the feeding time

Through a series of six semi-structured interviews (Roulston, 2022), which were conducted over a mixture of in-person and Zoom-based settings, we explored her MKT, her beliefs, and how these factors influenced her instructional actions. MKT interviews focused on Ms. R's understanding of slope and were adapted from Diamond (2020). The questions included tasks intended to explore how her knowledge might impact her teaching such as the Five Students problem (Figure 2) and follow-up questions that incorporated contexts from her classroom to explore the knowledge related to the classroom incident that is illustrated in the next section.

Five students are discussing the meaning of slope in a linear context. Student A says that slope is $\frac{y_2-y_1}{x_2-x_1}$. Student B says that slope is the steepness of the line. Student C says that slope is rise over run. Student D says that slope is the rate of change of the line. Student E says that slope is the number *m*.

Figure 2. Five Students problem (Adapted from Diamond, 2020).

Beliefs interviews focused on her beliefs about mathematical generalization and the capabilities of her students and allowed us to follow-up with her to confirm our conjectures about her beliefs. These interviews incorporated video clips from her classroom so that she could reason and provide context to the choices that she had previously made in teaching. This retrospective reasoning was not intended to understand her in-the-moment decision making, but it helped us to explore the beliefs that she holds.

We analyzed the interviews through a multi-phased qualitative process. Initial analysis focused on Ms. R's beliefs about her students' mathematical abilities and her MKT_{slope} and were coded using an open and axial coding approach (Strauss & Corbin, 1998). As a result, categories of her beliefs about students' knowledge and ability emerged as did her understanding of slope. Later interviews were modified based on previous data to continue to explore her beliefs and understanding. As a result, we created an account of explanations of how her beliefs and MKT influenced her teaching actions.

Background: Classroom Incident

Here we detail a classroom incident that sparked our curiosity about Ms. R's MKT_{slope} and beliefs. We share this incident as a separate section from the Results, as it is the event that initiated further data collection in the form of interviews to better understand both Ms. R's MKT_{slope} and her beliefs about her students. This incident occurred during the implementation of the Pet Sitter Task (Figure 1a). During the task's implementation, the students worked in groups to write inequalities. As they began to graph the solution sets on separate coordinate axes, the students asked Ms. R which quantity, feeding time or playing time, should go with which axis.

Ms. R decided to allow the students to choose how to orient their axes, stating, "Let's just see who comes up with what. I think that'll be better… that'll be cool to see." As the students continued to work on their graphs, Mr. R moved from one group to another and appeared to regret her decision to allow the students to choose their axes orientations. She said, "Man, I wish I had never said anything about y'all's axes." Despite this apparent regret, Ms. R nevertheless proceeded to foster a discussion about the situation, comparing two students' graphs with different orientations (Figure 1b).

Ms. R put the two graphs under the document camera, saying, "I thought it was interesting, um, how you guys graphed. So, the cats and the dogs, the axes were different and similar." She then asked the class, "Alright, so do you guys see the difference between these two graphs?" Several students responded that the dogs and cats were "flip-flopped" on the axes of the coordinate plane. Ms. R then highlighted the difference in the axes and drew the students' attention to the slopes of the two graphs. Some students claimed that both graphs had the same slope, whereas others believed that the slopes were different. In trying to navigate this disagreement, Ms. R drew the students' attention to the quantitative referents, claiming "they [both graphs] represent the feeding time… the one has cats as a *y*-axis, one has dogs as a *y*-axis." She then asked the students again, "So, would the slopes be the same or different?" One student pointed out that in comparing the two graphs, "the rise and the run would be, like, switched." Referring to the graph at the top (Figure 1b), another student said that the slope is "Negative 3 over 5 and, like, if you start with 40 cats [referring to the bottom graph in Figure 1b] and you go down 5 and over 3." In response to this argument, through employing the "rise over run" method, the majority of students concluded that the slopes were different, in fact, they were "flip-flopped," seeing the reciprocal values of the slopes as different.

Following this classroom incident, we were intrigued by Ms. R's expression of regret about allowing the students to choose their own axes orientations. We were also interested to understand why, despite this regret, Ms. R decided to still bring the two graphs into a whole-class discussion and why, during this discussion, she compared the slopes of these graphs.

Results

In this section, we initially focus on Ms. R's reflective interview concerning the classroom incident. Subsequent sections will dive deeper into her MKT_{slope} and beliefs about students, exploring how these factors may have influenced her instructional actions.

Ms. R's Reflection

We were curious about Ms. R's stated regret over her decision to let the students choose their axes orientations, particularly given that she then nevertheless used this as a learning opportunity by presenting two students' graphs to the class. We decided to conduct a reflection interview with Ms. R to gain insights into (i) her potential regret and its driving factors, and (ii) her decision to use the student graphs with different orientations. It was during this reflection interview that Ms. R's descriptions of the classroom incident suggested that her beliefs about students and her MKT_{slope} might impacted her actions.

Ms. R's beliefs regarding her "on-level" students' abilities may have influenced her perception of her instructional decision as a mistake, as she believed that discussing graphing in different orientations, or "axis flipping," was appropriate only for honors settings. She noted, "it [*referring to the axis flipping*] is only something that I think should be discussed in like honors setting," and added, "on level, I mean they already cannot figure out which like they are like which way does it go," indicating a preference to "let's just focus on the basics." This stance suggests she reserves more complex discussions for honors students, underlining a belief that on-level students are better served by focusing on basic graphing skills due to perceived limitations in handling advanced topics.

We also explored Ms. R's decision to use two student graphs with different orientations

(Figure 1b) in a class discussion despite her regret. During a video interview, Ms. R reflected on her decision watching a clip of herself. She noted her wish to have more clearly demonstrated the slope formula, citing concerns that some students (especially her "on-level" students) might misconstrue the graphs' similarity in decline and spacing, potentially assuming identical slopes. Ms. R remarked, "both of them [graphs] are decreasing and they look about the same spread," highlighting a potential misunderstanding outside an honors context where students might overlook differences, emphasizing, "I can see if that had not been in honors gifted class, it would have easily been oh yeah everything is the same." Her intention was to clarify that slope analysis goes beyond visual inspection to require formula application, aiming to show, "we are just looking at how this vertical distance is changing over this horizontal distance," to discern the distinct slope values. Our interpretation is that Ms. R's understanding of the slope concept and her MKT_{slope} may have significantly influenced her teaching approach, as she emphasized the importance of the formula over visual steepness in understanding the concept of slope.

The emphasis Ms. R placed on the slope formula and the numerical values of slopes while comparing the two graphs sparked a line of inquiry for the research team as there are other ways of thinking about slope including slope as rate of change[3]. Given the value of understanding slope as a rate of change, particularly for interpreting the two graphs in the pet sitter task, we wondered why Ms. R discussed the meaning of slope as a formula instead of slope as a rate of change. It could have been interesting to see how both Ms. R and the students could conclude whether the slopes of those lines were different or the same when considering the rate of change meaning that is connected to quantities in the context of the problem. We argue that the slopes of these two graphs would be the same as both graphs show the same quantitative relationship: "every time you are done feeding 3 dogs, you can feed 5 more cats." This understanding would require someone to think unconventionally (see Moore et al., 2014, for "breaking conventions," p. 151) about how we represent inputs and outputs in a Cartesian plane.

Conjecture #1: Ms. R's MKT_{slope}

Given Ms. R's emphasis on slope as formula in the initial interview, we hypothesized that her understanding of slope, as well as her MKT_{slope}, might not include the concept of slope as a rate of change. To verify this hypothesis, we conducted MKT_{slope} interviews, drawing on Diamond's methodologies, to explore her perspective. Contrary to our hypothesis, Ms. R demonstrated a multifaceted understanding of slope, primarily as a rate of change between two quantities, often using real-world examples like fuel costs to illustrate this relationship. She considered this interpretation applicable in various contexts beyond formulas or procedures.

We wanted to get further insight into Ms. R's views on students' understanding of slope. Presented with a task (see Figure 2), she highlighted her focus on slope as a rate of change, viewing it as a deeper, more meaningful understanding than just a memorized technique. She considered conceptualizing slope as a formula more substantial than seeing it as mere "rise over run" and deemed understanding slope as steepness, represented by "*m*," as the most basic level.

Ms. R used practical examples, such as "25 miles/hour," broken down into a relatable format ("for every 1 hour, the car goes 25 miles"), to teach slope as a rate of change. Her goal was to enable students to create similar phrases and apply this understanding across different mathematical representations, like graphs, equations, and tables.

[3] We adopt Ms. R's terminology, using "rate of change" to describe the "ratio" understanding of slope, despite our awareness of the conceptual differences between the two terms.

In order to get her insights into how she would compare the slopes of the two graphs oriented differently (Figure 1b) form the rate of change perspective, we designed and presented a task where a hypothetical student claims the following regarding the two graphs in Figure 1b: *Slope is the rate of change. So, both graphs show that "For every 3 dogs you are done feeding, you can feed 5 more cats". So, the rate of change in both graphs are the same. Therefore, the slopes are the same. The student also knows that inputs can be represented on the y-axis and outputs can be represented on the x-axis.* Our goal was to see how Ms. R would interpret the hypothetical student's understanding. Ms. R indicated that the student's emphasis lay in understanding the relationship between quantities and the meaning of slope, rather than fixating solely on the numerical value of the slope. According to her, "these numbers [*referring to the numbers in the student's phrase*] represent something and have meaning."

When directed to the aspect that the student also asserts that the slopes are equivalent, she explained, "The phrasing [*referring to the student's phrase*] to me is more about like a relationship. And they're saying, okay it's [*i.e., slope*] a rate of change. So, their rate of change is the same" because "these two graphs represent the same relationship although they just look different visually." Although she acknowledged that "the slopes are technically different"—using "technically" to denote "the literal exact value"—she argued that by conceptualizing the slope as a rate of change, the slopes are indeed identical. The interview data revealed that Ms. R emphasized slope as a rate of change connected to varying quantities. It was therefore more confusing that she did not adopt the rate of change perspective in her teaching, especially when comparing two graphs. This finding adds complexity to our understanding of her teaching approach regarding the concept of slope.

Conjecture #2: Ms. R's Beliefs about Students

Our initial interview with Ms. R suggested she held deficit beliefs about certain students. Therefore, we created an alternative hypothesis that perhaps her beliefs mediated the way she implemented her MKT_{slope}. To test our hypothesis, we investigated Ms. R's stance on the feasibility of engaging her students in a discussion about slopes as rate of change and, more importantly, a discussion about the equivalence of slopes—as exemplified by the hypothetical student's response. Results confirmed our conjecture. Ms. R's beliefs about student behavior issues, abilities, and their future paths played a mediating role in implementing her MKT_{slope}.

Ms. R recognized the value of teaching slope as a rate of change but emphasized its complexity, noting, "I think that's a good idea and a good thing to talk about, but I also recognize how big of an idea that is," and contrasting it with simpler, procedural methods like the slope formula. She observed that students struggle with abstract concepts, expressing, "like we are talking about a relationship and meaning versus the concrete smaller procedural like 'let's do slope formula.'" Concerned about lower-level students' reactions to difficult material, she mentioned, "when they're confused, it's like they're angry and they start misbehaving," leading her to prefer straightforward approaches to minimize disruptions. Ms. R pointed out that in a gifted setting, complex topics were more feasible due to fewer behavioral issues but anticipated "blank stares" and resistance from lower-level students. Additionally, she linked behavioral issues to external factors like home life, suggesting, "a lot of it [*referring to behavior issues*], I would say probably stems from something happening at home … if they [*referring to parents*] were more proactive, I think that would help a lot with kids being more engaged."

Ms. R's beliefs about her students' readiness to understand concepts like switching *x* and *y* axes on the Cartesian plane influenced her use of MKT_{slope} in the classroom, particularly hesitating to introduce such topics to lower-level students. She considered these concepts more accessible to gifted students and challenging for others, noting, "I think that is a big jump for those, that level of kids [*referring to lower-level students*] to handle the different orientations." This provided additional evidence that her beliefs about students' ability moderated the enactment of MKT_{slope} as she decided to not bring slope meaning as rate of change when comparing the two graphs. In other words, even though she had more powerful MKT_{slope} (slope as a rate of change), her deficit beliefs interfered with them leveraging that MKT. Moreover, Ms. R expressed doubts about teachers' understanding of slope as a rate of change, saying, "as for like teachers as a whole, like, honestly, I don't know that teachers even understand it." Crediting her own understanding of the slope as a rate of change to being labeled as gifted, she observed, "I don't want to sound cocky, but I think it's because I was labeled gifted as a kid in school," and noted a tendency among teachers towards rote learning. This stance implies she views the rate of change concept of slope as potentially too complex for standard classroom settings, fitting more for advanced learners and educators.

Moreover, Ms. R held varying expectations for her honors and lower-level students, influenced by her perceptions of their future career paths. For honors students, she emphasized challenging mathematics tasks relevant to their projected careers requiring advanced skills. She stated that the rigorous mathematics is important "for the ones that I'm thinking that want to go to, like a four-year college and potentially major in something where they're gonna have to use a good bit of math." In contrast, she expected less from lower-level students, tailoring instruction to simpler concepts she deemed more practical for their potential vocational paths like "nursing," and noted, "I think the advanced, the depth of math they need is just depending on where they want to go." Additionally, Ms. R highlighted how external factors such as social class and parental education, especially in lower socio-economic backgrounds, impact students' educational directions, observing, "I think it's because the parents don't know [about career options]... so it's harder for them to educate their own kid about it."

In summary, Ms. R's deficit beliefs about certain student groups and her perception of their abilities and future paths significantly influenced her implementation of MKT_{slope}, particularly in her approach to teaching slope concepts.

Conclusion and Discussion

Our findings indicate that Ms. R's beliefs about students mediated her MKT_{slope} to influence instructional actions and decisions in various ways. Initially, she regarded the decision to allow students to choose their own axis orientations as a mistake, driven by her beliefs about their abilities, leaning towards a "focus on the basics." However, once she recognized this perceived error, she used it as a learning opportunity. Guided by the interaction between her beliefs about students and her MKT_{slope}, Ms. R emphasized the formulaic meaning of slope while discouraging the steepness interpretation. This combination of beliefs and knowledge led Ms. R to lead a discussion about graph differences and their respective slopes, redirecting students' attention from visual appearances to the numerical aspects of slope as a formula. Furthermore, despite Ms. R's MKT encompassing the concept of slope as a rate of change, she chose not to introduce the rate of change interpretation when comparing the two graphs, influenced by her deficit beliefs about student behavior issues, her perception of students' abilities, and future career pathways.

This paper highlights the profound influence of teachers' beliefs on the implementation of MKT in the context of teaching slope. Through an in-depth case study of Ms. R, it provides nuanced insights into how a teacher's perceptions of students' abilities and potential can shape instructional practices, particularly in complex mathematical concepts like slope. Moreover, our findings extend the discourse on the interplay between teachers' MKT and their beliefs, offering a unique perspective on the dynamic interactions that occur in real classroom settings. By focusing on slope as rate of chance—a concept that is pivotal for students' deeper mathematical understanding—this study sheds light on the missed opportunities for enriching students' learning experiences due to the constraints imposed by deficit thinking. Thus, it calls for a reevaluation of teaching practices and belief systems in mathematics education, aiming to empower teachers with the knowledge and strategies to effectively nurture and leverage students' mathematical understanding, irrespective of their backgrounds. This research underscores the necessity of addressing and challenging deficit beliefs within teacher professional development programs, advocating for a more holistic approach that includes fostering an understanding of diverse student capabilities and promoting instructional strategies that are inclusive and supportive of all learners.

HOW MENTORS PROVIDE FEEDBACK TO ELEMENTARY TEACHER CANDIDATES ON ELICITING STUDENT THINKING IN MATHEMATICS

Casedy Ann Thomas
Virginia Tech
casedyt@vt.edu

Mentor teachers may have the most immediate influence on teacher candidates' (TCs) practices, suggesting that teacher educators must continue to explore the messages conveyed about ambitious mathematics instruction in field-placements to bridge the gap. The purpose of this case study is to explore mentors' perceptions of eliciting student thinking in mathematics and to understand how they go about modeling and providing feedback to their TCs about such practices. Data were collected with four TC-mentor dyads via recorded mathematics lesson observations, coaching conversations and interviews. The findings focus on how the TCs and mentors made meaning of what it means to elicit student thinking, the structures of the feedback conversations, and the coaching moves used during feedback conversations.

Keywords: Instructional Activities and Practices, Preservice Teacher Education, Elementary School Education, & Teacher Educators

Problem Statement and Conceptual Framework

TCs learn across both the university setting and in K-12 classrooms (Grossman et al., 2012); however, for some time, scholars (e.g., Feiman-Nemser & Buchmann, 1985) have cautioned us to be cognizant of the lack of a shared vision across these two settings, especially in mathematics education. And still, researchers have emphasized (Smagorinsky et al., 2006; Ronfeldt et al., 2018a) how mentors are seen as having the most immediate and enduring influence on how TCs teach. Thus, if we as mathematics teacher educators within teacher education programs (TEPs) hope to truly impact TCs' teaching practices, we have to seek avenues by which we can cultivate a shared vision of ambitious mathematics teaching (Walkowiak et al., 2018) with mentors.

This notion of a shared vision and partnership not only incorporates communal ideals around best mathematics practices but also ideals surrounding the various roles that mentors play (Butler & Cuenca, 2012; Parker et al., 2021). Mentors' conceptualization of such roles is influenced both by their beliefs (Rozella & Wilson, 2012) and their perceptions (Leatham & Peterson, 2010). Matsko and colleagues (2020) reflect upon the various ways in which a mentor is both a model of teaching practices and a coach, as they intentionally target TCs' learning. Early work defined *coaching* as ongoing cycles in which a coach facilitates "observation and feedback" to improve implementation of new teaching strategies (Joyce & Showers, 1981, p. 170). Other work has moved beyond these earlier definitions by focusing on components of coaching conversations (e.g., Knight, 2007), alternative structures for coaching (e.g., Gibbons & Cobb, 2017), and the multitude of modalities for *how* one should provide coaching and within varying contexts (e.g., Dozier, 2006). Hoffman et al. (2015) review what we can learn across various studies surrounding what it means to *coach* a TC and what we can learn from those interactions.

Thus, we seek to understand not only how mentors are modeling mathematics teaching practices for their TCs as teacher educators but also the ways in which they go about communicating feedback (Lawley, 2014) and coaching their TCs about ambitious practices. Yet, in approaching this work, we are cognizant of, just as teaching is complex work, there are many differing contextual factors at play that may impact mentors' work (Roegman & Kolman, 2020) and TC learning (Grossman et al., 2012).

Eliciting Student Thinking in Mathematics Education

The *eight mathematics teaching practices* provide a framework for standards-based or ambitious mathematics instruction (NCTM, 2014). *To elicit and use evidence of student thinking* is defined as, "…us[ing] evidence of student thinking to assess progress toward mathematics understanding and to adjust instruction continually in ways that support and extend learning" (NCTM, 2014, p.10). This practice heavily overlaps with *posing purpose questions*. We are interested in five aspects of *eliciting*, including: 1) formulating questions to elicit and probe student thinking, 2) posing questions, 3) listening to and interpreting student thinking, 4) developing additional questions based on student responses, and 5) making sense of what students know and can do (Shaughnessy et al., 2020).

Purpose

A broad goal for this work is to enhance the quality of elementary mathematics instruction by understanding the skills of mentors with practices of eliciting student thinking in mathematics and providing feedback (Cohen et al., 2020; Ronfeldt et al., 2018b) to their TCs about such practices. This nested case study sought to understand how such practices were being implemented; while the larger research study has sought to explore how we can use these findings and materials to support and develop (Matsko et al., 2020) the skills of mentor teachers, who will, in turn, better support the next generation of TCs during such uncertain times.

Research Questions

There were three research questions for this work, but we have focused heavily on Research Question 3 within this proposal, as seen in the findings.

1. How are the TCs within this study eliciting student thinking? What are their perceptions of the practice of eliciting?
2. What are the mentors' perceptions of what it means to elicit student thinking? What are the mentors noticing about the TCs' practices with eliciting student thinking?
3. How are the mentors providing feedback to their TCs and coaching them about the practice of eliciting student thinking?

Methods

For this study, we followed a case study design (Yin, 2018), examining the four, teacher-TC dyads within our elementary TEP, who were all serving a diverse student population.

Sample

The participant group for this research consisted of four mentor-TC dyads. The mentors were each recommended as experienced mentors who had worked locally with our TEP for at least five years. The four TCs were all seeking degrees in our elementary undergraduate program and were student teaching at the time. We sought to have more diversity represented within our sample, but unfortunately, as reflective of the teacher population in our area and nationally, the majority of experienced teachers working within the TEP were white women.

In what follows, we outline the dyad information for pairing of mentors and TCs. Jade (white woman) a second-grade mentor teacher worked with Thea (white woman). Kali (white woman) a kindergarten mentor teacher worked with Raya (white woman). Maria (white woman) a first-grade mentor teacher worked with Imani (woman of color). And lastly, Phoebe (white woman) a third-grade mentor teacher worked with Alex (white man).

Data Collection

The four TCs were each asked to submit two recorded mathematics lessons (approximately 30 minutes each) taught within their internship placements. The TCs were asked to select lessons that specifically focused on eliciting student thinking. The respective mentor teachers were asked to engage with their TCs, following each mathematics lesson, in recorded feedback conversations. These conversations were approximately 20 minutes each. The mentors were not given a substantial amount of guidance, but were told that we wanted to learn more about how mentors provide feedback to TCs on eliciting student thinking in mathematics.

Later, the mentors and TCs were each individually interviewed (approximately 30 minutes) to discuss their experiences with these feedback conversations. The TC interview focused on perceptions of *when* and *how* they attended to eliciting student thinking as well as unpacking how they felt about the coaching received. Sample mentor interview questions included: 1) How do you provide feedback to your TC about his/her mathematics instruction; 2) how do you decide how to provide feedback to your TC about eliciting student thinking; and 3) are there specific strategies or coaching moves that you use to give feedback? If so, please explain.

Data Analysis

All eight of the mathematics lessons and the eight feedback conversations were recorded and transcribed. Additionally, in reviewing all of the video materials, we kept detailed fieldnotes as if we were in the elementary classrooms. Further, all eight of the interviews were also recorded and transcribed. Throughout the interview process, analytic memos were written intermittently, data were coded in Dedoose, and all data sources were triangulated. We further engaged in peer debriefs to ensure credibility throughout this process aligning with research.

Results

Eliciting Student Thinking as a Practice

In examining the first two research questions, a number of themes emerged. It became evident that while these mentors have a great amount of expertise, their conceptions of what it means to *elicit student thinking* in mathematics did not always align with mathematics education research. For example, at times, there was a lack of depth in the mentors' comments and missed opportunities to coach for probing questions. Perhaps, this is because the TCs also grappled with expressing fully formed ideas of what eliciting student thinking looks like. This also translated into practice where we noticed that the TCs made efforts to initially pose "how" questions but they missed the mark with further probing the students' thinking or with making assumptions. Additionally, the mentor interviews revealed that the mentors' perceptions of their feedback and coaching often did not align with what was observed within the videos. For instance, they often thought that they provided much more tangible coaching on eliciting than what was observed.

Structures of Feedback Conversations

The feedback conversations, structured by the mentors, varied in approach. For example, some mentors like Phoebe were very intentional in making sure that the conversation had a beginning (asking Alex how he thought it went), a middle (in which most of the feedback for future work was provided and there was some practicing), and an end (bringing closure to the conversation and looking ahead to future practice). However, mentors like Kali had a list of points that she wanted to discuss and she simply worked through the list in sequential order. While these two examples stand out for being extremes of one another, the coaching conversations of Maria and Jade did not consistently follow a specific structure, rather the structure was seen as being highly dependent upon what happened during a given TC lesson and what seemed pressing to discuss. Overall, Phoebe's structure was seen as being most influential.

Coaching Moves within Feedback Conversations

While the structure of the conversations varied, the coaching moves also differed. For instance, Jade had more "suggestions for future moves" and rarely asked Thea questions about her teaching nor had her make future projections about practices. Similarly, across both feedback conversations, Kali did not ask Raya a single question, rather Raya only spoke when she wanted to interject or defend her decision making. Kali gave very directive comments, telling Raya what she should do the next time; Kali would often sit with a small white board and actively model instructional strategies. Maria and Phoebe both sought more of a balance between soliciting their TCs' ideas and providing suggestions and directives for future practice. Specifically, we saw how Maria and Phoebe posed questions to have their TCs reflect on what they did, while immediately making moves to transition into phrases like, "next time, I would really like to see you to try…". These directives were usually followed by additional questions like, "why do you think that would be better?" or "how do you feel about that?". In the following excerpt, we see some of Phoebe's coaching moves while attending to the practice of eliciting student thinking.

> Phoebe: So, after they had explored [by using manipulatives], we turned to the brownies (with 1/6), how do you think that that went?
> [Alex talks about the scenario which asked the students to consider where they would want to purchase brownies from, given the shape of the equal parts.]
> Phoebe: Then, we did the discussion and a couple students answered, but what could you have done to make sure that everyone was understanding?
> Alex: I could have asked another question… to demonstrate that no matter how it was cut, it was still 1/6.

Implications & Conference Theme

The first finding asserted that mentors who work within our TEP could use professional development on the practice of eliciting student thinking as a teacher learner to ensure consistent understanding of these practices. In reflecting upon the latter two findings, we noted that even with a small sample size, the coaching that our TCs received varied substantially, having impacts on their practice and their perceptions of their performance. This too points to potential professional development opportunities on what it means to coach and engage in effective coaching moves within the role of a teacher educator. A particular implication for teaching would be to have mentor teachers record and re-watch their own feedback conversations with TCs for professional growth, just as we often suggest with self-analysis of mathematics lessons.

Our research team affirms the value in establishing partnerships between university and school stakeholders. Specifically, we point to the need for a shared vision that enables TCs to develop equitable mathematics practices such as eliciting student thinking as we seek to envision the future of mathematics education in uncertain times. In recent years, teachers have faced immense challenges and feel the rippling effects of a global pandemic and political shifts, and so, in the face of such adversity, we must focus on the importance of building partnerships to support both practicing teachers and novices, for the sake of best serving the needs of learners.

EQUITY-DIRECTED MATHEMATICS INSTRUCTION THROUGH MATHEMATICAL MODELING PROBLEMS

Johana Thomas Zapata
Washington State University
johana.thomaszapata@wsu.edu

Amy Roth McDuffie
Washington State University
mcduffie@wsu.edu

This article explores equity-based and culturally responsive mathematics instruction in elementary education, with a specific focus on mathematical modeling (MM). Guided by the Noticing for Equity Framework, this case study of a 5th grade classroom identified and explored three key approaches: (1) selecting and adapting tasks relevant to students' lives, (2) launching tasks connecting to out-of-school knowledge, and (3) creating opportunities to learn and value input from peers. The findings illustrate the practical application of these approaches. The study highlights the importance of contextually relevant tasks, emphasizing the need for purposeful task selection and adaptation to create an equitable and engaging learning environment. Implications for teachers include recommendations to integrate familiar scenarios into lessons to deepen student understanding and appreciation for mathematics.

Keywords: Culturally relevant pedagogy; Equity, inclusion, and diversity; Modeling; Teacher noticing.

In elementary mathematics education, a transformative shift is underway—one that recognizes the impact of lived experiences on students' learning journeys (Turner et al., 2021). In the United States, the Common Core State Standards for Mathematics (NGA Center & CCSSO, 2010) call for activities that allow students to "apply the mathematics they know to solve problems arising in everyday life, society, and the workplace" (p. 7). The process of mathematical modeling (MM) aligns with this standard. MM involves the application of mathematical concepts and procedures to solve real-world problems by formulating a mathematical question, selecting computational methods, interpreting results, and creating generalizable models to apply to other situations (Suh et al., 2021). While engaging in MM, students use their knowledge and experiences to identify quantities and mathematical relationships (Aguirre et al., 2020; Turner et al., 2019). Moreover, student-centered pedagogies that emphasize contextual relevance and culturally responsive mathematics instruction can be incorporated into teaching and learning with MM (Turner et al., 2019; Suh et al., 2021).

Researchers and policymakers advocate for engaging students in tasks that foster both mathematical reasoning and problem-solving, as well as equitable instructional practices that attend to students' backgrounds, experiences, and cultural perspectives and traditions (National Council of Teachers of Mathematics, 2014; NGA Center & CCSSO, 2010). Despite these calls, a persistent gap remains in understanding how to implement equitable instruction in ways that align with students' interests and experiences (Suh et al., 2021; Turner et al., 2024). We argue that presenting situations that are relatable and significant to students supports meaningful mathematics instruction and serves as a cornerstone for fostering equitable practices.

Purpose and Research Questions

We investigated the teaching and learning of MM with a focus on equitable and culturally responsive pedagogies. Our research focused on deepening understandings of teaching practices and classroom interactions that incorporates students' lived experiences in MM instruction. We explored the following research question: *How do elementary teachers notice equity in planning and enacting MM instruction?*

Research Informing the Study

This study centers on equity-directed instruction in the context of MM. MM problems provide opportunities to enact equitable practices as students experience real-world connections between mathematics and their own lives (Suh et al., 2017, 2021). Our theoretical framework for studying teaching and learning of MM centers on the *Noticing for Equity Framework* (van Es et al., 2022). "Noticing" in this body of literature represents ways teachers attend to elements within the classroom, make sense of them, and provide appropriate responses (Jacobs et al., 2010). van Es and colleagues (2022) applied noticing research to equitable teaching practices to develop the *Noticing for Equity Framework,* and they identified critical ways to notice and foster equity in mathematics education. This framework is built on previous work on equitable practices, including research from Gutiérrez (2007) and Rubel (2017). Correspondingly, their constructs for equity and equitable practices informed our research as we focused on culturally responsive and sustaining pedagogies, access, achievement, identity, and power. Through a lens of the *Noticing for Equity Framework,* we examined culturally sustaining practices, such as positioning students as capable through discourse, recognizing students' sociocultural selves, and promoting academic success (van Es et al., 2022).

Methodology

We conducted a case study involving classroom observations and analysis of mathematics lessons and lesson artifacts (e.g., instructional materials and worksheets) (Yin, 2015). Case studies provide rich examples for educators to consider when improving their own practices. Through purposeful selection, we identified and recruited two experienced 5th-grade teachers, Anna and Liz, along with their respective students at Sunset School, located in the northwestern United States (all names are pseudonyms to protect confidentiality). This public school serves K-5 students with diverse backgrounds, ensuring representation across different demographics, in line with equity-based instructional principles (Rubel, 2017). Data collection included teacher interviews before and after each lesson and lesson observations. Interviews focused on mathematics instruction, decision-making, equitable practices, and students' learning. We observed four mathematics units, with each unit featuring three mathematics lessons, resulting in 12 observed and video-recorded lessons.

Data analysis involved multiple coding cycles to identify themes, patterns, and differences (Saldaña, 2021). During the first cycle of coding, we used *in vivo* and descriptive coding to identify content relevant to the research question (Saldaña, 2021). For the second cycle of coding, we used Atlas TI (qualitative data analysis software) and employed axial and thematic techniques, integrating first-cycle codes, as well as codes from relevant research and theory (e.g., fund of knowledge, mathematics thinking, academic success). This stage involved deeper examination of the data to identify overarching themes and synthesize information (Saldaña, 2021). We wrote analytic memos throughout data collection and analysis. Finally, we ran reports and used functions in Atlas TI to test emerging themes and generate findings.

Findings

Guided by the *Noticing for Equity Framework* (van Es et al., 2022), our analysis revealed three primary approaches for planning and enacting MM instruction as teachers noticed for equity, including: (1) *selecting and adapting tasks* that are meaningful to their students' lives, (2) *launching tasks* to connect to students' out-of-school knowledge, and (3) creating opportunities for *learning from and valuing input from peers*. We illustrate these three ways in an example from a lesson Anna taught. For context, we first describe the MM task. Next, we discuss our findings for the three approaches Anna used in planning and enacting the lesson.

For this lesson, Anna selected the "Better Buy" task from her curriculum materials. For this task, students analyzed the cost-effectiveness of purchasing 8 granola bars for $10 compared to buying 20 bars for $23 (Matassa et al., 2017, p. 27). Anna *selected* this task because she thought it had strong potential for engaging students in MM. The Better Buy task prompted students to consider real-world prices and relationships, a crucial aspect of the modeling process (Turner et al., 2021). While this task did not involve generalization, it encompassed other key components of MM, such as formulating a mathematical question, selecting computational methods, and interpreting results, making it suitable for students in aspects of MM (Suh et al., 2021).

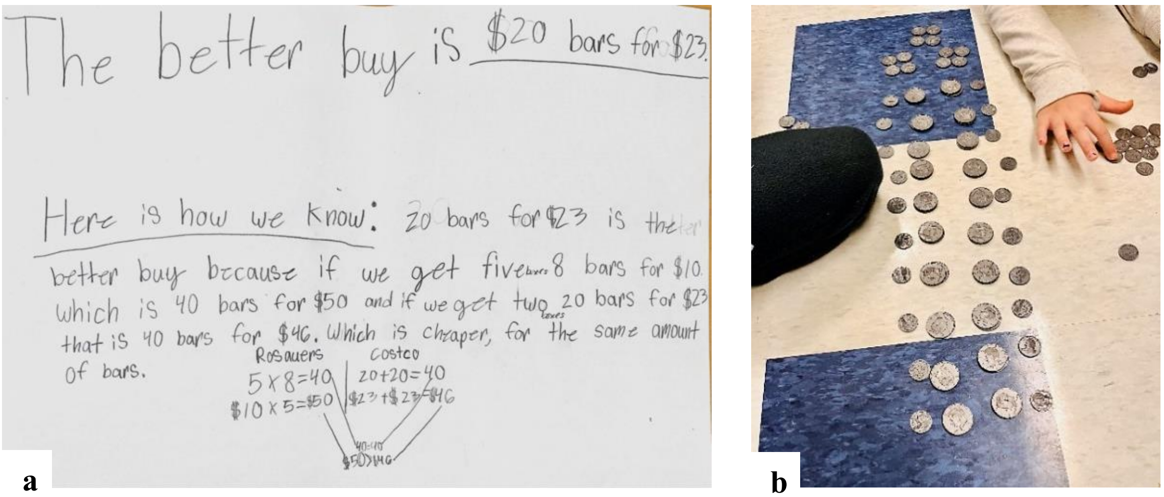
Anna evidenced noticing for equity when she stated that students would connect with the experience of buying granola bars. In the post-lesson interview, Anna said:

> I think that's what happened today. It [the Better Buy task] made sense for them [students], because that was completely a familiar context. ... "I will go buy granola bars for all of us", or "I eat granola bars every day at snack, and I need to find the cheapest ones around. So, I need to figure out what's the better deal."

To further support connections to students' out-of-school knowledge, Anna *adapted* the task by setting it in the context of grocery stores that were familiar to her students, using the names of "Rosauers" and "Costco." Anna's strategic framing of the task within the context of familiar grocery stores allowed students to draw upon their lived experiences and enabled students to apply mathematical reasoning in a real-world setting, forms of noticing for equity (van Es et al., 2022). During the lesson, Anna *launched the task* by prompting students to recall instances of their experiences with grocery shopping, deliberately facilitating connections to students' lives. Anna also asked students to share scenarios in which they might need granola bars (e.g., birthday parties, social gatherings). Anna facilitated group work and ensured that students *valued input from peers* while students shared different strategies to solve the task. At the end, students presented their strategies to the class and explained the rationale for their final decision on the best deal for granola bars. Anna viewed making posters and having a class discussion as a way for students to *learn from peers*. These three approaches (i.e., selecting and adapting tasks, launching the tasks, and valuing peer learning) aimed to ensure that all students could relate to and engage meaningfully with the MM activity.

Next, we present students' work on the task to demonstrate the effectiveness of the identified approaches in fostering meaningful engagement in the MM task. A substantial number of students drew on their personal experiences shopping at both grocery stores as they solved the task. For instance, one student confidently stated, "Of course, we all know Costco is cheaper than Rosauers." When another student asked about the reason for his assumption, he explained that he compares prices while accompanying his parents to both stores.

Students’ group work demonstrates the effectiveness of the identified approaches and illustrates additional strategies used by students while working on the MM tasks. In Figure 1 (a) students chose to equate both deals to 40 bars for comparison. Students identified 40 as a common multiple of 8 and 20, which facilitated the comparison by providing an equal basis for evaluating each deal. In Figure 1 (b), another group showed their work by comparing both prices using coin models as a visual representation to aid their understanding and decision-making process. By representing each price option with coins, they could visually compare the quantities and values to analyze the situation.



a b

Figure 1. Students’ Work

Anna reflected on the task and stressed the value of grounding mathematics in real-life contexts. In the post-lesson interview, Anna explained:

> It is good if you can give them [students] a context that makes sense for them.... There are random questions that don’t necessarily have that [meaningful context]. ... So, if [students] don’t have the background knowledge to even understand what a question is asking, then ... that’s where the hang up continues to be.

Anna’s perspective underscores the potential challenges students face when presented with abstract or disconnected mathematical problems, emphasizing the need for teaching contextually relevant tasks. She deliberately addressed this challenge by *selecting* the scenario of choosing the best buy for snacks and *adapting* it by using familiar store names. This scenario resonated with students, making MM relevant for decision-making in their daily experiences.

Conclusion and Implications

Our analysis revealed three effective approaches for elementary teachers in noticing for equity while planning and enacting MM instruction. Anna’s enactment of the “Better Buy” task exemplified how real-life scenarios can be integrated into MM, prompting students to draw from their personal experiences. The implications for research and practice stemming from this study underscore the need for equitable practices in mathematics education, particularly in elementary classrooms. For teachers, this implies a focus on purposeful task selection and adaptation, along with deliberately facilitating engaging learning environments. By integrating familiar scenarios with MM, teachers can foster a deeper understanding and appreciation for mathematics among students. At the same time, teaching MM with a focus on equity is complex work, and teachers might need support to engage in this work. Moving forward, it is essential to continue exploring and developing equity-directed approaches in mathematics education. Ongoing collaboration between researchers and practitioners can support efforts to prioritize equity and access in elementary mathematics classrooms through mathematical modeling tasks.

In this paper, we propose a mathematics professional development tool designed to support teachers' noticing for equity and improve their ability to provide powerful mathematics and an inclusive discourse community for each and every student. Used within the context of coaching cycles, this tool serves as a reflection guide for teachers to consider the extent to which all students had opportunities and access to rigorous mathematics and a discourse community and were engaged as doers and communicators of mathematics during a lesson. Our theoretical basis for the tool and iterative design process are described, followed by an example of its utility. We conclude with a discussion of what we learned from our retrospective analysis of our process.

Keywords: Classroom Discourse, Teacher Noticing, Professional Development

The significance of teacher noticing to promote effective mathematics teaching and learning has been highlighted in mathematics education research. Definitions of noticing call for teachers to identify classroom events and act on them during instructional interactions (Jacobs et al., 2020). Teacher noticing includes teachers paying attention to student thinking and using their mathematical knowledge for teaching to make sense of students' mathematical ideas (Sherin et al., 2011). It is often conceptualized as comprising three interrelated skills: attending, interpreting, and deciding how to respond (Jacobs et al., 2010). Such definition emphasizes the dynamic nature of noticing, which goes beyond observing a moment during classroom interactions to asking that the observer (often teachers) use their knowledge to make sense of the moment and make decisions in responding (Jacobs et al., 2010; van Es & Sherin, 2021).

Noticing is not an isolated concept and has to be considered within a broader framework for analyzing instruction. Schoenfeld (2011), for example, stated "teachers' decision making is shaped by what teachers notice...But what teachers notice, and how they act on it, is a function of the teachers' knowledge, goals and orientations." Therefore, Schoenfeld claimed that noticing had to be "situated within the larger picture of teacher decision making" (p. 233). Tying noticing explicitly to equity, van Es et al. (2022) indicated that "teachers' noticing of classroom activity shapes who is invited to participate, who is valued, and whose forms of knowing are included in mathematics classrooms" (p. 114). They suggested that supporting mathematics teachers' noticing is critical for an equitable mathematics learning environment (van Es et al., 2022).

Although noticing is key for equitable instruction, not all teachers inherently engage in noticing and noticing skills do not necessarily develop solely through teaching experiences (Jacobs et al., 2020). Some teachers might learn to notice effectively in their own classrooms, but professional development (PD) can support teachers in being more attuned to this practice and cultivating understanding about what to notice in the moment and how to interpret and act on those significant moments. In their review of the literature, Jacobs and Spangler (2017) stated that PD initiatives focused on enhancing teacher noticing have shown that teachers can learn to gain in-depth insights into their students' mathematical thinking and learn to make productive instructional decisions, such as improving the quality of instructional tasks and increasing opportunities for students to engage with mathematical concepts.

This paper focuses on the question of how to support teachers' noticing for equity in mathematics instruction within the context of a PD program. In response, we share our development of a tool for teacher noticing for equity and its use in coaching cycles. We have designed the tool to support mathematics teachers and coaches' noticing for equity and improve teachers' ability to provide powerful mathematics, as well as an inclusive discourse community for each and every student. The tool also serves as a reflection guide for fostering productive coaching conversations on equitable practices in mathematics classrooms.

In what follows, we first present the PD context for which the proposed tool was developed. Then, we provide theoretical background that contributed to the design of the tool and describe the design process. We conclude by providing an illustrative example within the tool. Additionally, we suggest recommendations for and discuss the implications of the tool's utility, while also acknowledging its limitations.

Context

Beginning in 2010, Project AIM (All Included in Mathematics) received a series of grants from the National Science Foundation (NSF) to develop and test comprehensive educative PD materials (Davis & Krajcik, 2005) for K-2 mathematics. Originally, these materials comprised a core teacher PD program (AIM-PD) and a facilitator preparation program and were designed for school-team participation with local facilitators. These AIM materials were tested and revised across six implementation cycles that involved over 230 teachers and 14 facilitators. Additional components including a school-leader program (AIM-LP), a coach preparation program (AIM-CP), and materials for coaching cycles were recently developed to extend the set of PD materials.

Project AIM built on successful discourse techniques established in elementary literacy instruction to develop its 30-hour core teacher program. Throughout the AIM-PD, while teachers learn the AIM mathematics discourse techniques (Sztajn et al., 2021), they are asked to immediately integrate them into their classroom instruction. Teachers then use their experiences to examine what it takes to implement the techniques effectively and how to use them purposefully to improve high-quality mathematics discourse for their students.

By providing teachers with techniques that can be immediately implemented, the AIM-PD "flipped the script" (Guskey, 2020) on PD design to allow teachers to quickly change aspects of their practice before they reevaluate their knowledge and beliefs. The PD starts with lesson organization, moves into the implementation of purposeful AIM discourse techniques, and circles back to connect teachers' reflections on implementation to knowledge about high-quality mathematics discourse (Sztajn et al., 2021). The Project AIM team calls this quick change in aspects of teachers' practices "getting it going." Over the years, the project has demonstrated the impact of its flipped script on participants' knowledge, beliefs, and practice (Alnizami et al., 2019), reinforcing the understanding that teachers in the AIM-PD get changes in their practice going. To extend and enhance the impact of AIM-PD on teachers–or as Project AIM team refers to it, to move from "getting it going" to "getting it good"--Project AIM added the AIM-LP and the coaching cycles.

Coaching is considered a productive way to bring knowledge into practice (Joyce & Showers, 1981, 1982) and evidence of the positive impact of coaching on teaching is growing (Campbell & Makus, 2011; Russell et al., 2019). In the context of AIM, the coaching component particularly focuses on teacher noticing for equity (van Es et al., 2017) to promote transformative changes in practice. Leadership also plays a critical role in shaping teachers' practice (Cobb et al., 2003), influencing the way teachers interact with coaches and fostering the ways in which teachers incorporate PD experiences into their practices (Coburn & Russell, 2008). Thus, AIM-LP engages school leaders in establishing a shared vision for high-quality mathematics instruction and envisioning what productive mathematics classrooms look like.

Theoretical Background

The National Council of Teachers of Mathematics (NCTM) committed to approach mathematics education research through an equity lens, highlighting the growing importance of equitable mathematics learning for all students (NCTM, 2000; NCTM, 2014). This commitment significantly influenced the way mathematics educators explore equity and equitable practices in mathematics instruction. For instance, Gutiérrez (2007; 2012) provided a structured framework with four dimensions for equity in mathematics education: access, achievement, identity, and power. Access involves tangible resources for participation in high-quality mathematics; achievement focuses on tangible results; identity centers on whether mathematics is meaningful and relevant to students' cultural and linguistic background, and power analyzes voice in the classroom. NCTM's (2014) access and equity position statement highlights what equitable mathematics instruction entails:

> Being responsive to students' backgrounds, experiences, cultural perspectives, traditions, and knowledge when designing and implementing a mathematics program and assessing its effectiveness... Addressing equity and access includes both ensuring that all students attain mathematics proficiency and increasing the numbers of students from all racial, ethnic, linguistic, gender, and socioeconomic groups who attain the highest levels of mathematics achievement. (p. 1)

Moschkovich (2012) offered a synthesized understanding of equitable practices in mathematics classrooms by reviewing several works (e.g. Esmonde, 2010, Gutiérrez, 2012, Wagner & Borden, 2012) that highlighted:

> a) supporting mathematical reasoning and mathematical discourse (because we know these lead to conceptual understanding and learning);
> b) broadening participation for students from non-dominant communities (because we know that participation is connected to reasoning and learning) (p. 100).

As researchers explore what equitable mathematics instruction entails, teachers' noticing in their instruction appears essential for supporting teachers in forming equity-focused perspectives and implementing equitable practices (Hand, 2012; Turner et al., 2012). Thus, over the past decade, researchers initially explored the concept of teacher noticing, recognizing it as a fundamental construct in effective teaching (van Es et al., 2022). Research on high-quality mathematics instruction has provided evidence that noticing underpins teachers' in-the-moment decision-making as they attend to and make sense of important moments during instruction (Jacobs et al., 2010, Jacobs & Spangler, 2017; van Es & Sherin, 2021). Furthermore, researchers have provided evidence that teachers' noticing of students' mathematical thinking influences teachers' instructional practice and students' mathematics learning (Jacobs & Spangler, 2017; van Es et al., 2022).

However, noticing students' mathematical thinking and activities is insufficient for fostering equitable learning environments (Turner et al., 2012). It is imperative to extend noticing to equitable practices (Jacobs & Spangler, 2017). van Es et al. (2017) define "noticing for equity" as "how mathematics teachers observe classroom activity with consequences for whether particular groups of students feel more or less empowered to engage in mathematical reasoning" (p. 252). Others indicate noticing for equity calls for attention to aspects like classroom participation (Wager, 2014), access (Gutierrez, 2007), positionality (Esmonde, 2012; Hand, 2012), identities (Gutierrez, 2012), as well as culture and home knowledge (Turner et al., 2012).

Studies on equitable instructional practices also call for exploring teachers' noticing for equity (van Es et al., 2017). These studies indicate that equity-focused teachers notice key aspects of practice such as equitable discourse opportunities, access, how students position themselves and are positioned, the role of power, and the role of culture and language in mathematics classrooms (Jacobs & Spangler, 2017). Additionally, equity-focused teachers engage in pedagogical practices "that do not perpetuate deficit (or privileged) perspectives about groups of students" (van Es et al., 2017, p. 254).

Project AIM Perspective on Equity and Noticing for Equity

Several research studies highlight various aspects to be noticed with an equity lens, yet teachers often maintain a holistic perspective on classroom practices, leading to simplistic and general inferences based on their observations (Wager, 2014). They usually do not notice nuanced details related to equitable practices such as who engaged with the mathematics and how during the lesson (Hand, 2012; Wager, 2014). They tend to notice classroom mathematical activities as distinct from other forms of classroom participation (van Es et al., 2017). Addressing this issue, Hand (2012) suggested teachers should cultivate a lens of noticing for equity. This is essential for implementing equitable classroom practices and responding to noticing in equitable ways. To cultivate such a lens, it is critical to offer teachers both support and opportunities for "more frequent and nuanced noticing of classroom participation" as it contributes to a deeper understanding of equity issues (van Es et al., 2017).

Project AIM's coaching component supports teachers to notice equitable practices in mathematics instruction by creating opportunities for them to engage in nuanced noticing with an equity lens. We contend that noticing for equity needs to attend to both the dominant (access, achievement) and critical (identity, power) components of instruction (Gutiérrez, 2007). For us, "dominant noticing" regards teachers' use of their MKT as they learn to attend to, interpret, and decide how to respond to students' thinking (e.g., Jacobs et al., 2010). "Critical noticing," however, focuses on attending to, interpreting, and responding to equitable discourse practices. The project also focuses on including *each and every* student in mathematics discourse, attending particularly to emergent multilingual learners (Malzahn et al., 2019). It promotes instructional practices that have been shown to foster equity such as attending to the role of language and status in classroom discourse participation, positioning all students as competent, and welcoming students' home knowledge and language (Jacobs & Spangler, 2017; Wilson et al., 2019).

Design Process

The tool developed is Project AIM's reflection tool for use by teachers and coaches. Our primary focus is fostering growth and improvement in teachers' noticing for equity through the use of this tool in the coaching cycle. The design of the tool incorporated several key decisions, which emerged from the wealth of knowledge and insights derived from Project AIM, literature on noticing for equity and equitable mathematics instruction, and individual and collective reflections within the research team during three iterative design cycles.

First Cycle: Design Decisions

We began our design with Moschkovich (2012) emphasis on the pivotal role of mathematical reasoning and discourse in supporting conceptual understanding and learning alongside broadening participation for students from non-dominant communities. This resonates with Project AIM's emphasis on providing high-quality mathematics to each and every K-2 student, focusing on equitable discourse practices, and supporting teacher noticing with a focus on equity. Thus, we identified two critical aspects for the tool, adapting Moschkovich's (2012) nomenclature, and named them initially: 1) Powerful mathematics and 2) Communication/Inclusive learning environment.

The research team proposed a matrix format to unpack the actions of both teachers and students in the classroom, specifically homing in on how teachers notice these actions within each aspect. Recognizing the complexity of teaching, our tool design aims to support teachers in noticing for equity within significant moments, considering the challenge that they cannot attend to every event during classroom instruction (Jacob & Spangler, 2017). Thus, in the design process, our intentional focus is on leveraging the insights and experiences teachers acquire through the AIM-PD to identify and engage with these significant moments.

Our collective reflection meeting led us to focus on detailing the actions of both teachers and students, emphasizing noticing lenses of *opportunity* and *access* mainly in Teacher Actions, and *participation* and *power/voice* mainly in Student Actions (Column headings of the tool). These areas were chosen within the overarching context of Powerful Mathematics and Communication/Inclusive Learning Environment aspects (Row headings of the tool). Each intersection represented by a cell (See Table 1).

Subsequently, we decided to incorporate characteristics of equitable practices in a mathematics classroom as noticing actions within each cell of the tool. To identify these noticing for equity actions, the research team reviewed the related literature (e.g. Gutiérrez, 2012; Hand, 2012; Jacobs et al. 2010; Jacobs & Spangler, 2017; Munter, 2014; Moschkovich, 2012; Sherin et al., 2011; van Es, 2017) and conducted individual written reflections to address a key design question:

> If we want teachers to notice for equity as it relates to students' mathematical thinking/reasoning and student participation/communication, what specifically do we want them to pay attention to during the lesson and/or think about in planning?

Individual written responses to these questions were analyzed by a team member and organized within each cell of the tool. This process helped us pinpoint the initial noticing for equity actions within each cell. For instance, in cell of Communication or Inclusive classroom learning environment-opportunity& access (teacher actions), we included “Implementing techniques and moves to encourage and support student participation and draw on their assets” and in participation voice/power (student actions), we included “patterns of participation” as noticing actions.

Second Cycle: Design Decisions

In the tool’s second iteration, instead of presenting a mere list of noticing actions, we decided to delve deeper into each cell. This involved identifying focal actions within each cell, incorporating reflection questions, and reorganizing the placement of those actions identified in the first cycle under the new focal actions. The bolded noticing actions were purposefully selected and/or synthesized from the initial version of the tool to represent key practices that teachers pay attention to within each cell. We used Teach Math (McDuffie et al., 2014), and existing AIM-PD resources such as the Math Discourse Matrix (Sztajn et al., 2021) to identify the initial focal noticing actions.

Reflection questions were also purposefully added to help teachers reflect on or examine each focal noticing action. The reflection questions were not broad inquiries such as "what teachers notice about"; rather we created questions to promote reflection on specific qualities of equitable practices in mathematics classrooms. For instance, we unpacked the initial noticing action of "patterns of participation" by including questions like, "To what extent do the reciprocal interactions among students and teacher-student contribute to the development of shared understandings of mathematical concepts?” We placed this question under the focal noticing action of "Who participates? Where does the majority of the math 'work' take place in the classroom (e.g., front of the room, small group, individual desks) and how does this contribute to participation?" within Communication or Inclusive classroom learning environment-access & opportunity (teacher actions). These noticing actions and questions within the tool are not exhaustive, but represent key points of emphasis in Project AIM that address equitable instructional practices highlighted in the literature.

During collective reflection meetings, we decided to fine-tune the tool for better accessibility and user-friendliness for teachers and coaches.

Third Cycle: Design Decisions

In this cycle, we refined key elements of the tool, including the renaming of aspects and revising focal noticing actions, as well as revising the reflection questions. In the first cycle, we initially named the second aspect of the tool as "Communication/Inclusive learning environment." However, given Project AIM's commitment to equitable discourse practices, and the acknowledgment that all actions emphasized in the tool contribute to an inclusive learning environment, we decided to rename this aspect "Inclusive Discourse Community."

We decided to use language in the reflection questions to prompt thoughtful consideration rather than evaluation or yes/no answers. Specifically, we chose to frame questions with prompts such as "in what ways" and “how” rather than "to what extent" or “do/does.” For instance, instead of inquiring about “to what extent are students encouraged/expected to ask each other questions that press for mathematical reasoning, justification, and connections among ideas?”, we revised the question to "How are students encouraged/expected to ask each other questions that press for mathematical reasoning, justification, and connections among ideas?"

While "how" questions can effectively encourage teachers in noticing their actions, the same approach for student actions lacks the specificity needed for teachers to notice which students engaged in powerful mathematics and discourse. Consequently, we made the decision to rephrase the questions related to student actions, incorporating both "how" and "which/who." For example, in powerful mathematics-participation & power/voice cell, under the "Engage in math reasoning for sense-making of concepts " focal noticing action, we modified the question to be more targeted: "Which students are making meaningful connections between procedures and concepts? How?"

Table 1 presents the short version of the final tool (without the reflection questions) as a result of the three iterative design cycles.

Table 1: Tool for Teacher Noticing for Equity: Short Version

	Opportunity & Access (Teacher Actions) *Notice what the teacher does to create equitable opportunities and access to powerful mathematics and discourse.*	Participation & Power/Voice (Student actions) *Notice who is engaged and how in powerful mathematics and discourse*
Powerful Mathematics	● Selects a challenging, discourse promoting task ● Implements the task to maintain challenge while building on students' prior knowledge ● Promotes student thinking and sense-making Capitalizes on students' mathematical, cultural, and linguistic assets as resources for learning	● Engage in problem solving for conceptual development ● Engage in math reasoning for sense-making of concepts ● Utilize prior knowledge, resources, and assets to understand and engage with the math
Inclusive Discourse Community	● Attends to socio-mathematical norms for engaging in high-quality and equitable math discourse ● Values, encourages, and supports multiple modes of communication ● Creates structures to encourage and support broad participation ● Promotes academic language	● Use multiple modes of communication to share and justify their math thinking and reasoning ● Critique others' thinking and reasoning and form math connections among ideas ● Take ownership/responsibility for the math discussion ● Collaborate with and utilize peers as resources to make sense

	of each other's thinking and the math ideas

In this paper presentation, we also unpack the inclusive discourse community aspect of the tool. We share the reflection questions related to focal noticing actions in the cell and discuss the utility of the tool. For instance, for the focal action "Use multiple modes of communication to share and justify their mathematical thinking and reasoning," the reflection question was "Which students are representing a concept or solution using one or more modes in addition to language – gestures, writing/drawing, technology, concrete objects, mathematical symbols? How?"

Discussion and Conclusion

Our work as designers of Project AIM has repeatedly led us to appreciate the power of tools that bring concepts from research into teachers' professional learning and support aspects of their professional practice. That is, the tools form a foundation for learning and improvement by providing practical ways of engaging with new ideas in the PD setting and applying those ideas in teachers' school and classroom experiences. We consider these tools to be boundary objects (Sztajn et al., 2014) spanning this territory of research, professional learning, and teaching practice. We were intentional about which aspects and actions to highlight, knowing that a tool can't include everything and still be practical and useful. We spent considerable time deciding which actions to include in the tool and engaged multiple design cycles to avoid overwhelming users.

In our current work, we set out to create a new tool to support coaches and teachers who will engage in coaching cycles for a year following their experience in the existing AIM-PD. Undertaking this work allowed us to be attentive to and reflective on our process for creating the kind of boundary objects we have found supportive for bridging research, professional learning, and teaching practice. Although we did not set out with a defined process for this work, in retrospect, we discovered three identifiable cycles in our design work that mirrored the territories we intended for the tool to bridge. This intention includes (1) drawing on research generated concepts; (2) providing teachers access to these concepts in ways that meaningfully connect to their experiences; and (3) engaging teachers in applying these concepts to reflect individually and collectively on their learning and how it informs their teaching practice.

We found that the three design cycles we identified in our work largely align with these three intentions. The First Cycle aligned with the first intention. We began with powerful concepts from research literature to define the overall domain, Noticing for Equity (Jacobs & Spangler, 2017, van Es et al., 2017) and the space of the tool as a two-by-two matrix crossing aspects of equitable mathematics instruction (Moschovich, 2012) with actions to notice which tie to dimensions of equity (Gutierrez, 2007, 2012). Finally, we identified multiple actions in related research and located them in this space.

The Second Cycle centered on the second intention, providing teachers and coaches access to the many concepts incorporated in the tool. Two key steps made up this cycle: organizing actions into a smaller number of categories recognizable to teachers, and framing these actions within questions teachers and coaches could consider, answer, and discuss when examining specific instances of their own practice. We drew on tools with similar purposes from our own (Sztajn et al., 2021) and colleagues (McDuffie et al., 2014) work to inform these steps.

Finally, in the Third Cycle we addressed the third intention of promoting teachers' and coaches' application of the tool. Two main decisions arose in this cycle, renaming one aspect of equitable mathematics instruction (Inclusive Discourse Community) to more closely align it with what would be familiar to teachers when examining practice in AIM-PD, and rephrasing the reflection questions to promote thoughtful and critical reflection on instances of practice rather than evaluative or binary (yes/no) judgments. This design decision was crucial for the tool's accessibility and usability, reinforcing that it represented familiar ideas reorganized and unpacked to highlight aspects of equity.

This retrospective examination of our work uncovered a process for developing tools as boundary objects for professional learning to improve mathematics instructional practice, specifically for equitable practice. Reconsidering and recounting our experience allowed us to codify for ourselves and offer to other developers specific intentions and actions for engaging in and studying the design of tools for mathematics teachers' professional learning experiences.

Acknowledgments

This work was supported by NSF awards DRL-2200370 and DRL-2200371. We would like to express our appreciation to the rest of the AIM project team: Anna Throp, Edith Gummer, Jessica Dula, Lindsey Sachs, Julia Schnegg, and Orna David, and acknowledge author 1 and 2 contributed to the paper equally.

Alabama's Practitioner Leaders for Underserved Schools in Mathematics (APLUS in Math), funded by the National Science Foundation, is a group of secondary (grades 6-12) mathematics teachers recruited from 20 schools across 10 school districts, creating two cohorts of Master Teacher Fellows to become masters of instruction and teacher leaders. Utilizing two measures with validity evidence, we examine the relationships between classroom observation data on teaching practices collected at multiple points of the school year and the National Board for Professional Teaching Standards (NBPTS) portfolio rubric scores obtained during the same year as the observation data. Significant results include strong relationships between classroom observations and specific portfolio results. We highlight validity evidence and measures with findings towards accomplishing the project's overarching goals to improve instructional quality, student experiences, and school change.

Keywords: Professional Development; Instructional Activities and Practices; Teacher Educators; Instructional Leadership; Assessment; Instrumentation, Validity Evidence

Since 2000 on a macro-scale, the teaching and learning of mathematics in the United States has been guided primarily by the National Council of Teachers of Mathematics (NCTM). The Standards for Mathematical Practices [SMPs] (NGA & CSSO, 2010) rooted in the NCTM mathematical processes (NCTM, 2000), along with the Mathematics Teaching Practices [MTPs] (NCTM, 2014) present opportunities for dynamic mathematics classrooms. Teacher professional development (PD), at the micro-level, has tended to reflect these practices as higher priorities for the last decade-plus. Classroom teachers that incorporate the Mathematics Teaching Practices and engage students in the Standards for Mathematical Practices in concert during instruction can, arguably, be described as providing an effective environment for the teaching and learning of mathematics for all students. Moreover, mathematics classrooms that regularly demonstrate the MTPs and SMPs in concert provide ideal clinical settings for field-based experiences of teacher candidates (TCs) as they work towards establishing productive dispositions and early career teaching practices. This brief research paper focuses on the early analysis and findings of the relationship between live observation ratings of secondary teachers using the Mathematics Classroom Observation Protocol for Practices [MCOP^2] and the National Boards' Component 2 (Differentiation of Instruction) and Component 3 (Teaching Practice & Learning Environment) portfolio scores. National Boards is much more related to affective domains of teacher beliefs, attitudes, and self-efficacy, whereas live observations of instruction are actual teacher behaviors. There has been conflicting evidence as to whether teacher espoused beliefs about their teaching of mathematics are their actual enacted practices and behaviors (Buehl & Beck; 2014; Polly et al., 2013). We wonder the degree to which National Boards results align to that of the MTPs and SMPs classroom enactment.

Foundation and Framework

Measurement Framework

Over the past decade, nearly 50 mathematics education researchers have assessed the validity of measures in mathematics education. A subset of this group analyzed the validity evidence of affective and behavior "teacher education instruments" published in 24 mathematics education field journals. Within the domains of affective and behavior measurement, it has been found that a significant portion of these instruments lacked strong validity evidence or in some cases no evidence (Gallagher et al., 2022).

The MCOP^2, developed by Gleason et al. (2017), evaluates student engagement (SE) with Standards for Mathematical Practice (SMPs) during classroom instruction, as well as teacher facilitation (TF) related implicitly to the NCTM Mathematical Teaching Practices (MTPs). Gleason et al. (2017) published validity evidence for content, reliability, response processes, and internal structure. Later, Zelkowski et al. (2016, 2024) have published addition evidence for the consequences of use, and relationships to other variables strengthening the validity argument for using the MCOP^2 with live observations of classroom mathematics teaching to capture the two factors of interest (i.e. SE and TF).

The National Professional Boards for Teaching Standards (NPBTS) has witnessed a significant rise in nationally board-certified teachers (NBCTs), with states offering salary incentives for certification and two to three times as much for teaching in high-need and/or hard-to-staff schools (Gooden et al., 2023; Darling-Hammond & Sykes, 2003). States, districts, and schools have developed support mechanisms, professional development, and writing peer mentorship groups as an effort to support teachers in their pursuit of such certification. The NPBTS assesses four domains, including affective and behavior dimensions (Components 2, 3, 4) and content knowledge (Component 1), through established rubrics with some demonstrated validity evidence in scoring (NBPTS, 2016) yet virtually no empirical published research connected to the degree to which NBCT mathematics teachers demonstrate the MTPs and their students engage in the SMPs.

Professional Development

A professional development [PD] program requires extensive planning for design, implementation, and assessment to make change as needed to maximize the program's goals (Penuel et al., 2007; Kennedy, 2016; Loucks-Horsley et al., 2009). Some of the five goals of the APLUS in Math project include teachers reaching "teacher leadership" status through ongoing PD to become masters of instruction, leading PD, mentoring other teachers and TCs. The project is a five-year, three-phase designed PD project. Phase-1 consisted of 15 months of foundation graduate coursework (18 credit hours) in content knowledge, pedagogy, and teacher leadership, whereas Phase-2, the target phase of this research, consisted of professional workshops and pursuit of National Boards over two academic years [AY] as a means to "master instruction" demonstrating regular use of the MTPs and student engagement in the SMPs. Phase-3, not the focus of this report, includes the implementation of teacher leadership projects.

This initial research focuses on understanding the relationship between observed instructional practices (SE, TF) with the MCOP^2 and National Boards' differentiation of instruction (Component 2) and teaching practices and classroom environment (Component 3). This early work aimed to inform adjustments for future professional development in the project, improve instructional practices, and guide national board workshops while looking for additional validity evidence related to the MCOP^2, National Boards, the MTPs, and the SMPs.

Our research question: What is the relationship between MCOP^2 SE and TF observation ratings and National Board Component 2 and 3 portfolio scores?

Methodology

To assess the impact of Phase-1 and Phase-2 PD, three MCOP^2 classroom observations are collected during each AY spread apart by about 2-3 months. According to Gleason et al. (2017), three observations of a teacher provide enough data for an annual measure of SE and TF (previously discussed). During year 1 of the project, baseline observations were conducted in the 2020-21 and again in year 2 (2021-22) when MTFs were working on Component 2 in the fall and Component 3 in the spring. In December of 2022, results of both components of the first cohort of MTFs were received which are reported in this paper.

We conjectured that baseline year MCOP^2 SE and TF scores would not be significantly related to Component 2 and 3 scores given they occurred in different school years, whereas we further conjectured that the SE factor score would be more likely related to Component 2 [differentiation] and that the TF factor score would be more likely related to Component 3 [teaching practices] given the foundation and framework discussion during the year of teachers working on national boards. We performed Spearman correlations given the interval level scoring of NB rubrics and then followed that with regression analyses to account for highly correlated independent variables with Component 2 and 3 as the dependent variables (interval scored, a caution to consider), with the MCOP^2 SE, TF, total score ratings, and then MCOP^2 item level ratings as the independent variables using a stepwise forward procedure to understand the variance explained by the observation measures on the national board's performance level. Eleven MTFs had Component 3 scores, and ten MTFs had Component 2 scores. All MTFs had year 1 and year 2 MCOP^2 observation ratings.

Results

Spearman Correlations two-tailed tests were significant, in order, as follows ($p<0.05$):

COMP2 ~ [Yr 2 MCOP^2 item 13, total score, SE score, TF score]

COMP3 ~ [Yr2 MCOP^2 item 7, 6, 4, 13, total score, TF score]

All MCOP^2 items were highly significant in relation to each other (rho>0.7). To address multicollinearity and to understand the better potential predictors, the secondary analyses found significant regression equations explaining 58.3% and 59.6% of the variance respectively of Component 2 and 3 based on MCOP^2 observation recorded data.

EQ1: COMP2 (rubric rating) = 1.653 (MCOP^2 SE Factor Score in year 2)

EQ2: COMP3 (rubric rating) = 1.485 (MCOP^2 TF Factor Score in year 2)

The constants were non-significant in the models whereas the MCOP^2 coefficients were significant ($p\leq 0.01$). Year 1 MCOP^2 factor scores were non-significant.

After recognizing the two factors that were statistically significant for components 2 and 3, we conducted additional analyses of the respective factor score items from the MCOP^2 in relation to the component scores. The results indicated one TF item and one SE item were statistically significant in predicting the associated component score. However, the results were surprising which we discuss. The relationships explained 51.2% and 62.0% respectively where:

EQ3: COMP2 (rubric rating) = 0.847 (MCOP^2 Item 13 rubric mean from year 2)

EQ4: COMP3 (rubric rating) = 1.429 (MCOP^2 Item 6 rubric mean from year 2)

The constants were again non-significant in the models whereas the MCOP^2 coefficients were significant ($p<0.02$). Year 1 MCOP^2 items on each respective factor were non-significant.

Lastly, we were curious as to whether there were any relationships to the content knowledge assessment (component 1) with respect to the MCOP^2 observational data. Again surprisingly, there was one MCOP^2 item with a significant relationship to the total component 1 score, item 7 was significant, the modeling focused item.

EQ5: COMP1 (rubric mean score) = 2.578 + 0.632 (Item 7 rubric mean from year 2)

None of the sub-scores (exercises 1, 2, or 3, and multiple response) on Component 1 had significant predictors in the data, but the total component score generated a significant model.

The Spearman Correlational analyses initially found the items that were statistically significant in relationship to NBCT component scores. Given the high correlations of multiple variables (rho>0.5), we then explored which variables are the greater predictors to understand which were most related in understanding NBCT related scores. The MCOP^2 scoring can be interpreted as follows. The mean SE and TF factor scores ranging 2.5-3.0 would be "excellent" with 2.0-2.49 as "very good". Further, 1.5-1.99 would be "good to average" and less than 1.5 is below average teaching practices. Based on EQs (1, 2, 3, 4, 5), we find that Component 2 is strongly related to the level of student engagement observed throughout the year's observations during initial NBCTS submission. The model explains nearly 60% of variation in the outcome scores. Important to note, a mean score of ~1.8 on the MCOP^2 SE factor is related to a Component 2 score of 3 (clear evidence of accomplished teaching). This is a lower score than anticipated. With the differentiation component mostly about how teachers plan to engage all students in their planning and enactment and a purely written component of portfolio artifacts, it is not so surprising in hindsight. Component 3 though tells a different story. A mean MCOP^2 TF factor score requires slightly more than a 2.0 to warrant clear evidence of accomplished teaching on Component 3 (teaching practices). This is an expected score range.

Discussion

In making early programmatic decisions about our PD design, these findings allow us to make some initial points related to the PD design (Penuel et al., 2007). Our initial findings with the first cohort of MTFs demonstrates significant relationships even with a small sample size less than 15 teachers. However, by going even deeper into the item-level analyses, we see the importance of a "conceptual teaching focus" with the TF item 6 on teaching practice construct outcomes (need >2.0 mean on item 6), as well as the SE item 13 on differentiation of instruction to engage students with a high-quality classroom culture (need ultimately a 3.0 mean) to warrant accomplished teaching for the differentiation construct. That is not to say that the other Spearman significant correlations are not worth considering. Items 4&7 are also important. Item 4 focuses on both TF and SE factors, pointing to teachers who facilitate lessons with a focus on students critically examining mathematical strategies. Item 7, modeling, is also important as we found a relationship to content knowledge with a post-hoc exploration. We were not initially examining the Component 1 content knowledge relationship to MCOP^2 observations, it was secondary that we found some significance with the modeling item 7 though a similar finding exists (Yenmez et al., 2017).

We believe this finding begins to shed potential that modeling may be more present in teachers' classrooms with greater content knowledge. We will be interested to see if this finding holds up with the second cohort when data collection is available May 2024. Holistically, there were also TF, SE, and total MCOP^2 scores that were important. We view this holistically that most items are important on each factor, but certainly as our data set grows, we expect to see more granular findings in future research analyses. We would need further analyses, interviews, and a larger data set to fully begin to draw some conclusions.

EXPLORING THE INTERPLAY OF PROOF VALIDATION AND CONSTRUCTION: A STUDY OF STUDENTS' RATIONAL BEHAVIOR

Yuling Zhuang
Texas A&M University
ylzhuang@tamu.edu

This study explored the transformability of student rational behavior between proof validation and construction in a university-level online transition-to-proof course. Through a combined "proof validation-construction" activity, this study investigated how students recontextualized their rational behavior from proof validation to subsequent proof construction activities according to Habermas' three components of rationality. The results emphasized the need for additional support and practice in proof construction, extending beyond proof validation, to adequately fulfill the requirements of epistemic and communicative rationality. The study also demonstrated the positive impact of proof validation on proof construction, emphasizing the interconnectedness between two proof activities.

Keywords: Reasoning and Proof, Research Methods, Instructional Activities and Practices, Design Experiments.

Validating arguments and constructing mathematical proofs are essential skills for all mathematicians, and they constitute vital components of advanced mathematics courses in higher education. Proof construction is the process of developing correct proofs and proof validation involves evaluating these proofs to assess their correctness (Selden & Selden, 2017). Research has shown that most university students have experienced substantial difficulties with proof validation and construction (Alcock & Weber, 2005; Selden & Selden, 2003; Sommerhoff & Ufer, 2019; Weber, 2010). Although proof validation and construction are distinct activities, with construction involving the identification and application of theorems and definitions and validation dealing with the understanding and verification of these elements (Selden & Selden, 2017), research indicates that the two activities are closely connected. For instance, Kirsten and Greefrath (2023) investigated different kinds of validation activities (e.g., reviewing, rating, etc.) used by 11 undergraduates in constructing a proof. They found that students' difficulties in constructing proofs may stem from insufficient validation strategies and a lack of suitable criteria for accepting their own proof constructions. Powers et al. (2010) found that students learn written proofs better by providing them with opportunities to validate proofs in an abstract algebra course. Therefore, some researchers have proposed that proof validation and construction should be taught together for better learning (Kirsten & Greefrath, 2023; Powers et al., 2010; Stylianides & Stylianides, 2009) because "constructing or producing proofs appears to be inextricably linked to the ability to validate them reliably, and a 'proof ' that could not be validated would not provide much of a warrant." (Selden & Selden, 2015, p. 9).

Although it is suggested that proof validation can influence students' performance on proof construction, limited studies have explored the specific knowledge or skills acquired through proof validation that mediates this effect. The present study implemented a combined "proof validation-construction" activity to explore how students' rational behavior (cf. Habermas, 1998) was recontextualized from proof validation to subsequent proof construction activities according to Habermas' three components of rationality.

Theoretical Framework

Habermas' (1998) construct of rational behavior has been adopted by a few researchers (e.g., Boero, 2006; Boero & Planas, 2014; Morselli & Boero, 2011; Zhuang, 2020, 2023; Zhuang & Conner, 2018, 2020, 2022) into mathematics education as a theoretical framework for studying a variety of mathematical activities, including argumentation, modeling, proving, and problem-solving process. In these studies, Habermas' construct was used to analyze students' or teachers' rational behavior according to the three rationality components: epistemic rationality (focuses on the knowledge that use and play with); teleological rationality (focuses on how strategically choose tools or means to achieve the goal of the activity); and communicative rationality (focuses on the use of language toward reach understanding in the given community). The proof is a specific kind of mathematical activity in which students are expected to strategically choose specific tools to achieve the validity claims (teleological rationality) on the basis of mathematical rules, theorems, axioms, and principles (epistemic rationality), and communicate in a precise way with the aim of being understood by the given community (communicative rationality), which corresponds to Habermas' elaboration about rationality requirements in discursive practices (Boero et al., 2010; Boero & Planas, 2014). In order to analyze students' rational behavior in applying proof methods within set theory, as examined in this study, the requirements of the three components of rationality were defined as follows, adapted from Habermas' (1998) construct of rational behavior:

Epistemic rationality. Accurately validate or apply set theory definitions or operations (e.g., set difference, set inequality); ensure the sufficient and correct use of reasons and warrants in developing mathematical arguments.

Teleological rationality. Accurately validate or apply proof methods (e.g., proof by contradiction and contrapositive); ensure the use of proof methods is strategic in achieving the goal of the proof.

Communicative rationality. Accurately validate or write proof statements using correct mathematical language, visual representations, or symbolic notations; ensure a clear and concise proof structure without any irrelevant or distracting elements.

Methodology

This critical case study (Yin, 2018) focused on a cohort of mathematics graduate students from an online transition-to-proof course. Students' proof skills were exercised through a review of proof methods and their applications to set theory. The main objective of this course was to equip students who were pursuing a master's degree in mathematics with the proof skills needed before they proceed to advanced graduate-level mathematics courses.

In the initial weeks of the course, the instructor introduced the Proof Validation Framework (PVF; for more details, see Zhuang, 2023) and guided students in using it to validate proofs based on the three rationality requirements. Following this, students were expected to use the PVF to complete the weekly Proof Writer's Workshop (PWW) assignment individually, which required them to validate at least one purported proof common to the new proof methods covered in the course. Then, students were assigned to complete a weekly Proof Written (PW) assignment, which contains proof problems similar to the ones in their PWW assignment. The data of this study consisted of the written responses of 16 participating students to one of their weekly PWW assignments and PW assignments (see Figure 1), focusing on the week when they were introduced to proof by contradiction and proof by contrapositive methods. This study employed a microanalysis approach (Corbin & Strauss, 2015) to examine the written responses provided by each participating student.

Proof Writer's Workshop

> **Theorem 1:** Suppose $A \subseteq B$ and C is any set. If $x \in A - C$ then $x \in B - C$.

Proof. We will give a proof by contradiction. Suppose for contradiction that $x \in A \setminus C$ but $x \notin B \setminus C$. From the definition of set difference, this tells us that $x \notin B$ and $x \in C$. But $x \in A \setminus C$ tells us that $x \in A$ and $x \notin C$. It is impossible to have $x \in C$ and $x \notin C$, so we have a contradiction. Therefore the theorem statement is true. □

Proof Written Assignment

1.1 Suppose $A \subseteq B$, $a \in A$, and $a \notin B - C$. Prove by contradiction that $a \in C$.

1.2 Prove that if $A - B = A$, then $A \cap B = \emptyset$.

Figure 1: Proof Writer's Workshop (PWW) and Proof Written (PW) Assignment

Results

Proof Writer's Workshop

The results showed that out of the 16 students, 14 students were assigned either a revised or a failed grade to the purported proof presented. Among 14 students, 11 correctly identified errors about the definition of set difference (epistemic rationality), with some offering corrections, "using the definition of set difference and DeMorgan's [law] it should be $x \notin B$ or $x \in C$" or by offering a counterexample. Three students mistakenly believed that the writer accurately stated the definition of set difference. Of eight students who focused on teleological rationality, half correctly assessed the use of the proof by contradiction, while the others had an incorrect understanding of assumptions used for proof by contradiction. One student suggested that a direct proof method could potentially reduce the length of the proof. A consensus was reached on the clarity in writing of the purported proof for eight students who attended the communicative rationality component.

Proof Written Assignment

Four students struggled with epistemic rationality in exercise 1.1, failing to justify their arguments using existential quantifiers. One student wrote, "$a \in B$ contradicting $a \notin B$" but did not provide adequate warrants for where the assertion "$a \in B$" came from. All students successfully applied the proof by contradiction method with correct assumptions (teleological rationality). Several students included unrelated or redundant points (e.g., restating the definition in a general sense) in their proof writing (communicative rationality). For exercise 1.2, it was observed that 8 students failed to meet the requirements of epistemic rationality. Many students struggled to interpret the set inequality "$A-B \neq A$" (epistemic rationality) when using proof by contrapositive method. One student wrote, "We know that $x \notin A-B$, but since $x \in A$, we can conclude that $A-B \neq A$" without explaining why the exclusion "$x \notin A-B$" held, showing a gap in their logical reasoning. Regarding the teleological rationality, 14 students established the correct assumptions and worked logically toward the final claim based on the proof method they had chosen. One student failed to employ any proof method, and another student started with proof by contrapositive but lost track of what needed to be proven in the end. A few students presented unclear statements and constructed their proofs using lengthy sentences which made the proof harder to follow (communicative rationality). Table 1 presents students' rational behavior within PWW and PW assignments. The table provides the number and percentage of students who satisfied the requirements of each rationality component, taking into account the varying total number of students attending to specific rationality component in the PWW assignment.

Table 1: Students' Rational Behavior within Proof Writer's Workshop (PWW) and Proof Written (PW) Assignment

Components of Habermas' rationality	Number and percentage of students who met the requirements of rationality					
	PWW assignment		Exercise 1.1 (PW assignment)		Exercise 1.2 (PW assignment)	
	n	%	n	%	n	%
Epistemic Rationality	11	79	10	63	8	50
Teleological Rationality	4	50	16	100	14	88
Communicative Rationality	8	100	9	56	8	50

Note. The number of students counted in the PWW assignment may vary depending on how many students attend the specific rationality component.

Discussion and Conclusion

Table 1 illustrates a decline in the percentage of students meeting the requirements for epistemic and communicative rationality from proof validation to construction. It showed that merely knowing definitions or theorems (epistemic rationality) and checking languages or notations (communicative rationality) in proof validation did not guarantee students meet the requirements of these rationality components in subsequent proof construction exercises. The results reveal that proof construction is more challenging than validation, supporting the argument made by Selden and Selden (2017). On the other hand, the results of this study suggest that students' rational behavior in the three rationality components can be partially transferable from proof validation to proof construction. While some students did not fully satisfy the requirements of rationality in proof construction, they demonstrated the ability to bring accurate definitions of set difference (epistemic rationality) and to apply the proof by contradiction method (teleological rationality) learned from proof validation. These results support the previous studies (e.g., Kirsten & Greefrath, 2023; Powers et al., 2010; Stylianides & Stylianides, 2009; Yee et al., 2018) in underscoring the interconnectedness between proof validation and construction and the benefits of fostering them together. Further research is needed to continually explore the interrelationships between two proof activities and the advantages of fostering them together.

Drawing on Habermas' (1998) construct of rational behavior, this study examined the transformability of students' rational behavior between proof validation and construction. The adaption of Habermas' construct enables a thorough examination of students' attention, interpretation, and response to the three components of rationality, which help us better understand students' cognitive processes and abilities in these proof activities. Sometimes, students may arrive at a correct judgment while providing incorrect interpretations in terms of rationality components, as found in this study. Examining students' rational behavior in proof activities can offer valuable information for gaining insights into their understanding of mathematical concepts, strategies, and language.

AFFORDANCES AND LIMITATIONS OF PRISMS MATH VR SIMULATIONS FOR STUDENTS' MATHEMATICAL REASONING ABOUT RATIO AND SLOPE

Theodora Beauchamp

Candace Walkington
Southern Methodist University
cwalkington@smu.edu

Virtual Reality (VR) provides unique learning experiences that allow students to immerse themselves in three-dimensional environments where they can explore mathematical ideas. Prisms VR is a suite of VR simulations for mathematics that allows students to have simulated real-world modeling experiences while working through topics such as ratios and proportionality. We examine affordances and constraints of VR for mathematics learning, focusing on manipulating and switching attention between different dynamic representations of mathematical principles, some of which involve immersion. Findings showed that some students enjoyed the immersive experiences and were able to be successful moving between the representational forms in VR, while others struggled with the overwhelming environment.

Keywords: Cognition, Learning Theory, Technology, rational numbers, proportional reasoning

Introduction

Virtual Reality (VR) in math education provides learning opportunities for students through a multimodal approach, using body movements, hand gestures, and perspective-taking to interact with objects in virtual worlds. VR is when a user is transported to a fully virtually-rendered world, often by wearing a headset that completely overlays their visual field with dynamic digital graphics. There is currently a lot of enthusiasm about the possibilities of VR for mathematics education, with many meta-analyses highlighting VR's positive results on learning (Cao, 2023; Villena-Taranilla et al., 2022; Yu, 2023). Prisms Math (Prisms of Reality, 2020) is the first widely-available and relatively-affordable suite of VR mathematics simulations for middle and high school, intended for use at scale in schools. But research on this program has again focused on its positive effect on pre- and post-scores (WestEd, 2023), without an accounting of what happens as students engage in mathematical reasoning in these environments. Our research question is: What are the affordances and constraints of immersive VR simulations for middle school students' mathematics learning?

Theoretical Framework

Contemporary VR systems can allow students to interact with virtual objects using their bodies to manipulate and move around the objects. This capitalizes on embodied views of the nature of cognition (Lakoff & Núñez, 2000; Nathan, 2021), which posit that all conceptual knowledge is understood and experienced through the body and is action-based in nature. Embodied views of mathematical cognition often give rise to learning pedagogies where students engage in perceptual, sensorial, and motor activities to deepen their understanding of mathematical ideas (e.g., Abrahamson & Sánchez-García, 2016; Dimmel & Bock, 2019; Smith et al., 2014), including through gestures.

Here we examine three affordances of VR highlighted by Dimmel et al., (2021) – these include that spatial inscriptions in VR can be: (1) viewed from different visual perspectives, (2) explored at different scales, and (3) interacted with in three spatial dimensions. When students interact with 3D objects in VR, they do not only move their hands but their entire bodies as part of their perceiving processes (Bock & Dimmel, 2021; Dimmel et al., 2021).

In terms of constraints of VR, Walkington et al. (2021) found that mathematics teachers highlight their technical and logistic limitations, as well as issues with behavior management and content coverage. In another work, Ke and Carafano (2016) conducted a mixed-methods study where the authors explored an immersive, flight-simulation learning game for high school students. The found that the more immersive simulation generated distractions and sensory overload, potentially hindering learning, with additional challenges in physical setup.

Methods of inquiry

Participants and Procedures

Participants included 9 middle school students who were participating in a district summer school. The students consented to participate in a VR summer tutoring program from a larger study. The students self-identified three as male and six as female; six identified as Hispanic and two as African American. Students wore the Oculus Quest VR headset for 1-4 afterschool tutoring sessions that lasted 30 minutes – 1 hour. They played the VR math game “Prisms Math” while being supported by a trained math tutor.

Within Prisms Math, students were given two simulations to work through. Each simulation started with an interactive immersion activity (Table 1: Immersive Satellite, Train). In the first simulation of ratios, students attempted to hit the “send” button to send location and time data back to Earth from a satellite. In the second simulation of rate of change, students were stopping the train but pulling down the brake lever to calculate “thinking distance.” In both simulations, after the initial immersive experience was complete students were brought to the “lab” to figure out if the satellite was in its orbit in the ratios simulation and the rate of change train simulation to calculate various types of weather conditions (Table 1: tasks Lab Satellite, Lab Train).

Description	Image	# of Ss Reached
Immersive Satellite: Students are in a control center and manipulate where a satellite goes with their hands at different angles, learning about ratios.	 	9
Lab Satellite: Students are moving the satellite to find the distance traveled for multiple measures such as ½ and ¾ of the orbit. They use this information to calculate the unit rate.	 	9
Immersive Train: Students are in a moving train roleplaying being a train conductor. The goal is to stop the train with minimal reaction time.	 	5
Lab Train: Students compared the thinking distance of a train conductor through three types of weather to see if the weather had an impact on the time it takes to stop the train.	 	5

Table 1: Descriptions of the Simulations Used in Prisms Math

Kosko, K. W., Caniglia, J., Courtney, S., Zolfaghari, M., & Morris, G. A., (2024). *Proceedings of the forty-sixth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Kent State University.

Data collection and analysis

Participants took a pre-survey. They used the Meta Oculus 2 VR goggles through four sessions working through the Prisms simulations of *Ratios* and *Rate of Change*. After each session, students were given post-surveys regarding their experience with Prisms and the VR headset. Participants were also video-recorded and their videos coded into three categories. The first category was *manipulation of the satellite simulation*, or the number of times students moved the satellite to show the satellite's distance traveled and fill in the table with the correct distance. While doing this a few times showed engagement and immersion in the VR context, we saw that doing this many times indicated struggle. For the second (*switching representations in satellite simulation*) and third (*switching representations in train simulation)* categories, in both simulations, students had to move within the visual field to four sections: a data table, an interactive simulation of the satellite or train, a hint button with a hint displayed, and an answer tab where they fill in their answer. This movement to complete the task was counted, as again we saw that having to switch rapidly between these 4 different complex and immersive representations signaled difficulty.

Next, videos were coded using thematic analysis (Clark & Braun, 2017) where we looked broadly at affordances and constraints of the VR. For this coding, we focused in on elements of what was occurring that were *unique* to the environment being VR – that would that have been as likely to happen if the same simulation was on a flat screen. Themes were determined inductively, and multimodal analysis (Walkington et al., 2023) was then conducted for each theme to look at students' functional actions, speech, and gestures in the VR environment.

Results

In our results, we give one emergent theme for the affordance of VR for mathematics learning and two emergent themes for the constraint of VR for math learning. Our theme for the affordances of VR was that the simulations allowed some students to successfully *immerse themselves in a real-world scenario using 3D visualizations*. In Figure 1, the student manipulates the satellite by moving the handle to calculate distance. As they moved the handle the Virtual Assistant in the simulation filled in the table automatically. The transcript shows that this student, an eighth grade, male Hispanic, EL learner, was able to move fluidly between mathematical representations that were situated in real-world activities (i.e., the satellite moving) and more formal mathematical representations (i.e., the table and calculating the numerical answer) in the immersive environment (Lines 1-2 Figure 1). This affordance is supported by the data showing students making fewer satellite moves and left to right movements in both simulations. The students' positive response to the environment is further highlighted in their post-survey response, where they said with respect to the VR simulation: ("It is intesesing and is not boreag" (It is interesting and not boring)).

1. **Virtual Assistance (VA):** [Explains the task given to the student], *(Student moves satellite one click at a time and each time turn head to the left to check the graph being filled in with the angle. P1-P2)*
2. **Student (S):** *(student does not have 1/2 of the orbit and attempts to press on the graph. Then goes back to the satellite model and manipulates it clockwise to the ½ of the orbit which then completes the graph. P2)*

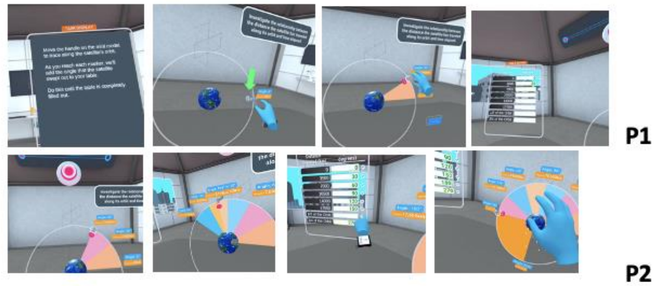

Figure 1: Using Ratios Simulation in Prisms VR

Our first theme for constraints of VR is that students *struggled to move between different representations* presented in the VR environment. The immersive simulation, along with different math representations and hints, overwhelmed some students. Those who didn't understand the satellite's role tended to manipulate it excessively. In both simulations, we observed students frequently scanning the visual field from left to right. In the post-survey answers to the question, "What didn't you know about VR that you do know?", an eighth-grade, male Hispanic student said, "That math is more hard in VR the in real life". Another post-survey question was "What did you dislike about VR?" An eighth-grade Hispanic male, responded, "I need more hints than just one."

Our second theme was that the facilitator *struggled to understand the issues students were experiencing* due to not being able to see from their immersed first-person perspective (Figure 2). Figure 2 shows the researcher communicated with the student multiple times to try to assist. However, the student struggled to explain where they were in the visual field (Line 4, P2). They also say in Figure 2, "I don't know what to divide it by" and "Maybe I can times it by 3?" showing that the facilitator was not able to provide assistance.

1. **Student (S):** OK OK so 3100 all of these are unit travel. 60 minutes so right there and I'm like right here so 12345678 9 so 9 minutes your travels we don't know. Oh, I need help. *(Student toggles around the space not sure where to start. -P1)*
2. **Researcher (R):** What part are you on? Where are you at? *(Researcher waits for student to explain)*
3. **(S):** I think the rate the amount of drivers in a minute is 3500 and I'm trying to and I don't know what to divide it by. *(Student attempts to use calculator and is not sure what exactly needs to be done so solve it. -P2)*
4. **(R):** What do you see? What does it say in the hint? *(Student doesn't share what they see, student reads the hint. -P2)*

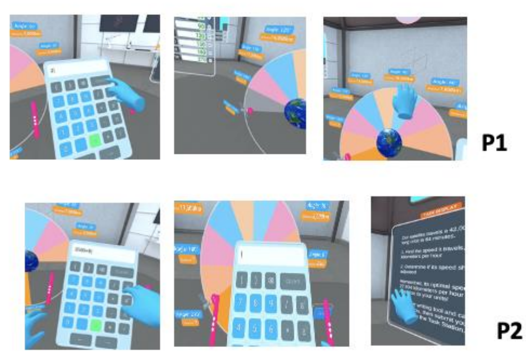

Figure 2: Communication Issue Using Ratios Simulation in Prisms VR

Discussion and Conclusion

This study analyzed rich, in-the-moment interaction data as students used a commercial VR simulation suite for secondary mathematics – Prisms Math. We found that the immersive nature of the simulations of real-world phenomena (driving a train, controlling a satellite in orbit) was a huge affordance of VR, as were the positive affective reactions students had to this environment. However, we also found that students struggled to make sense of the multiple, immersive representations of mathematical ideas in a very crowded and sensory visual field, and the facilitator struggled to provide meaningful assistance to students without access to their first-person view in the VR. One implication of this research is that additional and new considerations of how to scaffold students' mathematical learning need to be brought in VR environments. Scaffolds are needed that focus students' attention, reduce visual and sensorial complexity, and allow teachers to deeply understand what they are experiencing in their immersive environment. A second implication of this research is that future VR designs should follow Prisms Math in leveraging immersive, real-world, even fantastical situations (like controlling a satellite from a space station or driving a train), which students would be unlikely to ever experience in real life. This kind of immersion can be powerful for student engagement.

THE BEST START: A BLOOMSIAN PERSPECTIVE ON AI-POWERED INNOVATIONS IN MATHEMATICS EDUCATION

Anastasia Betts
University of Buffalo SUNY
albetts@buffalo.edu

Diana Hughes
Fellow, EdSafe AI Alliance
hughes.di@gmail.com

Sunil Gunderia
Age of Learning, Inc.
sunilgunderia@gmail.com

The field of mathematics education faces multifaceted challenges in uncertain times, and preparing learners for the future of work and participation in society requires fostering essential skills and knowledge, including quantitative literacy and mathematical reasoning. Aligning mathematics education with emerging societal trends necessitates a strategic approach, leveraging technologies like AI to enhance instruction while mitigating associated risks. This call to action uses Bloom's (1984) Four Objects of Change as a framework for discussing recommendations for AI supported designs and solutions for learners, educators, curriculum content and materials, and families.

Keywords: Early Childhood Education, Learning Theory, Policy, Systemic change, Artificial Intelligence, Technology

Introduction

The field of mathematics education presently faces a myriad of multifaceted challenges that demand a re-evaluation of our current practices and a renewed commitment to addressing persistent issues. The conference theme which asks us to consider the "*future of mathematics education in uncertain times*" urges us to confront the complexities of the present moment while charting a course towards a more equitable and effective future.

At the heart of any discussion about the future of mathematics education is an acknowledgment of present challenges. Consider that despite decades of effort and substantial investment of time, energy, and capital, we have not substantially increased the mathematics achievement of nearly two-thirds of students in the United States to grade-level proficiency (deBrey et al, 2019; NAEP, 2022). Additionally, the concept of "uncertain times" encompasses a range of challenges, including a worldwide pandemic that saw an explosion of edtech solutions and alternative schooling options, raising concerns about quality and equity, and exacerbating mathematics achievement challenges (Dorn et al., 2021; Patrinos, Vegas, & Carter-Rau, 2022). Furthermore, recent developments in AI have increased its integration into education spaces underscoring the need for more strategic foresight and critical examination of its impacts (U.S. Department of Education, 2023).

Preparing Learners for the Changing Nature of Work & Society

Preparing learners for their future involves two things: (1) understanding the future students will inhabit, and (2) facilitating educational experiences that empower learners with the requisite skills, attitudes, and knowledge to succeed in that future. Though the purpose of education has been defined in different ways over time, more recent conceptions include its framing as an economic good for both society and individuals (Locatelli, 2018; Murray, 2023). Meaning, an educated citizenry not only promotes the successful functioning of a society through economic prosperity as a whole, but also through the economic prosperity of the individual.

The future of work and society is already here. Technological advancements are changing the nature of work and society at a pace unseen in human history. Current projections show that "by

2030, activities that account for up to 30 percent of hours currently worked across the US economy could be automated—a trend accelerated by generative AI" (Ellingrud et al., 2023, p. iv). These changes predict increased occupations in the field of healthcare, STEM, and development (i.e., building and construction)--all of which require strong mathematical knowledge and reasoning. Analyses conversely estimate dramatic reductions in jobs earning the lowest wages with the least educational requirements: "Automation's biggest effects are likely to hit other job categories. Office support, customer service, and food service employment could continue to decline" (Ellingrud et al., 2023, p. iv). These changes are coming fast, with workers in the lowest wage quintiles (i.e., pay ranges of $30K to $38K) 10 to 14 times more likely to need to change occupations by 2030 (Ellingrud et al., 2023).

Work is not the only aspect of adult life that is changing; the past few years have seen unprecedented change in society as well. Students today swim in a sea of data, bombarded by a proliferation of unsubstantiated information, biased interpretations, "alternative facts," "fake news," and more. Successful navigation of adult life today and for the foreseeable future requires acute quantitative literacy that empowers individuals to evaluate, interpret, and develop insights from data in new ways (Elrod, 2014; Yeom, 2021). Calls "for educational approaches that can promote an understanding of how mathematics and statistics are used to serve social power structures or manipulate and shape public opinion" (Gal & Geiger, 2022, p.7) are growing in response to the changing social, civic, and political landscapes.

The implications of these changes in the future of work and society are monumental. They require us to create mathematics education systems that empower learners with deeper mathematics knowledge, stronger mathematical competencies, more creative problem solving, and more rigorous quantitative reasoning. In a world where computational and procedural aspects of work are done by machines, tasks that can't be automated or synthesized, or predicted by large language models, will need to be done by humans who have the ability to think critically, engage in high level problem posing and creative problem solving, and to reason logically. As Pink (2006) said decades ago, "we are moving from an economy and society built on the logical, linear, computer like capabilities of the Information Age to an economy and a society built on the inventive, empathic, big-picture capabilities of what's rising in its place, the Conceptual Age" (p. 2). Learners with strong math knowledge and skills who reason quantitatively, think critically, and creatively problem-solve, will have a distinct advantage in the future they face.

Given this, important questions to ask as stakeholders in mathematics education include:

(1) What is being done to develop learner competence in these areas (e.g., mathematical knowledge & skills, problem-solving, quantitative reasoning, etc.)?
(2) How are we leveraging emerging technologies (such as generative AI) to facilitate learner competence in these areas at scale?
(3) How are we applying the learning sciences to increase learner mathematics competence across the PreK-12 learning cycle?

Perhaps a further question we might pose is, *how will we know our efforts are succeeding?* Presently, we lack the proper instruments to truly answer this question. Consider that even though some progress has been made in moving from assessments that measure procedural knowledge to better measure conceptual knowledge and higher-order reasoning (Thompson, 2008), state and national measures of achievement only have limited means of assessing student critical thinking, creative problem solving, and real-world applications of their mathematical knowledge (Manouchehri et al., 2016). Moreover, in the broader field of education, resistance (at best) or denial (at worst) permeates efforts to change. Tripses (2019) points out that "a lack of deep motivation exists, whether individually or on a societal level, to understand how innovative education differs from past practice. At most, innovations are tolerated as long as they lead to adequate performance on traditional measures. Assessments are almost all geared for classical subject matter and rarely offer the means to assess the flexible, cooperative thinking required for interdisciplinary thought" (p. 25). Conversely, another challenge includes a rush to adopt and implement new technologies (such as generative AI), which can be viewed as problem-solving panaceas, without critical thought about how best to do so (U.S. Department of Education, 2023; NCTM, 2024). That being said, new paradigms for thinking about the future of mathematics education are vital if we hope to prepare learners for the additional challenges the future will bring.

AI's Potential Impact

The rapid evolution and adoption of artificial intelligence (AI) has the potential to contribute to the development of these new instructional paradigms. However, the speed of development and adoption has far outpaced the adoption of frameworks and policies that guide the use of AI. This discrepancy leaves room for misuses that can undermine educational objectives or compromise student privacy. As professional organizations and government organizations alike begin to grapple with AI's implications for education, two themes emerge. First, AI has the promise to enhance mathematics instruction, in part by "creat[ing] positive pressure to avoid the 'shallow assessment' trap and create assignments and assessments that blend the fundamentals and creative thinking." (NCTM, 2024). Second, AI has the potential to limit opportunities, perpetuate biases, and spread misinformation (OSTP, 2024), so a cautious and judicious approach is warranted.

Theoretical Framework

In considering how to obtain maximum benefit from AI while reducing its risks, it is helpful to consider a learning sciences approach as a framework for investigating AI's potential impact on mathematics education. Bloom's (1984) research showed that learners working one-to-one with an expert tutor using a mastery-based approach were able to increase their achievement two standard deviations over that of their peers in a business-as-usual classroom condition. Much of Bloom's subsequent work centered on how to adjust the conditions of the whole class environment such that the achievement of these students could begin to approach the desired achievement of those working with an expert tutor. As part of this work, Bloom identified four "objects of change" which could be acted upon to produce better outcomes for student learning which included the *(1) child, (2) materials, (3) teacher,* and the *(4) environment,* which for Bloom largely meant family and peers.

Often interventions or initiatives designed to improve mathematics performance may only focus on one or two of these four objects. For example, programs may focus on improving learning materials only, or perhaps they might add in "implementation" training for the teacher. However, Bloom viewed these objects as the focus of critical, sustained efforts to improve quality. In other words, serious and ongoing professional development for the teachers to increase their content area and pedagogical expertise in the subject area (e.g., mathematics), not just providing training for program implementation. Bloom further explained that working only through one of the objects was less likely to produce the desired outcomes as working through multiple objects, essentially adopting an ecosystems approach.

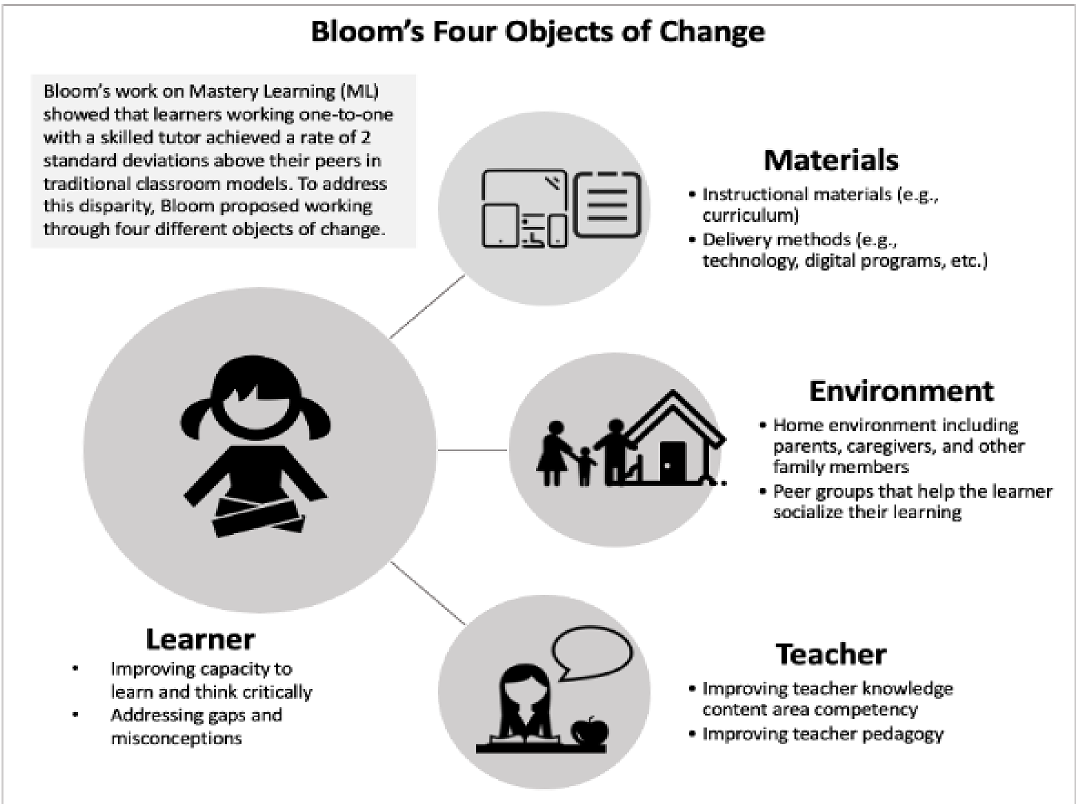

Figure 3: Bloom's Four Objects of Change (from Authors, Date)

Bloom's recommendations that efforts to increase student learning and achievement by leveraging these four objects of change seem, on the one hand, perfectly self-evident. Of course initiatives targeting to improve student learning should seek to work through all avenues possible – and yet so often, efforts do not give equal attention to each of these objects. More often than not, programs and initiatives may overly focus on one object (e.g., the materials and content) and only tangentially focus on the others (if at all). However, in recent years, adopting an ecosystems approach to learning, which involves giving equal attention to increasing the quality and performance of all parts of the system (e.g., child, materials, teacher, families, etc.), has received more concentrated attention (Authors, Date). This has included international calls from the Office of Economic Cooperation and Development (OECD), stating "to attain the desired outcomes of a curriculum reform (i.e., students' development and application of knowledge, skills, values, and attitudes) necessitates more than changing teaching and learning outputs. It involves making coordinated, multifaceted changes at the classroom, school, and policy level." (Taguma & Barrera, 2019, p.3).

A Bloomsian Perspective on the Future of Mathematics Education

Bloom's four objects of change, combined with a future learning landscape disrupted by evolving applications of artificial intelligence, provides a useful theoretical grounding for an examination of the future of mathematics education. With Bloom's framework and AI in mind, we can begin to think about the child who sits at the heart of the mathematics learning ecosystem, how their mathematics learning journey begins in early childhood, and the ways AI can be leveraged to give every child the very best start (NAEYC & NCTM, 2010).

The Future Early Mathematics Learner

Early childhood is a pivotal time for shaping a child's trajectory in mathematics. During these formative years, children are inherently equipped with a remarkable capacity for learning, characterized by extensive neuroplasticity that allows for the rapid absorption and integration of new knowledge (Muthukrishnan et al., 2019). This period is critical for embedding fundamental mathematical concepts such as number sense, pattern recognition, and spatial understanding, which serve as the building blocks for all future mathematical learning (Clements & Sarama, 2020).

Early childhood is the best time to prevent gaps in foundational mathematics knowledge before they form (Claessens & Engel, 2013; Duncan et al., 2007). However, even as early as pre-kindergarten, learners are beginning formal schooling with a patchwork of "math readiness" knowledge and skills (Authors, Date). This uneven foundation leads to variability in learners' ability to learn, and the pace at which they can learn the required skills in kindergarten. Though teachers may wish to attend to the personalized needs of every student, the constraints of traditional classroom environments often prevent such personalization.

The potential of artificial intelligence to enhance personalization through the identification and amelioration of student errors and misconceptions, even in early childhood, represents a significant area of promise (Authors, Date). A model, when trained with the learning experiences of a vast number of students, ranging from hundreds of thousands to millions, could be capable of discerning the typical mistakes and underlying misconceptions students possess (Lin, Luo, & Qian, 2023). Once these errors and misconceptions are recognized, a model that has been educated on examples of skillful instructional methods can generate corrective feedback. This feedback, specifically designed to address the misconception directly, could then guide a student through the necessary steps to comprehend the correct solution. This approach ensures that students receive the precise assistance they require in a timely manner, thus minimizing time spent on ineffective strategies and maximizing engagement with the most effective pathways to successful learning outcomes. Examples of this exist and are already deployed with thousands of Prekindergarten through Second Grades students, and more importantly, are producing learning outcomes at scale (Authors, Date; Bang, Li, & Flynn, 2023; Thai, Bang, & Li, 2022).

It is important to acknowledge that the strategies mentioned herein are not inherently innovative; the effectiveness of personalized learning has been understood for decades. The transformative potential of AI lies in its capacity to emulate these effective classroom practices within digital platforms, enabling dramatic amplification and scaling.
