Los tres investigadores participamos en el análisis de los videos de las clases de una maestra de matemáticas de secundaria en México (voluntaria) con experiencia en el uso de tecnología y con disponibilidad para ser grabada. Esta maestra participó previamente, junto con otros profesores, en un taller de 20 horas sobre CAS con la calculadora (TI-82). De manera general, el taller trató sobre cómo resolver problemas algebraicos usando las funciones *factorizar, desarrollar, resolver* y *evaluar*. La discusión en el taller estuvo centrada en las diferentes maneras en las que se puede resolver un problema algebraico con calculadora, así como cuándo es adecuado usar CAS en una clase, cómo y para qué. Decidimos observar y grabar dos clases regulares de la maestra, sin que los investigadores determináramos el tema y tratamiento didáctico al mismo. La maestra durante el taller mostró tener conocimiento de las reglas del CAS y su uso con la calculadora, así como, habilidades para explorar nuevas situaciones relacionadas con las reglas propias de esta herramienta y proponer nuevos usos a sus alumnos. Cabe señalar que se han reportado resultados de otro estudio

(García-Campos & Rojano, 2008) en el que se menciona que para que el uso de CAS logre impactar en la práctica docente es necesario brindar mayor acompañamiento a los profesores, pues a corto plazo éstos no logran incorporar CAS de manera cotidiana en el aula.

En este reporte nos centraremos en los resultados del análisis de la práctica de la maestra Clementina, de quien sabemos que en el momento de la investigación tenía más de 20 años de experiencia dando clases en secundaria, dominaba los contenidos a enseñar y conocía las componentes de la calculadora que permiten tener, de manera simultánea, distintas representaciones para los objetos algebraicos (tablas, gráficas y expresiones algebraicas), y las instrucciones para resolver ecuaciones.

Para el análisis de los datos se hizo una transcripción de los episodios que los tres investigadores seleccionaron al haber identificado conocimientos didácticos del contenido expresados a través de las siguientes estrategias didácticas.

Estrategias Didácticas como un Acercamiento a Aspectos del Conocimiento Didáctico del Contenido Matemático

Los autores proponemos estas tres estrategias didácticas como resultado de un estudio más amplio en el que se ha estado trabajando mediante el análisis de videos de clases de más profesores de matemáticas de secundaria (incluso telesecundaria). En dichas clases hemos identificado estas estrategias, las cuales dan cuenta además de algunos de los conocimientos especializados que los profesores generan y movilizan al momento de impartir sus clases (*To be enacted*) como lo señala Davis (2014). Los resultados de tal investigación serán comunicados ampliamente en un futuro.

En el análisis de los videos de las clases de Clementina identificamos que su conocimiento especializado se manifestó en tres estrategias didácticas:

- Mantenimiento de la planeación de la clase. Consiste en la toma de decisiones para mantener el desarrollo de la clase de tal manera que se cumplan los propósitos de aprendizaje que planteó el profesor considerando el contenido del currículo a enseñar y los recursos a su disposición. Estas decisiones son, por ejemplo, elección de soluciones, procedimientos y errores para discutir o mostrar con el grupo completo, recapitulaciones, balances, formalizaciones, etc. En esta estrategia se hace énfasis en los conocimientos del profesor en los subdominios KMT y KMLS.
- Rol otorgado a los estudiantes. Un mismo profesor puede promover distintas formas de participación en sus estudiantes en una misma clase (KMT). Por ejemplo, que exploren sus soluciones y las expongan, que pasen al pizarrón o usen CAS (con el TI presenter) para explicar sus procedimientos, soluciones o hipótesis, o que simplemente sigan las instrucciones.
- Usos de las herramientas tecnológicas. Los profesores proponen el uso de los recursos tecnológicos disponibles para verificar resultados, explorar procedimientos y soluciones, aplicar técnicas, entre otras. (KMT y KFLM)

En este reporte nos centraremos en los resultados del análisis de la práctica de una maestra que llamaremos Clementina. De la entrevista, sabemos que en el momento de la investigación Clementina tenía más de 20 años de experiencia dando clases en secundaria, dominaba los contenidos a enseñar y conocía las componentes de la calculadora que permiten tener, de manera simultánea, distintas representaciones para los objetos algebraicos (tablas, gráficas y expresiones algebraicas), y las instrucciones para resolver ecuaciones.

Análisis y Discusión. El Caso de Clementina

A continuación, presentamos resultados del uso de las estrategias para dar cuenta del tipo de conocimiento que Clementina moviliza en la clase. Este análisis nos permite describir la dinámica de cómo las componentes del MTSK se entretejen. La maestra tiene una *planeación* detallada y precisa de su clase usando CAS. Ha preparado un problema específico. Al parecer, ella misma lo redactó o hizo la adaptación correspondiente. Tanto en la planeación como en el desarrollo de la clase se evidencian dominio y experiencia en el manejo de las ecuaciones de primer grado (KMLS), cómo enseñarlas (KMT) y las diferentes posibilidades de sus alumnos para abordar la tarea propuesta (KFLM).

Breve Descripción de las Acciones de la Maestra en la Clase

Al inicio de la sesión, la maestra dicta el problema, el objetivo y da instrucciones de cómo trabajar en la clase, como se muestra en el siguiente fragmento.

> Maestra: Tema: Ecuaciones lineales. Propósito general: Despejar literales en diferentes tipos de fórmulas. Relacionar una fórmula con la tabla de datos que genera y con su gráfica.
> Problema: En una tienda se compran 9 paquetes de libros, el cual tiene un precio adicional de $75 [sic]. ¿Cuánto cuesta cada paquete si en total se pagan $1400?
> Maestra: Leer el problema. Ya que lo tengas planteado, puedes usar la calculadora para resolverlo. Lo pueden resolver entre tres o dos o uno, los que sean en cada mesa.
> [Fragmento 1, sesión 1]

A pesar de que sus clases son muy estructuradas y se desarrollan de acuerdo a la planeación definida, se observa que en su práctica siempre da un momento de reflexión y lectura del problema, seguido de uno de exploración con los recursos y estrategias que los alumnos decidan. Los alumnos usan la calculadora libremente y levantan la mano para preguntar dudas a la maestra. Ella recorre el salón, pasando entre los equipos y aclarando las dudas que surgen. Consideramos que ésta es una manifestación de su conocimiento sobre cómo se aprende este contenido (KFLM).

Un Problema Didáctico no Previsto en la Planeación

Un problema didáctico que emerge en la clase está vinculado con la palabra "adicional" usada en la redacción del enunciado del problema. Los estudiantes tienen problemas para interpretar a qué se refiere y, espontáneamente, comienzan a explorar con valores numéricos específicos. Entonces la maestra interviene de la siguiente manera.

> Maestra: Tu compañera dice que cuando se emplea el término *adicional* se está refiriendo …
> Alumna: A que le tienes que aumentar.
> Maestra: En este caso, ¿cuánto le tienes que aumentar?
> Alumna: 75
> Maestra: ¿Cómo quedaría tu ecuación? […] ¿En qué consiste el problema? Tú vas a elaborar una tabla [se dirige a una estudiante] ¿En base a qué vas a elaborar la tabla?
> [Fragmento 2, sesión 1]

En el fragmento 2 podemos identificar dos intervenciones de la maestra. La primera es para ayudar en la traducción del problema al lenguaje algebraico. La palabra *adicional* se traduce como *aumentar* o *sumar*. La segunda ayuda consiste en sugerir que se enfoquen primero en encontrar una ecuación que modele el problema. Además, les dice a sus alumnos que partir de la ecuación podrán hacer cuentas, encontrar valores y construir la tabla de variación correspondiente, al revés de lo que ellos están haciendo: explorar con valores numéricos para establecer la ecuación. Cabe señalar que en México es una práctica recurrente obtener primero la expresión algebraica y después la tabla o la gráfica. Esto se propicia desde el mismo programa de estudios (SEP, 2011).

Desde nuestra perspectiva, lo anterior es una manifestación de que la maestra aplica la primera estrategia: *mantiene la planeación de la clase*. Aunque los estudiantes exploran con ejemplos numéricos con objeto de establecer las relaciones dadas en el problema, Clementina interviene para orientar esos procedimientos y hallar la ecuación que modele el problema (KFLM y KMT). De esta manera, resuelve el problema didáctico que se le presentó y mantiene su planeación.

Pero las dudas y confusión continúan. Entonces, la maestra hace una intervención grupal. Toma las dudas de uno de los estudiantes para discutirlas y aclararlas grupalmente. El estudiante ha estado probando con varios posibles valores para el costo de cada paquete. Al parecer, ha recurrido al *ensayo y error* (aproximaciones numéricas sucesivas) para ajustar los valores.

Maestra: ¿Qué es lo que quiere saber tu problema? [inaudible] Quiere saber cuánto cuesta un paquete, ¿cuántos paquetes compró?

Alumna 2: Nueve

Maestra: Ese nueve qué le harías. Dice tu compañera que tiene que elaborar una tabla. Pero, ¿cómo lo establecerías? […]

Alumno 3: Mil cuatrocientos treinta y nueve (1 439)

Maestra: Y entre qué lo vas a dividir, ¿y los adicionales? [Siguen discutiendo]

Maestra: Otra vez, un paquete no te puede costar $75. Es adicional. Vamos a considerarlo como un aumento […] ¿Cómo te quedaría tu ecuación? Nuestro tema, ¿qué dice? [los estudiantes leen lo que la maestra dictó al inicio de la clase] por lógica tenemos que sacar una ecuación [...] Muchos ya se fueron a tabular, ¿qué vas a tabular? Yo quiero ver nada más el planteamiento.

[Fragmento 3, sesión 1]

Las intervenciones de la maestra [fragmentos 2 y 3] orientan la clase hacia identificar la incógnita, las relaciones entre los datos y la incógnita, y la igualdad. Nuevamente, mantiene su objetivo principal para esta sesión: obtener una ecuación que modele el problema (KMLS). En este momento ella se enfrenta a otro problema didáctico, pues los estudiantes siguen obteniendo distintos resultados numéricos sin encontrar ninguna ecuación.

Una de las alumnas encuentra una ecuación y la maestra le pide que pase al pizarrón. La alumna escribe "$9x + 75 = 1400$". La maestra elige socializar en el grupo esta solución y, al mismo tiempo, deja sin discutir soluciones diferentes, como las numéricas obtenidas mediante ensayo y error. Así, la maestra privilegia la ecuación resultante de la traducción del problema (y su solución numérica), sin importar las técnicas que se puedan usar para resolver la ecuación, con lápiz y papel o con CAS (presencia de conocimientos KMT y KFLM).

Después de planteada esta ecuación (objetivo principal de la clase), la maestra pide a los estudiantes que la resuelvan, dándoles libertad de tiempo y de elegir usar calculadora o lápiz y papel. Para Clementina, el uso de CAS es opcional. Se trata de la estrategia que define el *uso que se da a la tecnología*.

Una vez resuelta la ecuación pasa a los equipos para presentar sus soluciones, en su mayoría son numéricas. Entonces elige a una alumna que resolvió la ecuación algebraicamente, paso a paso y con lápiz y papel. Esta solución se muestra en la Figura 2(a).

Al percatarse de que la mayoría de los alumnos no están de acuerdo con el valor $x = 147.22$, pregunta qué soluciones encontraron. Aquí la maestra pone en marcha otra de sus estrategias: usa las producciones de sus estudiantes (*rol de los estudiantes)* para contrastarlas, confrontar errores y procedimientos (los últimos en este caso) y hacer aclaraciones (presencia de KFLM y KMT).

9x + 75 – 75 = 1400 – 75 9x = 1325 9x/9 = 1325/9 **x = 147.22** 147.22 x 9 + 75 = 1400 (a)	75 1400.00 725 /9 = 80.55 (residuo 1) x 9 - 675.00 675 0725.00 **R = 80.55** (b)

Figura 2. Soluciones propuestas (a) algebraica y (b) numérica

Ante las dudas que siguen manifestándose, la maestra promueve que los alumnos expongan sus soluciones. Los estudiantes tienen claro que ella había pedido que plantearan una ecuación que modelara el problema, por eso preguntan "¿pero con ecuación?". Entonces, la maestra elige a una alumna que obtuvo una solución numérica, la de la Figura 2(b). Al parecer, el procedimiento de la alumna es aritmético: deshace las operaciones. La maestra aprovecha esta solución para indagar, preguntando: "¿cada paquete dices que cuesta?" Y La alumna responde "$80.55". Posiblemente, la maestra identifica que la diferencia entre los dos procedimientos está determinada por el lugar en que se pone el paréntesis. Es decir, las ecuaciones correspondientes a los procedimientos de la figura 2 serían: $9x + 75 = 1400$, la primera; y $9(x + 75) = 1400$, la segunda. En esta intervención la maestra da muestra de su conocimiento de cómo los alumnos están interactuando con la ecuación y las ideas matemáticas (jerarquía de operaciones, asociatividad) que están detrás de estas propuestas (KLM). Quizás por ello, después de la explicación, pasa a la alumna que resolvió algebraicamente la ecuación para corregirla. Sin embargo, esta alumna agrega paréntesis a la comprobación: (147.22 x 9) + 75 = 1400, para obtener la respuesta correcta. La maestra dice que no se trata de ver quién está bien, sino de quién tiene el procedimiento válido. En sus palabras: "¿Cuál de los dos procedimientos creen ustedes que conviene? Repito: no es por mayoría."

En las intervenciones de la maestra, se evidencia que está enfocada en la estrategia didáctica que le permite enfatizar *el rol de los alumnos*, promoviendo la comparación de las distintas interpretaciones de las relaciones entre los datos y la incógnita del problema que los estudiantes han hecho. Los alumnos se enganchan en esta comparación, dan argumentos tanto a favor como en contra. En nuestro análisis identificamos que la maestra hace explícitas y pone a discusión dos interpretaciones de la palabra "adicional": 1) *adicional por paquete*, esto es, $9(x + 75)$; y 2) *adicional por los nueve paquetes*, $9x + 75$.

En términos de la riqueza de la discusión matemática que los alumnos desarrollan en esta parte de la clase, el problema ha sido fructífero: hay argumentaciones, comprobaciones, se usan los distintos medios tecnológicos y las distintas técnicas (CAS y lápiz y papel). Pero, en este momento, el tiempo de la clase prácticamente se ha agotado; así que el objetivo central de la clase ha quedado incompleto en lo que se refiere a "Relacionar una fórmula con la tabla de datos que genera y con su gráfica". La maestra intenta hacer un cierre de la discusión preguntando lo siguiente:

Maestra: ¿Cuál de los dos planteamientos o soluciones (procedimientos) consideran ustedes que es el correcto, de los problemas?
Alumnos: Los dos.
Maestra: Esto quiere decir que alguno de los dos está fallando [...] No necesariamente tienen que ser exactitos sin sobrar [...] Vamos a redondear [...], a uno le faltan dos centavos y al otro, cinco centavos […] Puedes perder décimas.

[Fragmento 6, sesión 1]

Clementina explica que los dos procedimientos tendrían que dar el mismo resultado y que no es el caso. En su argumentación apela a la unicidad de la solución de una ecuación, tema que al parecer no ha sido abordado en la clase. Tampoco es algo que haya sido considerado en su planeación (posible deficiencia en KMLS).

Hasta antes de este momento, la maestra había entretejido las estrategias de *mantener la planeación* y la del *rol de los alumnos* (manifestaciones de KMT y KFLM). Sin embargo, en este momento toma la decisión de modificar la planeación de su clase adaptándola a las necesidades de sus alumnos, a sus interpretaciones generadas tanto con lápiz y papel como con CAS. En los minutos restantes permite que los alumnos usen estrategias de solución en las que se sienten más cómodos y confiados, no necesariamente los típicos algebraicos (como el despeje de la incógnita). Abre espacios para que la alumna que planteó la ecuación y la alumna que propuso la interpretación aritmética expongan nuevamente al grupo sus interpretaciones y cómo obtener la solución. La maestra le pide a la alumna del procedimiento "aritmético" (Figura 2 (b)) que explique, en el pizarrón. Esta alumna dice que con otra compañera llegaron a la conclusión de que su procedimiento es correcto.

Alumna: Es que ahí en el problema no se comunicaba si eran 75 por cada uno o por todos. Y aquí ya comprobamos que si eran 75 por todos. Porque no puede ser por cada uno porque no queda, serían 1447.95

[La maestra pide a varios equipos que le lean el problema a la alumna para aclarar si los 75 eran por todos por cada uno.]

Maestra: ¿Habla [se refiere al enunciado] del paquete o de todo?

Alumna: Al enunciado le hizo falta una palabra.

Maestra: ¿Cuál sería?

Alumna: Que te dijeran que son 75 pesos adicionales por cada paquete [...]

Maestra: Para eso sirven los problemas, para ver cuando no están bien planteados, cada alumno lo va a resolver de diferente forma… Aquí de lo que se trata, hay que leerlo…

Alumna: si yo fuera maestra este problema tendría dos objetivos… No sólo es leer sino establecer las relaciones entre los datos y la solución.

[Fragmento 6, sesión 1]

Grupalmente, los niños llegan al acuerdo que los 75 adicionales son por los nueve paquetes, y que entonces la ecuación correcta es: $9x + 75 = 1400$. La maestra despliega un conocimiento de la enseñanza que le resulta efectivo en este momento: "cede" el control de la clase a sus estudiantes.

Reflexiones Finales

En el desarrollo de su clase, Clementina se enfrentó a un problema didáctico no previsto en su planeación debido a la redacción ambigua de la situación problemática planteada. Es por ello que hizo adaptaciones al objetivo de la clase, a su planeación y a la participación y los roles que tenía contemplados para sus estudiantes. Además, en este proceso, Clementina adaptó su propio rol, modificó sus expectativas, sus intervenciones e incluso cedió temporalmente el rol de "maestra hipotética" a una de sus estudiantes. Posibilitó el consenso entre el colectivo, cediendo el control de la clase a los estudiantes, y logrando establecer el significado de adicional y su implicación en la ecuación ($9x + 75 = 1400$). En el cierre de la clase retomó el objetivo planteado inicialmente, ubicándolo en el trabajo realizado y sin dejarlo a la deriva. Este tipo de adaptaciones de la planeación, del problema, de los objetivos, de las formas de participación de los estudiantes, pero también de las intervenciones y del rol mismo del profesor requieren de gran flexibilidad y adaptabilidad en los conocimientos especializados de los profesores. Consideramos que esta flexibilidad y adaptabilidad no son previsibles ni tematizables como contenidos a desarrollarse en programas de estudios de formación inicial. Para adquirirlos es necesario construirlos en la práctica. Indagar a mayor profundidad sobre estas estrategias y la interacción entre distintos tipos de conocimientos, puede tener implicaciones fructíferas para la formación de profesores, así como para la propia investigación en el área.

Agradecimientos

A PRODEP-SEP por el financiamiento del proyecto 23244-UPN-CA-100.

We present results of the analysis of knowledge used by a secondary school mathematics teacher in her classroom practice. This knowledge takes shape and is displayed as specific teaching strategies in the management of her class when she incorporates Computer Algebra Systems. Based on observations of regular classes, we find that her knowledge (mathematical, pedagogical and technological) is put into action at various moments during the lesson and through a variety of teaching strategies. These strategies depend on many factors, such as the planned objective of the lesson, the specific moment in the class, student participation, and the use of technological tools. Within such complexity, the teacher applies her teaching strategies in a flexible way, and manages to control and even modify the course of her class.

Keywords: Mathematical Knowledge for Teaching, Algebra and Algebraic Thinking, Middle School Education, Technology

Introduction

To approach the professional knowledge and practices of teachers of mathematics, several methodologies and frameworks for analysis have been suggested (Ball, Thames and Phelps, 2008; Ponte and Chapman, 2006; Gaeber and Tirosh, 2008). Ponte and Chapman (2006) propose the importance of considering the complexity of this sort of knowledge and its close relation with practice, working conditions and explicit and implicit objectives. Davis (2014) notes that the knowledge required by a mathematics teacher is a complex network where there is interaction between “a sophisticated and largely enactive mix of various associations /instantiations of mathematical concepts and an awareness of complex processes through which mathematics is produced” (P. 155). In fact, “the most important knowledge for teaching tends to be enacted and tacit” (p. 155).

With respect to the research on the use of digital technology (DT) in the teaching of mathematics, incorporating Computer Algebra Systems (CAS) into classrooms has been discovered to generate change in mathematical practice (Pierce and Stacey, 2004), and the teacher has a key role in providing conditions that help students understand mathematics with these tools (McFarlane, Williams and Bonnett, 2000).

We chose to study the teaching of algebra with CAS because it can be used to give meaning to algebraic transformations and expressions. Many investigations have provided solid evidence that technology can be an active element in building algebraic knowledge (Puig & Rojano, 2004; Hitt and Kieran, 2009; Kieran and Drijvers, 2006; or by Solares and Kieran, 2013.) We seek to understand how teachers mobilize this knowledge (mathematical, pedagogical and technological) and how they make sense of it in terms of their practice (Ponte and Chapman, 2006). We specifically want to know how pedagogical and mathematical knowledge is put into action during a lesson where CAS is used; and how this knowledge is revealed through teaching strategies.

Theoretical Perspective: Mathematics Teacher’s Specialized Knowledge

We have taken into account the *Mathematics Teacher’s Specialized Knowledge* (MTSK) model (Carrillo, Climent, Contreras & Muñoz-Catalán, 2013) as a starting point for analysis and in our consideration of the specificity of the knowledge that teachers put into action when they teach school algebra.

This model refers to the mathematics teacher's specific knowledge, which consists of two domains: Mathematical Knowledge (MK) and Pedagogical Content Knowledge (PCK). The first domain is composed of three subdomains: Knowledge of Topics, of the Structure of mathematics and of the Practice of Mathematics. The second, Pedagogical Content Knowledge is composed of: Knowledge of Mathematics Teaching, of Features for Learning Mathematics and of Mathematics Learning Standards.

We concentrated on the second domain (PCK) due to the characteristics of our research objective. Its three subdomains are briefly described as follows: *Knowledge of Mathematics Teaching* (KMT) is the integration of mathematics and teaching. "It is the kind of knowledge of resources from the point of view of their mathematical content or the knowledge of approaching a structured series of examples to help pupils understand the meaning of a mathematical item" (Carrillo et al, 2013, p. 2991); *Knowledge of Features for Learning Mathematics* (KFLM) include theories and models of how student learn mathematics, that is to said, how certain concepts are learned, intuition, mistakes, and the way students interact with specific mathematics content; and finally, *Knowledge of Mathematics Learning Standards* (KMLS) refers of "curricular specifications, the progression from one year to the next, conventionalized materials for support, minimum standards and forms of evaluation […] We include objectives and measures of performance developed by external bodies such as examining boards, professional associations and researchers" (Carrillo et al, 2013, p. 2991).

In our research, we focus on the knowledge that teachers display within classroom practice and that acquires a specific form as teaching strategies that they modify as they manage their lessons.

Methodology

Three researchers participated in the analysis of videos of a voluntary secondary school mathematics teacher in Mexico. The teacher had already participated in a 20-hour workshop on CAS with calculators (TI-82). In general, the workshop was about solving algebra problems using functions such as *factorize, develop, solve* and *evaluate*. The workshop discussion was centered on the various ways in which an algebra problem can be solved with a calculator, as well as when it is adequate to use CAS in the classroom, how and why. We decided to observe and make video recordings of two of the teacher's regular classes, without a prior decision by the researchers about the topic and how it would be treated from a pedagogical perspective. During the workshop, it was clear that the teacher knew the rules for CAS, as well as the skills to explore new situations related to these rules and propose new uses to students. It should be mentioned that a previous study (García-Campos & Rojano, 2008) states that in order for CAS to impact teaching practices, it is necessary to provide more support for teachers, because in the short term, they do not incorporate CAS on a daily basis in the classroom.

In this report, we focus on the results of the analysis of the practice of Clementina, a teacher who, at the moment of our research, had more than 20 years of experience teaching at secondary school level, had good proficiency of the mathematical topics to be covered, and was familiar with the elements of a calculator that allow a variety of simultaneous representations of algebraic objects (tables, graphs, expressions), and the instructions to solve equations.

Data analysis was developed using a transcription of the episodes selected by the three researchers once they had identified the pedagogical content knowledge expressed by means of the following teaching strategies.

Teaching Strategies as an Approach to Aspects of Pedagogical Content Knowledge (PCK)

We propose the following three teaching strategies that result from a broader study in which we have been working by analyzing videos of secondary school mathematics teachers. The strategies have been identified in these classes and account for some of the specialized knowledge that teachers generate and enact when they are teaching. The results of this investigation shall be published in detail in the future.

In the analysis of the videos of Clementina's lessons, we identified that her specialized knowledge was clear in three teaching strategies:

- Maintaining the lesson plan. This involves making decisions to keep the lesson going in such a way that the learning objectives determined by the teacher according to curriculum content and available resources are achieved. Examples of these decisions include: choice of solutions, procedures and mistakes to discuss or show to the entire group, summaries, assessments, formalizations, etc. The emphasis is on the teacher's knowledge of the KMT and KMLS subdominions.
- The role given to students. Teacher can promote various forms of participation in the same class (KMT). For example, students can be invited to explore and share solutions, to come to the board or use CAS (with the TI presenter), to explain procedures, solutions or hypothesis, or simply to follow instructions.
- The use of technological tools. Teacher proposes the use of technological resources available to verify results, explore procedures and solutions, apply techniques, etc. (KMT and KFLM).

Analysis and Discussion. The Case of Clementina

The results of the use of teaching strategies to account for the type of knowledge promoted in class by Clementina, are presented below. Our analysis allows us to describe how the components of MTSK come together. The teacher has a detailed and precise plan for the use of CAS in her class. She has prepared a specific problem, which she apparently wrote herself. Both planning and progress of the class show proficiency and experience in the solution of linear equations (KMLS), how to teach them (KMT), and the various ways her students will approach the task proposed (KFLM).

Brief Description of the Teacher's Actions in The Lesson

At the start of the session, the teacher dictates the problem and the objective of her lesson plan, and provides the instructions regarding how to work in the lesson, as shown in the following fragment.

> Teacher: Linear equations. General aim: Solving literal equations. Relating a formula to a table of data and its graph.
> Problem: We buy 9 packs of books that have an additional cost of $75 at a store [sic]. How much does each pack cost if the total price is $1400?
> Teacher: Read the problem. When you have posed it, you can use the calculator to find the solution. You can work on your own, or in groups of two, three or as many as there are at each table.
>
> [Fragment 1, Session 1]

Although her classes are very well structured and they develop according to a well-defined plan, we observe that Clementina always provides their students a moment to read and reflect on the problem, followed by time to explore resources and strategies. Students use the calculator freely, and raise their hands when they have questions. The teacher goes around the classroom from one team to another, answering questions as they arise. We consider that this demonstrates her knowledge regarding how to learn this subject matter (KFLM).

A Teaching Issue not Foreseen in Planning

A teaching issue related to the use of the word "additional" in the sentence that formulates the problem arises in the class. Students do not know how to interpret what the word refers to, and spontaneously begin to explore with specific numerical values. Then the teacher takes part in the following way:

> Teacher: Your classmate says that when you use the word *additional,* it means…
> Student: That you have to increase.
> Teacher: In this case, how much do you have to increase?
> Student: 75
> Teacher: What would your equation be like? […] What is your problem about? You are going to make a table [referring to a student] What is your table going to be based on?
> [Fragment 2, Session 1]

In Fragment 2, there are two moments at which the teacher intervenes. The first is to help translate the problem into algebraic terms; the word "additional" means to *increase* or *add* as she helped the student to realize. In the second instance, she suggests that the students should focus first on finding an equation that models the problem. In addition, she tells her students that with the equation they will be able to do the numbers, find values and build a corresponding table, which is the opposite of what they were actually doing: exploring numerical values to establish the equation. It is worth noting that in Mexico it is often observed that students first get the algebraic expression and then the table or graph. This practice is promoted by the national curricular plans (SEP; 2011).

From our perspective, the above shows that the teacher applies the first strategy: *maintaining the lesson plan.* Although the students explore the problem with numerical examples to establish the relationships posed by the problem, Clementina orients these procedures and to find the equation that models the problem (KFLM and KMT). In this way, she solves the teaching issue that arose and goes on with her lesson plan.

However, the questions and confusion continue. The teacher then invites the students to a group discussion. She picks up on the questions of one of the students to discuss and clarify them together in a group. The student has been trying several possible values for the costs of the packs of books. Apparently, he is applying a *trial and error* strategy (successive numerical approximations) to adjust the values.

> Teacher: What does your problem want to find out? [inaudible] It wants to know how much a pack costs, how many packets did it buy?
> Student 2: Nine
> Teacher: What would you do to that nine? Your classmate says she has to make a table. But how would you do that? […]
> Student 3: One thousand, four hundred and thirty-nine (1439)
> Teacher: What will you divide it by? And the additional? [Discussion continues]
> Teacher: Once again, the pack can't cost $75. That's additional. Let's consider it as an increase […] What would your equation be like? What does the general aim of the lesson tell you? [Students read what the teacher dictated at the start of the lesson], we logically have to obtain an equation [...] Lots of you have started to make tables, what are you going to tabulate?
> [Fragment 3, Session 1]

The teacher's participations (Fragments 2 and 3) orient the class to identifying the unknown quantity, the relation between the data and the unknown quantity, and the equation. Again, she maintains the objective of her lesson: obtaining an equation that algebraically models the problem (KMLS). Now she faces yet another teaching issue as her students begin to obtain different numerical results and still haven't found an equation.

In spite of the students difficulties, one of them finds an equation and the teacher asks her to come to the board. She writes "*9x + 75 = 1400*". The teacher chooses to discuss this solution with the group while she ignores other solutions, such as those obtained by trial and error. Thus, the teacher favors the equation that results from translating the problem and its numerical solution, no matter the techniques that can be used to solve it, either paper and pencil or CAS (KMT and KFLM knowledge).

Once the equation has been proposed (which was the main objective of the lesson), the teacher asks the students to solve it, giving them the time and freedom to choose a calculator or paper and pencil for this purpose. For Clementina, the use of CAS is optional. This is the strategy that defines *the use given to technology* for this lesson.

When the equation has been solved, the teacher asks the teams to present their solutions, which are mostly numerical. She then chooses a student who solved the equation algebraically, step by step, with paper and pencil. The solution is shown in Figure 2(a).

9x + 75 – 75 = 1400 – 75 9x = 1325 9x/9 = 1325/9 **x = 147.22** 147.22 x 9 + 75 = 1400 (a)	75 1400.00 725 /9 = 80.55 (residuo 1) x 9 - 675.00 675 0725.00 **R = 80.55** (b)

Figure 2. Proposed solutions (a) algebraic and (b) numerical.

When the teacher realizes that most students do not agree with $x = 147.22$, she asks for the solutions they found. Here she puts into action another of her strategies: she uses what the students have produced (role of the students) to contrast, compare mistakes and procedures, and to clarify (presence of KFLM and KMT).

As questions continue to arise, the teacher invites students to present their solutions. They understand that she had asked them to propose an equation that could model the problem, so they ask, "With an equation?". Then the teacher selects a student that obtained a numerical solution, shown in Figure 2 (b). Apparently, the student's procedure is arithmetical: she did the operations separately, written both operations and results. The teacher uses this solution to ask "What is the cost of each pack?" And the student answers "$80.55". It may be that the teacher identifies in this moment that the difference between the two procedures is the placing of brackets. In other words, the equation that corresponds to the procedure in Figure 2 (a) would be: $9x + 75 = 1400$, while for Figure 2 (b) it would be $9(x + 75) = 1400$. Now the teacher shows she knows how the students are interacting with the equations and mathematical ideas (order of operations, associativity) that are behind these proposals (KMT). Possibly due to this, after explaining, she asks the student who came up with the algebraic solution to go the board and correct the equation. However, in order to obtain the correct answer, she adds brackets to the verification: (147.22 x 9) + 75 = 1400. The teacher adds that the point is not to see who is right, but who has come up with the valid process. In her own words: "Which of the two processes do you think is convenient? Let me be clear, it's not a majority vote."

The teacher's participation shows that she is focused on the teaching strategy that allows emphasis on the *role of the students*, causing them to compare the various interpretations they have made of the relations between the data and the unknown value of the problem. The students get caught up in this comparison, arguing for and against. In our analysis we identify how the teacher makes explicit and promotes the discussion of two different interpretations of the word "additional": 1) *additional per pack,* i.e., $9(x + 75)$; and 2) *additional per nine packs*, $9x + 75$.

In terms of the richness of the mathematical discussion carried out by the students, the problem has given fruits: there has been reasoning, verification, use of different technological media and a variety of techniques (CAS, paper and pencil). Nevertheless, at this moment class time is almost over and the main objective of the lesson is not complete with regards to "relating a formula with the data table it produces and with its graph". The teacher tries to close the discussion with the following question:

Teacher: Which of the two approaches or solutions to the problem do you consider to be correct?
Students: Both.
Teacher: This means that one of the two is not right [...] They don't necessarily have to be exactly the same [...] Let's round off [...], one is missing two cents, and the other five cents […] You might lose a few decimals.

[Fragment 6, Session 1]

Clementina explains that both procedures should come up with the same result, and that this is not the case. She argues on the unicity of the solution of an equation, a topic that apparently has not been dealt with in class; it hasn't been considered in the lesson plan either (a possible deficiency in KMLS).

Until now, the teacher has intertwined the strategies for *maintaining the lesson plan* and the *role of the students* (manifestations of KMT and KFLM). However, she now makes the decision to modify her lesson plan and adapt it to her students' needs and to the interpretations they have come up. In the remaining minutes, she allows students to use the solution strategies they feel most comfortable and confident with, not necessarily those typically algebraic. She allows the student who proposed the equation and the one who proposed an arithmetic procedure to show their interpretations to the class on how to obtain the solution to the problem once more. The teacher asks the student with the "arithmetic" procedure (Figure 2 (b)) to explain on the board. This student says that she and one of her classmates have concluded that her procedure is right.

Student: The thing is that the problem didn't state clearly if it was 75 for each one or for all of them. And here we proved that it was 75 for all of them. Because it can't be for each one because it doesn't work, it would be 1447.95
[The teacher asks several teams to read the problem to the student to clarify if the 75 referred to all or to each one of the packs.]
Teacher: Is the sentence talking about the pack or all of them?
Student: The sentence is missing a word.
Teacher: Which word?
Student: It should tell us if it's 75 additional pesos for each pack [...]
Teacher: This is what problems are for, to see that if they are not stated well, each student will solve them in a different way… What this is about is, you have to read it …
Student: If I was the teacher, this problem would have two objectives… It's not just about reading, it's about determining the relation between the data and the solution.

[Fragment 6, Session 1]

The children of the class agree that the additional 75 pesos are for the nine packets, so the correct equation would be: $9x + 75 = 1400$. The teacher exhibits pedagogical knowledge that is effective at this moment: she "gives" control of the lesson to her students.

Final Remarks

During her class, Clementina faced an unforeseen teaching issue due to the ambiguous description of the problem situation. Consequently, she modified the class objectives, her lesson plan, as well as the roles and participation she had planned for her students. In the process, she also adapted her own role, modified her expectations and participation, and even gave up her role as “teacher” to one of the students. She allowed the group to reach a consensus, giving control to her students and establishing the meaning of the word “additional“ and its implication in (9x + 75 = 1400). At the end of the lesson, she went back to the initial objective, related it to the work done in class and gave it meaning. Such adaptations to the lesson plan, the problem, objectives, forms of participations of the students and even the role of the teacher require great flexibility and adaptability from teachers and their specialized knowledge. We believe flexibility and adaptability like this cannot be anticipated nor is it possible to include as a topic within a teacher training program; they can only be acquired through classroom practice. Inquiring more deeply into these strategies and the interaction between various types of teaching knowledge may have productive implications in the formation of teachers, as well as on research in the area.

In this study we extend our prior exploration focused on the extent to which middle school teachers appropriately identified proportional situations and whether there were relationships between attributes of the teachers and their ability to identify proportional situations. For this study, we analyzed both a larger dataset (n=32) and two dynamic scenarios in which participants were asked to consider aspects of the relationship shown in the diagrams. We found teachers who were correctly able to discern that a situation was not proportional were more likely to use important knowledge resources to evaluate the tasks.

Keywords: Teacher Knowledge, Rational Numbers, Mathematical Knowledge for Teaching

Purpose and Background

Proportional reasoning is an important mathematical concept in middle school mathematics. Despite its prominence in both the mathematics (National Governors Association & Council of Chief State School Officers, 2010) and science standards (NGSS Lead States, 2013), proportional reasoning has not enjoyed a rich history of research relative to its importance (e.g., Lamon, 2007). Research available on teachers' understanding is sparse, but indicates that, like students, teachers struggle with proportions (e.g., Akar, 2010; Harel & Behr, 1995; Izsák & Jacobson, 2017; Orrill, Izsák, Cohen, Templin, & Lobato, 2010; Post, Harel, Behr, & Lesh, 1988; Riley, 2010).

One necessary element of a robust understanding of proportions for teachers is the ability to distinguish those situations that are proportional from those that are not. Orrill et al. (2010) observed that the middle school teachers in their studies had trouble identifying situations as appropriate or inappropriate for using proportional reasoning. For example, when teachers were given a problem with three values and asked to find a missing fourth value, teachers tended to treat those situations as directly proportional even if the actual relationship was inversely proportional or linear. Teachers also struggled to apply proportional reasoning in a qualitative task (e.g., one that does not rely on manipulating numbers) that asked them to compare one pile of blocks to another pile, similar to those tasks used by Harel, Behr, Post, and Lesh (1992), instead they relied on additive reasoning.

Such findings led us to wonder how pervasive these issues were, what kinds of situations might confuse teachers, and what knowledge teachers rely on to determine whether a situation is proportional. In this paper, we extend our earlier findings (Nagar, Weiland, Brown, Orrill, & Burke, 2016) related to this topic by looking at data from more teachers and by expanding our task set to include a dynamic task that appropriately modeled a proportional relationship with a "thermometer" representation (see Figures 1 & 2). Specifically, we consider which knowledge resources were most frequent and what trends emerged among teachers who were able to differentiate proportional from non-proportional relationships versus those who struggled to do this. This work is at the crossroads because it brings together theory and practice in a way that is expressly aimed at impacting practice. By understanding how teachers think about proportional situations, we are better able to create teacher professional development experiences that meet the teachers where they are, thus maximizing the potential for impacting students' experiences with mathematics.

Theoretical Framework

We work from the knowledge in pieces perspective (diSessa 1988, 2006), which asserts that individuals develop understandings of various grain sizes that are used as knowledge resources in a given situation. These resources are connected, over time, through learning opportunities that lead to the refinement of the resources and the development of rich connections. More rich connections between knowledge resources allow them to be available in more situations. This is parallel to the research on expertise that has shown experts have both more knowledge and a different organization of knowledge than novices in their domain (e.g., Bédard & Chi, 1992). It is also aligned with Ma's (1999) interpretation the need for teachers to have profound understandings of fundamental mathematics. By having a robust set of knowledge resources that are coherently connected, we posit teachers will be more able to access their understandings to apply them to a wider range of mathematics and teaching situations than others whose knowledge resources are less coherently connected. We refer to this richly connected collection of knowledge resources as being *coherent* and assert that more coherent teachers will be better able to support student learning (e.g., Thompson, Carlson, & Silverman, 2007). This approach differs from much research on teacher knowledge in that we are not trying to identify deficiencies in teachers' understanding of mathematics, rather, we are trying to understand how teachers understand the mathematics they teach and how different knowledge resources are drawn upon for solving problems and teaching.

Methods

This study is part of a larger project investigating teachers' knowledge of proportional reasoning for teaching. The participants included a convenience sample of 32 in-service, grade 5-8 mathematics teachers, whose teaching experiences ranged from one to 26 years. The participants were from four states. They taught at a variety of schools (public, private, and charter). Twenty-four of the teachers identified as female and eight identified as male. Six of the teachers identified as a race other than white.

The data analyzed for this study were collected through a task-based clincial interview that was videotaped using two cameras trained on the participant's hands to ensure we captured anything the participant wrote or pointed to in the interview. Each interview lasted about 90 minutes. Additional data were collected in the form of a written assessment of proportional reasoning that included the LMT Proportional reasoning instrument (e.g., Hill, 2008) augmented by additional questions focused specifically on whether participants could discern proportional situations from non-proportional situations.

The qualitative analysis of the participant's clinical interview responses was carried out by coding the participants' utterances using a coding scheme that was developed using emergent coding focused on the knowledge resources participants used to reason about a variety of situations. This coding scheme, which included of 23 codes, relied on codes from the literature (e.g., Lobato & Ellis, 2010) as well as from open coding (Corbin & Strauss, 2007). This approach of relying on both literature and emergent codes is consistent with certain grounded theory approaches (e.g., Charmaz, 2014). To create the coding scheme, we coded several interviews, with 2-5 members of the team coding each interview until we were certain that the coding scheme included all the relevant resources we were observing. The full coding scheme included knowledge resources related to reasoning about ratios and proportions, the relationship between fractions and ratios, the relationship between similarity and proportions, the use of representations to reason about proportions, and a few pedagogically-related code, such as one to capture those instances in which a teacher indicated she would ask the student for additional information. For the purposes of this study, we present only those codes that appeared across both studies (shown in Table 1) specifically relevant to proportions (e.g., excluding those for representations and pedagogy). Our coding relied on a binary approach in which each utterance was coded as a 1 or a 0 based on whether a particular knowledge resource was observed. Once the coding scheme was stable, each interview was coded by at least two researchers and 100% agreement was reached on all coding.

Table 1: Codes of Knowledge Resources Used in Thermometers Task

Code	Description
Comparison of Quantities	States that ratio as a comparison of two quantities.
Multiplicative Comparison	Participant sees that there is a way of describing the relationship of the quantities in the ratio that is multiplicative
Covariance	Recognizes that as one quantity varies in rational number the other quantity must covary to maintain a constant relationship.
Unit Rate	Uses the relationship between the two quantities to develop sharing-like relationships such as amount-per-one or amount-per-x.
Equivalence	Describes proportion as a relationship of equality between ratios or fractions.
Constant Ratio	Recognizing the invariant multiplicative relationship between two quantities.
Scaling Up/Down	Uses multiplication to scale both quantities to get from one ratio in an equivalence class to another.
Horizon knowledge	Demonstrates knowledge that extends into mathematics beyond proportions
Rule	Shares a verbal or written rule (e.g., Red = Blue - 2) stated in a way that conveys a generalizable relationship.

For this analysis, we revisited the Thermometers task from our earlier study (Nagar et al, 2016). The thermometers task relied on a dynamic sketch presented to participants with two thermometers, one red and one blue, whose lengths could be varied by dragging a point on a number line (as shown in Figure 1 and Figure 2). Two scenarios were shown to participants (one at a time) and with each scenario participants were asked: (a) whether there was a relationship between the thermometers; (b) whether the relationship was proportional; (c) whether they could provide a rule and a story problem or real-world situation for that relationship; and (d) whether they see a scale factor involved in the situation. For the original study, we analyzed 13 participants' responses to the first scenario in which the thermometers were designed to maintain a constant difference of two units in length of the lines as the point on the slider is dragged from left to right (Figure 1). This situation represents a non-proportional linear relationship between the two thermometers. Our earlier findings showed that five of the 13 teachers initially misidentified the situation as proportional. In that analysis, we also found that two teachers (Group 3) remained convinced that the situation shown in Figure 1 was proportional, whereas the other three teachers (Group 2) started out thinking it was proportional, but then changed their mind. The eight teachers in Group 1 started out, and remained, convinced that the situation was not proportional. We then analyzed which knowledge resources the teachers relied on to determine that the situation was not proportional. Our analysis showed that teachers in Groups 1 and 2 used *Rules*, *Scaling Up/Down*, and *Equivalence* to appropriately identify this Thermometers task as non-proportional. We also found that across all three groups, teachers used language that sounded very additive rather than relying on multiplicative reasoning language.

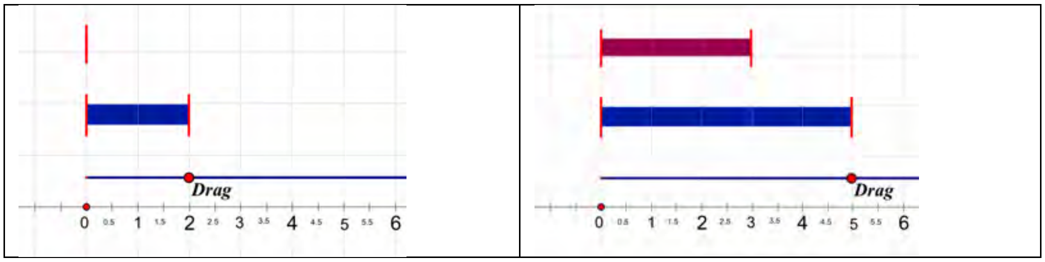

Figure 1. Screenshot of thermometers scenario 1 task.

In the study reported here, we extend the earlier work in two ways. First, we now have our entire dataset analyzed for the Thermometers Scenario 1 task (Figure 1), therefore, we consider 32 teachers' responses to that item (this includes the 13 teachers in the original study plus 19 additional teachers). Second, we analyzed Scenario 2 in the Thermometers task, a situation in which the dynamic environment models a proportional relationship (see Figure 2).

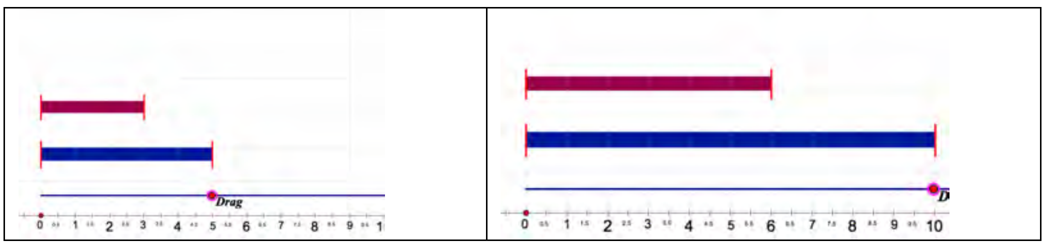

Figure 2. Screenshot of thermometers scenario 2 task.

Results

Our driving research question for this study was: what knowledge resources do teachers seem to rely upon in determining whether a situation is proportional or not proportional? We will first consider this question for Scenario 1 (the non-proportional situation), then for Scenario 2 (the proportional situation). In both scenarios, we focus on trends in the groups. All names reported in this section are pseudonyms.

Scenario 1: Linear Relationship

We began by separating the participants into groups the same way we had in the earlier study. The analysis of 32 teachers in the non-proportional Scenario 1 task showed that 19 teachers (59%) correctly identified the situation as non-proportional (Group 1). Seven participants (22%) first identified the situation as proportional but changed their mind during the interview to identify the situation as non-proportional (Group 2). And, six participants (19%) identified the situation as proportional (Group 3).

As in our earlier study the subset of codes shown in Table 1 were used in making sense of the situation. The most notable trend in the dataset was that the Group 3 teachers relied very little on these knowledge resources to make their determination. In fact, only three members of Group 3 (50%) used any of these resources. Peter used both *Unit Rate* and *Equivalence* while David used only *Equivalence* and Bridgette used *Horizon Knowledge*. In contrast, in Group 1, only four teachers (21%) did not use the knowledge resources included in this analysis. And, across the teachers there was much more variation with at least one person using each of the listed knowledge resources at least one time. For Group 2, two of the teachers (29%) did not use any of the resources.

Table 2: Number of Occurrences of Each Code by Group for Each Scenario

	Scenario 1				Scenario 2			
Code	Group 1 (*n*=19)	Group 2 (*n*=7)	Group 3 (*n*=6)	*Total (n=32)*	Group 1 (*n*=19)	Group 2 (*n*=7)	Group 3 (*n*=6)	Total (*n*=32)
Comparison of Quantities	1	0	0	1	3	1	0	4
Multiplicative Comparison	0	4	0	4	13	2	4	19
Covariance	3	1	0	4	5	1	1	7
Unit Rate	2	0	1	3	5	3	0	8
Equivalence	5	2	2	9	3	2	1	6
Constant Ratio	4	2	0	6	11	1	3	15
Scaling Up/Down	6	2	0	8	12	4	1	17
Horizon knowledge	5	3	2	10	5	1	1	7
Rule	21	6	9	36	12	4	1	18

Consistent with our earlier study, *Scaling Up/Down, Equivalence,* and *Rule* were some of the most used knowledge resources on this task. We note that *Scaling Up/Scaling Down* was not used at all by Group 3. It was used somewhat consistently in Group 1 with five of 19 teachers (26%) using it a total of six times. In Group 2, only one teacher out of seven (14%) used *Scaling Up/Down* in her reasoning twice. *Equivalence* was used nine times across all the teachers for Scenario 1, making it the third most commonly used code. In Group 1, three (Diana, Greg, Larissa) of the teachers used *Equivalence* a total of five times. In Group 2, two teachers each used it one time, and in Group 3, two teachers used is one time each.

Interestingly, the two most commonly used codes for this larger dataset on Scenario 1 were *Rule* and *Horizon Knowledge*. An example of *Horizon Knowledge* in this context would be recognizing that Scenario 1 is not a proportional relationship because the *y*-intercepts for the blue and red bars differ, as Alan did:

> Oh, as an eighth grade math teacher you'd say they have the same slope but a different Y intercept. Yeah, I know it's probably not what you're thinking about but, yeah when you go all the way back here it's, this is always going to be two ahead. So that starts a zero, this starts two, but then they grow at the same rate, so it's always two ahead.

The commonality of the *Horizon Knowledge* code is interesting as it suggests that having more formal understandings of mathematical structures to be able to generalize might matter in Scenario 1. It also suggests that understanding related mathematical topics may support teachers in invoking knowledge resources to better understand a given situation.

The *Rule* code was the most frequently observed in this coding scheme for Scenario 1. In Group 1, 14 of the teachers (74%) were able to generate a rule describing the relationship. For example, Diana said, "Red plus 2 would be blue." In Group 2, this dropped to three of seven teachers (43%). However, Group 3 had four of six teachers (67%) able to generate a rule relate to the situation. This suggests that the teachers in Group 3 may not be connecting their knowledge resources for determining whether something is a proportion to their generalization of a mathematical situation. For example, Brianna (in Group 3) clearly stated that the relationship was, "Whatever red is plus 2 would equal blue" but, she maintained that the relationship was proportional. This suggests that explicitly understanding the mathematical structure of the problem may not be necessary to generate a rule about the relationship presented.

Scenario 2: Proportional Relationship

In Scenario 2 (Figure 2), we asked the same questions of our participants about a similar dynamic representation that showed a proportional relationship. Many more of the teachers got this task correct. In fact, only eight teachers (25%) gave wrong responses and two of those changed their response to be correct during the course of the interview (one in Group 2 and one in Group 3). Of the teachers who answered incorrectly and did not change to a correct interpretation, three were in Group 1, one was in Group 2, and two were in Group 3. This is consistent with our earlier finding that teachers have an easier time recognizing situations that are proportional than those that are not proportional (Nagar et al., 2016).

While *Scaling Up/Down* and *Rule* continued to be important in Scenario 2, *Equivalence* became less important and two new codes became more important: *Multiplicative Comparison* and *Constant Ratio*. *Multiplicative Comparison* was used only when an utterance demonstrated the participant understood a relationship between the quantities of the ratio as multiplicative. For example, understanding the blue thermometer is 5/3 as long as the red thermometer. While only one person (Kanita in Group 2) used *Multiplicative Comparison* as a resource for Scenario 1, in Scenario 2, 12 participants (38%) used it one or more times. In Group 1, nine participants used this knowledge resource 13 times for Scenario 2. In Group 2, two participants used *Multiplicative Comparison* two times in Scenario 2. Only one member of Group 3 (Patricia) used *Multiplicative Comparison* four times.

Constant Ratio was coded when participants indicated there was a fixed relationship between the two numbers in a ratio. It was not as precise as *Multiplicative Comparison* in that participants needed only to note the relationship existed without specifying the nature of that relationship (i.e. that it is multiplicative). In Scenario 1, six participants (19%) used this knowledge resource whereas 15 participants (47%) used it in Scenario 2. In Group 1, this was used eleven times across nine participants (47%) in Scenario 2. For Group 2, it was used just one time, and in Group 3, it was used three times by one participant (Patricia). This trend in *Constant Ratio* and *Multiplicative Comparison* codes suggests that there is something different about the way many members of Group 1 use their knowledge resources than the members of Groups 2 and 3. We note that Patricia in Group 3 appears to be an outlier in terms of her use of knowledge resources.

Generating rules was harder for teachers in Scenario 2 than in Scenario 1, but was still an important code with 18 instances across all three groups. For Scenario 2, six Group 1 teachers (32%) generated 12 rules, four Group 2 teachers (67%) generated four rules, and one Group 3 teacher (Patricia) generated one rule (17%). An example of one teacher's rule was Ella's, "So if I say the red bar is 3/5 of the distance to the blue bar, so the blue… so the blue bar… let me see if five… I don't want to like change this up. Five equals… so that would be like B=5/3R." The relative struggle the participants experienced in identifying a rule is interesting given that teachers were more successful identifying the situation as being proportional and reinforces our assertion that teacher knowledge is shaped by the specific context.

Conclusions

Consistent with our earlier findings, this study showed teachers are better at determining whether a situation is proportional if it is actually proportional. In the current study, 13 of the 32 teachers started out believing Task 1 was a proportion and only seven changed their thinking to recognize that the situation was not proportional. In contrast, only eight teachers were unable to initially identify a proportional situation as such, with two of those eight figuring out the situation was proportional as they worked. This is consistent with research on students that also shows problems discerning proportional relationships from non-proportional ones (De Bock, Van Dooren, Janssens, & Verschaffel, 2002).

When this finding is combined with the particularly sparse use of relevant knowledge resources by teachers in Group 3, one reasonable assertion would be that teachers need more opportunities to apply their understandings and make connections between those understandings. For example, we are confident that middle school teachers understand ratios must be equivalent for a proportion to exist. However, few teachers applied this understanding, which could have helped provide evidence that Scenario 1 was not a proportion.

We also note that there may be some need for additional development of knowledge resources. For example, *Multiplicative Comparison*, which is a critical understanding for reasoning about the relationships within a proportion, was seen in a relatively small number of utterances. In Group 1, almost 2/3 of the teachers used it, but in Groups 2 and 3 combined, the resource was used by only three teachers. This suggests that having the *Multiplicative Comparison* resource available may lead teachers to be more accurate in their ability to discern proportional relationships. It also suggests that several teachers are lacking, or failing to activate, a critical understanding of proportional reasoning.

We assert that the lack of presence of *Multiplicative Comparison* may also explain the limited presence of the *Rule* code in Scenario 2, while it was very prevalent in Scenario 1. It may be that in teacher preparation and professional development teacher educators are over-emphasizing linear situations rather than multiplicative ones. It is also possible that the lack of comfort with the multiplicative relationship between quantities, implied by the limited use of the *Multiplicative Comparison* code, prevents teachers from seeing applications of proportional relationships in the real world. Perhaps focusing more on problem generation and the multiplicative nature of the relationship between quantities in a proportion would strengthen teachers' abilities to recognize proportional situations.

Combined, the findings of this study intersect theory with research to inform practice. By looking at teachers' actual use of knowledge through the knowledge in pieces lens, we are able to suggest that professional development be sensitive to both knowledge resources development and the development of connections between and among those resources. Failure to address both of these approaches creates a situation in which teachers are unable to capitalize on the knowledge they have to support their students.

This paper describes seven in-service teachers' interpretations of student statements about slope. The teachers interpreted sample student work, conjectured about student contributions, assessed the students' understanding, and positioned the students' statements in the mathematics curriculum. The teachers' responses provide insight into their Knowledge of Content and Students (KCS) and Knowledge of Content and Curriculum (KCC). Results suggest these teachers value academic terminology related to slope, have limited perspectives on slope in real world contexts, and struggle to describe the extension of slope to precalculus.

Keywords: Algebra and Algebraic Thinking, Mathematical Knowledge for Teaching, Teacher Beliefs, Teacher Knowledge

Introduction

Ball, Thames, and Phelps (2008) introduced the Mathematical Knowledge for Teaching (MKT) Model based on Shulman's (1986) work as a means to consider the multifaceted knowledge that teachers need for their craft. MKT consists of two different types of knowledge: pedagogical content knowledge and subject matter knowledge. Pedagogical content knowledge has been outlined in terms of three domains: Knowledge of Content and Curriculum (KCC), Knowledge of Content and Students (KCS), and Knowledge of Content and Teaching (KCT). In this study, we focus on KCS, how students learn mathematics, and on KCC, where the mathematical topics students are learning fit in the curriculum. Subject matter knowledge also has been portioned into three domains. We will focus on Horizon Content Knowledge (HCK), which refers to understanding future mathematical topics and how the math at hand provides a foundation for those topics. We investigate these areas of MKT as related to the concept of slope, a key topic in the middle school mathematics curriculum upon which advanced mathematical (Moore-Russo, Connor, & Rugg, 2011) and statistical (Casey & Nagle, 2016; Nagle, Casey, & Moore-Russo, 2017) ideas are built. In addition to coverage across the curriculum, the multitude of ways in which students can reason about slope make it well suited for this study.

Slope Network

Nagle and Moore-Russo (2013a) proposed a network of five slope components, each with visual and non-visual as well as procedural and conceptual subcomponents (see Table 1).

The slope network outlines the multi-faceted nature of slope, but research has not described how these subcomponents may interrelate and be leveraged to help students develop a connected understanding of slope. In this study, we consider teachers' interpretations of student statements related to the various slope components (KCS) and their accounts for how they fit together across the secondary mathematics curriculum (KCC). Using this lens, we consider teachers' perspectives on the relative sequencing of these components and gain insight into their valuation of the components. In particular, we investigate the following research questions:

1. How do teachers interpret common student statements about slope? What notions of slope do teachers value in student thinking?

Galindo, E., & Newton, J., (Eds.). (2017). *Proceedings of the 39th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* Indianapolis, IN: Hoosier Association of Mathematics Teacher Educators.

2. What are teachers' perceptions of how the notion of slope is developed across the secondary curriculum?

Table 1: Slope Network (adapted from Nagle & Moore-Russo, 2013a)

Slope Component	**Description**	**Subcomponents (shown as subscripts)** v = visual, n = nonvisual, p = procedural, c = conceptual	
Ratio	Slope viewed as a ratio; extends to explain why linear behavior results in a constant ratio.	$R_{v,p}$: rise/run or vertical change over horizontal change	$R_{v,c}$: similarity of slope triangles yields a constant ratio of rise/run regardless of the position on the graph
		$R_{n,p}$: change in y over change in x; $(y_2\text{-}y_1/x_2\text{-}x_1)$	$R_{n,c}$: constant rate of change between two covarying quantities; equivalence class of ratios thus a function
Behavior Indicator	Relates slope to the increasing or decreasing behavior of a linear function or graph; links sign of the quantity m with the function's or graph's behavior.	$B_{v,p}$: increasing (or decreasing) lines have positive (or negative) slope	$B_{v,c}$: positive (or negative) rise corresponds to positive (or negative) run for an increasing (or decreasing) line, yielding a positive slope
		$B_{n,p}$: value of m in the equation for a linear function indicates whether f is an increasing (m>0) or decreasing (m<0) function.	$B_{n,c}$: If function f is increasing then $f(x_1)<f(x_2)$ for every $x_1<x_2$, so $[f(x_2)\text{-}f(x_1)]/(x_2\text{-}x_1)>0$; similar generalization for decreasing function
Trig. Conception	Describes slope in terms of the angle of inclination of a line with a horizontal; extends to relate steepness to the tangent of the angle of inclination.	$T_{v,p}$: steepness of a line; slope as the angle of inclination of the line with a horizontal	$T_{v,c}$: the angle of inclination determines the rise/run; a steeper line has a greater rise per given run than a less steep line
		$T_{n,p}$: slope is calculated as $\tan\theta$ where θ is the angle of inclination	$T_{n,c}$: the angle of inclination determines the ratio of $(y_2\text{-}y_1/x_2\text{-}x_1)$, which is equivalent to $\tan\theta$.
Determining Property	Property that determines if lines are parallel or perpendicular; property can determine a line if a point on the line is also given.	$D_{v,p}$: parallel (perpendicular) lines have the same (negative reciprocal) slope; slope and point determine unique line	$D_{v,c}$: parallel lines have the same vertical change for a set horizontal change; may be seen in terms of congruent slope triangles
		$D_{n,p}$: $y_2\text{-}y_1/x_2\text{-}x_1$ is equal for parallel lines and results in negative reciprocals for perpendicular lines; slope and a point determine a unique linear equation	$D_{n,c}$: parallel lines have equivalent differences in y values for a set difference in x values, yielding equivalent slope ratios
Calculus Conception	Limit; derivative; a measure of instantaneous rate of change for any (even nonlinear) function; tangent line to a curve at a point	$C_{v,p}$: slope of a curve at a point is the slope of the tangent line to the curve at a given point	$C_{v,c}$: visual interpretation of secant lines approaching tangent line
		$C_{n,p}$: derivative f' is used to calculate slope of function f at a particular point	$C_{n,c}$: $f'(x) = \lim_{\Delta x \to 0} \frac{f(x+\Delta x)-f(x)}{\Delta x}$ as the average rate of change over increasingly small intervals

Methodology

Participants

Participants included seven secondary mathematics teachers who elected to participate in a funded, year-long professional development cohort focused on promoting conceptual understanding. Of the seven participants, two had fewer than 5 years teaching experience, four teachers had between 5 and 10 years, and one had over 10 years of experience. All teachers reported experience teaching introductory algebra, including the concept of slope.

The Tasks

Prior to the first professional development meeting, each teacher submitted responses to a series of tasks related to slope PCK. The task analyzed in this study is provided below. All teachers in the cohort were emailed the task and given three weeks to complete it. The student statements below were generated by the researchers as typical responses noted in past research.

As an instructor, you asked each of the students in your class to make a statement about slope. For each student response [in Table 2]*, please answer all of the following.*

a. Provide a visual representation (a graph, an equation, etc.) that you would expect each student could easily have created to accompany her statement about slope.

b. If each student had been asked to contribute a problem to a study sheet on slope, provide an example of a problem that each would have been most likely to submit.

c. Using the scale [in Table 3]*, rate (and justify) each student's understanding of slope.*

d. By which level of schooling would you expect each student's response? Explain.

Table 2: Student Statements Regarding Slope and Associated Slope Components

Slope Component	Student Statements Given to Teachers
Ratio	A: Slope is rise divided by run of a graph. B: Slope is found by taking the change in *y* values divided by the change in *x* values. D: Slope tells the rate of change between two variables, *x* and *y*. K: The slope of a line is constant regardless of which two points on the graph are chosen to calculate the value.
Behavior Indicator	J: Slope indicates if a line is increasing, decreasing, or constant.
Determining Property	I: Slope can be used to determine if lines are parallel or perpendicular.
Trigonometric	C: Slope describes the steepness of a line. F: Slope is related to a line's angle of inclination with respect to a horizontal line.
Calculus	G: The derivative function tells the slope of a function at a particular time.
Open – No specific component intended	E: Slope is represented by *m* in equations and formulas. H: Slope can be used in real world situations. L: Slope refers to the straightness of a line; the fact a line doesn't curve.

Table 3: Scale for Rating Each Student's Understanding of Slope

	1 - Strictly Procedural	*2- Procedural with Limited Conceptual*	*3- Emerging Conceptual*	*4- Robust Conceptual Understanding*
Description	*Demonstrates a strictly procedural focus on how to calculate slope through rote manipulation without any interpretation of the meaning of the concept*	*Demonstrates a primarily procedural focus on how to calculate slope with very limited attention to interpreting the meaning of the concept*	*Demonstrates an understanding of the meaning of slope in a particular situation or context*	*Demonstrates a flexible, deep understanding of slope that allows for understanding in multiple situations or contexts*

Data Analysis

Using the slope network (from Table 1), two researchers coded the teachers' responses to parts *a* and *b* of the task for the slope components and the visual or non-visual subcomponent evidenced. A number of responses did not provide enough detail to code the conceptual versus procedural subcomponents, so this coding was omitted. The researchers also recorded each teacher's rating of student understanding and recorded the level of schooling at which the teacher expected such a response. The schooling responses were categorized into PreAlgebra, AlgebraI/II, Geometry/Trig/Precalculus, and Calculus categories. The researchers completed all coding independently before meeting to compare codes. When discrepancies were found, a third researcher was brought in to discuss the coding until a consensus was reached. When all the data had been coded, all three researchers looked for trends within and across teachers' responses.

Results and Discussion

The teachers' responses to the student statements are summarized in Table 4. For each student statement (A-L), the first column indicates the slope component(s) and subcomponent(s) illustrated in the teachers' responses to parts *a* and *b* of the task. The data were combined for these parts of the task. Thus, only one slope component is recorded when the teacher used the same component for both the representation and example. When two slope components are listed, that means that the teacher included both slope components in both parts of the tasks or that the teacher included one component in part *a* and the other in part *b*.

Key: P=PreAlgebra, A=AlgI/II, G=Geometry/Trigonometry/Precalculus, C=Calculus, vr=varies

In a few instances, the researchers thought the response showed strong promise of indicating the conceptual subcomponent according to the slope network. In those cases, an asterisk is marked in the table. The second column reports teachers' responses to part *c* regarding the procedural versus conceptual rating (on the 1 to 4 scale). We distinguish between responses that did not align with any slope component (^), were left blank (-), or acknowledged uncertainty of how to interpret the given statement (?). Part *d* responses are below those to part *c* in Table 2. Consider the row 1 and column A intersection in the table. It reveals Teacher 1 responded to student statement A by providing a representation and example problem aligned with the *Ratio (visual)* component of slope, rated the statement as *1 (strictly procedural)* and placed the statement in PreAlgebra.

In the following sections, we report on teacher responses to the specific student statements in light of the anticipated slope components (from Table 2).

Results for Ratio Components

Statements A, B, D (*Ratio* component). All seven teachers' responses to these statements included the *Ratio* component. Furthermore, all teachers included a visual interpretation of statement A and a non-visual interpretation of statement B, as expected. Interesting trends emerge across the various *Ratio* components. Although statements A, B, and D all express that slope is a ratio, statement A describes it visually, statement B does so non-visually, and statement D describes it as a rate of change. Despite the statements' similarity, teachers interpreted them quite differently. All teachers rated statement A as strictly procedural and at the PreAlgebra level. Five of the seven teachers rated statement B (that had received R_n codes) as either more advanced in grade level or more conceptual (or both) than statement A (that had received R_v codes). Teachers 1 and 4 rated both statements as strictly procedural and at the PreAlgebra level. For the rest of these teachers, the visual approach seemed to be de-valued, as was apparent in many teachers' written explanations. Teacher 2 wrote, "B understands the idea of the slope as the change in the values, instead of just rise over run," and Teacher 7 wrote, "B is using academic vocabulary that suggests that she has a basic understanding of slope." Furthermore, six teachers reported that statement D was more conceptual or more advanced (i.e., grade level) than both the other ratio statements. Several teachers related the "rate of change" language of statement D to using slope in real world situations. Teacher 2 explained, "D has a firm grasp on how slope is applied in real life scenarios," and Teacher 3 justified her rating of this statement as robust conceptual understanding by stating, "the student understands the concept and can relate it to everyday solutions." These teachers are equating the phrase "rate of change" with slope applied to real world situations and conceptual understandings of slope.

Statement K (*Ratio* component). Responses to this statement varied from strictly procedural to robust conceptual. Teachers tended to put it at the PreAlgebra or Algebra level. Teachers 3 and 6 provided sample problems that the researchers felt showed promise of relating to the conceptual *Ratio* subcomponent, with Teacher 3 doing so with a visual emphasis while Teacher 6 did so in a strictly non-visual manner.

Results for Other Components

Statements C, F (*Trigonometric* component). Teachers' responses to statement C were quite consistent. Despite the researchers' interpretation of this statement as being open to visual and non-visual sub-components, every teacher's response emphasized a visual interpretation. These often included graphs of several lines with varying slopes, indicating that the line got steeper as the absolute value of slope increased. Interestingly, four teachers provided a real world context comparing two or more roads or roofs and making reference to steepness. Despite the potential to link steepness to the slope in these contexts, none of these teachers did so in a meaningful way that involved reference to the angle of inclination nor described steepness in terms of a ratio. All seven teachers saw statement C as a PreAlgebra interpretation of slope, with some variation in whether it was more procedural or more conceptual. Statement F was seen as emerging or conceptually robust by all teachers, and was categorized at the Algebra I/II level or later. Most teachers' responses emphasized a visual interpretation. Teachers' 6 and 7 responses suggested their inabilities to interpret this statement or place it in the curriculum.

Statement J (*Behavior Indicator* component). All teachers saw this as a PreAlgebra interpretation of slope, and six of the seven teachers' responses illustrated the *Behavior Indicator* component split equally between visual and non-visual interpretations. Visual interpretations tended to show graphs of increasing, decreasing, and horizontal lines with positive, negative, and zero slopes labeled accordingly. Non-visual representations tended to give the equation of a linear relationship and described the relationship in terms of the parameter *m* in the equation. Teacher 1 provided a graph of a line and asked whether it was increasing, decreasing, or constant but never linked this with slope. Thus, this response could not be linked with any slope component. Teacher 1's sample problem presented the graph of a horizontal line and asked what the graph represents. The research team interpreted this as asking for the equation of the line—which would not require use of the *Behavior Indicator* component. All but one teacher saw this statement as more procedural than conceptual (1 and 2 ratings).

Statement I (*Determining Property* component). Teachers' responses consistently evidenced the intended component. Non-visual representations generally presented two linear equations and asked whether the lines were parallel, perpendicular, or neither. Four teachers incorporated both visual and non-visual representations in their responses. Responses incorporating both representations included equations and graphs of the lines—showing how the relationship between the slopes was displayed graphically via lines that never intersected, intersected in right angles, or intersected in some other way. There was very little variation in the example problems and representations presented. All seven teachers agreed this notion of slope would appear in Algebra I/II, and most teachers rated this as a 2 (mostly procedural understanding), with one 3 and one 4 rating. Overall, the teachers were in agreement with where this fits in the curriculum.

Statement G (*Calculus* component). It is interesting that with this open statement, only one teacher linked this to a visual representation of a function's graph with tangent lines drawn at various points. Most teachers included $f'(x)$ notation and provided an example involving finding the derivative of a polynomial. Six of the seven teachers unsurprisingly placed this conception as occurring in Calculus. There was, however, great variation in whether teachers viewed this as procedural or conceptual in nature. Two teachers rated this as strictly procedural and three teachers rated it as robust conceptual understanding, highlighting a very distinct mismatch. Teacher 7 indicated that she was not sure how to rate this problem.

Statement E (*open* - no component). Three teachers' responses to statement E did not link any understanding of slope to the statement. Each gave a problem or representation that provided an equation in slope-intercept form and then labeled *m* in the equation as the slope with no indication of what *m* meant for the equation or its graph. Three of the remaining teachers linked this statement with R_n, acknowledging *m* in the equation $y=mx+b$ and writing $m=(y_2-y_1)/(x_2-x_1)$. It is interesting that these teachers viewed these algebraic representations as related, especially since none showed how one formula could be manipulated to achieve the other. All teachers viewed this understanding as strictly procedural, and all but one placed it in PreAlgebra.

Statement H (*open* - no component). The researchers expected this statement to elicit a variety of slope components in teachers' responses, but the teachers' responses were relatively uniform. Four of the teachers linked this statement to the *Ratio* component of slope, with two teachers focusing on non-visual aspects, one on visual aspects, and one on both. The link with the *Ratio* component was made via an equation or graph labeled with real world variables and a description of the slope in terms of the problem context. The final three teachers provided responses that could not be coded as indicating any slope understanding. For instance, Teacher 3 sketched a picture of a car driving up what appeared to be a hill with no indication of how slope was demonstrated. The others acknowledged that the statement itself did not indicate much about the student's understanding.

Teacher 4 wrote: “H does not show much with this statement. Sure it can be used in real world situations but how? If she knows how, then we are getting somewhere.” Thus, this code does not mean that this teacher misinterpreted this student’s understanding, but acknowledged the lack of clarity in the statement itself. In terms of responses, the most interesting result may be the absence of the *Trigonometric* component. One of the fundamental uses of slope in real world situations is to consider steepness of physical objects (e.g., ramps). In the one instance where such a connection was hinted at, the connection stopped short of showing how slope was demonstrated. The ratings and grade levels for this statement varied greatly. Interestingly, the three teachers who did not attach this statement to any particular conception of slope ranked it as strictly procedural. The remaining four teachers, who had interpreted this statement as being linked with the *Ratio* component, all rated the statement as mostly conceptual. For those teachers who linked this to a *Ratio* component, they seemed to value the use of *Ratio* in a real world context as indicating a more robust understanding of slope.

Statement L (*open* - no component). Statement L proved to be surprisingly difficult for teachers to interpret. Only three teachers provided codable responses, with two stating that they did not understand L’s statement and the remaining two providing vague responses that couldn’t be coded (e.g., a graph of a line and the graph of a curve with no mention or indication of slope on the graph). Of the three who did provide codable responses, two interpreted it using visual aspects by providing the graph of a line and describing in words or denoting on the graph that every time “you move right one unit on the graph, the corresponding vertical change on the graph is constant.” This was accompanied by statements such as “therefore the function will be a line.” Teacher 1 linked this statement with the *Determining Property* by asking how many lines can be drawn through a given point with a specified slope. She also asked whether three points lie on the same line, linking to R_n. Teachers’ responses regarding grade-level and knowledge rankings varied greatly, adding to evidence of their overall uncertainty about this statement.

Implications

The results reveal important insight into the teachers’ PCK in terms of their KCC and KCS. In particular, teachers’ responses revealed (1) their valuation of academic language, (2) the nature of real world problems for slope and (3) their views of slope beyond the algebra curriculum.

Value of Academic Language

The responses to statements A, B, and D suggest that teachers value student use of academic terminology. Although attending to precision and using correct mathematical terminology is a key part of the mathematics curriculum (NGA & CCSSO, 2010), these results raise a red flag that teachers may equate academic terminology with conceptual understanding. Teachers’ responses to statements A and B suggest that the teachers may devalue visual thinking by equating it with non-mathematical terminology. Likewise, responses to statement D suggest teachers valued the academic language of “rate of change” even though that expression could be used as a mnemonic just as “rise over run” often is. Together, these results highlight two important aspects of teachers’ KCS: (1) distinguishing between students’ use of terminology and their understanding of the terminology and (2) encouraging students to connect multiple representations to integrate academic terminology with visual reasoning.

Rate of Change and Real World Situations

Teachers’ responses also revealed some interesting trends related to the role of real world situations in students’ learning about slope. The real world situations provided by teachers either demonstrated the *Ratio* component within the context of a functional situation (e.g., time worked versus dollars earned) or the *Trigonometric* component within the context of physical situations (e.g., steepness of roof). Furthermore, when physical situations were mentioned, they were done so trivially without explicit attention to how slope was related to steepness. These results suggest teachers may miss valuable opportunities to help students connect the *Ratio* and *Trigonometric* components of slope through real world situations (KCS). As a result, their students may fail to connect the ideas of slope and steepness (Nagle & Moore-Russo, 2013b).

Role of Slope in Advanced Mathematics

The results raise questions about how the teachers view slope as informing students' work with non-linear functions. Nagle and Moore-Russo (2014) describe the CCSSM's high school focus on extending the notion of a constant rate of change of linear functions to interpret and understand non-linear functional relationships. Recall that teachers generally were not sure how to interpret statement L that "slope refers to the straightness factor of line," a statement that links naturally to CCSSM's focus on moving from linear to non-linear relationships by understanding variable rate of change. Furthermore, other than the *Calculus* component of slope, the teachers tended to provide algebraic interpretations of slope, even when statements were open to more trigonometric or geometric interpretations. Even teachers who do not teach beyond the Algebra I/II curriculum, should have sufficient knowledge of the curriculum (KCC) and how slope is foundational to more advanced concepts, such as the derivative (HCK), to include more advanced interpretations of slope.

Future Work

By analyzing teachers' interpretations of student statements, we have described the teachers' apparent values related to student thinking about slope. We have not investigated how these values are carried out through teachers' intended or enacted instruction on slope. Future work should investigate to what extent the tendencies described for teachers do or do not play out in their intended and enacted lessons on slope. Doing so will allow for confirmation of these valuations and for exploration of the manner and extent to which teachers' valuations of understanding inform their written and enacted lessons (KCT).

TEACHERS' QUANTITATIVE UNDERSTANDING OF ALGEBRAIC SYMBOLS: ASSOCIATED CONCEPTUAL CHALLENGES AND POSSIBLE RESOLUTIONS

Casey Hawthorne
Furman University
casey.hawthorne@furman.edu

While the mathematics education community encourages teachers to support students in developing a more meaningful contextual understanding of algebraic symbols, very little is known about teachers' quantitative understandings of algebraic symbols themselves. The goal of this study was to fill this gap and examine secondary teachers' ability to contextualize algebraic symbols, in particular notation that results from algebraic generalization. The results led to the identification of various conceptual hurdles that teachers encountered as they endeavored to articulate the underlying quantities as well as various conceptualizations they invoked, both productive and unproductive, in their attempt to overcome these challenges.

Keywords: Mathematical Knowledge for Teaching, Algebra and Algebraic Thinking

Introduction

Traditionally, algebra instruction in the United States has focused on symbol manipulation. Teachers tend to emphasize formal methods, involving abstract mathematical symbols, over other approaches that involve representations that are more closely grounded in context such as diagrams, tables, and graphs (Kieran, 2007; Smith & Thompson, 2007; Yerushalmy & Chazan, 2002). Unfortunately, such an approach has failed to meet the needs of many, if not most, students. Struggling to cope with abstract notation, abruptly introduced and presented as detached from a coherent system of referents, students often fail to develop meaningful interpretations of algebraic symbols and the associated operations (Kieran, 2007; Harel (2007); Knuth, Alibali, McNeil, Weinberg, & Stephens, 2005; Sfard & Linchevski, 1994).

The ability for students to not only manipulate symbols, but interpret the contextual quantities that expressions represent has been emphasized as a core component to algebraic thinking. The Common Core State Standards (2010) underscores this understanding, including it as one of the eight practice standards (SMP 2: Reason abstractly and quantitatively) as well as a high school algebra content standard (HSA.SSE.A.1). Likewise, many scholars have articulated the significance of this understanding. Kaput and colleagues (2008) noted that without such an understanding, students' actions are guided strictly by the rules of the notational system without support from the previously learned structure of the reference field. As such, knowledge is more fragile with students tending to overgeneralize symbolic rules such as $(a + b)^2 = a^2 + b^2$.

To support students in developing a contextual understanding of symbols, researchers have advocated for the introduction of algebra through inquiry-based activities grounded in more concrete representations such as tables, situations, and words (Koedinger & Nathan, 2004; Nathan, 2012). One example of such an approach is through figural pattern generalization. These are tasks in which students are provided drawings of sequential stages and asked to find subsequent stages and eventually write an expression to model their understanding of a general stage. Exploring these patterns affords students the opportunity to convey their generalizations through a variety of increasingly abstract representations, leading to a more meaningful interpretation of the eventual symbolic forms.

In order to support students in developing a quantitative understanding of the notation, teachers must possess specialized content knowledge that goes beyond simply the ability to write expressions (Ball, Thames, & Phelps, 2008). They must understand how to relate, with precision, the various mathematical representations to the contextual quantities they represent. Although several researchers have investigated students' understanding of representations in algebra (e.g., Knuth, 2000; Nathan & Kim, 2007), less attention has been given to examining teachers' understandings of algebraic notation and their ability to draw connections to the context. Stylianou (2010) studied middle school teachers' beliefs about the instructional use of multiple representations, but not their knowledge. Harel, Fuller, and Rabin (2008) documented ways in which teachers failed to support students to develop meaningful interpretations of symbols, but without exploring teachers' symbolic reasoning or other potential causes for the failure.

While the field has emphasized the need for students to develop a contextual understanding of symbolic representations, we know very little about teachers' understanding in this area. Having a better image of the specific challenges teachers face and how to overcome these challenges will inform teacher educators how to better support teachers in working with their students to develop this ability. Therefore, the goal of this study was to examine secondary teachers' understandings of the quantitative meanings of algebraic symbols, in particular notation that results from algebraic generalization. The results led to the identification of various conceptual hurdles that teachers encountered as they attempted to make sense of and connect the underlying quantities and quantitative relationships as well as various conceptualizations they invoke, both productive and unproductive, in their attempt to overcome these challenges.

Theoretical Perspective

Although there is a lack of empirical studies addressing teachers' understandings of mathematical representations, considerable thought has been devoted to establishing the importance and role of representations theoretically. Multiple scholars have developed theoretical rationales to explain why the ability of expressing the meaning of numeric and algebraic figures is foundational to the understanding of mathematical notation.

Quantitative Reasoning

In order for students to be able to contextualize algebraic notation, they must possess a strong understand of the quantities the symbols represent. Therefore, a key component to possessing a deep understanding of algebraic symbols is quantitative reasoning. According to Thompson (1994), "quantitative reasoning is not reasoning about numbers, but reasoning about objects and their measurements (i.e., quantities) and relationships among quantities" (p. 8). As such, problem solving is not about determining the sequence of operations that will result in the correct answer, but about developing a conceptual understanding of how the quantities in a given problem are interrelated and how they combine to create new quantities. By focusing on the relationship between quantities, students develop a deeper understanding of the problem situation. Smith and Thompson (2007) argue that students must possess a sophisticated enough understanding of the structure of the problem to warrant the use of algebraic tools. Without a grasp of the quantities that shape the problem situation, students are unable to see algebraic notation as a representation that communicates quantitative relationships and consequently are left interpreting symbolic expressions as simply a tool that serves to calculate numerical values.

Symbolization

While understanding the contextual situation is foundational for developing meaning of algebraic expressions, for such an understanding to become embedded in abstract symbolic forms and for students to see notation as communicating the quantitative structure, various cognitive developments must take place. Kaput, Blanton, and Moreno-Armella (2008) described a process they refer to as *symbolization,* in which through one's experience in working with mathematical ideas, their related understandings become infused in the mathematical objects used to represent the phenomenon. They noted that over time and with multiple iterations of reflection, students' understanding of the context becomes instilled in more and more densely compressed forms of symbolization. Initially, students use more contextually connected representations such as oral, written, and drawn descriptions to express their experiences. They then use these representations to reflect on this same experience. This process leads to a newly mediated conceptualization of the mathematical phenomenon and possibly to new representations. Each interaction with the mathematical phenomenon, whether individual and or socially mediated, results in a new conceptualization. Eventually these conceptualizations converge into a conventional and compact symbolic form, establishing a rich, densely packed interpretation of the mathematical phenomenon. Kaput and colleagues noted that in the end, instead of the symbols' representing the referent as a separate entity, the two become interpreted as one. Actions applied to the symbols are construed as actions on the referent itself. At this stage, a student does not look *at* symbols, but *through* them, seeing the mathematical phenomenon and the notation as one.

Connections Between Representations

The role of multiple representations in mathematics and the importance of teachers to engage students in making connections among mathematical representations has been recognized by many scholars (National Council of Teachers of Mathematics [NCTM], 2014). Several studies have demonstrated the ability to translate between representations as a characteristic of more robust and flexible knowledge (e.g. Pape & Tchoshanov, 2001; Stylianou & Silver, 2004). In particular, Lesh, Landau, and Hamilton (as cited by Lesh, Post, & Behr, 1987) observed that students working through mathematics problems seldom came to the solutions successfully using a single representational mode. Explaining this phenomenon, Tripathi (2008) noted that using these "different representations is like examining the concept through a variety of lenses, with each lens providing a different perspective makes the picture richer and deeper" (p. 439). Extending this idea, Dreyfus and Eisenberg (1996) argued that representations differ not only in the way information is expressed, but also in terms of the information itself. They maintained that "any representation will express some, but not all of the information, stress some aspects and hide others" (pp. 267). Subsequently, mathematical ideas are not embodied by a single representation but rather lie, at the intersection of these representations. Finally, Lesh et al (1987) asserted that establishing a relationship from one representational system to another supports students in developing a stronger understanding of the various properties within the situation as they are encouraged to focus on what structural characteristics are preserved in the mapping.

Methods

To investigate the various conceptual hurdles associated with teachers' quantitative understanding of the algebraic notation used to describe figural generalizations, I engaged four 8^{th} grade teachers each in a 1.5-hour individual semi-structured clinical interview (Ginsburg, 1997). Wanting to identify particular challenges associated with connecting algebraic notation to quantities as well as productive conceptualizations teachers formulate to overcome these difficulties, I chose teachers with significant experience with algebraic generalization. The teachers selected all had previously participated in multiple days of professional development focused on algebraic generalization as well as significant experience teaching and interviewing students in this area. Although a study of a more representative group of teachers might provide more generalizable information, choosing more knowledgeable participants allowed me to investigate in detail the subtleties of contextualizing algebraic notation.

During the interview, the teachers were presented two different figural generalizing tasks (see Figure 1). These afforded many different decompositions including interpretations of groups of varying sizes and overlapping groups. Also, the two patterns picked differed in that one was more conducive to being construed as consisting of a constant number of groups of increasing size, while the other could be more readily understood as comprising of an increasing number of groups of constant size. During the interview the participants were asked to provide numerical expressions for specific stages and a general algebraic expression for the n^{th} stage. After each expression they formulated, I asked them to explain what each symbol represented. In addition, I asked the participants to analyze the quantitative meanings of students' work to examine their understanding of decompositions that might differ from their own. Throughout the interview, questions focused on the teachers' understandings of individual symbols and collections of symbols. In addition, I asked participants to comment on their interpretations of various initial symbolic rules as well as on intermediate expressions that arise through syntactical manipulation.

Each interview was videotaped and transcribed. Teachers' responses were reviewed using a grounded theory approach (Strauss & Corbin, 1994) in which I used open coding and the constant comparison method to analyze their responses. I began by identifying particular areas of difficulty across the four teachers. I then compared the actions and comments in these areas among the participants as well as among similar items on different problems.

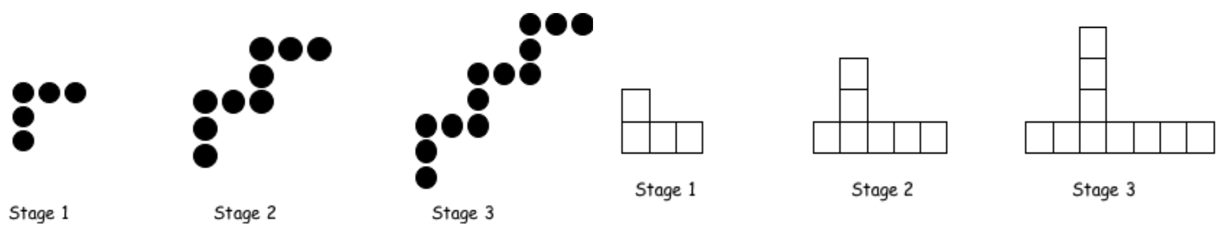

Figure 1. Figural Generalizing Tasks

Results

All four teachers approached the generalizing tasks quantitatively. That is, rather than using a procedure based on numerical values to arrive at a correct linear expression, they began by decomposing the figures into various quantities and then formulating expressions to express their understanding of the quantities they saw. In addition, all of the participants were successful in writing different expressions that corresponded to distinct decompositions of the pattern when asked to analyze the pattern differently and were able to explain possible interpretations of the pattern when exposed to students' expressions that differed from their own. That being said, while the teachers were able to connect the expressions to the quantities in the pattern in general, they struggled articulating the precise contextual quantities that symbols represented. In the end two different challenges emerged along with 3 different conceptualizations to overcome each challenge, one unproductive and two productive.

Challenge #1. Interpreting the Coefficient of *x*

The first conceptual difficulty centered on the participants' understandings of the coefficient of x and its relationship to the variable. Initially, all four participants described the coefficient and the variable together as representing groups of a particular size (i.e. $5x$ represents the number of groups of 5), but struggled to disentangle the two and articulate the specific meanings of the symbols independently.

Unproductive conceptualization: Detaching meaning of the symbols from details of context. To overcome this challenge one participant, Denise, reconceptualized the coefficient as the constant difference between stages even when such a construal was inappropriate for the context. To illustrate this type of thinking, I describe Denise's explanation of the expression $3x+1$ for the second task.

Initially, she stated that the *3* and the *x* both represented number of groups of 3. When asked to clarify, she began vacillating between various interpretations (the number of groups of three, three tiles, the number 3, the three added on) before ultimately concluding that it represented the three tiles that were being added at each stage. When asked to highlight "the three added on" in the figure, she seemed to imposed her notion of adding three on the diagram, selecting tiles that did not correspond to how the pattern changes between stages. Initially she said it did not matter which ones, circling what seemed like arbitrary groups of 3 dots (see left image of Figure 2), before eventually deciding the three additional tiles each stage were the one far left tile and the two far right tiles (see right image of Figure 2).

Denise's vague and even problematic explanations of the various symbols' referents are evidence that she was not using symbols to communicate her interpretation of the figure. Instead, she seemed to reinterpret the coefficient as representing a decontextualized growth factor and attempted to improvise a quantitative interpretation on the figure.

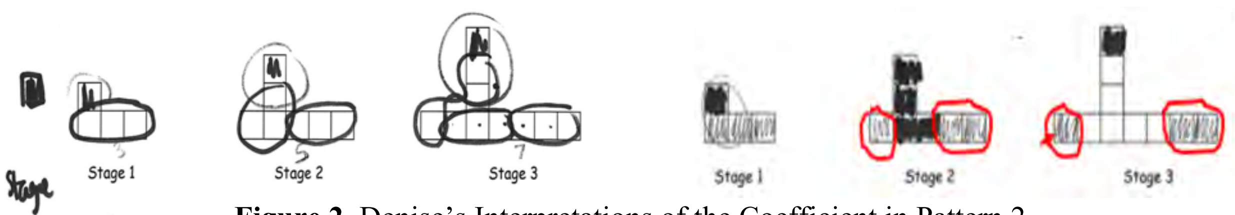

Figure 2. Denise's Interpretations of the Coefficient in Pattern 2.

Productive conceptualizations: Interpreting the variable as the number of groups and coefficient as a ratio of tiles per group or vice versa. While the other three participants also struggled identifying the meaning of the coefficient and variable separately, they eventually disentangled their meanings, describing the variable as the number of groups and coefficient as a ratio of dots or tiles per group for the first task. Notable was their explanation of the symbols in the expression $3(x - 1) + 4$ for the second task. While two of the participants switched their interpretation of the symbols relative to the first task, with the coefficient now representing the 3 constant groups and the variable corresponding to their varying size, the third teacher did not. To make sense of the 3, he imagined orbits of 3 tiles being added to each stage. Such a conceptualization matched his previous interpretation of the variable as the number of groups with the coefficient representing its size. While all three participants had quantitative interpretations of the symbols, the first two flexibly adapted their interpretations of the symbols to accommodate their quantitative understandings of the figure, while the third had a more fixed view of the symbols, reconceptualizing the quantities in the figure to match his previously formulated understanding of the symbols.

Challenge #2. Interpreting Expressions Where the Variable Appears More Than Once

The second conceptual challenge that emerged for the teachers was negotiating the meanings of variables that appeared more than once in a single expression or between expressions after algebraic manipulation. Such a situation exists in the first pattern when decomposing the figure into overlapping groups of 5, first with the expression $5x - (x - 1)$ and then in the subsequent simplified expression $4x + 1$. Initially all four participants interpreted the various xs in these expressions as representing different quantities in the figure. They understood the x in $5x$ as the number of groups of 5, the x in $x - 1$ as the number of overlapping dots, and the final x in 4x as the number of groups of 4. Expecting a single variable to a have a consistent meaning, they struggled to explain this apparent conflict.

Unproductive conceptualization: Imposing the interpretation of one variable onto another.

Three of the participants, in an effort to coordinate the symbols' referents, initially imposed an interpretation of the *number of groups of five* on the *x* in the expression *x – 1*. In doing so they then incorrectly reinterpreted the minus *1* as accounting for the difference in sizes of the groups of five and the groups of four (i.e., the difference in the number of dots) rather than the difference between the total number of groups of five and the number of overlapping dots. While all three teachers devoted at least 5 minutes to this incorrect construal, eventually they all noticed their inappropriate interpretation. Of these three teachers, two then formulated productive conceptualizations of the variables to overcome this problem, while the third participant did not. Instead, in an attempt to resolve this inconsistency, she oversimplified the symbols' referents, arriving at a final interpretation of all the *xs* as simply a dot. Accordingly, she construed *5x* to mean 5 dots and *4x* to mean 4 dots, but was unable to indicate which exact dots in the figure. Such a conceptualization of *x* as a dot essentially treats the variable as a label and the coefficients as decontextualized numbers, removing any quantitative meaning of the symbols and failing to explain any quantitative relationships between the symbols.

Productive conceptualizations: Coordinating numerical values and reinterpreting symbols to align quantitative meanings. Two of the participants were able to articulate viable, yet different solutions to reconcile the diverging meanings of the symbols. Although both teachers initially tried to make sense of the *x*s by using a literal translation of the words like the participant described previously, they eventually formulated productive conceptualizations.

The first participant did so by a**ssociating the quantities numerically.** By evaluating the expressions multiple times and stating the quantities and their numerical relationships, she was able to see that the number groups, initially of 5 dots, is always equal to the number of overlapping dots to be removed, which is equal to the number of groups of 4 dots. In the end, although she continued to interpret the same variable as different referents, she realized that the numerical value of each of these quantities is always equal.

The second productive conceptualization resulted through a reinterpretation of the quantitative meanings of the variables. Similar to the previous participant, the third teacher verbalized his understanding of the various variables in the expression *5x–(x+1)* and *5x–x+1*, while carefully examining their values. This process helped him to not only coordinate the values of the two quantities (groups of 5 and overlapping dots), but also to connect them physically, noticing that the overlapping dots were members of the same groups of 5. In addition, he had added, apparently somewhat serendipitously, a coefficient of *1* in front of the second expression (resulting in *5x–1x–1)*. Together, these various semiotic acts supported him in reconceptualizing the overlapping dots as group of size 1. This conceptualization allowed him to reinterpret *x* as the purely the number of groups, without attaching a size, and the varying coefficients as the size. In the end, he was able to formulate an understanding of the variable so that it retained consistent quantitative meaning throughout as well as explained the varying coefficients.

Discussion

As this analysis reveals, contextualizing algebraic notation is challenging, even for experienced teachers. There are many nuances that experts overlook when they use algebraic expressions to solve problems and communicate their generalizations. In this final section I will revisit some of these challenges and discuss implications that I see stemming from these results.

Conceptual Complexities of Interpreting Algebraic Expressions

To highlight the complexity of contextualizing algebraic notation, I want to revisit a particular conceptualization that emerged. This example serves to not only illustrate the sophisticated understanding necessary, but also emphasizes that the quantities the teachers came to see in the notation were not intrinsic properties in the figure but rather, mental constructs that they themselves created.

One challenge identified in this study was articulating, with precision, separate meanings for the variable and coefficient that explained the relationship between the two. To overcome this difficulty, participants not only interpreted *x* as the number of groups and the coefficient as the size of each group, but also reversed this mapping and conceptualized the coefficient as the number of groups and the variable as the group size. To see both ways requires an abstract and flexible interpretation of the symbols. To illustrate the abstraction of perceiving both ways, I will use an alternative figure (see Figure 3) in which the transition between these two views requires only a subtle, cognitive shift in defining the group. As I point out, while this pattern can be modeled by the expression of *3n*, depending on your perspective, the 3 and then *n* can take on different meanings. In interpretation 1, the *n* indicates the number of groups of size 3 and in interpretation 2, the *n* represents the number of dots in the constant 3 groups.

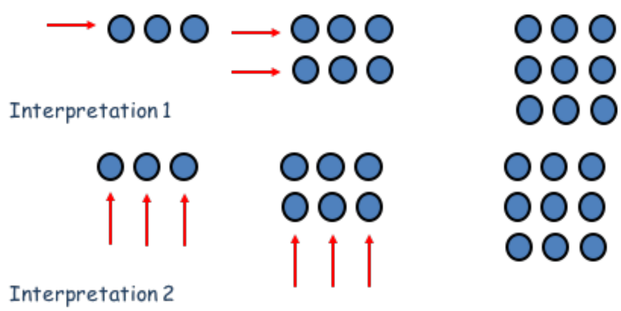

Figure 3. Flexible Conceptualization of Variable and Coefficient.

As this example illustrates the quantitative structure of the pattern is not an inherent characteristic of the figure or of the corresponding notation used to communicate it. The capacity to interpret symbols in multiple ways is an understanding that must be explicitly developed.

Implications

While I see several implications that stem from this study, I will highlight two which are interrelated. As noted in the introduction, algebra classrooms are dominated by a symbolic focus without attention to meaning. While only a few studies have specifically tackled this issue from the teacher's perspective, the consensus seems to be that the primary cause is teachers' orientations. The results of this study indicate that the challenge to transform the current symbolic focus in algebra classrooms is not simply an issue of beliefs. By detailing teachers' struggles with the complexity of this topic, this study demonstrates that, at least in part, the difficulties teachers experience in shifting their instruction is connected to their knowledge bases. Consequently, a second, related implication is the need for teacher preparation programs to explicitly develop this understanding. While definitely a daunting task, the results of this study contribute to this endeavor by identifying both conceptual hurdles and conceptual resources on which to focus instructional attention to support teachers in developing this knowledge and ultimately helping their students foster a deeper, quantitative understanding of the notation.

CONCEPTUALIZING MEASURES OF MATHEMATICAL KNOWLEDGE FOR TEACHING IN TERMS OF UNDERLYING COMPONENTS

Erik D. Jacobson
Indiana Univeristy
erdajaco@indiana.edu

Most existing measures of mathematical knowledge for teaching (MKT) assume a unidimensional structure and report scores that reflect the "amount" of MKT possessed by each examinee. These measures aggregate scores on MKT items that each tap different kinds of teacher work (e.g., explaining concepts, using representations) and different curricular topics. Although this approach is useful for some purposes, the author argues that a new way of conceptualizing measures of MKT will be more useful for gathering data to address open questions about MKT. A review of existing measures is used to argue that conceptualizing measures of MKT in terms of underlying components has promise for building MKT theory.

Keywords: Mathematical Knowledge for Teaching, Teacher Knowledge, Teacher Education-Preservice

Only in the last decade has teachers' mathematical knowledge been reliably linked with student achievement. The breakthrough was writing job-embedded items that require teachers to coordinate specific kinds of teacher work with specific curricular topics in order to assess mathematical knowledge for teaching (MKT; Ball et al., 2008; Hill, Ball, Schilling, 2008). In existing MKT measures, however, teachers' responses on work- and topic-specific items are aggregated. The resulting scores subsume many different kinds of teacher work and span large content areas such as all of elementary or secondary mathematics (e.g., Baumert, et al., 2010) or content covered over one or more years such as algebra (McCrory et al., 2012), geometry (Herbst & Kosko, 2014) or number and operation (e.g., Hill, Rowan, & Ball, 2005).

Efforts to measure MKT have come to an important crossroads. General MKT scores provided by existing measures are important for answering some questions but are too coarse to reveal how underlying components of MKT (i.e., the kinds of teacher work and the specific curricular topics) are related to instructional quality, student learning, or teacher development. These questions are critical for improving MKT theory, and in this paper, we propose a new way of conceptualizing how MKT is measured in terms of its underlying components, that—if realized—promises useful data for building theory.

Existing Measures of MKT

Three large-scale studies have found correlations between MKT and student achievement (Baumert et al., 2010; Hill et al., 2005; Tchoshanov, 2010). Ball, Thames, and Phelps (2008) proposed a framework for MKT that can be used to classify the different approaches used by these studies. The framework extends the notion of *pedagogical content knowledge* (PCK) introduced by Shulman (1986) by grouping PCK with content knowledge and identifying strands within both categories of teacher knowledge. The term PCK captured Shulman's seminal idea that teachers' knowledge of the content they teach is transformed by and merged with their knowledge about how to teach it to form a new domain of knowledge. Within the MKT framework, one kind of PCK is *knowledge of content and students* (KCS), a category that includes, "familiarity with common errors and deciding which of several errors students are most likely to make" (Ball et al., p. 401). Within the MKT framework, two kinds of content knowledge are *common content knowledge* (CCK), the knowledge expected of educated adults including knowledge of the content that students will learn, and *specialized content knowledge* (SCK), knowledge that teachers but few other adults or professionals would possess, such as knowing how tasks and representations correspond with mathematical ideas and evaluating non-standard student reasoning.

Each of the research teams on the three large-scale studies of MKT took its own approach. Tchoshanov (2010) designed the Teacher Content Knowledge Survey (TCKS) measure with three subcontracts, all "closely aligned with … standardized tests for students" (p. 148); thus, it measured CCK. The Learning Mathematics for Teaching (LMT, Hill et al., 2005) measure included CCK items in addition to SCK items involving job-embedded mathematical tasks, for example, to determine the mathematical validity of student strategies. The CCK and SCK items were modeled on the same scale. Items were also developed to measure KCS, but factor analysis revealed "significant problems with multidimensionality" (Hill, Schilling, & Ball, 2004, p. 26).

The COACTIV project (Baumert et al., 2010) created an MKT measure that had two distinct dimensions: content knowledge and what they called PCK. The content knowledge dimension was similar to the instrument used by Tchoshanov (2010) and focused on teachers' understanding of mathematical topics in the curriculum. The PCK dimension included identifying multiple solutions for tasks (PCK-Tasks), understanding students' thinking (PCK-Students), and selecting representations and explanations for instruction (PCK-Instruction). Thus, it overlapped with all three categories of CCK, KCS, and SCK in Ball et al.'s (2008) framework. Baumert et al. (2010) argued the LMT instrument assessed (their) PCK: "mathematical knowledge related to the instructional process" (p. 141).

Categories of Teacher Work

As the COACTV case suggests, the terminology and definitions of the Ball et al. (2008) framework have been influential but have not proved canonical. Several other research groups have defined and validated large-scale MKT measures after delimiting and subdividing the MKT domain in other ways. Table 1 shows three crosscutting categories of teacher work emphasized in the constructs and sub-constructs of published MKT measures. First, teachers use mathematical knowledge to (1) understand what they teach. The second and third categories of teacher work reflect the components of PCK specified by Shulman (1986, p. 9). Teachers use mathematical knowledge to (2) appraise students' conceptions and reasoning and to (3) select and use instructional representations. Moreover, Table 1 illustrates how terms one might expect to have common meanings (e.g., PCK) do not agree across projects.

Table 1: Three Categories of Teacher Work Intersect Subconstructs of MKT Measures

	Categories of Teacher Work

Curricular Topics

Projects also differ in how they divide and delimit MKT relative to mathematical topics. Often, the mathematical demarcations are explicitly related to curriculum. For example, two of LMT instruments measure “Number and operation (K-6)” and “Geometry (3-8)” (Learning Mathematics for Teaching Project, n.d.). The curricular focus of MKT measures can be quite broad; both the TEDS-M and COACTIV projects measured MKT for entire mathematics curricula across multiple grades. Focal content can also be quite narrow; many small studies have used interviews and observation to investigate MKT over a range of specific curricular topics (see review, Depaepe et al., 2013). Rather than being empirically grounded, these divisions of MKT reflect divergent conceptualizations.

As is clear from this review of measures, MKT does not have a simple structure. The LMT excluded KCS pilot items because they were multidimensional. In spite of this complexity and lack of agreement between projects, all these projects except DTMR used unidimensional psychometric models to construct measures, and—differences in how the domain of MKT is defined and divided notwithstanding—all reported unidimensional measures that had sound psychometric characteristics. It may be that the item selection process used to create these measures reduced the diversity of the retained items in non-obvious ways, with each project converging on a different dimension within a multidimensional space.

Conceptualizing A Novel Way to Measure MKT

The inconsistent results and framings of MKT across the field stem in part from scholars who disagree on the paradigmatic foundations of MKT. Two such concerns are whether MKT can be distinguished from mathematical knowledge and whether MKT is situated knowing-to-act that depends on classroom context or if it is cognitive knowledge-about-action that can be validly assessed with survey questions (Depaepe, Vershaffel, & Kelchtermans, 2013; Graeber & Tirosh, 2008; Mason, 2008; Petrou & Goulding, 2011). Different kinds of data than are now available are required to address these gaps and open questions in MKT theory.

At the elemental level, I conceptualize MKT as the mastery of a specific kind of teacher work for a specific curricular topic in mathematics. Rather than assuming a single general structure (i.e., a unidimensional latent trait), I hypothesize that MKT may be multidimensional and structured by the kind of work and the curricular topics involved. I propose developing new MKT measures that systematically vary the kind of work and topic. By leveraging recent advances in psychometrics (Rupp, Templin, & Henson, 2010), a 16-item test (4 kinds of work crossed by 4 topics) could provide a score on each of the 8 components for every examinee. Data from such an assessment bear on several pressing open questions about MKT.

One question concerns how the components of MKT shape and constrain the knowledge teachers develop. I hypothesize that knowledge for a certain kind of teacher work learned in relation to a specific curricular topic may not readily transfer to different topics even if the teacher work is similar. In a study of 40 experienced first-grade teachers, Carpenter, Fennema, Peterson, and Carey (1988) found they could identify which whole number addition and subtraction problems would be most difficult for their students but could not explain why. It is unlikely that teachers could apply tacit professional knowledge such as this to different curricular topics such as fraction addition or subtraction. Comparing relevant MKT component scores could confirm this hypothesis.

A second question concerns how different kinds of teacher work and different curricular topics moderate the relationship between teacher knowledge and student learning. Sadler and colleagues (2013) found that middle grade science teachers’ knowledge of student misconceptions for an individual student item predicted large gains for that teachers’ students on the same item at the end of the year; however, teachers’ average knowledge of misconceptions across all items was only weakly related to increases in their students’ overall scores. When it comes to the teacher work of identifying common student errors, MKT may affect student learning very narrowly, topic by topic. Correlation analysis between student achievement for specific topics and teacher MKT for corresponding topics would shed light on this question.

Conclusion

Existing MKT items are written to combine specific kinds of teacher work with specific curricular topics, yet existing measures are not sensitive to these components. New kinds of MKT measures should be developed that can resolve MKT in terms of the specific kinds of teacher work and curricular topics assessed. Such measures coupled with fine-grained, mixed-methods, and longitudinal analyses, have promise for addressing the critical gaps in MKT theory.

HIGH SCHOOL TEACHERS' PEDAGOGICAL CONCEPTIONS THAT SUPPORT TEACHING THROUGH PROBLEM SOLVING

Olive Chapman
University of Calgary
chapman@ucalgary.ca

This study investigated the pedagogical conceptions held by three exemplary high school mathematics teachers for teaching about and through problem solving and how the conceptions were held that made them effective in supporting students' engagement with problem solving. It was framed in a perspective of mathematics problem-solving knowledge for teaching [MPSKT] consisting of five components of knowledge. Analysis of data, consisting of interviews and class-room observations, indicated that there were important relationships in how the teachers held their conceptions, with one component of their MPSKT forming the core knowledge that gave meaning to the other four components. A core knowledge of "knowledge of students" was a critical factor in supporting their problem-solving-based classrooms.

Keywords: Problem Solving, Teacher Knowledge

Problem solving [PS] is a central aspect of learning and doing school mathematics as well as teaching it. Teaching through PS is promoted as a way to foster students' development of mathematical thinking and autonomy to solve challenging, meaningful problems (e.g., National Council of Teachers of Mathematics [NCTM], 2000). However, this learner/learning-focused approach to teaching is likely to be a challenge for teachers depending on their understanding of PS in mathematics. Similar to the perspective of Ball, Thames, and Phelps (2008) that suggests general mathematical ability does not fully account for the knowledge and skills needed for effective mathematics teaching, the knowledge teachers need to effectively engage students through PS should be more than general PS ability (Chapman, 2015; Schoenfeld, 1985). Understanding this knowledge from a practice-based perspective can provide insights to support teachers' learning and use of it. This paper contributes to this understanding based on a study that investigated the conceptions held by three exemplary high school mathematics teachers regarding teaching about and through PS and how the conceptions were held that made them effective in supporting students' engagement with PS.

Related Literature and Theoretical Perspective

In recent years, considerable attention has been given to mathematics knowledge for teaching (MKT) (e.g., Ball et al, 2008; Rowland & Ruthven, 2011) as a basis for understanding and improving the teaching of mathematics. *Mathematical problem solving knowledge for teaching* (MPSKT), an important aspect of MKT, requires specific attention to address how to support teachers in creating PS-based classrooms. PS is considered here as "engaging in a task for which the solution method is not known in advance" (NCTM, 2000, p. 52). In PS-based classrooms, students are engaged in PS as a way of thinking mathematically and doing and learning math.

Several studies have highlighted issues with teachers' PS ability and knowledge of PS. For example, they tend to lack flexibility in choice of PS approaches (van Dooren, Verschaffel, & Onghena, 2003), apply a stereotypical solution to a problem (Leikin, 2003), have a lack of strategies for interpreting the information given to them in word problems and to recognize the appropriate procedure to use (Taplin, 1998) and make sense of PS as a linear process (Chapman, 2005). However, less attention has been given to teachers who hold knowledge that supports PS-based classrooms, which is the focus of the study being reported in this paper.

The study is framed in a theoretical perspective of MPSKT suggested by Chapman (2015). Based on a structure similar to Ball et al.'s (2008) perspective of MKT, two categories of MPSKT are adopted in this study. Category 1 (PS content knowledge) has three components: knowledge of problems, PS, and problem posing. Description of these components includes understanding of meaningful problems, of mathematical PS as a way of thinking, of how to interpret students' unusual solutions and implications of students' different approaches, and of problem posing before, during and after PS. Category 2 (Pedagogical PS knowledge) has two components: knowledge of students as problem solvers and instructional practices for PS. This includes understanding what a student knows, can do, and is disposed to do and understanding how and what it means to help students to become better problem solvers.

The participants' knowledge is based on their conceptions of each component connected to their teaching of and through PS.

Research Process

This study is part of a larger project that investigated prospective and practicing elementary and secondary school mathematics teachers' thinking and teaching of PS. It focuses on three of the high school teachers who consistently taught through PS. They were experienced grades 10 to 12 mathematics teachers with 16 to 20 years of teaching experience. They were from different local public schools and received teaching awards as excellent mathematics teachers.

Main sources of data were open-ended interviews, PS tasks, classroom observations, role play, teaching/learning artifacts, and students' work. The interviews explored the participant's conceptions of and experiences with PS. This included questions/scenarios on: PS ability; nature of tasks, PS, and learning; instructional approaches; contexts; planning; and intentions for PS in their teaching. Participants also commented on the nature of five different types of relevant school mathematics problems and on when and how they may or may not use them in their teaching. Interviews were audio recorded and transcribed. Classroom observations and field notes focused on the teachers' actual instructional behaviors and students' engagement during the lessons. Ten lessons (60 to 85 minutes each) involving PS or when a new concept was being introduced and developed were observed and audio-recorded.

Data analysis involved the researcher and a trained research assistant working independently to thoroughly review and code the data and identify themes, which were validated through an iterative process of identification and constant comparison. Coding was guided by the five com-ponents of MPSKT. This included highlighting participants' conceptions and what they valued regarding each component. For example, for PS, their conceptions included: "It's like anything else that you don't know what the outcome will be and you're kind of game for anything, so you just take your chances and you try and use the tools that are available to you, see what happens." "It is a process, it is not a solution. It is whatever takes you to get to that solution. So, thinking, trying out things, writing, using whatever tools you have to find a solution." The data were also examined for connections that were consistently expressed in their conceptions as a basis for understanding how they held their MPSKT. For example, their conceptions of problems were always expressed in relation to the problem solver/learner/student regardless of the context involved; e.g., "Using problems in class, the big thing is that they have to be interesting to some-one, to those kids." "All word problems are real problems if students have not encountered them before." "Students don't have a predetermined solution process." "It's a problem you want to have the answer to, … something that is needed, is practical, is worthwhile, that has some kind of relevance to the student." In general, for all participants, explicit connections to *students* was dominant for each component of MPSKT, which was consistent with their observed classroom actions. Thus, *knowledge of student* emerged as central to how they held and used their know-ledge. Further analysis focused on unpacking and confirming the relationships with *students.*

Finding

While there were differences in the teachers' conceptions and teaching approaches, only the common features that were central to how they engaged students in PS are presented here. The teachers held conceptions that showed positive disposition to PS. They viewed PS not as separate topic but as a central aspect of learning mathematics that should be integrated throughout a course. Their PS-based classrooms included engaging students in solving challenging problems, exploring patterns, designing tasks, formulating and checking conjectures, reasoning and generalizing, and communicating/discussing ideas and outcomes. New concepts were introduced through PS. For example, Teacher 1 started her Grade 11 unit on functions by giving students a set of graphs and asking them "to put them together in some form, like group them or look at them in some way that they are mathematically connected or similar or not." This was followed by further exploration. Teacher 2 started her unit on relations and functions with the following scenario for which students had to determine independent and dependent variables with justification, represent the scenario in three different modes, explain the type of graph and reason for it, explain the meaning of the steepness and intercepts.

> You are running in the Terry Fox Run at school. One of the ways to earn money in support of the Terry Fox Run is to obtain sponsorship. The school has decided the sponsorship rate will be $1/km run in the designated time slot.

Table 1 summarizes central aspects of the teachers' conceptions of the components of MPSKT that defined their teaching.

Table 1: Teachers' MPSKT

Components of PSKT	Teachers' Conceptions
Students	Students are designers, interpreters, evaluators, inquirers and agents of their learning and doing of PS.
Problem	A problem emerges based on how the student experiences the task. The task provides possibilities, while the student provides the interpretation that gives meaning to the problem, e.g., as interesting, relatable, and challenging or not.
Problem posing	Problem posing involves students creating tasks, modifying/redesigning tasks contextually and extending a problem. It allows them to realize their interests and be creative.
PS	PS involves what students are able to do that makes sense to arrive at a solution.
Instructional strategies	A key strategy is not teaching heuristics or concepts in an explicit way, but allowing them to emerge out of students' experiences in trying to solve a problem and reflecting on the process and concept.

In addition to the nature of the teachers' conceptions, an important finding is that the components of MPSKT were not held by the teachers in isolation of each other but were connected through one component that formed the core of a network consisting of the five components. For these teachers, the core knowledge was *knowledge of students*. Students were viewed in terms of their ways of learning/knowing and affective factors/beliefs impacting them as problem solvers/ learners. Knowledge of each of the other four components was held in relation to knowledge of student. For example, *problems* were viewed as relationship between student and task. *Problem* *posing* was viewed in relation to students as task designers. For example, after mentioning the Goldilocks story as an example, Teacher 3 assigned the following task to her grade 12 students:

> … rewrite a children's story to solve permutations or combinations. The math should be an integral part of the story line, perhaps illustrating difficult decision making or large numbers of choices to be made. …This is a children's story, so make the story line and illustrations simple, although the problems encountered should be relatively complex in nature.

PS was viewed in relation to the students' thinking/inquiry process and instructional strategies were viewed in relation to supporting students' agency and autonomy in engaging in PS. As Teacher 3 explained:

> I go around and listen to the groups. …I can sit next to any group and they talk, and I ask them questions if they're stuck but that's about it. I simply watch how the groups are working together and if I see a group is stuck, I try to come up with a question that will allow them to continue, but I will not give anybody the answer at any time …they can always ask a question, but if they want to know how to do it, or are they right, they may not talk to me.

Conclusion

This study contributes to our understanding of the nature of and relationship between exemplary teachers' MPSKT and practice. It indicates the nature of the teachers' MPSKT and that they held their conceptions of the five components of MPSKT, not independent of each other but, as a network of interdependent knowledge with one component forming the core or anchoring component that gave meaning to the other four components. The findings suggest that the nature of this core component is a critical factor in supporting PS-based classrooms. In particular, they suggest that a teacher's MPSKT with a core component of *knowledge of students* as genuine problem solvers is important to enable the teacher to support PS-based classrooms with "effective teaching that engages students in meaningful learning … to make sense of mathematical ideas and reason mathematically" (NCTM, 2014, p.7). Ongoing investigation in the larger project explores this relationship between MPSKT, core component, and teaching to empower students in learning about and through PS and the implication for teacher education.

KNOWLEDGE FOR TEACHING INTEGERS: ATTENDING TO REALISM AND CONSISTENCY IN A TEMPERATURE CONTEXT

Jennifer M. Tobias

George Fox University
nenzinger@georgefox.edu

Dana Olanoff
Widener University
dolanoff@widener.edu

Research has illustrated that prospective teachers struggle to construct word problems for integer operations. This paper extends the current research by examining the ways in which four classes of prospective teachers responded to a child's temperature story for an integer addition number sentence (i.e., -9 + -6 = □). One hundred prospective teachers responded to whether they believed that the story matched the number sentence and provided justification for their reasoning. The child's story, an actual story posed by a Grade 5 student, did not utilize temperature realistically (realism), nor was it consistent with the given number sentence (consistency). The results indicated that when prospective teachers were asked to evaluate the child's story, they tended to either focus on realism or consistency, but not both. Benefits of using children's thinking during instruction as well as implications for research are discussed.

Keywords: Number Concepts and Operations, Teacher Education-Preservice, Mathematical Knowledge for Teaching, Teacher Knowledge

Background

Research has shown that prospective teachers (PTs) struggle to think conceptually about integer addition and subtraction, often focusing on procedures (e.g., Bofferding & Richardson, 2013). Additionally, both children and PTs have difficulties when posing stories for integer number sentences (Kilhamn, 2009; Roswell & Norwood, 1999). Since PTs will need to extend their own knowledge about integer operations (Chrysostomou & Mousoulides, 2010) to make sense of children's reasoning with contexts for integer addition and subtraction, we developed a study focusing on the ways in which PTs attended to a child's posed temperature story for an integer addition number sentence.

Utilizing Contexts with Integer Addition and Subtraction

Research has illustrated that both children and PTs have varying degrees of success when generating stories for integer operations (Kilhamn, 2009; Wessman-Enzinger & Tobias, 2015). Difficulties include posing unrealistic stories, changing the number sentence to a different number sentence, and using contexts that do not support opposites (Kilhamn, 2009; Wessman-Enzinger & Mooney, 2014). Wessman-Enzinger & Tobias (2015) found that although some PTs could successfully pose temperature stories, many either posed unrealistic stories or did not use temperature as a context. Likewise, Kilhamn (2009) asked PTs to solve and describe their thinking for integer number sentences (e.g., -8 – -3= □). Kilhamn found that only a small amount of PTs utilized a model or context to explain the mathematics. Interestingly, those who did either used number lines or temperature to explain their reasoning.

Though the research described above has given us some insight about how children and PTs struggle with posing stories for integer operations, little is known about how PTs reason about children's thinking. This study seeks to extend current research by examining the multiple ways PTs responded to an integer temperature story posed by a fifth-grade student and what their understandings of the child's story means for their own content knowledge for teaching. Consequently, the guiding research question for this study was: *What do PTs attend to when they evaluate a child's temperature story related to integer addition?*

Methodology

Background

One hundred and three elementary and middle school PTs in four different classes participated in a study on integer addition and subtraction. The PTs were enrolled in an introductory mathematics content course focused on number concepts and operations. Two of the three authors were professors for this course and all three of the authors analyzed the written tasks from the PTs. The mathematics content course was designed to promote conceptually oriented discourse. PTs were first given problem situations. Then they worked on the problems individually and/or in small groups. This was followed by whole-class discussions where the instructor acted as a facilitator. Throughout the course PTs were asked to solve problems in multiple ways, present their own solution strategies, make sense of the reasoning of others, and ask questions when clarification was needed.

Data Collection and Analysis

Data were collected across two academic semesters, Fall 2013 and Spring 2014. The PTs were given four integer addition and subtraction number sentences with stories that Grade 5 children posed for those number sentences. The PTs were asked to provide a response for whether the child's story made sense and justify their responses. PTs' responses to one of these stories, The Sabrina Task (see Table 1), is the focus of this report.

Table 1: The Sabrina Task

Student	Number Sentence	Story
Sabrina	-6 + -9 = □	It is -6 degrees 2 days ago. It was -9 yesterday. Now it is -15 degrees.

The data for this study were comprised of the PTs' written responses (i.e., responding yes or no for matching and their explanations). Of the 103 written responses, only 100 explanations were readable and consequently analyzed for the study.

When coding the responses, we analyzed them to determine themes for coding, such as attention to language, attention to the solution, attention to realism, and attention to consistency. We then went through an initial pass of coding, checking to see if these themes were evident in each PTs' response. As we discussed themes like language and attention to solution, we noticed that our discussions for this problem centered on realism and consistency. Realism focused on PTs' attention to the fact that adding temperatures from previous days does not determine the temperature the following day as well as everything within PTs' responses being realistic. Consistency included PTs' attention to the story not being consistent with addition, and PTs' explanations themselves being consistent. After each round of coding, the authors met, compared codes, and negotiated any differences. We then obtained counts and percentages of these codes to make sense of the qualitative data (Miles & Huberman, 1994).

Results

Of the 103 PTs responses, 17 thought that Sabrina's story did match the number sentence. Eighty-four PTs thought that Sabrina's story did not match, and 2 PTs thought that Sabrina's story did and did not match at the same time. The responses from PTs contained various levels of attention to consistency and realism.

Attention to Consistency

When attending to consistency we found that fifty-three of the 100 PTs' written responses mentioned that the story was not consistent with the addition sentence. 47 did not mention a consistency issue, including students who claimed that the story was consistent with a subtraction problem instead of an addition problem. Additionally, 28 of the PTs themselves suggested an inconsistent story when trying to fix Sabrina's problem.

When PTs recognized that there was not an addition operation present in the story they expressed this in various ways – utilizing language such as "no addition," "no operation," "no relationship," or "no math." An example of this is PT B20's response: *Sabrina's sentence did not make sense because in her sentence she just stated different degrees on different days. There was no mention of any addition or subtraction.* This PT noted that there was no mention of addition or subtraction and that the story just lists the temperatures from different days.

Attention to Realism

When coding for realism we found thirty-eight of the 100 PTs' responses mentioned that it is not possible to sum previous days' temperatures to obtain the next day's temperature. Sixty-six of the 100 responses were entirely realistic.

We found PTs whose entire justification included the idea that combining the previous two days' temperatures do not give you the temperature for the third day. For example, PT B4 wrote:

The separate days' temperatures don't affect today's temperature. So, the problem doesn't make sense. Others, such as PT B21, also stated that Sabrina's story was not realistic. However, PT B21 offered a suggestion that was coded as unrealistic, because it involved adding the two temperatures together.

> … her story does not make sense. The temperature from two days ago and one day ago do not necessarily dictate what the temperature will be today, there is no relationship there. It would have been fine if she asked, "what are these temperatures together?"

Though PT B21 noted that the temperatures from the previous two days do not determine the temperature for the third day, she stated that Sabrina should have asked what the two temperatures are together, which is unrealistic in the context of temperature.

Discussion and Implications

Our results indicated that PTs used varying levels of justification when discussing Sabrina's story and were generally successful in determining that Sabrina's story did not match the number sentence (81 out of 100 PTs). Of these, only 13 attended to the fact that Sabrina's story was both unrealistic and inconsistent with the number sentence. The majority (64 of 81) focused on only one aspect, either realism or consistency, and four did not attend to either. These results provide insight into PTs' mathematical knowledge for teaching as well as extend previous research focusing on PTs' understanding of integer operations.

Providing PTs with a task that included examining a child's story that was both unrealistic and inconsistent may have helped them to focus on realism and consistency more so than if they had just been asked to pose a story themselves. We found that the majority (76 PTs) did this automatically by discussing realism, consistency, or both even when instructed to just explain whether Sabrina's story matched the number sentence. Giving PTs this story may have given them an avenue to reflect on what makes a story realistic or consistent as previous research has suggested that PTs do not necessarily attend to these same aspects when posing their own stories (Wessman-Enzinger & Tobias, 2015).

The results also indicate that PTs used a variety of justifications when analyzing an integer addition story for a given number sentence. Focusing discussions around these justifications can be a productive way for PTs to develop an understanding of the limitations of certain contexts that support integer operations as well as what it means to operate with integers. For example, the Sabrina Task included a temperature situation that was not possible (adding two temperatures together). By exploring realism, PTs can develop an understanding of why contexts, such as temperature, are not possible for integer addition when the second addend is negative. These conversations can then lead PTs to develop similar understandings for subtracting with a negative as it is also not realistic for a temperature to drop by a negative amount.

Conclusion and Final Remarks

PTs' responses to the Sabrina Task highlight the need for content and methods courses in mathematics education to provide PTs with a variety of classroom experiences, including but not limited to posing problems, examining stories in multiple contexts, and analyzing children's thinking in the domain of integers. The results extend previous research by providing insight into the ways in which PTs coordinate various contextual nuances with temperature and integers, such as realism and consistency in comparison to a given number sentence. We found that despite having experiences with temperature and integers, PTs did not readily extend this knowledge to children's thinking. In addition, although many of the PTs attended to realism and/or consistency in their responses, some stated other things that were unrealistic or inconsistent. Thus, as mathematics educators, we have an indispensable responsibility to provide PTs with opportunities where they can make sense of children's thinking to deepen their own content knowledge as well as prepare them for what they will be required to do in their own classrooms.

MEASURING MATHEMATICAL KNOWLEDGE FOR TEACHING: THE EFFECT OF THE "I'M NOT SURE" DISTRACTOR

Tibor Marcinek

marci1t@cmich.edu

Arne Jakobsen
University of Stavanger
arne.jakobsen@uis.no

This paper presents a quantitative analysis of data from an MKT instrument administered on a sample of 284 practicing teachers in Norway and Slovakia. It confirms concerns raised by several qualitative studies: Some teachers choose the "I'm not sure" distractor despite having solid knowledge. On the other hand, we found that the statistical impact of these cases is limited and a qualified use of the MKT measures is likely to provide valid and useful information.

Keywords: Mathematical Knowledge for Teaching, Measurement, Teacher Knowledge

Discussions of the knowledge needed to teach mathematics and issues with the related measures have received notable coverage in research literature. One of the most cited models of teachers' professional mathematical knowledge is the Mathematical Knowledge for Teaching (MKT) that emerged from the research at the University of Michigan (Ball, Thames, & Phelps, 2008). These researchers also developed measures of MKT (the MKT measures, sometimes referred to as the LMT measures) that served many important purposes. For example, they were used to statistically validate the existence of various domains of MKT (Hill, Ball, & Schilling, 2008) and demonstrate the positive effect of teacher's MKT on students' achievement (Hill, Rowan, & Ball, 2005). Due to the unique properties of the MKT measures, several international researchers (see for example Blömeke & Delaney, 2012) adopted them and studied their validity in new cultural contexts.

Our study builds on the cross-national MKT measures adaptation research and involves data from Norway and Slovakia collected by using the same MKT instrument (MSP_04_formA containing 61 multiple-choice items with known IRT parameters for the U.S. population). This report focuses on a specific result that our data set revealed: How the "I'm not sure" distractor affects the response patterns and potentially the overall validity of the MKT instruments.

Theoretical Background

The MKT measures were developed as multiple-choice questions to allow a robust quantitative analysis involving several thousands of respondents. To discourage guessing, which may occasionally result in a correct answer without having the knowledge, the authors of the measures included the distractor "I'm not sure" (coded as incorrect, cf. Hill, 2007). However, the format of the MKT measures was criticized by some researchers and multiple issues were raised. For example, a multiple-choice approach to measuring teacher knowledge ignores its complexities (Beswick, Callingham, & Watson, 2012), and as such might be measuring constructs different from the intended one (Schoenfeld, 2007). Other researchers employed qualitative methods to study how answering MKT measures relates to the actual teacher knowledge or their performance in a classroom. For example, Hill and colleagues describe a case of a teacher who scored significantly high on the MKT instrument (89^{th} percentile) and yet her quality of instruction was only average with undue emphasis on routines and mnemonics (Hill, Umland, Litke, & Kapitula, 2012). Fauskanger (2015) combined MKT measures with constructed-response questions to reveal the cognitive types of knowledge teachers use when answering MKT measures. She found that one teacher (out of 28 in the study) provided three incorrect responses on multiple-choice items and yet demonstrated connected conceptual knowledge in related constructed-response questions. On the other hand, 13 teachers chose correct multiple-choice answers and yet their constructed responses indicate limited, instrumental understanding. In another qualitative study, Fauskanger and Mosvold (2015) looked at the reasons for choosing the "I'm not sure" option and found out, that out of 15 teachers in the study, six choose this distractor because they lacked the knowledge, five had limited, instrumental understanding of the content and four chose "I'm not sure" even though they possessed connected, conceptual (relational) understanding.

Research Questions

Research suggests that at least in some cases, there is a mismatch between teacher's MKT scores and their actual knowledge for teaching mathematics and that teachers choose the "I'm not sure" option even if they possess deep, conceptual understanding of the topic. This is problematic as the "I'm not sure" option is coded as incorrect and thus affects calculations of the test parameters and consequently teachers' abilities. If the number of knowledgeable teachers who chose the "I'm not sure" distractor is relatively high (relative to the number of teachers who chose it for the lack of knowledge) then item difficulty estimates can be inaccurate. Similarly, the ability estimates can be inaccurate for teachers who chose this option repeatedly.

We therefore decided to investigate if the quantitative patterns in our data can reveal how the overall knowledgeability of respondents is related to their decision to choose the "I'm not sure" option. Particularly, we were interested in answering the following questions:

3. Does our quantitative data support the findings of other qualitative studies? Identification of respondents who choose the "I'm not sure" option despite their high overall level of knowledge will provide such support.
4. If so, what is the statistical importance of such cases? Specifically, we will try to assess the extent to which these cases affect the item parameters (and consequently teachers' abilities).

Methods and Results

Our instrument contains 61 MKT items and we administered it in Slovakia and Norway to collect data from 284 practicing elementary teachers. The sample size allows us to use a two-parameter Item Response Theory (IRT) model. IRT scales the person's MKT (ability θ) and item difficulty (b) on the same continuum: A person with the ability (MKT) of θ has a 50% chance to answer an item with the difficulty $b = \theta$. The parameters are scaled so that the average θ for the whole population is 0 and the population standard deviation is 1.

We performed several data simulations to explore various assumptions. We recoded all "I'm not sure" answers the same way as "No Answer" is coded to be ignored in the calculations. Our new estimates of item difficulties (denoted b') and teacher abilities (θ') thus operate on an assumption that teachers were choosing these two options interchangeably and their inclination towards the "I'm not sure" option does not indicate lacking knowledge.

For each item, we then recorded the ability estimates (θ') of all teachers who chose the "I'm not sure" option for that item. In other words, we created ability profiles of teachers who choose the "I'm not sure" option across all items. We did the same analysis for missing answers. Only the items with more than twenty "I'm not sure" or skipped answers were included in the analysis.

Table 1 summarizes important parameters and shows that the mean ability of teachers who chose "I'm not sure" is lower than the mean ability of teachers who chose not to answer items. The difference is statistically significant ($t(40) = -2.85$, $p < 0.005$). This result indicates that statistically, the distractor "I'm not sure" works as intended: teachers who choose it are more likely to be "less knowledgeable" than the ones who simply skip the answer.

Table 1: Ability estimates θ' of teachers who chose "I'm not sure" or skipped answers

	Number of items with frequency >20	Ability (θ') mean	Std. deviation
"I'm not sure"	24	-0.495	0.229
No answer	32	-0.335	0.170

The analysis of individual items provides further insight. Points in the scatter plot in Figure 1 represent the average abilities θ' (y-axis) of those teachers who selected "I'm not sure" for a given item (x-axis). Vertical segments show the standard errors of the θ' estimation. The plot provides visual information on the relationship between the average ability of teachers who selected "I'm not sure" option for a particular item and the population mean (bold horizontal line θ' = 0).

We can see that even if the teachers who choose "I'm not sure" are overall likely to select it for the lack of their knowledge to choose another option, concerns raised by Fauskanger and Mosvold (2015) are valid. For example, the group of teachers who chose "I'm not sure" for the item 16 is on average significantly more knowledgeable than the whole population. As many such teachers are knowledgeable overall and some of them are very knowledgeable (six teachers ranked above the 87th percentile), it is likely that their choice of "I'm not sure" was not caused by the lack of their knowledge. Similarly, the teachers who chose this option for the item 43 or 37 are on average not significantly less knowledgeable than the population average. Further insight into the possible reasons for choosing "I'm not sure" can be gained from a closer analysis of these items and the national samples; Such analysis, however, is beyond the scope of this report.

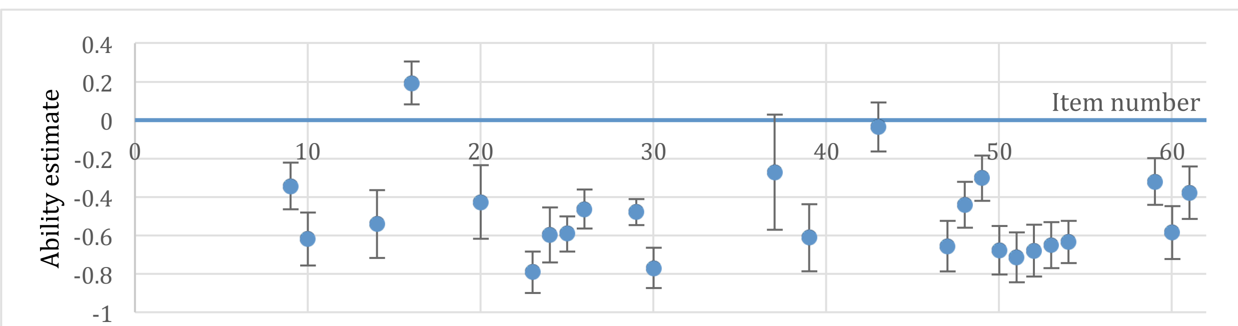

Figure 1. Average abilities of respondents who chose the "I'm not sure" distractor.

When assessing the statistical importance of this group of knowledgeable teachers, we selected all teachers (26) who chose "I'm not sure" in either of the questions 16, 37 and 43, and whose ability estimates were above the population mean (taking the standard error into account). We assumed that these knowledgeable teachers likely chose "I'm not sure" for reasons other than the lack of knowledge. We removed these respondents and recalculated the test parameters.

Due to a limited scope of this paper, we only present a partial analysis of the item difficulties calculated from the new sample (b'') and the original difficulties (b). We can see from the Table 2 that the new difficulties b'' of the items 16, 37 and 43 are within the standard errors of the original difficulty estimations b. The extension of this analysis to all items yields similar results: The group of knowledgeable teachers, who choose the "I'm not sure" option for reasons likely unrelated to the lack of their knowledge does not significantly affect the test parameters.

Table 2: Original (b) and Simulated (b'') Difficulties of the Items 16, 37 and 43

	Item 16	Item 37	Item 43
original item difficulty b and the standard error	0.51 ± 0.22	-0.19 ± 0.44	-1.36 ± 0.3
new item difficulty b"	0.39	-0.22	-1.2

Conclusion

Our quantitative results confirm that concerns raised by the qualitative analyses of Fauskanger and Mosvold (2015) are valid. The analysis of the items 16, 37 and 43 revealed knowledgeable teachers who occasionally choose the "I'm not sure" option for reasons likely not related to the lack of their knowledge. On the other hand, we saw that the group of teachers who chose "I'm not sure" is on average less knowledgeable than those who skipped the answers. Moreover, the statistical impact of the group of teachers who choose the "I'm not sure" option despite their sound knowledge was not significant in our data. We view these results as a reminder of the importance of a qualified use of the MKT measures. If an MKT instrument, such as ours, is used to assess the ability of an individual teacher (e.g. for certification purposes), it is possible that the resulting MKT score will not correctly capture their actual knowledge. If, however, it is used for the purpose, for which it was designed (for example to measure knowledge growth of a group of teachers participating in a professional development), it is likely to provide valid and useful results.

Vast amounts of money are spent on professional development for teachers, but little is known about its quality or efficacy. IMPRINT, an 18-month long professional development project, was aimed at improving the teaching of proportional reasoning using mathematical tasks set in authentic contexts. IMPRINT framed teachers' analyses of student work using particular domains of MKT. Outcomes indicate that IMPRINT positively influenced participants' MKT in ways that fostered more student-centered instruction, with students working on authentic application tasks set in engaging and motivating contexts. Compared to a control group, students of IMPRINT teachers showed greater knowledge and understanding of ratio and proportion.

Keywords: Teacher Education-Inservice/Professional Development, Mathematical Knowledge for Teaching, Middle School Education; Teacher Knowledge

Introduction

Proportional relationships are foundational to much of the mathematics curriculum, and have been called the capstone of elementary concepts in mathematics (Lesh, Post, & Behr, 1988). However, evidence exists that teachers' knowledge of proportional reasoning, and how to teach it, is not robust (Izsak, Jacobson, & de Araujo, 2012). Although professional development is conducted in virtually every district across the United States, empirical evidence regarding the relationships among professional development, teacher growth, and student learning is scant (Desimone, 2009). Few studies demonstrate a link between professional development and measures of teacher learning, instructional performance, or student learning outcomes at scale. Gersten, Taylor, Keys, Rolfhus, and Newman-Gonchar (2014) found that only two forms of professional development had positive effects on students' achievement in mathematics: intensive courses in mathematics content with follow-up workshops, and lesson study.

Cognizant of these challenges, we designed the **I**mproving **P**roportional **R**easoning **I**nstruction through e**N**gineering **T**asks (IMPRINT) professional development to enhance teachers' mathematical knowledge and pedagogical skill in developing strong understandings of ratio and proportion. IMPRINT was designed around the idea that improvement of mathematics teaching requires expansions of teachers' mathematical knowledge for teaching (MKT) (Ball, Thames & Phelps, 2008). Devising teacher learning environments situated in the demands of instruction (Ball & Cohen, 1999) guided our work. To develop teachers' MKT, we designed mathematically rich experiences anchored in what teachers see as their real work. Mathematical tasks played a large role because teachers are engaged with mathematical tasks in their daily work. The research described in this paper sought to understand whether and how teachers' MKT (Ball, Thames & Phelps, 2008) in proportional reasoning was enhanced through their participation in IMPRINT's professional development program of intensive mathematics content with follow-up workshops and lesson study over an 18-month period, and how this affected student learning in turn.

Methods

Participants in this study were the 16 elementary and middle school teachers who completed the IMPRINT program, which, included working on mathematical tasks that feature proportional relationships in authentic STEM contexts, evaluating word problems in school curricular materials, studying student thinking including known misconceptions in proportional reasoning, revising and creating mathematical tasks for proportional reasoning, and analyzing student work collaboratively. The Survey of Enacted Curriculum (CCSSO SEC, 2005) was administered to teacher participants as both a pre- and a post-test to measure any changes in instructional practice. Improvement in participants' MKT in proportional reasoning was assessed with the Learning Mathematics for Teaching (LMT) 4-8 Proportional Reasoning Assessment (Hill, Schilling, & Ball, 2004) used as a pre- and post-test for project teachers and a control group. Students of IMPRINT and control group teachers were assessed for their knowledge of proportional reasoning using a project-developed 11-item assessment at the beginning and end of the project.

Teachers' analysis of student work provided qualitative data. Teachers administered a proportional reasoning task twice during the project. Each time, teachers used the same task, analyzing it collaboratively. Their analyses focused on the varied strategies students used. In another analysis cycle, a task was chosen by each teacher and administered twice, focusing their analysis on their own students and the specific problem they wanted to do with their students.

LMT data were analyzed using non-parametric tests to detect any statistically significant differences between IMPRINT and control group teachers, and SEC data were analyzed using two proportion *z*-tests to detect any changes in the IMPRINT teachers during the project. Teachers' analyses of student work were categorized, coded, and examined for emerging patterns and themes (Miles & Huberman, 1994). Triangulation of data ensured the reliability of the study.

Results

Teachers reported in surveys that their understanding and teaching of proportional reasoning improved during IMPRINT, and analyses of the quantitative and qualitative data bear this out.

> Through the time that I have been a part of IMPRINT I have definitely strengthened and expanded my knowledge of ratios, rates, and proportional reasoning. Before beginning IMPRINT, I thought I had a solid understanding of these concepts and that I was doing a good job teaching these concepts to my students, however there were so many new and different ways of thinking, teaching, and looking at the concept of proportional reasoning, rates, and ratios.

As this teacher noted, we saw instances of deeper thinking about the content as well as how to teach the content. Below, we provide further evidence bolstering self-reports of improved MKT.

Quantitative Evidence

Due to small sample sizes, the LMT pre-test results were analyzed with a Mann-Whitney U test. The project and control groups were not significantly different (p=.0.582). When the differences from pre- to post-test for each group were tested for significance using the Wilcoxon signed rank test, the control group did not show any significant differences from pre-test to post-test (p=0.330), while the project group showed a significant positive difference (p=0.017).

Post-test results of the student assessment were analyzed using ANCOVA, controlling for pre-test scores. At α=0.10, a significant difference in favor of the project group was found (p=0.087). At α=0.05, ANCOVA also revealed significant differences in favor of the IMPRINT group on two of the individual items (p=0.02 and p=0.04).

We used sections of SEC pertaining to instructional and assessment practices and teacher opinions/beliefs. When the SEC items were analyzed, statistically significant changes from pre- to post-test were detected in the proportions of participants who answered items in ways consistent with the goals of IMPRINT.

Taken together, the LMT results show that IMPRINT teachers' MKT in proportional reasoning increased over the life of the project, while the SEC results demonstrate that IMPRINT teachers were changing instruction in ways that aligned with the project's objectives. Moreover, students of the project teachers outperformed those of a control group of teachers on the 11-item proportional reasoning assessment.

Fostering Teachers' MKT With Student Work

Teachers analyzed their students' work on two different proportional reasoning tasks assigned at two different times. The goal was to develop teachers' MKT by having them appraise students' responses and strategies. The assignments encouraged teachers to track different solution strategies, as well as examine their own and students' habits in solving proportional reasoning problems. This supported development of a wide variety of solution strategies.

Building on this work, teachers chose and implemented a proportional reasoning task. Next, they responded to questions about the tasks they chose, explained why they selected them, and shared student work. They also commented on one another's selections. Analysis of tasks selected and reasons for selecting them shows IMPRINT teachers most valued tasks relevant to students' lives. They also preferred open-ended proportional reasoning tasks leading to multiple solution pathways or leading to fruitful discussions. These discussions often touched on the MKT domain of Knowledge of Content and Students (Ball, Thames, & Phelps, 2008).

We also found teachers slightly more concerned with what students did not understand than what they did understand. We surmise that concern with lack of understanding stems from their efforts to improve the task and students' understanding of it, hence their focus on what students did not understand. There was little mention of specific errors or explanations for errors in the student work, possibly due to the nature of questions teachers were asked as they analyzed their results. Regardless, there is strong evidence teachers were focusing on students' proportional reasoning, some teachers more so than others.

After analyzing what teachers noticed in students' work, we looked at their task revisions. We categorized the revisions as consistent, somewhat consistent, or inconsistent with what they noticed. For example, one teacher used a problem which asked students to find ratios of different colored LEGO pieces. She noticed that students struggled with comparing multiple parts to a whole, as well as filling in a ratio table. She revised the task, but only addressed the ratio table where students lacked understanding of equivalent fractions. We coded this as a "somewhat consistent" revision with a shift in the content of the lesson. The revision was coded "somewhat consistent" because only one part of what was noticed was used in revising the task. Shifts in the content of the lesson occurred when teachers decided to teach a different concept based on observations made from teaching an earlier concept. In the LEGO example, the teacher went from comparing parts to parts and parts to wholes to focusing solely on equivalent fractions, because it is "foundational to proportional reasoning." Changes in the direction of instruction occurred when teachers reflected on students' learning trajectories as a result of analysis. They shifted to more challenging content or reviewed content they deemed their students lacked. In the LEGO example, after implementing a revised task on equivalent fractions, the teacher decided to also teach addition and subtraction of fractions. Finally, we also observed teachers' deliberations on the revision cycle based on analysis of student work. For example, one teacher wrote:

> In this problem, students had to calculate the hourly pay rate and then use that to determine how much money they would earn for a given number of hours worked. It was very straightforward, however, and didn't lend itself to much discussion. There was only one right answer although students could come up with the answer in different ways. The new task I created is much more engaging and has multiple answers.

For this teacher, the correct calculation of a proportion was insufficient. She sought discussion, engagement, and creativity in her students' work. We see this as evidence of improved MKT.

Discussion and Implications

In sum, the IMPRINT experience contributed to teachers' improved MKT and fostered more student-centered teaching practices aligned with content standards in mathematics. We also observed teachers' growing interest in using tasks that featured authentic applications of mathematics. Participating teachers commented that interesting and motivating contexts were reasons for their choice of tasks. Finally, our interpretation of the quantitative data analysis suggests that the students of participating teachers had increased knowledge and understanding of proportional relationships by the end of IMPRINT, in comparison with the control group. This suggests that extended attention to authentic tasks, immersion in rich and focused mathematics content, and the fine-grained collaborative analysis of student work contribute in positive ways to the teaching of proportional reasoning, and ultimately, to student learning.

PRESERVICE MATHEMATICS TEACHERS UNDERSTANDING OF MODE

Md Amiruzzaman	Karl W. Kosko	Stefanie R. Amiruzzaman
Kent State University	Kent State University	Kent State University
mamiruzz@kent.edu	kkosko1@kent.edu	sbodenmi@kent.edu

This paper explores two preservice mathematics teachers' understanding of mode. Participants' initial understanding and understanding following use of an interactive virtual manipulative is examined. Findings suggest that participants initially operated with less-effective definitions of mode. Preservice teachers' developed understanding following a learning trajectory is discussed.

Keywords: Data Analysis and Statistics, Middle School Education

Purpose

Mode is a statistical representation, often in the form of a single value or classification, for the distribution of a data set. Mode is an important concept that is typically introduced to students as early as middle school. Unfortunately, researchers have found that a significant portion of students at various levels (i.e., middle-grade, high school, and undergraduate) have difficulty understanding and explaining the concept mode (Groth & Bergner, 2006; Jacobbe & Carvalho, 2011). Given that teachers' mathematical conceptions can influence those of their students (Ball, Thames & Phelps, 2008; Jacobbe & Carvalho, 2011), the present study focuses on the nature of teachers' understanding of mode. Thus, it is the purpose of the present study to explore preservice mathematics teachers' (PSMTs) conceptions of mode.

Perspective

Relatively few studies have focused specifically on conceptions of mode of either teachers or students. Those that have generally done so in the context of or in relation to statistical mean. Groth and Bergner (2006) interviewed PMSTs to investigate their understanding of mean, median, and mode. Their research study suggested that most PSMTs (34 out of 45) believed that a data set may have only one mode, as they defined mode as 'most frequent number.' Only a few participants (3 out of 45) believed that a data set may have more than one mode or no mode at all (Groth & Bergner, 2006). Jacobbe and Carvalho (2011) reported that often preservice and inservice mathematics teachers confuse the concept of the mean with the concept of mode. In fact, many mathematic teachers (over 30%) defined mode incorrectly (Jacobbe & Carvalho, 2011). Barr's (1980) observation of college students revealed that 68% of the participants considered the frequency count, and not the classification (in this case, a number) as the mode. Thus, even at the collegiate level where students learn to become teachers, many consider mode in a manner that does not meet the mathematical definition.

While previous studies reported lack of PSMTs' knowledge about the mode, they only reported PSMTs' amount of understanding, but did not provide reasons as why that is the case. Furthermore, prior study has not examined how conceptions of mode develop or evolve. By contrast, the present research study sought to explore PSMTs' understanding of mode and provide descriptions of learning trajectories regarding conceptions of the mode.

Method

An individual teaching experiment was used to guide this study. In an *individual teaching experiment*, a researcher (a.k.a. teacher-researcher) interviews individual students on one-on-one basis with the intent to model their conceptual understanding of a particular topic (Steffe & Thompson, 2000). Also, the researcher observes and identifies individuals' actions so that the researcher can model learning processes, conceptions, and less-effective understandings. Because of its flexibility, an individual teaching experiment allows a researcher to focus on one student or participant at a time.

The present study consists of nine teaching episodes across a period of nine weeks. Consistent with teaching experiment design guidelines, an observer-researcher was present in all episodes to improve reliability of researcher-constructed models of PSMTs' conceptions. For each episode, tasks were prepared ahead of time. While main tasks were designed to focus on a specific topic or concept (e.g., definition of mode, finding mode of a given data set), probing questions were used during each episode) to clarify participants' answers and press them to explain or explore aspects of the task.

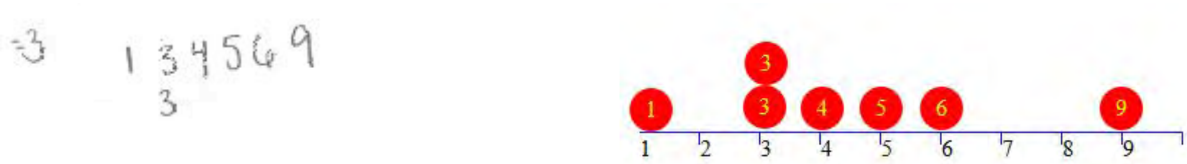
In order to facilitate PSMTs' engagement in tasks related to the mode, a computer-based virtual manipulative in the form of a number line was used. Number lines are widely considered as an appropriate tool for investigating various measures of central tendency (Amiruzzaman & Kosko, 2016; Gravemeijer, 2004). Thus, the Interactive Statistical Number Line (ISNL) was incorporated within specific tasks (see Figures 1 and 2 for screenshots of ISNL). ISNL allowed PSMTs to manipulate the location of data as discrete elements within a dataset. For mode-based tasks, this generally resembled a line plot. Although visually similar to a paper-based line plot, use of ISNL was hypothesized to engage participants in considering how all elements are represented aspects of the data set, given the virtual manipulation of each element in the data set.

Analysis and Findings

Two Preservice Mathematics Teachers participated in this study: Alex and Bob. Considering the length of this paper only Alex's answers are presented here. Data were collected from a larger study focusing on various aspects of measures of central tendency (mean, mode, & median). However, only data focusing on PSMTs' interaction with mode-based tasks is reported. Considering the length of this paper, we limit our description of the analysis and findings of Alex's actions within episode 4.

Episode 4 was intended to explore Alex and Bob's understanding of the mode. Given the initial task to find the mode of a given data set, Alex sorted the data set as, 1, 3, 3, 4, 5, 6, 9, and then told me that mode is 3 (see Figure 2). Following this, he used the ISNL to develop a mathematical model for the data set and indicated 3 as a mode of the data set. To explain his work, he said that he needed to sort the data set, so that he could see the repeated numbers. In the example, there are two 3s, Alex saw them together once he sorted the numbers. He said, "[after sorting] …now I see two 3s…so 3 is mode." Alex knew that the mode is a repeated number and his algorithmic scheme helped him to find the mode (see Figure 1). We refer to this scheme as *algorithmic* because Alex followed a step-by-step procedure to find the mode.

To confirm the model and his initial understanding, Alex was asked to define the mode. Alex answered, "What occurs the most is mode, in the example, 3 occurred the most, so 3 is mode." So, Alex was asked to find mode from, 1, 2, 3, 4. He responded that all of them are mode as all of them occurred most. Thus, Alex's algorithmic scheme aligns with a definition of mode as "the most."

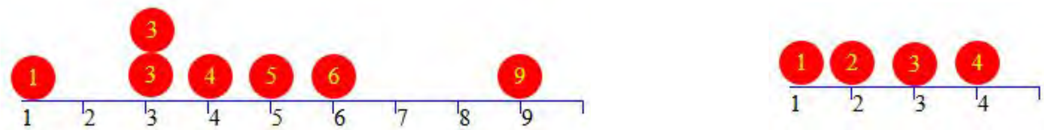


(a) (b)

Figure 2. Alex's approach to find mode from a data set for Task 1 (a) and Task 2 (b).

Galindo, E., & Newton, J., (Eds.). (2017). *Proceedings of the 39th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* Indianapolis, IN: Hoosier Association of Mathematics Teacher Educators.

To press Alex's use of this definition, the teacher-researcher asked him to compare the first data set (1, 3, 3, 4, 5, 6, 9) with the second data set (1, 2, 3, 4). Alex used the ISNL to model both data sets (see Figure 2). While he was comparing models of both data sets, he identified some differences, "I see that … data sets are not same….in the first data set, there was a repeated number which was the mode… in the second data set there were no repeated numbers…" After analyzing both data sets via the ISNL, he decided to revise his definition of mode (see Figure 2).



(a) (b)

Figure 3. Alex's models for two data set. One with repeated number and another without repeated number.

Alex modeled additional datasets on the ISNL to find a mode before revising his definition. He said, "The mode is the value that appears most often in a set of data. A data element will be considered to be a mode if it has a frequency of at least two and there is no other data element that has a higher frequency than that. A data set may have no mode, or one mode, or more than one mode." After revising the definition of mode, Alex went back to find the mode of the data set consists of 1, 2, 3, 4. He analyzed the data set once again and developed a mathematical model using ISNL, and he claimed that the data set 1, 2, 3, 4 has 'no mode'. He further added, "…If there are no data elements that occur most frequently, then that situation indicates that the data set has no mode…"

Alex's initial understanding confirms the finding of Groth and Bergner (2006). Knowing that mode is the most frequent number is not enough. In fact, in some cases 'most frequent number' will help to find a mode of one data set, but not necessarily another (i.e., the first data set versus second). By comparing the two sets on the ISNL, Alex identified that his definition of the mode was incomplete and was not suitable for all scenarios or data sets. We conjecture that by manipulating the individual elements of data along a number line, with the purpose of finding the mode (to represent the set of data). Note that, Alex was confronted with scenarios that were at odds with his prior definitions. The comparison task, in particular, perturbed his acceptance of both his prior definition and operational scheme. Specifically, Alex initially considered his algorithm before considering the nature of the data. By the end of the episode, Alex demonstrated attention to the elements of the data as part of a dataset. Although seemingly a subtle distinction, this shift in how Alex operated on the data to find mode allowed for more flexible considerations, and more correct identifications of mode.

Conclusions

This paper described one PSMT's (Alex's) points of cognitive dissonance related to the concept of mode, and provides an initial learning trajectory. A key facilitator of Alex's developing conception of mode appeared to be his use of visualization of mathematical models. Such models may be helpful for both PSMTs and K-12 students to develop more sophisticated schemes in operating with data.

It is a common assumption in mathematics education that merely memorizing definitions and working with a few examples is not sufficient to develop a deeper understanding of concepts. Yet mode is often considered a simple concept, and this study provides evidence that many PSMTs (and potential their future students) may not know that they have understood less useful definition of mode (or even one considered incorrect by the discipline). Alex considered his definition of mode as insufficient only after he developed mathematical models and visualized both models side-by-side. However, some individuals may have needed additional models that can further press their definition of mode. Specifically, Alex visualized a comparison of multiple datasets, and manipulated elements within those datasets through construction of mathematical models. Such engagement pressed Alex to consider a different way of determining mode, and allowed a transition from an algorithmic scheme to a whole set unit scheme. In the *whole set unit* scheme, Alex considered the whole data set as a unit before finding the mode. A similar transition may be possible with other PSMTs or with middle school students. However, future study is needed to both confirm and extend the findings presented here.

Taking the perspective that a robust understanding is necessary for middle grades mathematics teachers, this study explores what particular knowledge resources teachers make use of in their own problem solving. We analyzed the knowledge resources used by 17 middle grades teachers as they solved proportional reasoning tasks in two protocols designed for this purpose. We report on how the occurrences of these knowledge resources were related to teacher performance on proportional reasoning LMT items.

Keywords: Rational Numbers, Mathematical Knowledge for Teaching

Purpose and Background

Proportional reasoning is an important component of the mathematics curriculum (Lamon, 2007; Lobato & Ellis, 2010) that has only increased in prominence and emphasis by being considered its own content domain in the *Common Core Standards for Mathematics* (National Governor's Association & Council of Chief State Schools Organization, 2010). While middle school mathematics teachers are required to guide students in their efforts to develop this complex set of understandings, research suggests that, like students, teachers struggle with proportional reasoning (e.g., Harel & Behr, 1995).

While research on teacher knowledge of proportional reasoning is limited (e.g., Lamon, 2007), there is a growing consensus about the kinds of understandings that may be important for teachers to have (e.g., Lobato & Ellis, 2010). For example, teachers need to understand that a ratio is a comparison of two quantities, where quantity is defined as "a measurable quality of an object- whether that quality is actually quantified or not" (Lamon, 2007, p. 630). A teachers' understanding of ratio should go beyond ways to express it, to include the understanding that a ratio is a multiplicative comparison and not an additive comparison (Lamon, 2007; Lobato & Ellis, 2010; Sowder et al., 1998). This is a critical understanding of the concept of ratio and is considered crucial for the transition from additive to multiplicative reasoning, and teachers need to be able to discern whether students are using additive or multiplicative reasoning (Sowder et al., 1998). Furthermore, a coherent and robust understanding of ratios for middle school teachers must go beyond that of their students (Clark et al., 2003; Lobato & Ellis, 2010). In order to have a robust understanding for teaching, teachers' understanding must also include specialized content knowledge and pedagogical knowledge resources (Ball, Thames & Phelps, 2008).

This study investigates teachers' knowledge resources used in solving proportion tasks. We aim to contribute to research on teachers' understanding of proportional reasoning. Specifically, we examine how the frequency of 17 middle school math teachers' use of knowledge resources, related to teaching proportional reasoning, was correlated with their scores achieved on the proportional reasoning *Learning for Mathematics Teaching* (LMT, 2007) assessment.

Theoretical Framework

We rely on the Knowledge in Pieces theory (KiP; diSessa, 2006) for this study. KiP asserts that individuals hold understandings of various grain sizes that are used as knowledge resources in any given situation (Orrill & Burke; 2013). For novices, these knowledge resources are not likely to be well-connected to each other. As expertise develops, interconnections among the knowledge resources allow them to be invoked in appropriate situations. KiP offers a unique lens for exploring the development of expertise, which is dependent not only on the amount of knowledge resources but also the extent of the *coherency of knowledge* (Orrill & Burke; 2013), which we define as multiple knowledge resources that are connected in robust ways allowing for *in situ* access to the resources. Coherence, combined with a robust set of knowledge resources, allows teachers to deal with complex situations in more efficient ways. This is consistent with previous research on expertise (e.g., Bédard & Chi, 1992) and Ma's (1999) concept of profound understandings of mathematics. We hypothesize that as a teacher develops coherence among knowledge resources, the teacher will be more fluent at teaching and doing mathematics.

KiP represents a departure from the deficiency model traditionally used in the study of teachers' knowledge. Much prior research has focused on what knowledge teachers do not "have" and the misconceptions that they display. In contrast, our application of KiP assumes teachers have a wide variety of knowledge resources available to them, but that different situations invoke different knowledge resources. Teachers develop these resources and make connections between resources depending on the situation or task they are facing. Thus, in KiP, the focus is on what knowledge resources are elicited and used by teachers and how those resources are connected. In this study, our focus is specifically on what knowledge resources elicited in novel proportional reasoning tasks were highly correlated to traditional measures (e. g. the LMT assessment) of teacher's mathematical knowledge for teaching proportional reasoning.

Methods

Data Sources

In this analysis, we used a convenience sample of 17 middle grades mathematics teachers from four states. Participants completed two task-based interviews as well as the LMT proportional reasoning assessment. One paper-based interview was mailed to participants and completed using a LiveScribe pen, which recorded their marks on the paper protocol as well as their spoken words. Participants were asked to speak aloud about their reasoning as they solved the tasks. A second interview was a 90-minute clinical interview conducted in person and recorded on video. Tasks included in the interviews were situated in the work of teaching in that some asked the participants to solve a novel proportional situation, while other tasks asked the participants to make sense of student work or respond to an inquiry made by another teacher.

Data Analysis

Interviews were transcribed verbatim and then analyzed by at least two members of the research team for reliability. Each utterance was coded for the presence of knowledge resources in participants' reasoning based on a set of 23 codes for teaching proportional reasoning grounded in literature as well as from the data (Weiland, Orrill, Brown, Nagar, & Burke, 2016). A correlational analysis was performed using Kendal's Tau correlation coefficients on the frequency of participant's use of the knowledge resources in the two interviews.

Results

Five knowledge resources were found to be significantly correlated with the participants' standardized theta scores on the proportional reasoning LMT (see Table 1). The codes that were significantly correlated with participant performance on the LMT pertained to understanding the structure of ratios or proportional reasoning, which are listed in Table 1. For example, recognizing the relationship between quantities is multiplicative or identifying a scenario as involving proportional reasoning.

Table 1: Significant Kendal's Tau Correlations between Participant's Frequency of Use of Knowledge Resources their Standardized Theta Scores on the Full 73 Item Proportional Reasoning LMT

Knowledge Resource	LMT item Theta	Description
Multiplicative comparison	.413* (.032)	Shares description of the relationship of the quantities that is multiplicative.
Covariance	.447* (.016)	Recognizes that as one quantity varies in rational number the other quantity must covary to maintain a constant relationship.
Ratio as measure	.391* (.036)	Identifies an abstractable quantity created from the combination of the two quantities (e.g., flavor or speed) or discusses the effect of changing one attribute in terms of its effect on the ratio.
Constant ratio	.538** (.004)	Recognizes the invariant multiplicative relationship between two quantities
Proportion situation	.421* (.020)	Recognizes that a situation involves proportional reasoning.

Discussion

Based on the results presented in Table 1, there is a significant relationship between the uses of the following knowledge resources: multiplicative comparison, covariance, ratio as measure, constant ratio, and proportional situation, and how well a participant did on the LMT assessment. Note that all relationships are positive so as the use of these knowledge resources increases, the success on LMT increases. The results also suggest knowledge of the structure of ratios is an important subset of knowledge resources teachers rely on to reason proportionally. In particular, recognizing the invariant multiplicative relationship between quantities in a ratio and recognizing that the quantities in a ratio must covary in a particular way to maintain their relationship are a particularly interesting finding. They suggest the presence and importance of dynamic understandings that would not necessarily be evident in familiar missing value proportion problems that teachers frequently and easily solve with procedures such as cross multiplication. The ability to recognize when reasoning proportionally about a situation was or was not appropriate is also shown to be a knowledge resource correlated with success on the proportional LMT. Previous research found teachers' identification of a situation as appropriately proportional was not correlated with their history of taking content or methods courses (Nagar, Weiland, Brown, Orrill, & Burke, 2016).

Implications

That there is a set of understandings that correlate to high performance on a measure of teacher knowledge can provide guidance for the design of learning opportunities for in-service and pre-service teachers. Opportunities to consider both proportional and non-proportional situations together could address the recognition of proportion. Ratio concepts that involve the idea of variation and invariance may benefit from tasks that are not static instances of equating two ratios, but rather involve some way of experiencing the invariance and covariation that simultaneously exists between quantities in a proportion. Resources higher-scoring teachers use would be powerful tools in the hands of all middle school mathematics teachers.

Keywords: Conocimiento del Profesor, Conocimiento Matemático para la Enseñanza

En este estudio piloto exploramos una aproximación metodológica para investigar el conocimiento colectivo para la enseñanza de las matemáticas en grupos de profesores basada, por un lado, en el *análisis de redes sociales* (Scott & Carrington, 2011) que tiene fundamentos en la teoría de gráficas, y por el otro en el *estudio de conceptos* matemáticos (Davis y Renert, 2014; Preciado-Babb, Solares-Rojas, Davis y Padilla-Carrillo, 2015) como modelo de formación profesional en el que grupos de educadores trabajan juntos para interrogar y discutir las asociaciones conceptuales de conceptos matemáticos a distintos niveles escolares.

Si bien el conocimiento para la enseñanza de las matemáticas es un tema prominente en la educación matemática, todavía existen preguntas sobre cómo se puede evaluar este conocimiento. Por ejemplo, Davis y Renert (2014) han enfatizado la necesidad de estudiar formas de evaluar el conocimiento colectivo de profesores de matemáticas. En este estudio analizamos las conexiones entre conceptos identificados de forma colectiva en distintos grupos con diferentes niveles de experiencia en matemática educativa. Proponemos que el estudio de estas conexiones puede generar información relevante para evaluar el conocimiento colectivo para la enseñanza de las matemáticas en grupos de profesores.

Uno de los autores impartió tres talleres basados en el *estudio de conceptos* compuestos de dos sesiones cada uno. Dos talleres tuvieron lugar en la Ciudad de México y el tercero en la Ciudad de Colima, México. El primer taller estuvo conformado por estudiantes de grado y de posgrado en educación matemática (n=14). El segundo taller estuvo conformado por académicos y estudiantes de posgrado en educación en matemáticas (n=15). El tercer taller estuvo conformado por estudiantes de licenciatura en educación (n=28). Los datos colectados incluyeron mapas mentales desarrollados como parte de las actividades del taller y una encuesta de salida. La encuesta incluyó preguntas sobre los conceptos clave discutidos durante taller, percepciones sobre el tema del taller (estudio de conceptos matemáticos), así como el impacto del taller en futuras prácticas docentes.

Para estudiar la relación entre los conceptos matemáticos identificados por los participantes del taller utilizamos medidas de centralidad de análisis de redes. Usamos el programa Gephi 0.9.1 para elaborar gráficas correspondientes a las *relaciones de centralidad*. Contrastamos la gráficas considerando los distintos niveles de experiencia en cada grupo. Encontramos que las diferencias entre las gráficas se pueden relacionar con los niveles de experiencia y conocimiento especializado de los grupos. Esto sugiere que esta aproximación metodológica permite evaluar el conocimiento colectivo para la enseñanza de las matemáticas en cada grupo.

Keywords: Teacher Knowledge, Mathematical Knowledge for Teaching

In this pilot study we explore a methodological approach to study collective knowledge for teaching mathematics in groups of teachers based, on the one hand, on *social network analysis* (Scott & Carrington, 2011), that has its foundations on graph theory, and, on the other hand, on mathematics *concept study* (Davis & Renert, 2014; Preciado-Babb, Solares-Rojas, Davis & Padilla-Carrillo, 2015) as a model for professional development in which groups of educators work together to interrogate and discuss conceptual associations of mathematical concepts at different school levels.

Although teacher's knowledge for teaching mathematics is a prominent topic in mathematics education, there still exist questions about how this knowledge can be assessed. For instance, Davis and Renert (2014) have stressed the need to study ways to assess mathematics teachers' collective knowledge. In this study we analyzed the connections collectively identified in different groups with different levels of expertise. We contend that studying these connections can generate relevant information to assess collective knowledge for teaching mathematics in a group of teachers.

One of the authors delivered three workshops based on *concept study*, with two sessions each. Two workshops took place in Mexico City and the third in Colima City, in Mexico. The first workshop included undergraduate and graduate students in mathematics education (n=14). The second workshop included academic staff and graduate students in mathematics education. The third workshop included undergraduate students in education (n=28). Collected data included mental maps created as a part of the workshops and an exit survey. The survey included questions about the key concepts discussed during the workshop, participants' perceptions on the workshop themes (mathematics concept study), as well as the impact of the workshop on future teaching practices.

We used network analysis measure of centrality to study the relationship between identified mathematical concepts during the workshop. We used Gephi 0.9.1 software to generate graphs corresponding *centrality relationships*. We contrasted the graphs against each other considering the different levels of expertise in each group. We found that the differences among the graphs can be related to the levels of expertise and specialized knowledge in each group. This finding suggests that this methodological approach allows us to assess collective knowledge for teaching mathematics in each group.

Keywords: Geometry and Geometrical and Spatial Thinking, Mathematical Knowledge for Teaching

Mathematics teachers utilize mathematical knowledge for teaching (MKT) during instruction. MKT includes not only common knowledge of content but also specialized content knowledge usually needed only by teachers (Ball, Thames, & Phelps, 2008). Prospective secondary mathematics teachers (PSMTs) often learn advanced content knowledge and pedagogical knowledge in separate courses. Grossman, Hammerness, and McDonald (2009) argued that this separation is problematic for PSMTs because it fosters a disconnect between content knowledge and the work of teaching in a classroom. Furthermore, they argued the separation of content and pedagogy can result in PSMTs inability to apply specific content knowledge when making pedagogical decisions in teaching.

As part of a national initiative, this project includes developing, piloting, and studying the effectiveness of modules for use in a College Geometry course that interweaves common and specialized content knowledge elements into a rigorous geometry content course. PSMTs engage in mathematical practices while developing a deep understanding of advanced content throughout three modules (Axiomatic Systems, Transformational Geometry, and Similarity). PSMTs also engaged in completing simulations of teaching practice activities that required them to draw on MKT in their responses. We posed the following question for this study: How does PSMTs' MKT change as a result of interacting with the Geometry Modules?

Data for this study included pre- and post-assessments that included open response items for which PSMTs responded to student thinking during a simulation of teaching practice. Other data sources included open response pre- and post-assessments of the geometric knowledge PSMTs believed necessary for teaching at the secondary level. Qualitative data were analyzed using Silverman and Thompson's (2008) framework which focuses attention on evidence of understanding student thinking, developing key developmental understandings, and decentering. In addition, PSMTs' MKT was measured in a pre- and post-assessment format using the Geometry Assessment for Secondary Teaching (GAST; Mohr-Schroeder, Ronau, Peters, Lee, & Bush, accepted). Preliminary findings indicate that PSMTs increased their MKT as measured by the GAST and developed key aspects of MKT. In particular, PSMTs moved from generalized discussion of student thinking to more specific responses that indicated application of MKT.

Keywords: Teacher Education-Preservice, Teacher Education- Inservice/Professional Development, Mathematical Knowledge for Teaching

In an elementary methods course, the first author references Gladwell's (2011) description of struggles to learn the counting number sequence in English. After observations, novice teachers asked the first author for support in teaching money concepts to students. Novice teachers cannot remember how they learned about numbers and coins. We, a mathematics education professor and two undergraduate mathematics students, want to re-create struggles to learn these concepts.

Conceptual Perspective

Ma (1999) wrote that American teachers struggle to explain subtraction with re-grouping well. The work in performing multi-digit subtraction is as an algorithm, without connection to place value. Rowland and colleagues (2005) described one component of their Knowledge Quartet as "structural connections within mathematics itself [and] awareness of the relative cognitive demands of different topics" (p. 263). In this study, participants encounter place value through tasks: familiar and unfamiliar coins.

Research Question and Design

Two questions guide this study. The first is in what ways do novice teachers' mathematical knowledge support answering word problems in unusual contexts? The second is in what ways do the same teachers' knowledge inhibit answering word problems? We will use task-based interviews to answer these questions. Novice teachers refer both to pre-service teachers and teachers in their first one or two years of teaching.

Data Collection Techniques

For place value concepts, participants work individually to count, add, and subtract using digital base-five blocks. Data include videos of work and participants' reflections. For money concepts, participants in small groups will be asked several questions using Euro coins correctly.
Data include scans of groups' written work to word problems and transcripts of discussions.

Preliminary Findings

One pre-service teacher attempted to coordinate the base-five system with the decimal system simultaneously. Another participant made the transition to the new base quickly. We conjecture the use of words in the American currency that convey limited or no decimal place value will create a struggle for these teachers to explain the Euro coins.

Keywords: Mathematical Knowledge for Teaching, Teacher Education-Preservice

The intent of this poster is to work towards building an overarching framework for the *mathematical knowledge for teaching teachers* (MKTT) needed for the content preparation of prospective elementary (K-8) teachers (PTs). Often the endeavor of elementary teacher preparation falls to those without explicit training in elementary mathematics education (Masingila, Olanoff & Kwaka, 2012). Given the diversity of backgrounds that Mathematics Teacher Educators (MTEs) bring to their practice, it is imperative to establish a framework for the knowledge needed to develop elementary PTs' Mathematical Knowledge for Teaching (MKT; Ball, Thames, & Phelps, 2008). We aim to build a foundation for such a framework by analyzing and synthesizing the existing literature on the work of MTEs through the lens of elementary mathematics content course development.

Much of the extant research conceptualizes MTE knowledge as an extension of teacher knowledge (Jaworksi & Huang, 2014). While such conceptualizations make explicit the theoretical domains that are critical to MTEs' work, such broad conceptualizations fail to capture the tacit knowledge embedded in MTEs' daily teaching practice (particularly in regards to teaching content courses for elementary PTs). Building off the work of Chavout (2009), we will consider and synthesize recently emerging theoretical mappings of MTE knowledge, while comparing and contrasting them with the well-established domains of MKT. Our goal is to provide insight as to how domains of MKTT are embedded in the work of developing elementary PTs' MKT.

The exploration of MKTT is a relatively new avenue for research in mathematics education; it resides at the crossroads of mathematics teacher knowledge and the development of MTEs. As the field grows, it becomes imperative to attend to how MTEs can be better supported for the demands of preparing elementary PTs. We believe our work in this area will have implications for improving both the preparation and professional development of MTEs.

This study investigated specific aspects of prospective elementary teachers' (PSTs') knowledge for teaching fraction addition. We examined changes in their use of the subconcepts underlying fraction addition and their use of models in their explanations. This is an important area of study because it can be difficult for PSTs to effectively utilize their specialized content knowledge for teaching (Morris, Hiebert, & Spitzer; 2009). Our research questions were the following: What underlying concepts do PSTs mention when describing how they would help a child understand fraction addition? When a drawn model is provided as a representation, how do PSTs use the model?

The setting for this study was a midwestern university where elementary education majors take two sequential mathematics content courses followed by a mathematics methods course. All three courses are taught in the mathematics department. The study occurred during a semester when seven different instructors each taught one section of the first mathematics content course. A pre-test, which including one item addressing fractions, was administered at the beginning of the semester in all sections of both mathematics content courses. A related item on the final exam also assessed similar concepts. At the beginning of the following semester, the pre-test was again administered in the second mathematics content course. This study compared PSTs' responses on the pre-test item with their responses on the same item administered in the second content course the following semester. The study also examined PSTs' responses on the final-exam item. The responses to the pre-test item and the final-exam item were analyzed using the six subconcepts underlying fraction addition identified by Morris, Hiebert, and Spitzer (2009). The responses to the final-exam item were also analyzed for PSTs' use of models, using the four pedagogical purposes for using drawn models identified by Izsak (2008).

Our results showed moderate changes, following completion of the first mathematics content course, in PSTs' use of underlying concepts in their written descriptions of how they would help a child understand fraction addition. Our results also revealed wide variations in PSTs' use of drawn models to add fractions, with some PSTs demonstrating no ability to use a drawn model, most using the model to *illustrate* the solution, and a few using the model to *deduce* aspects of the solution. Finally, our results indicated providing the drawn model could both promote and hinder PSTs' attempts to make the underlying concepts explicit.

Keywords: Teacher Beliefs, Modeling, Teacher Education-Inservice/Professional Development

Teachers' perspectives of mathematical modeling affect how modeling tasks are designed and implemented (Lesh & Lehrer, 2003). As reported in previous studies, middle grades (5-9) teachers were affected by their educational backgrounds and interpreted the term "mathematical model" in many different ways (Bautista, Wilkerson-Jerde, Tobin, & Brizuela, 2014).

This study analyzed the mathematical modeling views of four middle school teachers using interviews with the teachers, observations of teachers' task solutions and lesson development during a year-long professional development workshop, and student work samples provided by the teachers. This poster focuses on the manifestation of the teachers' views of mathematical modeling in their teaching and their implementation of tasks.

The theoretical framework of this study was created to connect the idea of *mathematical thinking styles* (Borromeo Ferri, 2006) to Kuhs and Ball's (1986) framework for *mathematics teaching styles* and Thompson's (1992) notion of *conceptions* regarding conceptual and calculational orientations. The three previous frameworks are related in their objective to describe teachers' views and the role of these views in their teaching practices. Borromeo Ferri (2006) found that teachers are likely to emphasize different aspects of the modeling process or even avoid certain modeling elements depending on their preferences toward a certain mathematical thinking style. This study extends her results by closely examining each teacher's view of what counts as a mathematical modeling task.

This framework allowed for a three-fold analysis. First, teachers' perceptions of mathematical modeling aligned with three common views in the literature. Second, teachers' views of mathematical modeling reflected specific elements of the modeling process that they emphasized during their teaching. All four teachers listed different criteria for the elements that constitute the successful completion of a modeling task. Third, teachers' perceptions of their role during the planning and implementation of mathematical modeling tasks aligned with their teaching views of modeling. These findings suggest that teachers should consider their own perceptions of mathematical modeling prior to implementing tasks in their classrooms.

GENERATING A FOLLOW-UP PROBLEM TO CONFIRM STUDENT THINKING AND UNDERSTANDING: WHAT CAN PRESERVICE TEACHERS DO?

Posing an additional problem to confirm or learn more about student thinking is a strategic move that teachers can make when eliciting student thinking. However, the selection of such a problem is not straight-forward. Teachers need to attend to critical features in tasks to strategically choose what to maintain and what to vary. This work draws upon mathematical knowledge for teaching (MKT) (Ball, Hoover, & Phelps, 2008). This exploratory study examines the preservice teachers' (PSTs') skills at generating a follow-up problem and articulating the rationale for using the problem to confirm a particular student's thinking.

We made use of a teaching simulation in which each PST engaged with a "simulated" student to elicit the student's process and understanding. Then, PSTs were asked to generate a follow-up problem that could be used to confirm their interpretations of the student's thinking (Shaughnessy & Boerst, in press). The student task is to find the total number of squares needed to cover a rectangle which has some squares drawn in. The "simulated" student uses the marked squares to determine the number of squares in a row and then iterates the row count (Battista et al., 1998). Our sample is 39 PSTs in three cohorts in a two-year elementary teacher education program: pre-admission (Pre-admits), beginning of year 1 (Yr1), and beginning of year 2 (Yr2).

PSTs from all cohorts generated follow-up problems for finding the total number of squares needed to cover a rectangle, but we found differences across cohorts in the features that they attended to or changed. For example, more Pre-admits and Yr2 PSTs created problems which had dimensions which were similar to the original problem than Yr1 PSTs. Examining PSTs' rationales for generating these problems, we found that more than two-thirds of the PSTs focused on confirming one core step of the student's process: counting by rows. They did so by either maintaining or changing some features of the problem: some generated similar problems that maintained all of the core features of the problem but others increased or decreased the difficulty.

These findings point to the need for further investigation of PSTs' capabilities in generating follow-up problems. Future studies might examine skill in generating follow-up problem for a range of content and instructional experiences that support the development of such capabilities.

PRESERVICE TEACHERS' GENERALIZATIONS ABOUT AN AREA STRATEGY

Rosalie DeFino	Xueying Prawat	Meghan Shaughnessy
University of Michigan	University of Michigan	University of Michigan
rdefino@umich.edu	xjprawat@umich.edu	mshaugh@umich.edu

Keywords: Mathematical Knowledge for Teaching, Teacher Education-Preservice

Skillful mathematics teaching involves being able to size up children's strategies and determine whether a strategy would work in general (Ball, Thames, & Phelps, 2008). This application of mathematical knowledge for teaching may be particularly challenging for novice teachers who have less familiarity with alternative or nonstandard approaches. Yet, valuing and leveraging student thinking is imperative for teachers to teach mathematics equitably.

This study focuses on preservice teachers' (PSTs') generalizations about the validity of a student's strategy for finding the area of a rectangle. The student's strategy is to use marked squares to find the number of squares in one row and then to skip count by that number (Battista et al., 1998). PSTs analyze a student work sample, interact with a "simulated" student, then engage in a structured interview about their interpretation of the student's process and understanding (Shaughnessy & Boerst, in press). We investigated: *What do PSTs attend to when generalizing about the validity of this strategy?* Our sample consists of 38 PSTs at three stages in a two-year elementary teacher education program: pre-admission, beginning of Year 1, and beginning of Year 2.

Through qualitative analysis of interview responses, we found that PSTs often attended to problem features such as having whole unit squares and no partial squares, but some did not articulate the core idea that each row needs to contain the same number of unit squares. Variation in generalizations was most evident when PSTs explained why the strategy would *not* work for a shape. All 38 PSTs accurately identified a shape for which the strategy would not work, but only 20 PSTs (54%) explained that the strategy would not work because such shapes lack the same number of squares in each row. PSTs who were further along in the program were more likely to articulate this reason. In addition, we noticed considerable variation in PSTs' attention to the properties of shapes and use of precise mathematical language.

Further investigation of these ideas could allow us to explore the relationship between program learning experiences and differences in mathematical knowledge for teaching. More broadly, use of generalization questions with simulations could allow researchers to distinguish between cases of superficial and deep understanding.

AN ANALYSIS OF STUDENTS' MISTAKES ON ROUTINE SLOPE TASKS

Peter Cho
Stockton University
young.cho@stockton.edu

Courtney Nagle
Penn State Behrend
crt12@psu.edu

This study extends past research on students' understanding of slope by analyzing college students' mistakes on routine tasks involving slope. We conduct quantitative and qualitative analysis of students' mistakes to extract information regarding slope conceptualizations described in prior research. Results delineate procedural proficiencies and conceptual underpinnings related to various slope conceptualizations that can help both teachers and researchers pinpoint students' understanding and make appropriate instructional decisions to help students advance their understanding.

Keywords: Algebra and Algebraic Thinking

Functions play a crucial role throughout the mathematics curriculum. The concept of slope is critical to the study of linear functions in beginning algebra and extends to describe non-linear functions in advanced algebra (Nagle & Moore-Russo, 2014), the line of best fit in statistics (Casey & Nagle, 2016), and the concept of a derivative in calculus (Stanton & Moore-Russo, 2012). Research has documented students' difficulties with interpreting slope in both functional and physical situations (Simon & Blume, 1994) and with transferring knowledge of slope between problem types (Planinic, Milin-Sipus, Kati, Susac & Ivanjek, 2012). Moore-Russo and her colleagues (Moore-Russo, Conner & Rugg, 2011) have refined and extended the conceptualizations of slope Stump (2001) offered, resulting in 11 conceptualizations which have been documented among secondary and post-secondary students and instructors (Nagle & Moore-Russo, 2013; Nagle, Moore-Russo, Viglietti & Martin, 2013). Procedural knowledge of slope is also important; students need a comprehensive knowledge of a procedure, along with an ability to make critical judgments about which procedure is appropriate for use in a particular situation (National Research Council, 2001).

In the case of slope, procedural knowledge includes familiarity with the symbols typically used in relation to it and the rules used to calculate it (e.g., m, $\frac{rise}{run}$, $\frac{y_2-y_1}{x_2-x_1}$) (Nagle & Moore-Russo, 2013). Conceptual knowledge enables students to make connections between the various notions of slope and to explain why particular procedures for calculating slope work. In a recent study of eleventh grade students' interconnected use of conceptual knowledge and procedural skills in algebra, Egodawatte and Stoilescu (2015) used error analysis to show how prevalent procedural errors sometimes indicated weak conceptual understanding. As described earlier, research has documented students' weak conceptual understanding of slope. However, findings that many students confuse *rise over run* and *run over rise* in the formula for slope and are unsure of the procedure to find a perpendicular line's slope also suggest that students may lack procedural knowledge of slope as well (Stump, 1999).

Since slope is the constant rate of change of two linearly related variables, it is important to consider how students apply covariational reasoning as they conceptualize slope. Described as the "mental coordination of two varying quantities while attending to the ways in which they change in relation to each other" (Carlson, Jacobs, Coe, Larsen & Hsu, 2002, p. 354), covariational reasoning has been identified as a key prerequisite for advanced mathematical thinking (Carlson, Oehrtman & Engelke, 2010). Carlson and colleagues (2002) describe five developmental stages of covariational reasoning. The first three stages, namely L1 Coordination, L2 Direction, and L3 Quantitative Coordination, are foundational for students' thinking about slope (Casey & Nagle, 2016).

The Present Study

Past research on slope has described the multitude of ways which students might conceptualize it and described students' limited proficiency. However, these areas of research have not been merged. In particular, past research has not engaged in error analysis of students' solutions on common slope tasks to extract information regarding students' procedural and conceptual knowledge of the various slope conceptualizations. We conduct quantitative analysis of students' solutions to routine slope tasks in order to delineate procedural proficiencies and conceptual underpinnings that can be attributed to those mistakes. We link these to the previously identified slope conceptualizations to provide insight into the procedural and conceptual knowledge underlying each notion of slope. The research questions are:

1. What mistakes did students make when solving the various slope tasks?
2. Which tasks did students have the most trouble with and what mistakes were most prevalent?
3. What do students' mistakes reveal about procedural proficiencies and conceptual understanding of different slope conceptualizations?

Methods

Participants and Assessment

Participants in this study were primarily college freshmen and sophomores at a single four-year college in the Northeastern region of the United States. Seven mathematics instructors representing 13 sections of Quantitative Reasoning (Elementary Algebra), Algebraic Problem Solving (College Algebra or Intermediate Algebra), and Precalculus agreed to administer the slope assessment to their students during class time. The assessment was administered during the second half of the semester, after slope was taught. In all, 256 students completed the assessment with fairly even distribution among the three courses: Quantitative Reasoning (QR, n = 79), Algebraic Problem Solving (APS, n = 94), and Precalculus (Precalc, n = 83). The researchers developed a 15-question assessment containing standard slope questions similar to those that students solved on homework and exams. The 15 questions belonged to six broad categories: (1) write an equation of a line given particular information, (2) write the equation of a line given its graph, (3) write the equation of a line given its graph and interpret in terms of a real problem situation, (4) use a table of values to write a linear equation, (5) determine whether graphs of two equations are parallel, perpendicular, or neither, and (6) sketch a line given particular information. One sample problem from each category, with an actual student response, is provided in Figure 1. The fifteen-item assessment included questions that called on nine of the eleven slope conceptualizations described by Moore-Russo, Connor, and Rugg (2011) as shown in Figure 1. Only the Trigonometric and Calculus conceptions of slope (Moore-Russo et al., 2011) were not reflected in the items included on the assignment.

Data Analysis

Coding began with one researcher grading all responses using a four-point scale: 4 points for a completely correct answer, 3 points for a mostly correct answer, 2 points for a half correct answer, 1 point for a partially (less than half) correct answer, and 0 points for a blank or nonsense answer. Next, the researchers used grounded theory (Glaser & Strauss, 1967) to code students' solutions for mistakes. For every answer that did not receive a perfect score, the researchers analyzed the students' solution to determine what mistake(s) were made. We define a mistake as a wrong action or inaccuracy or lack of action that was demonstrated in the problem solution. We recognize that the same mistake may stem from different sources of misunderstanding and we do not distinguish between these when coding for mistakes. Based on the students' solutions, we generated a list of possible mistakes. When a new solution suggested the need for an additional mistake category, the code was added to the list and all responses were revisited in light of the revised list. After generating a list of possible codes, one researcher revisited all student work and completed the coding according to the list of mistakes.

Results

Classifying Mistakes

In total, 18 mistake categories emerged from the grounded theory approach to coding students' solutions on the slope tasks. Table 1 provides a description of all such mistakes and indicates the assessment question(s) on which the mistake was made as well as the frequency of the mistake across all students and questions (n = 3840). Figure 1 illustrates sample responses with the corresponding mistake codes and overall item score (out of 4 points) assigned to the response.

Table 1: Mistake Codes, Related Questions, and Frequency

Code #	Abbreviation code	Description of Mistake	Related Questions	Frequency
1	*NoResponse*	No response or nonsense answer	All questions	496
2	*Arithmetic*	Any type of addition, subtraction, multiplication, or division mistake	All except 14	310
3	*SimpleFraction**	Not changing a fraction to the simplest form	All except 1, 3, 13, 14	128
4	*NoXvariable*	Don't put the *x* variable after the slope in the equation	All except 6, 11, 12, 13, 14	54
5	*SlopeRunRise*	Calculating a slope as run/rise instead of rise/run	2, 5, 6, 7, 8, 9, 10	57
6	*CoordiPoints*	Calculating $\frac{y_2-y_1}{x_1-x_2}$, hence getting the opposite of the actual slope.	2, 5, 6, 7, 8, 9, 10	17
7	*SubtractCoord*	Calculating $\frac{y_2-x_2}{y_1-x_1}$	2, 8, 9, 10	8
8	*OppSignSlope*	Putting a negative sign for an increasing line's slope or vice versa	5, 6, 7, 8	95
9	*BlockSlope*	Using blocks instead of axis' units to calculate a slope	5, 6	94
10	*MentalAction1*	Does not coordinate the *value* of one variable with changes in the other variable	7, 8	32
11	*MentalAction2*	Does not coordinate the *direction* of change in one variable with changes in the other variable	7, 8	30
12	*MentalAction3*	Does not coordinate the *amount* of change in one variable with changes in the other variable	7, 8	118
13	*CalcYintercept*	Don't know how to calculate the *y*-intercept with many non-routine points	9, 10	101
14	*NoSlopeInter*	Not revising a standard form to a slope-intercept form when using the coefficient of *x* as the slope	11, 12	55
15	*GraphOpposite*	Graphing opposite direction with a given slope	13, 14, 15	73
16	*PlotXYchange*	Plotting a point using *x*-coordinate value as a *y*-coordinate and vice versa	13, 14, 15	29
17	*NoOppPerp*	Using reciprocal but not opposite slope to apply to the perpendicular line's slope	4	32
18	*NoRecPerp*	Using same slope to apply to the perpendicular line's slope or just put opposite sign	4	29

*We recorded this as a "mistake" to track the frequency of its occurrence, but students were not penalized when a fraction was not written in simplest form.

Overall Performance on Slope Problems

The mean percentage on the assessment for all 256 students was 65.66%, with APS students scoring highest (66.76%), Precalc students scoring in the middle (65.13%), and QR students scoring lowest (64.92%). A single factor ANOVA showed no significant difference on overall percentage based on the students' course of enrollment [F (2, 253) = 0.15, p = 0.86 >> 0.05]. It is interesting that not only did Precalc students not score significantly higher than students in the more basic Algebraic Problem Solving and QR courses, but they actually scored lower in overall percentage (albeit not statistically significant) compared with the APS students.

Questions with Lowest Average Percentage Scores

Across the 15 questions, the four lowest average percentage scores were Questions 10 (45.4%), 4 (54%), 7 (55%), and 8 (55.5%). Figure 1 illustrates sample responses highlighting typical mistakes for these four questions. Despite being a standard task, students scored the lowest on Question 10. Many students made a mistake when coordinating points in the slope formula, resulting in a positive slope instead of a negative slope. Question 4 had the next lowest average score. The sample response to Question 4 (see Figure 1) illustrates the common mistake of calculating the y-intercept before finding the perpendicular line's slope. Although this solution uses the negative reciprocal slope of -2/3 in the final slope-intercept form of the equation, notice that the original slope of 3/2 was used when calculating the slope-intercept of the perpendicular line. The variable x is also omitted from the slope-intercept form of the equation. Questions 7 and 8 both required students to write an equation (given a graph) and interpret the equation in light of the real world context that was provided. These items, and their common responses, are discussed in the next section.

Covariational Reasoning and Overall Performance

Students' challenges on Questions 7 and 8 generally related to interpreting the equation in terms of the problem situation. The codes *MentalAction1*, *MentalAction2*, and *MentalAction3* emerged from students' difficulties interpreting the slope of this linear equation in context. A code of *MentalAction1* indicated that a student did not demonstrate knowledge of the two covarying quantities (L1 Coordination). This was often seen in responses that considered only a single variable changing. A code of *MentalAction2* indicates that a student *did* demonstrate L1 covariational reasoning but either did not attempt or made errors in L2 Direction covariational reasoning. This generally appeared when students described the direction of change incorrectly (e.g., "the value of the HDTV increases as the number of month increases"). The *MentalAction3* code indicates that a student demonstrated both L1 and L2 covariational reasoning but either did not attempt or made an error when reasoning using L3 Quantitative Coordination covariational reasoning. Generally, this code indicated that a student did not attend to the amount of change (e.g., "the value of the HDTV decreases over time") or did not correctly interpret the slope as a ratio of change in y variable over unit change in x variable. We conducted additional analysis of how students' covariational reasoning levels were related to their overall performance on the slope tasks. Students who exhibited higher levels of covariational reasoning scored higher on the slope assessment as a whole. Demonstrating fluency with L3 covariational reasoning on both Question 7 and 8 was correlated with a higher overall score on the slope assessment (r = 0.294). Fluency with L2 reasoning was also positively correlated with overall score (r = 0.203).

Discussion

Our study of students' mistakes on routine slope tasks has built on previous literature by analyzing particular mistakes that may hinder students' abilities to reason successfully with the various slope conceptualizations. A total of 18 mistake categories emerged from the grounded theory approach to coding students' solutions. The mistakes indicate that there are many procedural proficiencies required for students to work with the various slope conceptualizations. Arithmetic mistakes were the most widespread mistakes regardless of a student's class of enrollment. These errors carried over into algebraic manipulation with many students making mistakes when adding or subtracting a variable term to the other side of the equation or dividing by the coefficient of the x-term when converting from standard to slope-intercept form. This is a reminder that even when a student has a strong conceptual grasp, a lack of procedural proficiency may hinder his or her ability to reason successfully on slope tasks.

Procedural Proficiencies and Conceptual Underpinnings of Slope Conceptualizations

Past research has focused on describing the many different conceptions of slope. Our analysis in this paper does not attempt to distinguish between a student's procedural and conceptual understanding of slope. However, by analyzing the mistakes students made on problems related to each slope conceptualization, we were able to develop a preliminary list of the underlying procedural proficiencies and conceptual underpinnings that may have been linked with the mistakes we saw on the assessment. Next, by linking the mistakes with the slope conceptualizations each problem illustrated, we were able to make a preliminary list of the procedural proficiencies and conceptual underpinnings which may be linked to the various slope conceptualizations (see Table 2). This is an important step which allows teachers and researchers to begin to break down the underlying ideas and practices that are necessary for a student to work fluidly with a particular notion of slope.

Table 2: Procedural Proficiencies and Conceptual Underpinnings for Each Category

Category	Procedural Proficiencies	Conceptual Underpinnings
Geometric ratio	Count "units" for vertical change. Count "units" for horizontal change. Attach a sign to indicate direction (up or right is positive, down or left is negative).	Rise and run are oriented (signed). Units are determined by graph increments (not blocks). The "rise over run" ratio and "run over rise" ratio are reciprocals.
Algebraic ratio	Subtract y-coordinates for change in y. Subtract x-coordinates for change in x.	"Change" is oriented (signed). The "change in y over change in x" and "change in x over change in y" ratios are reciprocals.
Functional property	Interchange the word slope with the phrase "rate of change".	Slope describes the coordinated change of two covarying quantities.
Parametric coefficient	Algebraically manipulate an equation into slope-intercept form or point-slope form. Identify the coefficient m of x.	The coefficient of x reveals different information depending on the form of the linear equation.
Real-world situation	Identify the real-world quantity associated with the input and output variable (using any type of representation).	Interpret change as it relates to a real-world variable (i.e., a decrease in price shows depreciation over time).
Determining property	Calculate the negative reciprocal. Recognize that equal slopes indicate two lines are parallel. Recognize that negative reciprocal slopes indicate two lines are perpendicular.	Slope indicates the number of points shared by two linear relationships and how they intersect (if at all).
Behavior indicator	Visually determine if a line increases/ decreases.	An increasing (decreasing) relationship is one in which the variables change in the same (opposite) direction. MA2: A positive rate of change indicates two variables change in the same direction.
Linear constant	Choose any two points on a graph/in a table when given multiple points.	Slope is independent of the points chosen since the ratio of change between the dependent and independent variables is constant.
Physical property	Visually recognize a line's "steepness".	MA3: The rate of change indicates the amount of change in the dependent variable per unit change in the independent variable.

Future research should analyze the pattern of student mistakes to better understand whether procedural proficiency or conceptual grounding may be the root of the mistake. In particular, a simple isolated incident may mean a student made a procedural slip while repetition of a mistake across problem types and representations may indicate deep-rooted conceptual misunderstandings (Egodawatte & Stoilescu, 2015).

Slope Questions for Instruction

The questions on which students had the most difficulty can also provide important insight for teachers. Results suggest that teachers should consider including tables with x-values that have varying increments and which are non-monotonic. This is supported by students' difficulties with Question 10, a seemingly standard question other than the lack of a pattern in the x-coordinates provided in the table. Students' difficulties with Questions 7 and 8 highlight the need for teachers to link the *Algebraic* and *Geometric Ratio* conceptualizations with the *Functional Property* idea of slope as a rate of change of two covarying quantities. Many students struggled on these examples because although they were able to explain that the two variables changed together, many even describing the corresponding directions of change in the variables, they struggled to interpret the slope as the amount of change in the dependent variable per a unit change in the independent variable. Thus, our results remind teachers that L3 covariational reasoning is a conceptual underpinning that helps to link the *Functional Property* conception of slope as the rate of change of two variables with *Behavior Indicator* and *Physical Property* conceptions of slope that focus on the direction and magnitude of change, respectively.

Future Study

Our work has described procedural fluencies and conceptual underpinnings related to nine slope conceptualizations. Future work should repeat error analysis with more diverse pool of students to see whether other mistakes emerge. Future studies could also investigate the patterns of student mistakes over multiple items to analyze whether they indicate procedural errors or more foundational conceptual misunderstandings using the framework we have described.

COLLABORATIVE GESTURES WHEN PROVING GEOMETRIC CONJECTURES

Candace Walkington	Mitchell J. Nathan	Dawn M. Woods
Southern Methodist University	University of Wisconsin at Madison	Southern Methodist University University
cwalkington@smu.edu	mnathan@wisc.edu	dwoods@smu.edu

Research in mathematics education has established that gestures – spontaneous movements of the hand that accompany speech – are important for learning. In the present study, we examine how students use gestures to communicate with each other while proving geometric conjectures, arguing that this communication represents an example of extended cognition. We identify three kinds of "collaborative gestures" – gestures that are physically distributed over multiple learners. Learners make echoing gestures by copying another learner's hand gestures, mirroring gestures by gesturing identically and simultaneously with another learner, and joint gestures where multiple learners collectively make a single gesture of a mathematical object using more than one set of hands. The identification and description of these kinds of collaborative gestures offers insight into how learners build distributed mathematical understanding.

Keywords: Reasoning and Proof, Geometry and Geometrical and Spatial Thinking, Cognition

Introduction

Theories of embodied cognition posit that learners understand ideas, even abstract mathematical ideas, through their bodies and senses (e.g., Lakoff & Núñez, 2000). One important form of embodiment is *gesture* – physical hand movements that people spontaneously formulate to accompany speech. Hostetter and Alibali (2008) argue that gestures are an outgrowth of mental simulations of actions enacted by learners as they think and reason. Considerable research has suggested that gesture production predicts students' learning and performance across a variety of content areas, including mathematics (Goldin-Meadow, 2005; Valenzeno, Alibali, & Klatzky, 2003; Cook, Mitchell, & Goldin-Meadow, 2008).

While the importance of gestures to student learning has been established in a variety of studies, less work has been done detailing how gestures allow for cognition to be physically distributed over multiple learners. Here we focus on how multiple learners use gestures in their interactions with each other, during mathematics classroom learning activities. We argue that these gestures exemplify *extended cognition* (Clark & Chalmers, 1998), the idea that cognitive processes themselves include physical resources beyond the skull. We show evidence of extended mathematical cognition by documenting *collaborative gestures* – gestures made collectively by multiple students as they work together to make sense of mathematical ideas. We discuss the emergence of collaborative gestures in the context of proving geometry conjectures.

Literature Review

Justification and Proof

Justification and proof are central activities in mathematics education (National Council of Teachers of Mathematics, 2000; Yackel & Hanna, 2003). In fact, "proof and proving are fundamental to doing and knowing mathematics; they are the basis of mathematical understanding and essential in developing, establishing, and communicating mathematical knowledge" (Stylianides, 2007, p. 289). Research on mathematicians' proving practices has suggested that proof "is a richly embodied practice that involves inscribing and manipulating notations, interacting with those notations through speech and gesture, and using the body to enact the meanings of mathematical ideas" (Marghetis,

Galindo, E., & Newton, J., (Eds.). (2017). *Proceedings of the 39th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* Indianapolis, IN: Hoosier Association of Mathematics Teacher Educators.

Edwards, & Núñez, 2014, p. 243). The multimodal nature of proof is also evident for novice students in classroom settings, as students' proofs often take on spontaneous, verbal forms, as opposed to formal, written ones (Healy & Hoyles, 2000), and both teachers and students use gestures as a way to track the development of key ideas when exploring mathematical conjectures (Nathan et al., 2017). Thus, gestures serve as crucial embodied grounding mechanisms for proof-related reasoning in geometry classrooms.

Dynamic Gestures and Dynamic Geometry Systems

One type of gesture identified in prior research as being particularly important is *dynamic gestures* (Göksun, Goldin-Meadow, Newcombe, & Shipley, 2013; Uttal et al., 2012). These are gestures where learners use their bodies, usually their hands and fingers, to physically formulate and then manipulate mathematical entities (see Walkington et al., 2014). For example, when proving that the sum of any two sides of a triangle must be greater than the remaining side, a learner might physically formulate two sides of the triangle with straight hands, and then "collapse" these two sides to show that if the two sides were not larger, the triangle would not be able to close. The presence of dynamic gestures has been associated with more accurate proofs of geometric conjectures, with a medium effect size (Walkington et al., 2014; Nathan & Walkington, in press).

Dynamic gestures allow students to formulate shapes and lines with their bodies in a manner that can be similar to using dynamic geometry software (DGS). DGS allows users to construct, measure, and manipulate objects by dragging and connecting defined objects on a computer screen (Christou, Mousoulides, Pittalis, & Pitta-Pantazi, 2004). The direct manipulation of DGS allows users to experiment freely and to have instantaneous interactions with geometric objects and their spatial relations (Marrades & Gutierrez, 2000). Dynamic gestures are limited compared to DGSs in that there is no feedback on whether manipulations are mathematically possible, nor is there exact measurement of geometric objects. However, gestures are highly portable and meaningful to the learner, and are part of the natural way in which human beings communicate, making them a powerful tool for mathematical reasoning. Research has shown that when gesture is facilitated or directed, reasoning is improved (Goldin-Meadow, Cook, & Mitchell, 2009), and when it is inhibited, reasoning is impaired (Hostetter, Alibali, & Kita, 2007). Walkington et al. (2014) found that for geometry conjectures specifically, even the inhibition of sitting in a chair and having a pencil in-hand and paper available reduced the incidence of dynamic gestures, and caused students to formulate correct proofs less often.

Distributed and Extended Cognition

Work in professions involves the coordination of many different inscriptions and representational technologies by differently-positioned actors whose actions occur across a range of social and physical spaces (Goodwin, 1995; Hutchins, 1995). Through joint, coordinated activity, cognition becomes distributed over a patchwork of discontinuous spaces and representational media. In this conceptualization of *distributed cognition*, the environment is used to offload cognitive demands. Theories of *extended cognition* go even further to argue that the social and physical environment of learners is actually constituent of their cognitive system (Clark & Chalmers, 1998). The implication is that cognition, rather than existing in the head of an individual, is distributed over the bodies of multiple learners and the environment around them as they interact. One way in which cognition can be extended across learners is through the use of gestures that extend over multiple persons.

Prior research on students learning origami from instructors has identified *collaborative gestures* as gestures through which a learner interacts with the gestures of a communicative partner (Funiyama, 2000). In the context of this past research, these gestures often involved a learner pointing to or manipulating a teacher's gestures about origami folds. Here we reimagine the idea of collaborative gestures to be relevant to learner-learner interactions around mathematical sense-making, and take such gestures to be a case of extended cognition.

Research Purpose

In the present study, we address the following research question: *What are the ways that team members use collaborative gestures when proving geometric conjectures?* We focus specifically on cases where the physical, gestural activity is distributed over multiple learners, rather than cases of a single student gesturing and another student interpreting that gesture.

Method

Setting and Sample

Eleven undergraduate students enrolled in a teacher education program (ten female and one male) aged 20-22 years voluntarily participated in this 75-minute study. The undergraduates were enrolled in the elementary mathematics method course from a private university situated within a large city in the southwestern United States. Informed consent was obtained from all participants. Sixty-four percent of the participants identified as Caucasian, 18% identified as Asian, and the remaining 18% identified as Latino/a. The undergraduates had already declared a non-education major, but were simultaneously enrolled in a 33-credit hour undergraduate major in education preparing them to pursue teaching careers, work in the social sciences, or informal education paths in non-profit organizations. Students were divided into two groups around two separate gaming systems with each group being video recorded while playing the video game. We focus our analyses on one of the two groups of students, with four females and one male.

Procedure and Measures

The focus of the study was the playing of an educational video game about learning geometry (see Nathan & Walkington, 2017 for more information about the game). Specifically, through the Kinect video game platform, students were prompted to perform specific arm motions and then prove geometry conjectures that were related to those arm motions. While only one participant (the gamer) of each group controlled the Kinect with their body movements, the remaining participants in each group worked collaboratively with the gamer to mathematically prove or disprove the conjectures. The role of the gamer rotated throughout the group so that each participant had the opportunity to perform the directed arm motions and also to take the lead in communicating the proof. In this study, rather than focusing on the directed arm motions that the game directed learners to perform before proving the conjecture, we focus on the hand gestures they spontaneously made while formulating their proofs.

Before playing the video game, students were given a pre-test measuring their knowledge of geometry (basic properties of triangles, circles, and quadrilaterals) and their attitudes towards geometry (items drawn from Linnenbrink-Garcia et al., 2010). Although a detailed analysis of these pre-measures is beyond the scope of this paper, results suggest that the students had neutral or slightly negative attitudes about geometry, rating items like “I enjoy doing geometry and “Geometry is exciting to me” on average between 2 and 3 on a 5-point scale (SDs ≈ 1.0). In addition, results suggest that students had somewhat strong knowledge of basic geometric properties (pre-test items included statements like “the angles of a triangle add up to 180 degrees”), scoring an average of 80% (SD = 13%) on the pre-assessment.

Analysis Techniques

The video captured while the participants played the game was transcribed using Transana (Woods & Fassnacht, 2012) in order to integrate text and video data into the analysis. These transcripts and videos were then analyzed to find where the students performed collaborative gestures – gestures that were distributed in some way over multiple individuals. Transcripts from the group formulating proofs for their six conjectures were analyzed using multi-modal analysis (McNeil, 1992) of gestures. Multimodal analysis involves analyzing, interpreting, and reporting the use of gestures in conjunction with speech transcripts, in order to provide the fullest possible picture of learner reasoning. Here we employ a multiple case studies approach (Yin, 1994), since our research goal is to describe phenomena of potential theoretical importance, rather than the manipulation of a relevant behavior. Case study research recognizes that the rich context in which the interactions occur contain many variables interacting simultaneously.

Results

Through a multi-modal analysis of the focal group proving six conjectures, we discovered three types of collaborative gestures. Although we present a single group's activities, these gesture types were also present and important in subsequent work that examined 4 additional classes of students. We give a case for each gesture type. All student names are pseudonyms.

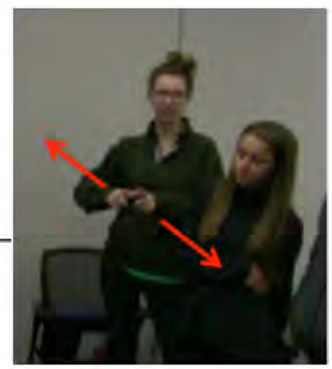
Echoing Gestures

Our first case is taken from the group proving the conjecture, "If you know the measure of all three angles of a triangle, there is only one unique triangle that can be formed with these three angle measurements." Tanya (bottom image, Figure 1) was in front of the game, with the other students, including Karen (top image, left, Figure 1), assisting her in formulating a proof.

1 Tanya: Okay, given that you know the measure of all three angles of a triangle, there is only one unique triangle that can be formed with these three angle measurements.

2 Karen: Because you can always…you have the…you can always scale it once you have those three lengths, like the three angles you scale it.

((Karen makes angles with her index fingers and thumbs and moves them in and out.))



3 Tanya: Okay, so I say false because you have certain angles, but you can bring them in and out to make the side lengths bigger or smaller.

((Tanya moves her hands up and down to show how to make the sides of the triangle bigger or smaller.))

Figure 1. Transcript of echoing gestures.

Once Tanya reads the conjecture (Line 1), Karen explains why the conjecture must be false, and uses a dynamic gesture where she formulates a triangle with her thumb and index fingers, making it grow and shrink (Line 2). Tanya seems to immediately understand and take up this gesture, repeating the gesture herself, and putting Karen's explanation into her own words (Line 3). Tanya and Karen performed echoing gestures, where one person made a dynamic gesture, and then a second person repeated that gesture while making the accompanying verbal reasoning her own. Other literature has identified *gestural catchments* as repeated similar or identical hand gestures used by a single gesturer

Galindo, E., & Newton, J., (Eds.). (2017). *Proceedings of the 39th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* Indianapolis, IN: Hoosier Association of Mathematics Teacher Educators.

(usually an instructor) to convey similarity of or highlight important conceptual connections (McNeill & Duncan, 2000). Next, we describe a related use of gesture where one learner echoes and repeats the gestures of another learner.

Mirroring Gestures

Our second case is taken from the group proving the conjecture, “If one angle of a triangle is larger than a second angle, then the side opposite the first angle is longer than the side opposite the second.” In this sequence (Figure 2), Haley, shown in the left of the images, works to formulate a proof using gestures. She first draws two angles of a triangle in the air with her fingers, and then points to the angles of the triangle (Line 4). At the same time, Karen (shown on the right, partially cut off) represents a side of the triangle with her arm, interweaving her reasoning (“and the side opposite the first…”; Line 5) into Haley’s narrative proof. Haley and Karen perform identical gestures where they form equilateral-like triangles with their thumbs and forefingers (Line 6). Haley then performs a dynamic gesture where she collapses one side of this equilateral-like triangle inwards in order to vary the angle measurements and check how this impacts the side lengths (Line 7). After the transcript ends, they come to a consensus that the conjecture is true, both repeating their prior gestures as they clarify their reasoning.

4 Haley: Okay, so if one angle is larger than the second angle...
((Haley points to a second angle of a triangle that she drew in the air with her finger while Karen connects the first angle with second angle with her forearm.))
5 Karen: ...and the side opposite of the first...
6 Haley: ...and the side opposite of the first angle...
Okay, so one angle of a triangle...
((Haley and Karen both represent a triangle with both index fingers and thumbs.))
7 I am just trying to picture a triangle ...is larger than the second angle.
((Haley swings the left side of the triangle to make a right triangle on the upper right side of the triangle.))
8 So it's like that then the side opposite of the first angle is longer than the side. Yeah, I would say it's true because if you're saying if this angle is here then there's more space here then this angle makes a smaller line.
((Haley points to where there is more space in her triangle.))

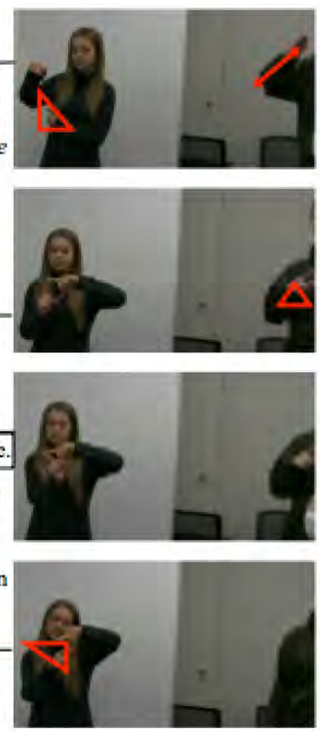


Figure 2. Transcript of mirroring gestures.

Karen and Haley performed *mirroring gestures* as they were gesturing at the same time in response to the same line of reasoning and jointly formulating a mathematical argument. In addition, at times their gestures were structurally identical. Mirroring gestures differ from echoing gestures in that they occur simultaneously – learners are using their bodies in conjunction with each other as they reason together in-the-moment. Echoing gestures, on the other hand, may capture instances where one learner’s reasoning is later taken up by another learner, *after* the initial string of reasoning has been communicated and interpreted.

Haley's and Karen's gestures are representing two distinct geometric shapes, with one shape being imagined in the air in front of each of them. In our final case, we observe gestures where two learners operate on a single imagined geometric object using gestures.

Joint Gestures

Our third case is taken from the group proving the conjecture, "The measure of any central angle of a circle is twice the measure of an inscribed angle intersecting the same two endpoints on the circumference." In this sequence (Figure 3), Karen begins by trying to represent both the circle and the angles using her gestures, but struggles to properly represent the conjecture (Line 9). Stephanie misunderstands the reasoning she is communicating using this gesture (Line 10), so Karen seeks a different approach to make her thinking clear to her group. She calls upon Haley to use her hands to make the circle (Line 15), and then Karen layers her hands over Haley's circle to formulate a central angle and then an inscribed angle.

Stephanie, who is controlling the game for this conjecture, then mimics their gesture (Line 20) and agrees with their conclusion that the central angle would be smaller (Line 22). Haley questions their reasoning at two points during the discussion (Lines 19 and 23), but ultimately the group concludes that the central angle is smaller than the inscribed angle (Lines 26-27). This is a common misconception – the central angle is the large angle since it sweeps out more space.

Discussion and Implications

Situated cognition holds that cognitive behavior is embodied, embedded, and extended. An embodied cognition perspective (e.g., Lakoff & Núñez, 2000) focuses on ways body states and body-based resources shape behavior. Embedded and distributed cognition holds that cognition is mediated by the physical and social environment and the environment is used to off-load operations that could otherwise be performed mentally (Hutchins, 1995). Extended cognition takes this further, positing that social actors and the physical environment, in concert with the mind of the one doing the reasoning, constitute the cognitive system (Clark & Chalmers, 1998).

Here we identified three novel ways in which students socially coordinate hand gestures and speech that exemplify extended mathematical cognition. In echoing another's gestures, one learner makes a hand gesture representing a mathematical object, and then another learner repeats it, often making the reasoning it illustrates personally meaningful. In mirroring gestures, two learners simultaneously make the same or similar gestures with each of their set of hands, as a way of following each other's' reasoning in real time. This strategy goes beyond simply observing another's gestures – by making the same gesture, learners may better understand a collaborator's reasoning. Finally, joint gestures illustrate how multiple learners collaboratively build and manipulate mathematical objects that are too complex for one set of hands. Taken together, these findings suggest collaborative gestures have the potential to provide learners with additional tools that facilitate mathematical communication and proof...."

An interesting question for future research is how collaborative gestures influence student learning – our third case shows an ultimately unsuccessful use of collaborative gestures – and whether collaborative gestures are more effective than other tools of extended cognition (e.g., manipulatives, pencil and paper, DGS). We are of the view that there is not one *optimal* tool for learning about geometric properties and conjectures; rather that students need a variety of experiences exploring geometric ideas with different tools for cognition and collaboration. In the present paper, we argue that collaborative gesture should be one element of students' toolboxes as they learn proof in geometry. In this way, we seek to answer the question "***How can we lay the groundwork for future crossroads between theory, research, and practice?***" We use educational research to lay the groundwork for the potential importance of collaborative gestures, connecting our research to theories relating to gesture and extended cognition. By studying these gestures within classrooms where students are engaged in mathematical reasoning, we begin to consider how this research might inform practice.

9 Karen: Well, I think of a circle and it's like the inside angle versus the outside angle and I feel like the outside angle is bigger because the inside angle would be like this whereas the outside angle is like this.

((Karen uses her fingers to draw an inside angle.))

10 Stephanie: Yeah, it would make sense. I would guess that it is true.

11 Karen: Oh no, I am saying the opposite.

12 Stephanie: Ok.

13 Karen: Right?

14 Stephanie: Oh no!

15 Karen: So like the top of the circle and like...can you hold your hands up for me? You have like this angle that you are drawing from the center, right?

((Karen has Haley make a circle with her hands and then uses the circle to draw an angle from the center.))

16 Stephanie: Mm mm.

17 Karen: That's going to be smaller than like any angle out here, isn't it?

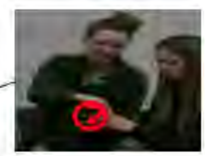
((Karen shows an angle on the outside of the circle.))

18 Stephanie: Sure.

19 Haley: What do you mean?

20 Karen: Yea, like if we have a circle and we draw like this, that point would be…

((Stephanie is tracing the central angle of her circle, while Karen is tracing the central angle of the circle Haley created with her hands.))



21 Karen: What is it called? Then central angle…

22 Stephanie: The central angle would be smaller.

23 Haley: But it is bigger than what angle?

24 Karen: Then the inscribed angle. And the inscribed angle is what the vertex is on the circumference.

((Karen is pointing to the vertex of an inscribed angle that is on the circumference of Haley's circle.))

25 Stephanie: So the central angle is smaller than the outside angle?

26 Karen: That would make sense to me but…

27 Stephanie: I would think too.

Figure 3. Transcript of joint gestures.

CONTEXTUALIZED MATHEMATICS PROBLEMS AND TRANSFER OF KNOWLEDGE: ESTABLISHING PROBLEM SPACES AND BOUNDARIES

Rebecca McGraw
University of Arizona
rmcgraw@email.arizona.edu

Cody L. Patterson
University of Texas at San Antonio
cody.patterson@utsa.edu

In this study, we examine how inservice secondary mathematics teachers working together on a contextualized problem negotiate issues arising from the ill-structured nature of the problem such as what assumptions one may make, what real-world considerations should be taken into account, and what constitutes a satisfactory solution. We conceptualize the process of negotiating these questions as the construction of a "problem space," characterized by the boundary between considerations deemed relevant or essential to the problem and ones thought to be beyond the scope of the problem. We use data from group discussions of the problem to consider ways in which problem spaces are co-constructed by learners, instructors, and problem authors and how these problem spaces evolve over time. We conclude by discussing implications of these findings for the design and implementation of contextualized mathematics problems.

Keywords: Problem Solving, Modeling, Classroom Discourse, Affect, Emotion, Beliefs, and Attitudes

Background

The focus of this paper is on teacher work on one particular mathematics problem. The problem is contextualized and open-ended and involves aspects of both problem-solving and mathematical modeling. Lesh and Zawojewski (2007) define *problem solving* as

> the process of interpreting a situation mathematically, which usually involves several iterative cycles of expressing, testing and revising mathematical interpretations – and sorting out, integrating, modifying, revising, or refining clusters of mathematical concepts from various topics within and beyond mathematics. (p. 782)

The problem we discuss in this paper requires integration of multiple mathematical concepts, as well as interpretation, modification, and revision of ideas within and outside of mathematics. With respect to mathematical modeling, when learners work on a problem involving a real-world context, part of the problem solving process may involve the construction of *mathematical models*, or systems of objects, relationships, and rules that can explain or predict the behavior of other systems (Doerr & English, 2003). Although we do not claim that the problem discussed in this paper is a modeling problem *per se*, participants engage in aspects of the modeling process (*e.g.*, developing a model and interpreting solutions) as they solve the problem. The problem used in this study is contextualized and ill-structured, and requires that the learner find and use information from the real world.

Our focus in this paper is on the negotiation of problem spaces. We defined a "problem space" as the collection of mathematical ideas and classroom and real-world issues and resources that learners take up and use as part of their solution process. These ideas, issues, and resources become visible as *the boundaries of the problem spaces* are constructed and explicitly negotiated. For example, while working on the problem of designing an enclosure with the greatest possible area given a fixed perimeter, a learner may decide (by themselves or by asking a teacher) that they only need to consider rectangular shapes. This decision about the problem boundary leads to a problem space that includes rectangles but not other shapes. By investigating the development of problem boundaries, we hope to better understand the ways in which problem spaces are created and how they evolve, as well as surface implicit assumptions about problem spaces and boundaries that we may take into our own mathematics teaching.

In our research, we assume that learners' problem-solving work is situated within particular mathematics classroom contexts, with associated norms and expectations that will influence the negotiation of the problem space, as will learners' previous experiences in mathematics classrooms. We assume that learners' beliefs about mathematics, and their mathematical and school-learner identities, will influence how problem spaces/boundaries are established, as will power and authority relationships among learners and between teachers and learners. Lastly, we assume that the establishment of problem spaces is an ongoing negotiation that takes place among learners, teachers, and "animated others" such as problem authors or representatives of the real world (e.g., people in a town, a business owner, etc.). Within this framework, we address the following questions:

4. How do mathematics teacher learners, engaged in an ill-structured contextualized problem, negotiate the problem space?
5. What boundaries do the teachers establish and how are they determined? How do the boundaries evolve throughout the problem-solving process?

Method of Study

Context and Problem Design

In Summer 2015, the authors taught an 80-hour mathematics content focused professional development (PD) course to 33 middle and high school mathematics teachers from three school districts in the Southwestern United States. Teachers spent most of their time during the PD working in small groups on problem sets and activities meant to highlight key ideas in middle grades and secondary mathematics.

One of these was the "Quantitative Reasoning Cards" activity, in which participants work in groups of four on a sequence of problems involving real-world contexts. Each problem consists of a statement and several pieces of information. For the problem analyzed in this study, both the statement and the information are on a single card given to the group member designated as the leader for the task. The text on the card is shown below:

> The town of Squareville (population 25,600) relies on a nearby lake for drinking water. The water has been tainted due to an industrial accident. The lake can be cleaned, but it will take about two weeks to do so. In the meanwhile, the state plans to use trucks to send clean water to Squareville from a town 23 miles away. How many trucks will the state need?
>
> In order to proceed to the next task, you (the person holding this card) must give a referee a convincing argument answering this question.

Figure 1. The Water Shortage Problem.

The leader may share the information on the card with other group members and help guide the discussion, but they are not permitted to write anything down nor look up any additional information. Other group members may write down their thoughts and mathematical work, but are not allowed to see nor touch the leader's card. Once the group reaches a consensus solution, the leader must explain it to one of the PD instructors (designated as the "referee"), who may then ask follow-up questions of the other group members. The design of the problem is meant to foster interdependence among group members (Cohen & Lotan, 2014); because the group leader cannot perform calculations, and other members have no direct access to the information on the card, group members must communicate about their overall problem-solving strategy as well as the details of the solution so that the leader can clearly describe the group's work to the referee.

The Water Shortage Problem, designed by one of the authors of this paper, requires participants to answer a practical question (how many trucks are needed to deliver water to a town) by analyzing rates of water consumption and delivery rather than absolute amounts. The information card intentionally leaves some essential questions unanswered, such as how much water a truck can carry, and how much water each person will need. The purpose of providing incomplete information is to stimulate discussion among participants about what quantities are relevant to the problem's solution, and to encourage participants to seek information from sources external to the activity.

The problem is designed to elicit thinking from participants about how to estimate quantities whose values cannot be determined exactly. For example, if a disaster preparedness website recommends that each person receive 2 to 4 gallons of water per day, should one assume that each person will receive 2 gallons, 4 gallons, or some amount between these two extremes? We have found in our own implementations of this and similar problems, given a range of possible estimates for a quantity, participants will often select an estimate at the middle of the range, even when a lower or upper bound might be more useful for the situation at hand.

The problem is also designed so that solutions that do not contain rate thinking (*e.g.*, thinking only about how many gallons total are needed for 2 weeks, rather than thinking about gallons per day) will likely lead to unreasonably large answers. This problem feature is intended to spur learners to reconsider their solutions and seek ways to decrease the number of trucks needed. For this to occur, participants must expand the problem space to include consideration of whether a given number of trucks is practically feasible; while a request for ten trucks is likely to be honored by an emergency management agency, a request for five thousand will almost surely be rebuffed.

Participants, Data Collection, and Analysis

During the problem implementation, we captured video and audio recordings of two groups of teachers working on the Water Shortage Problem. Each group consisted of four inservice secondary mathematics teachers. Group 1 consisted of three female middle school teachers and one male high school teacher; Group 2 consisted of one female high school teacher, one female middle school teacher, and two male middle school teachers. Group 1 spent 22 minutes on the problem, and Group 2 spent 30 minutes.

After the conclusion of the professional development course, the two researchers viewed both videos independently and made note of instances in which participants and instructors appeared to question or negotiate the boundaries of the problem. For each such instance, we attempted to identify factors in the group discussion, the instructor's comments, or the design of the task that may have influenced the group's decision about how to define the problem space. We repeatedly met together to compare analyses and come to consensus on any discrepancies. We report results of this initial work here; however, we intend to continue to refine our analysis process as we attempt to apply it to the data we have collected (video and audio) for small groups working on other contextualized problems.

Results

In both groups that participated in the study, the group leader read the task, and the group worked gradually toward a consensus solution, making assumptions about the situation described, making preliminary estimates, and refining these estimates to produce a reasonable and practically feasible solution. Along the way, each group confronted questions about which elements of the real-world situation should be taken into account and which considerations lay beyond their co-constructed boundaries. In this section, we analyze each group's negotiation of the problem space and observe how this space evolved over the duration of the group's work on the problems. All names used below are pseudonyms.

Shifting Responsibility for Boundary-Setting: The Case of Group 1

Vicki, the leader of Group 1, introduced the problem by reading her card aloud to her teammates Tina, Kenny, and Nalda. Shortly after reading the card, Vicki questioned whether the group was allowed to consider information not on the card. The question of how much discretion the group has in negotiating problem conditions and goals occurred again later, as Vicki asked whether the question was about "efficiency" or about how many trucks the state should send. Upon asking this, Vicki said, "I don't know how far we're allowed to take this," suggesting that authority for determining problem boundaries lay at least partially outside of the group itself. We hypothesize that many teachers' prior experiences with contextual problems (as teachers or learners) may consist mainly of problems for which the boundaries are largely pre-determined by the problem statement, or as structured by the teacher.

Table 1: Interactions Influencing the Problem Space for Group 1

Interaction	Action/response	Possible causes of interaction
Vicki: Are we allowed to extrapolate outside of what is on the card? We would need to know how much a truck could carry, average family size…	Tina begins to look up information on phone.	Contextual problems encountered in school often provide the information that is needed; no more, no less. In this setting the group must negotiate the boundaries of the problem space.
Nalda: Are we looking for realistic solutions to this? Because the state isn't going to pay for that many a day… each truck can make four trips…	Nalda's teammates assert that they are counting truckloads, not distinct trucks.	Nalda believes that in this case, issues of realism should at least be considered. Nalda uses the pronoun "we," while Vicki uses the pronoun "they."
Kenny: What if they don't have tankers, they have an average water truck?	Group considers both scenarios and produces an estimate for each.	The problem is ambiguous on the issue of which type of truck the state will use. The group does not have the resources to resolve this ambiguity, but is willing to manage it as a condition of the problem.
Tina: So did we answer the question? Vicki: I feel like we would need more parameters though to be able to really integrate the 23 miles. Nalda: I feel like they give us the 23 miles for us to estimate how many trucks.	Group begins to consider multiple trips per truck.	Task design: Tina cannot look at the card with the question on it. Nalda pushes the group not to set aside the mileage information. She reframes the problem so as to put group members inside the real-world situation.
Kenny: How long is a tanker? Nalda: I don't know. … Kenny: Where are they storing this? Nalda: Well, water towers. Kenny: I'm just thinking/ Nalda: /Half an hour to fill, half an hour to get there…	Tina pulls up a picture of a tanker on her phone and shows the group. Nalda redirects the group's attention to the calculation of the number of trucks.	Nalda seems to view Kenny's queries as outside of the problem's boundaries.

The group ultimately developed estimates for the number of trucks needed in two different scenarios: if the state sends large tanker trucks, and if it sends smaller water trucks. The group's initial approach assumed that each truck would make only one trip per day, and that each resident of the town would receive 90 gallons of water per day. This led to an estimate of 221 tankers per day. At this point Nalda raised the concern that sending 221 tankers per day would not be realistic, and suggested a model in which each tanker makes several trips per day. The group initially dismissed this suggestion, claiming that the problem was to estimate the number of truckloads, not tankers. However, by pointing out that the group had not used the information provided about the distance between the towns, which we interpret as an appeal to an external source (i.e., the problem author) in order to determine a problem space boundary, Nalda later persuaded her teammates to consider the possibility of allowing each truck to make several trips per day, and count the number of trucks rather than the number of truckloads of water. The group eventually produced an estimate of 56 tanker trucks.

Table 1 outlines some instances in which the problem space was negotiated, explicitly or implicitly, by members of Group 1. We note here that, for Group 1, interpreting the implicit intentions of the problem author appears to be a central part of their effort to negotiate the problem boundaries, and thus the problem space. At the same time, the group also attended to whether a particular approach or solution was realistic. In the data, we found multiple examples of this push-pull between school mathematics norms for contextualized problems (*e.g.*, figuring out what the problem author intends) and the desire to find a realistic solution. Importantly, we note that attention to realism may itself relate back to expectations about how we do mathematics in school when faced with contextualized problems for which some information is not given.

The Instructor's Role in Expanding the Problem Space: The Case of Group 2

Vince introduced the problem to his teammates Tobias, Darla, and Violet by summarizing the information on his card rather than reading it verbatim. The group immediately began searching the internet for information relevant to the problem and found that a water truck can carry 5000 gallons, and that the average American uses between 80 and 100 gallons of water per day. Based on this information, they obtained an initial estimate of 6450 trucks, which Violet deemed to be "excessive."

Spurred in part by the infeasibility of this estimate, the group then began to identify ways they could significantly decrease this estimate. Tobias suggested researching the minimum amount of water a person needs each day; based on his research, the group accepted a much lower estimate of 5 gallons per person per day. The group thus arrived at a more modest estimate of 358 trucks, still reflecting the implicit assumption that each truck will make only one run over the two-week period. The group presented this solution to Nancy, one of the PD facilitators. Nancy stated that the state did not have 358 trucks to spare, and that the group should try to determine the *minimum* number of trucks needed. After she left the group, Violet pointed out that the question did not ask for the *least* possible number of trucks, and Tobias claimed that Nancy had changed the question.

After this exchange, Tobias suggested considering how many trucks are needed per day (rather than for the entire two-week period); this brought the group's estimate from 358 down to 26. The group then gradually developed a plan in which six trucks take turns dropping water off at Squareville; at any given time, one truck is in Squareville dropping water, one truck is in the nearby town collecting water, and four other trucks are in transit between the two towns. Vince presented this solution to the other PD instructor, who endorsed it as an acceptable solution.

As the group worked on the problem, the problem space grew to encompass considerations of how much water a person needs during an emergency, and how much water an "average" truck can hold. However, only after Nancy visited the group and encouraged members to develop a more feasible solution did they seriously consider the possibility of having trucks perform multiple runs on the same day. This consideration entered the problem space at least in part due to Nancy's intervention. Table 2 below shows some instances in which Group 2 interacted to define the problem space and its boundaries, and our interpretations of possible causes of the interactions.

Table 2: Interactions Influencing the Problem Space for Group 2

Interaction	Action/response	Possible causes of interaction
Violet: Do we know how much water the trucks hold? Or how much each person needs? Vince: No.	Tobias starts to look for information on the internet using his tablet.	The problem cannot be solved without information that is not on the card.
Violet: Are they telling the people to limit the water? Because I feel like that would be beneficial.	Tobias determines that on average, a person uses between 80 and 100 gallons per day. The group doesn't pursue Violet's idea yet.	The group seems to feel that limiting water is beyond the boundaries of the problem.
Violet: It's 80-100 gallons per day, so do we just want to use 90?	Group calculated 90 x 14 x 25,600 = 32,256,000 gallons. Divided this by 5000 to obtain 6451 trucks.	Using the midpoint of a range as an estimator is possibly related to prior experience with school math problems; in this case, it may actually be worthwhile to use the lower end of the range in order to minimize the number of trucks needed.
Violet: 6451 trucks, that seems really excessive. Tobias: Let's see how much a person *needs* in a day. Violet: We don't know what limitations have been set for this town.	Group discusses different uses of water and eventually settles on 5 gallons per person per day, leading to an estimate of 358 trucks.	Initially, Violet seems to view the issue of water rationing as outside the boundaries of the problem. Eventually, the group shifts the boundaries to encompass this question.
Nancy: Yeah, well Circleville's also having a water issue, and I just don't have 358 trucks, so what's the minimum number I need? … Nancy: So think just a little more about how many trucks you *need*. Like what's the minimum number I can give you?	Group turns to the question of how long it takes for a truck to complete one cycle of loading, driving to town, unloading, and driving back.	Nancy observes that the group has not incorporated the possibility of trucks making multiple deliveries per day into the problem space; she uses the impracticality of a request for 358 trucks to encourage the group to reconsider the problem boundaries they have constructed.
Darla: How long does it take to unload a water truck? Violet: And how do you decide who gets water first? Are we figuring out the least? Is that the question? The least number? It just said how many trucks need to be sent, it didn't say least! Vince and Tobias: She changed it.	Group estimates how much time is needed for a delivery cycle and how many cycles are needed per day, and eventually decides upon 6 trucks.	Violet, Tobias, and Vince indicate their belief that they have been asked to enter a different problem space.

The push-pull between school mathematics and associated expectations of problem authors on the one hand and concerns for realism played out somewhat differently in this group. The group seemed initially unconcerned with limiting water, an aspect of the situation that would most certainly come into play in the real world. Yet, an unrealistic number of trucks did spur the group to reconsider water consumption, and this then became a part of the problem space. At this point, Violet raised another issue related to negotiating the problem boundaries, namely that the group did not know what limitations on water use had been put in place for the town in question. The group expressed frustration with the ambiguous nature of the problem space after the instructor questioned whether 358 was realistic.

Discussion

We offer this report as an initial analysis of the construct of "problem space" as it applies to contextual problems in mathematics. We make no claim that our findings generalize across all classes of mathematics problems and all groups of learners. The negotiation of a problem space may look markedly different in the context of a more closed-ended task, and may also vary according to the age and mathematical background of learners. One may argue that in this particular study the participants' shared familiarity with rate reasoning allowed them to devote additional attention to considering boundary issues such as which quantities in the problem should influence the problem's solution and which should not. Further study, with different types of tasks and with different populations of learners, is needed for a better understanding of how problem spaces develop in different settings.

The expectations that learners have of teachers, problems, and genres of mathematical tasks are central to the establishment of problem boundaries and spaces within them. If learners are accustomed to tasks in which all relevant and necessary information is explicitly provided, they may initially hesitate to consider external sources of information when presented with an open-ended problem. This may lead to learners attempting to work within a problem space that is too narrow to provide the intellectual resources necessary to construct a solution. At the same time, learners may make decisions to expand the problem space when faced with a problem that does not explicitly provide all the resources necessary for its solution. However, the boundaries defining the problem space cannot expand endlessly; learners must, at some point, accept that the situation they are attempting to analyze contains some details that are inaccessible to them and therefore cannot be modeled mathematically.

Our analysis of the negotiation of problem boundaries has implications for the practice of designing open-ended problems. In analyzing the groups' work on the Water Shortage Problem, we found that the problem worked as intended in at least one respect: both groups originally obtained infeasibly large estimates for the number of trucks needed, and thus were encouraged (without external feedback) to revise their assumptions. Both groups decided that the problem space should include some consideration of whether the solution obtained was fiscally responsible. Additionally, both groups decided to include some analysis of whether the solution obtained was physically feasible; for example, Group 2 developed a scheme in which six trucks rotate in and out of Squareville in succession, dropping off water as they arrive. Thinking about the problem at this level of detail helped the group develop confidence that a solution with six trucks was feasible and would deliver enough water. We posit that open-ended problems that contain supports for the development of detailed models and that encourage winnowing out unreasonable solutions may support learners in expanding problem spaces to include practical considerations.

Our analysis also has implications for the orchestration of open-ended problems. Both groups had questions that one could easily imagine asking of a teacher; for example, Vicki might have wanted to ask a PD instructor whether it was permissible to consider information outside of the problem statement. However, in the absence of instructor guidance, the group quickly decided that information from the real world lay squarely within the boundaries of the problem, since the information on the card was inadequate. Because problem spaces evolve over time, a teacher implementing an open-ended problem may wish to take an observer role initially and allow the problem space to develop according to the explicit and implicit demands of the problem.

We conclude this report by highlighting two ways in which the problem space of the Water Shortage Problem may communicate with the broader space of students' real-world experience. Since the time of the creation of this problem, serious water crises have occurred in places such as Flint, Michigan and Corpus Christi, Texas. In subsequent implementations of the Water Shortage Problem, the authors have noticed that teachers who have experienced water crises such as these sometimes interact differently with the problem; they are more knowledgeable about how water is actually distributed during a water crisis, and more attentive to logistical issues such as how a town should time and manage water collection. We offer this as an example of learners' real-world experiences interacting with the problem space. As an example of the problem space talking back to the broader world in which the learners live, consider the following comment from Violet: "If this [90 gallons per day] is what I use on a regular basis and this [4-6 gallons] is what I use in a disaster… like… I feel like *this* is the disaster!" Seeing the disparity between everyday water usage in the U.S. and recommended water usage during an emergency may heighten learners' awareness of the possibility of scaling back water consumption and using natural resources at a more sustainable rate.

EXPLICATING THE CONCEPT OF CONTRAPOSITIVE EQUIVALENCE

Paul Christian Dawkins
Northern Illinois University
pdawkins@niu.edu

Alec Hub
Northern Illinois University
ahub1@niu.edu

Abstract: This paper sets forth a concept (Simon, 2017) of contrapositive equivalence and explores some related phenomena of learning through a case study of Hugo's learning in a teaching experiment guiding the reinvention of mathematical logic. Our proposed concept of contrapositive equivalence rests upon set-based meanings for mathematical categories and negation, representing these sets by closed regions in space, and linking conditional truth to a subset relation between these regions in space. Our case study serves to portray that students must construct all of these elements to achieve a sense of necessity in the equivalence. This study thus contributes a set of learning goals for any introductory logic instruction using Euler (or Venn) diagrams, which has been little studied in the mathematics education literature.

Keywords: Reasoning and Proof, Problem Solving

Proof oriented mathematics instruction depends upon mathematical logic to ensure that students learn 1) to interpret mathematical statements the way mathematicians do and 2) to draw inferences that do not violate the mathematical community's norms. Prior research provides ample evidence that students' interpretations of mathematical conditionals (statements of the form "if…, then…") pose a number of difficulties (e.g. Durand-Guerrier, 2003) as does the logical equivalence of contrapositive (CP) statements (Stylianides, Stylianides, & Phillipou, 2004). There is little prior literature on how students are to come to learn CP equivalence (Yopp, 2017) or the meanings by which this can be a logical necessity. This paper seeks to fill this gap through a case study drawn from a larger series of teaching experiments guiding reinvention of mathematical logic through reflective use of mathematical language (Dawkins & Cook, 2016).

Logical Background

The CP of a conditional "If [P], then [Q]" is the conditional "If not [Q], then not [P]." Consider the statement, "If a triangle is obtuse, then it is not acute." Its CP is "If a triangle is acute, then it is not obtuse." Certainly these statements are both true, but how are their truths linked? In our prior studies we observe that students often reason about such statements using examples, properties, or sets (Dawkins & Cook, 2016). We encourage the reader to consider how both statements can be confirmed from the fact that any triangle has exactly one of the properties acute, right, or obtuse (a property-based strategy). Notice that so affirming both conditionals may not reveal the relationship between the two or why all conditionals with that relationship must share a truth-value. For this reason, we propose a distinction between a *CP inference* and *CP equivalence*. A student draws a CP inference when they infer a CP is true from the original conditional or when they use the original conditional to infer not [P] from not [Q] (*modus tollens*). CP equivalence instead entails students constructing a logical equivalence between any conditional and its CP rooted in generalizable meanings for conditional truth and reference.

We present our intended understanding of contrapositive equivalence in terms of Simon's (2017) explication of mathematical concepts. Simon explains, "A mathematical concept is a researcher's articulation of intended or inferred student knowledge of the logical necessity involved in a particular mathematical relationship" (p. 7). This concept thus reflects our understanding of how a student might come to understand the necessity of CP equivalence. Simon clarified that concepts result from reflexive abstraction and thus are anticipations based on the learner's activity. This characterization

Galindo, E., & Newton, J., (Eds.). (2017). *Proceedings of the 39th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* Indianapolis, IN: Hoosier Association of Mathematics Teacher Educators.

of a concept helps distinguish our work from other relevant studies. Stenning (2002) explored logical reasoning as a broadly assessed without attending to students' meanings for particular concepts or their sense of logical necessity. Stylianides et al. (2004) assessed whether students use a CP equivalence rule they were taught when assessing arguments, and found that students frequently did not apply CP equivalence as intended. They did not study the students' meanings for conditional truth or how they entail CP equivalence's necessity. Hawthorne and Rasmussen (2014) explored students' meanings for elements of formal logic such as truth tables, and found that many learned such formalisms disjoint from their ongoing mathematical activity. They lacked necessity for the learned rules.

We articulate the concept of CP equivalence as follows:

> (Point 1) A mathematical conditional is true whenever the set of objects satisfying the *if* part is a subset of the objects satisfying the *then* part. (Point 2) These two sets can be represented as closed regions in space with points representing the mathematical objects. (Point 3) The negation of a mathematical category refers to the complement set of mathematical objects. (Point 4) Therefore, whenever a conditional is true, its CP must also be true because the complement of the larger region is contained in the complement of the smaller region.

Original conditional		CP conditional	
"If for $x \in S$ $P(x)$, then $Q(x)$." is true whenever $\{x \in S \mid P(x)\} \subset \{x \in S \mid Q(x)\}$		"If for $x \in S$ not $Q(x)$, then not $P(x)$." is thus true because $\{x \in S \mid {\sim}Q(x)\} \subset \{x \in S \mid {\sim}P(x)\}$	
Figure 1. Euler diagrams portraying the subset meaning for a conditional and its CP.

Point 1) We propose the subset meaning for conditional truth as part of Dawkins and Cook's (2016) more general findings that set-based meanings were most propitious for students' reinvention of mathematical logic (over example and property-based meanings). Point 2) Logicians have long represented categories by closed regions (Stenning, 2002), but we find this is not always a natural step for participants in our reinvention. Students often prefer representations that maintain semantic meaning (e.g. the number line, example numerals, example shapes). Representing categories by closed regions reflects an abstract meaning for mathematical definition: any well-defined distinction among mathematical objects. Point 3) Dawkins and Cook (2016) explain that students' interpretations of negative categories do not always correspond to the complement set of examples, but this interpretation is necessary for interpreting CP equivalence diagrammatically. Point 4) CP equivalence is a necessary entailment of the topological relations portrayed in Figure 1. We do not claim that student understanding of CP equivalence must be mediated by visual diagrams (Yopp, 2017), but we anticipate that the necessity of CP equivalence rests upon isomorphic ways of reasoning across semantic content.

The Case of Hugo

In what follows, we shall explore the contours of our concept of CP equivalence through a case study of one student's participation in our guided reinvention teaching experiments. Hugo did not construct the concept of CP equivalence, though his interview partner did. We find Hugo's story of learning helpful because he made clear progress on diagrammatic reasoning about mathematical conditionals and in some way exhibited progress regarding each of the first three points of the concept. However, he still clearly lacked a sense of necessity for CP equivalence, though he observed the shared truth-values. We present this case both because it portrays the kinds of activity that we anticipate would foster students' abstraction of CP equivalence and the challenge inherent to such abstractions in mathematical logic. Furthermore, this case allows us to set forth three possible characterizations for logic learning in advanced mathematics, which we observe as an arena in need of clarification and disambiguation.

Methods

The methods of this study mirror those reported elsewhere regarding this series of teaching experiments guiding the reinvention of mathematical logic (Dawkins & Cook, 2016). Each teaching experiment involved pairs of volunteers recruited from Calculus 3 courses at a medium-sized, public university in the Midwestern United States. These students met with a teacher/researcher for 6-11 hour-long sessions. The sequence of activities consisted of presenting students with lists of statements of the same logical form (disjunctions, conditionals, and multiply-quantified) each with varied, familiar mathematical content. Students were asked to:

1. determine whether each was true or false,
2. formulate rules for when statements of the given form were true or false,
3. develop a method for negating statements, and
4. in the case of conditionals, explore the relationship between a conditional and its converse, inverse, and contrapositive.

Table 1: Sample Conditionals that Hugo and Elya Analyzed

1.	If a number is a multiple of 3, then it is a multiple of 4.
2.	If a number is a multiple of 3, then it is a multiple of 6.
3.	If a number is a multiple of 6, then it is a multiple of 3.
4.	If a number is not a multiple of 6, then it is not a multiple of 3.
5.	If a number is not a multiple of 3, then it is not a multiple of 6.
6.	If a triangle is not acute, then it is obtuse.
7.	If a triangle is obtuse, then it is not acute.
8.	If a triangle is not acute, then it is not equilateral.
10.	If a quadrilateral is a rectangle, then it is a parallelogram.
15.	If the sum of two integers x+y is even, then at least one of the numbers x and y is not odd.

The teacher/researcher generally provided minimal direct guidance besides clarifying mathematical facts about the content of each statement (e.g. 1 is not prime, a square is a rectangle), asking students to clarify explanations or compare claims about various statements, and asking partners to respond to one another's reasoning. Based on the earlier findings reported in Dawkins and Cook (2016), the teacher/researcher also explicitly guided Hugo and his partner Elya to focus on the sets of objects making each statement true or false. The interviewer attempted not to introduce any logical formalizations (i.e. notation, terminology, or diagrams) until the students seemed to recognize some relevant pattern or need to express their reasoning. All data was analyzed using the constant comparative method (Strauss & Corbin, 1999).

Results

Hugo and Elya studied conditionals during their third, fourth, and fifth experimental sessions. Elya was absent from the fourth session. During the third session, their initial task was to assign truth-values to (or *assess*) the conditionals. They assigned the same truth-values a mathematician would (*normative* truth-values). They did not exhibit set-based reasoning during this activity; the pair relied on examples and properties. For false claims, they recognized what constituted a counter-example to a conditional. For instance, Hugo denied statement #1 with the example 6 and explained this was sufficient for assessment: "So we came up with one case where it's false, so it is false." Hugo affirmed three statements using property-based reasoning. For instance, he reasoned about #8 saying, "not acute would mean either a right triangle or an obtuse triangle. Neither of those can be equilateral, so that would be true." In other cases when Elya affirmed a statement using properties, Hugo introduced examples. Regarding #15, Elya inferred that "one of [x and y] would have to be odd" to have an odd sum. Hugo chose 5 as the sum and considered the possible addends. It is unclear whether Hugo perceived this as a justification or simply an explanation, but it portrays Hugo's overall propensity toward example-based strategies for assessing conditionals even when Elya provided property-based explanations.

Point 1: The Subset Meaning of Conditional Truth

In the last 15 minutes of that session, the interviewer asked Hugo and Elya to consider sets.

I (1): Think about the set of all things that satisfy the *if* part and the set of all things that satisfy the *then* part. And tell me about the relationship between those two […]
H (2): I'd say, if the statement is true then the set for the first part—I'm sorry the set of the second part will be included in the set of the first part.
I (3): Okay. Why do you say that?
H (4): Um, because if we said that it's true then when we pick—something that's true for the first part, then it has to be included in the second part for the whole statement to be true.
I (5): […] So you're saying, if the statement is true then what was the relationship here?
H (6): Then the—*then* will be inside *if*.

Hugo's initial explanation (turn 2) suggests that he had not yet considered the sets of objects referred to by the categories in the given conditionals. It is possible that his reverse subset claim reflects attention to the set of properties in each statement. For instance #3 is equivalent to "If an integer is a multiple of 2 and 3, then it is a multiple of 3." The *then* property is "included" in the *if* property (turn 4), but the subset relation between the sets of integers goes the other way round.

When the interviewer asked Elya, she proposed the normative subset relation that the "*if* has to be in the *then*." She elaborated using statement #3, "all the multiples of 6 are contained in multiples of 3." The interviewer asked Hugo to respond using a particular statement.

H (7): Uh, you wanna talk about number 3. Um in like a circle, and multiples of 3—3,6,9,12. [draws a circle and inside of it writes the numbers he says aloud] Um, multiples of 6 will be included in that circle [draws smaller circle around 6 and 12]. Like 6 and 12 are multiples of 6. So there's an additional circle inside that includes some numbers but does not include others [completes the diagram in Figure 2].
I (8): Okay[…] which are you calling the *if* part and which circle are you calling the *then*?
H (9): The *then* part would be the bigger one [he labels the larger circle]. The inside would be *then*—sorry other way around. *Then* is on the outside. *If* is in [he labels the small circle].

By encircling his short list of examples, Hugo bridged his example-based representation into a set-based representation and acknowledged the normative set-based meaning for conditional truth. In this way, Hugo made initial steps toward the first point in our concept of CP equivalence, though his grasp was at times tenuous through the subsequent interviews.

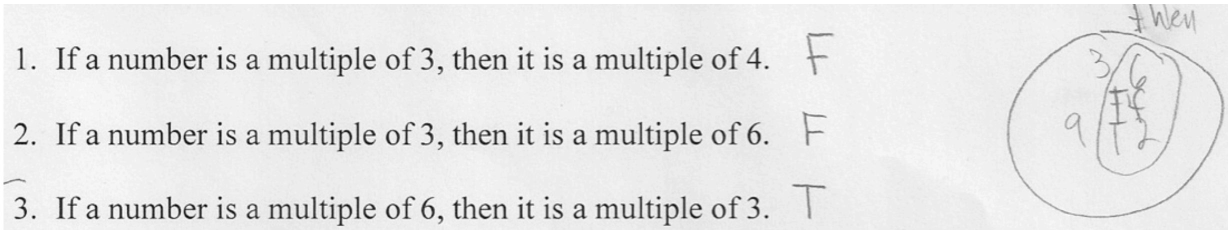

Figure 2: Hugo's first set diagram.

During this third session, Elya and Hugo recognized the syntactic relationships between conditionals traditionally known as *converse* (e.g. #6 and #7) and *inverse* (e.g. #3 and #4). They related CP statements as having undergone both transformations (e.g. #3 and #5, via #4). Using one of their subset diagrams, Elya provided an argument for why the original and CP statements should both be true in a manner compatible with Figure 1. We thus observe that she quickly and easily constructed our concept of CP equivalence from her fluency with set-based meanings and complement operations. Hugo showed little sign of following her reasoning, but he was exposed to a general explanation for why the CP must be true whenever the original statement is.

Point 2: Closed Regions and Their Topology

Elya was absent from the fourth session allowing Hugo to explore his understanding of conditionals and sets independently. Early in the session, Hugo considered statement #6. He appropriately explained that it was false because it failed the normative subset relation, "We said it was false 'cause our first set included… right triangles. So then it was only asking if it was only obtuse. So it could have been a right triangle or obtuse. Not just obtuse." Hugo went on to produce two diagrams to express his understanding of the two sets (Figure 3). The first reflected a traditional Venn diagram arrangement (with "O" standing for "obtuse"). As he unpacked the properties in the statement, he revised his diagram, "This is the *if*, "not acute" we said that could be a 90 triangle or obtuse. And then the *then* was, 'it is obtuse' so I guess that would be—this. So it's a little different than what I originally drew."

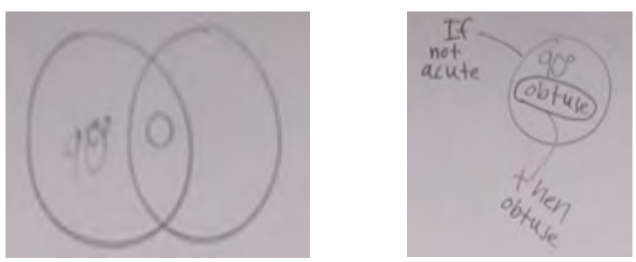

Figure 3: Hugo's two diagrams for statement #6.

Hugo recognized that one region of the Venn diagram did not contain any triangles and represented that in the topology of the two regions in his second, Euler diagram. In this instance, Hugo seemed to clearly make progress regarding the second point in our concept of CP equivalence by using closed regions to represent sets and using their topology to relate those sets.

We conjecture that Hugo's property-based reasoning the previous day influenced his diagram construction. He let the properties stand for the entire category without recourse to representative examples (as in his diagram produced the previous day). It is unclear the extent to which Hugo imagined the curves as encasing the sets of triangles imagined as points or whether they encased the words themselves that stood for the examples. One cause for questioning Hugo's interpretation of the circles and their reference arose when Hugo next considered statement #7. Though statement #7 contains the same categories, Hugo produced a completely new diagram like the second in Figure 3, except the *if* and *then* labels were reversed. The interviewer asked Hugo to compare the two diagrams, and, upon reflection, he said they were the same. He clearly did not anticipate this relationship.

Point 3: The Negation/Complement Relation

The interviewer invited Hugo to write the inverse statements to both #6 and #7 on the board. He then asked Hugo to assess these statements using the same diagram he produced for #6. Hugo considered #6's inverse, written "If acute, then not obtuse" in the following way:

> So "if acute" then we'd be talking about anything outside of the *if* circle, so everything outside of here, then "it is not obtuse"—right. 'Cause you're not—we're talking about everything except inside this circle. And obtuse is inside the circle. So that'd be true. We said this [statement #6] was false. So it was the opposite, or the negation.

Here, Hugo displayed two novel developments in his thinking. First, he associated the negation of a category with the complement of a closed region. Specifically, the region outside the larger circle represented acute triangles. Once again, we cannot be sure whether this inference was supported by 1) Hugo's knowledge that any triangle is exactly one of acute, right, or obtuse or 2) reasoning about the representational structure of the diagram. In either case, he used the *negation/complement relation*. Secondly, he did not affirm the inverse of #6 by the subset meaning, but rather notes that anything outside the large circle is not inside the small circle ("if *acute*, then not *obtuse*"). We call this the *empty intersection meaning for conditional truth.* This criterion is distinct from the subset meaning Elya used during the previous session, but formally equivalent to it. It depends upon the presence of *not* in the latter half of the conditional.

At the end of the previous quote, Hugo noted that the inverse statements had opposite truth-values, and anticipated this might be the case more generally. To explore this conjecture, the interviewer next asked Hugo about statement #7 and its inverse:

H (10): My guess is that it would be false 'cause it's—it'd be the opposite, but "if not obtuse," so anything that's outside of this little circle—then it is acute. That's not necessarily true because—that would—we still have 90 degree—triangles that are not obtuse but are still not acute. So that would still be false. Or that would be false.
I (11): Okay, now you anticipated it would be false. What was your basis for anticipating that it would be false?
H (12): That one. We took the inverse of this one, we got the opposite—the opposite truth-value.
I (13): […] What about the picture tells me which two [of the four statements] are true? […]
H (14): That if we limited it to this inner circle—the obtuse triangles. Then obviously we would not be talking about if it was outside of the circle. We're only talking about the inside
I (15): What about then this one [inverse of #6]? How can I see it in the picture, this one?
H (16): That if we're talking about anything outside of this circle, the bigger circle here, which would be all the acute. Then that would exclude anything inside the circle—obtuse triangles are only inside the circle. So then we would only be talking about the area out here.

In turn 10, Hugo denied the inverse of #7 because the non-obtuse triangles were not all acute. Hugo associated the negation of *obtuse* with the complement of the smaller region. He identified acute triangles (outside the larger circle) as counterexample to the conditional. Hugo noted that this example also affirmed his conjecture that inverse conditionals have opposite truth-values.

The interviewer noticed that Hugo was fluidly shifting between subset, empty-intersection, and counterexample meanings to assess the given conditionals. So, in turn 13 he asked Hugo to consider more generally which of the four statements (#6, #7, and their inverses) were true and how the diagram represented this. In turns 14 and 16, Hugo affirmed #7 and its CP both using the empty intersection meaning: the inner circle and outer complement were mutually exclusive. While this observation could provide a general sense of symmetry regarding the truth conditions for some CP statements, there was no evidence of Hugo abstracting this relationship at this point.

Point 4: CP Equivalence

To help Hugo see the syntactic relationship between the true statements he affirmed in the last interchange, the interviewer asked Hugo to specify all of the syntactic relationships among the four statements. Figure 4 shows the results of their discussion (Hugo and his partner used the term "switch" for converses). Using this diagram, Hugo noted that CP statements had the same truth-value: "if we have an *if-then* statement that's true, we take the inverse and the switch […] so far we've proved that it would be true [...] Well I'm observing but I'm trying to articulate why that is." He admitted that this was for him an empirical observation and he could not justify it.

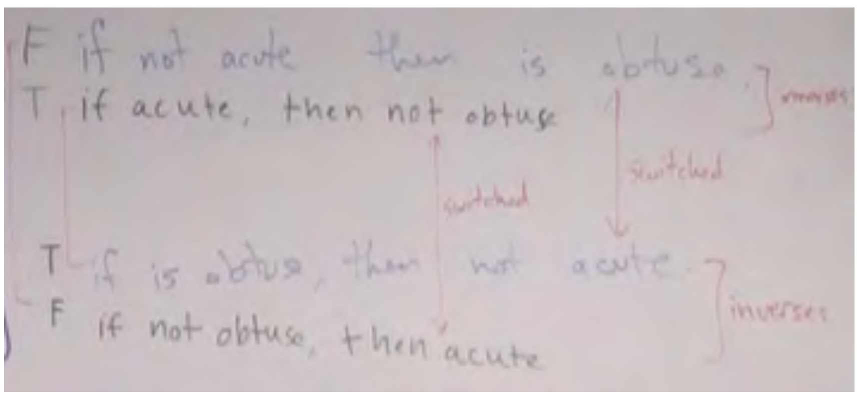

Figure 4: Exploring the syntactic relationship among a conditional quartet.

Not only did Hugo fail to see a general justification for CP equivalence, he was very inconsistent in his use of subset diagrams to assess conditionals about other topics. When asked to discuss the sets associated with statement #10 and its CP later in that session, Hugo drew separate and isolated circles above the words "rectangle" and "parallelogram" in #10. He recognized that all rectangles were parallelograms, but he did not use the topology of the regions to represent this. With prompting, he modified these diagrams to match the previous subset diagrams. Regarding the CP, Hugo began new circles rather than using the complements of the regions drawn for #10. Throughout the rest of that interview and the next, Hugo went on to consider at least three other quartets of conditional, inverse, converse, and contrapositive. Once prompted to produce a subset diagram, he consistently 1) affirmed the base conditional by the subset meaning, 2) denied the inverse and converse by counterexample or by failing to have a subset relation, and 3) affirmed the contrapositive by the empty-intersection meaning. However, he did not routinize creating such diagrams without prompting or begin anticipating the topological relations that would affirm a conditional and its CP. In short he did not construct the concept in such a way as to produce a sense of logical necessity for the shared truth-values.

Conclusions

Our goals in this paper were to 1) set forth our concept (Simon, 2017) of CP equivalence, 2) portray mathematical activity by which this concept could develop, and 3) convey the challenge these abstractions pose through Hugo's learning process. We claim that Hugo made progress regarding each of the first three points in the concept and empirically observed point 4, but did not perceive point 4 as a logical necessity. We presented evidence that Hugo understood that conditionals could be affirmed via a subset relation (Point 1). It is unclear whether this relationship was universal and reversible, or simply a sufficient condition. Hugo was able to represent the relationships between the categories in conditionals using closed regions and their topology (Point 2). At times he used these diagrams flexibly, as when he created the empty intersection meaning. He did not see such diagrams as a universal tool, judging by his alternating strategies and representations. He produced diagrams with different referential structures and often bypassed reasoning with the diagram by resorting to property-based inferences. While we appreciate that Hugo consistently connected his representation to the relevant mathematical categories (cf. Hawthorne & Rasmussen, 2014), he did not consistently use the diagram to draw new inferences about the mathematical categories. Hugo at times associated the negation of a category with the complement of either region in a diagram (Point 3), but he never coordinated two such complement regions simultaneously (as implied in Figure 1). Thus regarding each point of the concept, we see why Hugo's understanding did not support reflexive abstraction.

We intend for this analysis to emphasize the difficulty and nuance involved in constructing logical necessity in diagrammatic reasoning in the course of semantically-rich mathematical activity. We also propose that further literature on logic learning should clearly distinguish the kinds of understanding they intend. We propose three categories. *Reading* involves assessing mathematical statements in normative ways and drawing normative inferences. Hugo did this throughout. *Reflecting* involves finding general representations and criteria for assessing mathematical statements, such as Euler diagrams and the subset criterion. Hugo began this during the study. *Abstracting* involves reflexive abstractions yielding new insights from these representations and criterion. Elya, but not Hugo, displayed this kind of learning regarding CP equivalence. We anticipate that elaboration of these categories will facilitate future investigation.

Generalization is a critical aspect of doing mathematics, with policy makers recommending that it be a central component of mathematics instruction at all levels. This recommendation poses serious challenges, however, given researchers consistently identifying students' difficulties in creating and expressing normative mathematical generalizations. We address these challenges by introducing a comprehensive framework characterizing students' generalizing, the Relating-Forming-Extending framework. Based on individual interviews with 90 students, we identify three major forms of generalizing and address relationships between forms of abstraction and forms of generalization. This paper presents the generalization framework and discusses the ways in which different forms of generalizing can play out in activity.

Keywords: Cognition, Learning Theory, Reasoning and Proof

Introduction: The Importance of Mathematical Generalization

The act of generalizing is at the core of mathematical activity, serving as the means of constructing new knowledge. Researchers have argued that mathematical thought cannot occur in the absence of generalization (Sriraman, 2003; Vygotsky, 1986). As a result, "developing children's generalizations is regarded as one of the principal purposes of school instruction" (Davydov, 1972/1990, p. 10). Researchers have studied the importance of generalization for promoting algebraic reasoning (Cooper & Warren, 2008), mathematical modeling (Becker & Rivera, 2006), functional thinking (Ellis, 2011; Rivera & Becker, 2007), and probability (Sriraman, 2003), among other areas. Despite the importance of generalization to success in mathematical reasoning, research on students' abilities to generalize has identified pervasive student difficulties. For instance, Rivera (2008) reported results of 5 years of performance assessments on generalization given to more than 60,000 middle and early high school students; these findings revealed a stable ceiling value of only a 20% success rate in the construction of a general formula. Other researchers have similarly documented students' difficulties in creating correct general statements, shifting from pattern recognition to pattern generalization, and using generalized language (e.g., English & Warren, 1995; Mason, 1996).

Although student difficulties are well documented, the instructional conditions necessary for fostering more productive student generalizing are not well understood. Complicating the matter, the bulk of research on generalization has occurred with algebraic patterning tasks, situating generalization as a type of, and route to, algebraic reasoning (Becker & Rivera, 2006; Cooper & Warren, 2008). There remains a need to understand how students construct generality in more varied and more advanced mathematical domains. The goals of this study are to investigate students' mathematical generalizing from middle school through the undergraduate level in the topics of algebra, advanced algebra, and combinatorics. In particular, our aim is to elaborate the nature of students' generalizing, contributing to the field's knowledge base by extending the investigation of generalization up the grade bands. Based on clinical interviews with 90 students from 6th grade through the undergraduate level, we introduce a framework characterizing three major forms of generalizing activity: *relating*, *forming*, and *extending*. We also introduce and discuss relationships between forms of generalization and forms of abstraction.

Theoretical Framework

Forms of Generalization

Definitions of generalization vary, with the most prominent situating generalization as an individual, cognitive construct (e.g., Kaput, 1999). More recent sociocultural definitions position generalization within activity and context, as a collective act distributed across multiple agents (Tuomi-Gröhn & Engeström, 2003). These perspectives attend to how social interaction, tools, and history shapes people's generalizing, recognizing generalization as a social practice that is rooted in activity and discourse (Jurow, 2004). We borrow from both the cognitive and the sociocultural traditions to define generalizing as an activity in which learners in specific sociocultural and instructional contexts engage in at least one of the following three actions: (a) identifying commonality across cases (Dreyfus, 1991), (b) extending one's reasoning beyond the range in which it originated (Radford, 2006), and/or (c) deriving broader results from particular cases (Kaput, 1999). We use the term *generalizing* to refer to any of these processes, whereas *generalization* refers to the outcome(s) of these processes.

Borrowing from Lobato's (2003) transfer framework, we take an actor-oriented approach to studying students' processes of generalizing. This approach represents a shift from the observer's (usually the researcher's) stance to the actor's (the student's) stance. In particular, it compels us to abandon normative notions of what should count as a generalization, instead seeking to understand the processes by which students construct relations of similarity that they experience as meaningful. Our framework also builds on Ellis' (2007) taxonomy of generalizations, which distinguishes between students' activity as they generalize, called *generalizing actions*, and students' final statements of generalization, called *reflection generalizations*.

Forms of Abstraction

The second line of research we rely on examines the role of abstraction in developing generalizations (e.g., Dorfler, 1991). Abstraction has been characterized in multiple ways, but we focus particularly on reflective abstraction and the interrelationships among the actions and operations that constitute students' construction of mental objects. In particular, we distinguish three types of reflective abstraction salient in informing students' generalizing activity: *pseudo-empirical abstraction*, *reflecting abstraction*, and *reflected abstraction* (Montangero & Maurice-Naville, 1997; Piaget, 2001). Pseudo-empirical abstraction is based on the observation of perceptible results, in which new knowledge is drawn not just from the properties of objects, but from how the student has organized the activities she has exerted on those objects. We further distinguish pseudo-empirical abstraction from other forms by noting that pseudo-empirical abstraction includes reflection on the *outcome* of one's activity. The focus is on the products of a learner's actions, rather than the coordination and transformation of actions themselves.

In contrast, reflecting abstraction includes reflection on one's actions, not merely on the outcomes of those actions. One can transfer to a higher plane what he or she has gleaned from lower levels of activity, leading to differentiations that imply new, generalizing compositions at that higher level. In reflected abstraction, one becomes conscious of his or her actions, bringing awareness of qualitative differences between his or her actions. Through reflected abstraction, one is able to formulate, formalize, and subsequently operate on his or her thought.

Methods

We conducted a series of individual semi-structured interviews with middle school (ages 12-14), high school (ages 14-17), and undergraduate students in the domains of algebra, advanced algebra, discrete mathematics, and combinatorics. The algebra and advanced-algebra topics included linear, quadratic, higher-order polynomial, and trigonometric functions, and the discrete mathematics and combinatorics topics included counting problems, combination and permutation problems, and the binomial theorem. We conducted 10 middle-school, 11 high-school, and 10 undergraduate algebra or advanced algebra interviews, and 19 middle-school, 13 high-school, and 27 undergraduate discrete mathematics (combinatorics) interviews.

During the interviews we presented the participants with domain-specific tasks to elicit both near and far generalizations, and we asked the participants to identify patterns and themes, discuss any elements of similarity they noticed, and, where reasonable, explain and discuss the generalizations they formed. All interviews were videotaped and we used gender-preserving pseudonyms for all participants. Table 1 presents a sample of the interview tasks across the mathematical domains.

Table 1: Sample Interview Tasks

Interview Task	Domain and grade level
The rectangle below grows along the dotted path as shown:  Complete the following statement: When the length of the rectangle grows by _____, the area grows by _____.	Algebra, middle school
You have a 1 cm by 1 cm by 1 cm cube, and all sides grow at the same rate. How much additional volume does the cube gain when the sides each increase by 1 cm?	Adv. algebra, high school
You have a deck of number cards numbered 1-6. You create a two-card hand by drawing a card from the deck, putting it back, and drawing a second card. Determine how many possible two-card hands you could get. How many times the number of two-card hands would you have if you had twice the number of cards?	Discrete math, middle school
Suppose passwords consist of (uppercase) As, Bs, and/or the number 1. How many such passwords are there that are *n* characters long?	Combinatorics, undergraduate

Analysis

We relied on the constant comparative method (Strauss & Corbin, 1990) to analyze the interview data in order to identify forms of generalization and abstraction. For the first round of analysis we drew on Ellis' (2007) analytic framework for categorizing students' generalizing actions and reflection generalizations, using open coding to infer categories of generalizing activity based on students' talk, gestures, and task responses. This first round led to an initial set of codes, which then guided subsequent rounds of analysis in which the project team met weekly to refine and adjust the codes in relation to one another. This iterative process continued until no new codes emerged. A final round of analysis was descriptive and supported the development of an emergent set of relationships between forms of abstraction and forms of generalizing, characterizing the evolving nature of students' mental activity as they generalized.

Results: The Relating-Forming-Extending Framework

Based on data analysis from the 90 interviews we developed an empirically-grounded framework capturing the broad range of generalizing activity across a variety of grade bands and domains. We present the results in two major sections. First we introduce the framework itself, which provides definitions, descriptions, and examples of each form of generalization demonstrated by the study participants (Tables 2-4). Due to space constraints, we do not elaborate on every form of generalizing, but we instead present a data episode identifying the interrelationships between the forms of abstraction and forms of generalizing. This episode is meant to be representative of the explanatory power of the framework, which we limit to one student due to space considerations. The Relating-Forming-Extending framework distinguishes between *inter-contextual* forms of generalizing, in which students established relations of similarity across problems or contexts, and *intra-contextual* forms of generalizing, in which students formed and extended similarities and regularities within one task. Following the actor-oriented perspective, we made the inter/intra distinction based on evidence of whether the student perceived the establishment of similarity or regularity he or she formed to occur across different contexts or situations, or to occur within the same context.

Table 2: Inter-Contextual Forms of Generalizing (Relating)

<table>
<tr><th colspan="2">Form of Generalizing</th><th>Example</th></tr>
<tr><td rowspan="2">Relating Situations: Forming a relation of similarity across contexts, problems, or situations</td><td>Connecting Back: Formation of a connection between a current and previous problem or situation.</td><td>HS Adv. Algebra Student: All the sides are the same length. The formula is generally the same [as the prior problem], you’re just adding one more side for the 4-dimensional one.</td></tr>
<tr><td>Analogy Invention: Creating a new situation or problem to be similar to the current one.</td><td>MS Algebra Student: The more seconds he has, he’ll slow down. And the less seconds he has, he’ll speed up faster. Int: Okay, and how come? Student: You know how, if you had less time to go into the grocery store to get the foods on the grocery list, you would go faster if you had like 1 second to do it in? You would, like, be in and out real quick. Same thing here.</td></tr>
<tr><td colspan="2">Relating Ideas or Strategies (Transfer): Influence of a prior context or task is evident in student’s current operating.</td><td>HS Adv. Algebra Student: So in this case it’d be P plus, let’s do V for valence because that’s one word I know for outer ring. Int: Cool, is that from chemistry? Student: Yep. Like the valence electrons…how much that equals plus the previous one, would equal your new answer.</td></tr>
</table>

The inter-contextual forms of generalizing all involved a type of *relating* activity. The intra-contextual generalizing, however, occurred in two major categories: (a) *forming* a similarity or regularity, in which students searched for and identified similar elements, patterns, and relationships (Table 3); and (b) *extending* or applying a similarity or regularity (Table 4). In the latter case, students extended established patterns or relationships to new cases.

We illustrate several intra-contextual generalizations and their relationships to forms of abstraction by presenting the work of Willow, a middle-school algebra student, who worked on the growing rectangle task (Table 1). Willow initially established a numerical relationship between the length of 4 cm and the area of 6 cm^2:

> Well, the area is 2 more than the length so I would think if, however, if they grew like the same amounts of, if this (points to the area) grew by 2 in the area, so it would be 8 and this (points to the length) grew by 2 and it would be 6, then it would always be 2 more if they grew in the same, like, the same amount.

Table 3: Intra-Contextual Forms of Generalizing (Forming)

Form of Generalizing		Example
Relating Objects: Forming a relation of similarity between two or more present mathematical objects	*Operative*: Associating objects by isolating a similar property, function, or structure.	*Und. Adv. Algebra Student*: [Comparing $x = \sin(y)$ with $y = \sin(x)$ graphs] They're both representing the same thing…with equal changes of angle measures my vertical distance is increasing at a decreasing rate [tracing graph]…here it's doing the exact same thing.
	Figurative: Associating objects by isolating similarity in form.	*HS Adv. Algebra Student*: How does the volume equation relate to this cube? Well the three numbers are getting one bigger and the three sides got one bigger.
	Activity: Relating objects or ideas based on identifying one's activity as similar.	*MS Algebra Student:* I think it would be 2 more than the 6. *Int*: Two more than the 6? Okay, how come? *Student*: Because, like, same as this one [points to the prior problem] you're just adding it.
Search for similarity or regularity: Searching to find a stable pattern, regularity, or element of similarity across cases, numbers, or figures.		*HS Adv. Algebra Student*: I don't think it goes up by the same amount each time. Does it? That goes up by 3, and that goes up by 5, and that goes up by 7. Three, 5, 7. Yeah, it goes up by…okay.
Identify a regularity: Identification of a regularity or pattern across cases, numbers, or figures.	*Extracted*: Extracting regularity across multiple cases.	*MS Combinatorics Student*: For every addition problem that we do, like 6 plus 6 equals 12, it is always one more added to that every time.
	Projected: Describing a predicted or known stable feature.	*MS Algebra Student:* You could do, you could do 1.5 times growth and that would get you, times the growth in the length and then that would give you the growth in area.
Isolate constancy: Focusing on and isolating regularity – a stable feature – across varying features.		*HS Adv. Algebra Student*: This is like the one thing that you started off with [circles the original rectangle]. It's like the only constant really. And so each time it changes a little bit so it's really one of these is being added each time and so that's not really taking it into account, the 15 that was already there.

Willow *identified a regularity* by stating "It (the areas) would always be 2 more (than the length)". Although Willow's generalization is incorrect, it represented a pattern that she saw as valid. We also suspect Willow's generalization relied on a pseudo-empirical abstraction, not because her generalization was incorrect, but because she appeared to generalize based on the outcome of her activity. Specifically, Willow's operation was to take the difference of the numbers 4 and 6, and she generalized the difference remaining constant. She made an additive comparison between numerical values that did not appear to be based in quantitative operations relating length to area. When asked what would happen if the rectangle grew by another 4 cm, Willow responded, "So it grew by 4…would the area have grown by 4 too? It could be, like, 10." Here Willow *extended by continuing* the "area = length + 2" relationship she had established to a new case. She then further generalized by stating, "If the length grew by x, then the area would be 2 more than the total length," which she expressed as “A = 2 + T”. Here Willow *extended by removing particulars* in order to algebraically express the relationship she had established. We maintain that this string of generalizations remained grounded in Willow’s activity of pseudo-empirical abstraction. Her focus remained on the result of her operation, the difference of 2, and at no time did Willow coordinate the growth of the rectangle simultaneously with varying measures of length and area.

Table 4: Intra-Contextual Forms of Generalizing (Extending)

Form of Generalizing		Example
Continuing: Continuing an existing pattern or regularity to a new case.		*MS Combinatorics Student*: [Moves from a 7-card case to an 8-card case]: It is like the last time. You don’t count (8, 8) twice.
Operating: Operating on an identified pattern, regularity, or relationship in order to extend it to a new case.	*Near*: Making a minor change to a regularity in order to extend it to a new case.	*HS Adv. Algebra Student*: [After having established a pattern of adding 8 square units for every additional rectangle]: And then plus 8, or I could just do plus, um, 8 times 5, right? And so that would be 40.
	Projection: Making a major change to a regularity in order to project it to a far case.	*Und. Combinatorics Student*: [After solving cases with 3 and 4 combinations]: So now I believe if you gave me something where if there was 20 combinations I could solve how many combinations there are without having to write them all out: 2^{20} and whatever that equals.
Transforming: Extending a generalization and, in doing so, changing the generalization that is being extended.	*Constructing a Quantity*: Constructing a new quantity or a relationship between quantities in order to extend a regularity to a new case.	*HS Adv. Algebra Student*: [Exploring the three sides of a rectangular prism, the interviewer asks the student to express one side in terms of the other.] So it’s *x* plus 1, right?
	Recursive Embedding: Embedding a previous situation into a new one as a key component of the new task.	*Und. Combinatorics Student*: Okay, we’re definitely using 1, so we’re limiting ourselves to only 2 possible states for the entire password, A and B, which means it’s basically no different than what we did in one of the earlier examples. So that I’ll probably just figure, okay, 2 to the 3rd equals 8.
Removing particulars: Extending a specific relationship, pattern, or regularity by removing particular details to express the relationship more generally.		*MS Algebra Student*: I was thinking, like, trying to put it in an equation I guess, so it kind of makes sense…Well it could be, area equals 2 plus total length [writes A = 2 + T].

Right when the interviewer began to remove the task in order to transition to a new problem, Willow suddenly evidenced a shift in her thinking, saying, “Unless it will start at 0?”

> Because if you start it at 0…to find out the actual growth, then, say this is like the first they grew and this, kind of, so this grew by 4 first (gestures along the length) and then this grew by 6 (gestures to the whole figure, along the area). So this (the length) could grow by 4 again, and this (the area) could grow by 6 again.

Willow appeared to construct a dynamic image of the rectangle growing “from 0”. She further explained, “Because it would always be plus 4 and plus 6, so if you said when the length grows by 8, the area grows by 12.” Willow imagined the rectangle growing in chunks, iterating twice. Willow therefore *identified a regularity* that if the rectangle started growing from 0, then for every 4-cm increase in length, the rectangle would increase in area by 6 cm^2. This regularity, unlike the first one

Willow identified, was based on an image of growth in which Willow was able to coordinate an increase in length with a corresponding increase in area. This image was informed by the operations of forming a ratio and iterating it. It was also a product of reflecting abstraction in that Willow reflected on her activity in order to coordinate iterating her formed ratio with the number of times it was iterated. Therefore, she could then state that the length would increase by 4 again, resulting in another increase of 6 for the area. Willow *extended by continuing* the relationship, and she did so by relying on her ability to coordinate growth in one quantity with growth in the other.

We take further evidence that Willow engaged in reflecting abstraction by what occurred next. Namely, she was able to *extend by operating* on the relationship she had formed, multiplying each term in the 4:6 ratio by 4, then by 10, ½, ¼, ¾, and 5/4 in order to generate new length:area pairs. This extension was significant because it included the use of both whole number and fraction values. It also suggests that Willow had reflected on her operation of forming a ratio in order to develop a flexible, generalizable relationship with which she could meaningfully operate. Willow ultimately developed a unit ratio, explaining, "Each time the growth in length goes up by 1, the growth in area, I think the growth in area equals [writes $A = 1.5 \times L$]." Thus Willow *identified a new regularity* and then *removed particulars* for this regularity. When she removed particulars, she reflectively abstracted a ratio from the phenomenological bounds in which it was created, and Willow's subsequent flexible use of this ratio with messy numbers is evidence that she could imagine it holding for any arbitrary value.

Discussion

The Relating-Forming-Extending framework identifies forms of generalizing based on data from multiple grade bands and mathematical domains, addressing the need to understand how students construct generality in more varied and advanced mathematical contexts. Willow's work provides evidence that students can and do generalize their reasoning on a variety of problems beyond typical patterning tasks. In particular, in contrast to much of the literature identifying how students inductively generalize patterns, Willow abductively (Peirce, 1931-1958; Radford, 2006) developed a generalization from just one case. Willow's reflective activity enabled her to develop, solidify and apply generalizations in two ways. Firstly, she generalized an additive comparison based on the numerical relationship she established between 4 and 6 (a pseudo-empirical abstraction). Secondly, she generalized by forming and operating on a ratio between quantities that was rooted in her image of the rectangle's length growing in tandem with its area (a reflecting abstraction).

The Relating-Forming-Extending framework extends prior work by distinguishing and characterizing three forms of generalizing activity and by coordinating these forms of generalizing with forms of abstracting. The case of Willow shows that students can engage in many forms of generalizing, such as *identifying regularities*, *extending by continuing*, and *removing particulars*, based on either pseudo-empirical or reflecting abstraction. Other forms of generalizing, such as *extending by operating* or *transforming*, appear to be more typically grounded in reflecting abstraction, as they often entail differentiations based on activity in order to support new compositions. By attending to both abstraction and generalization in students' sense-making, we can begin to characterize how students can leverage initial abstractions into first-pass generalizations that they can then reflect on and transform in further activity. Further analysis of these relationships between abstraction and generalization will inform a better understanding of the conceptual mechanisms driving generalizing activity in a variety of mathematical contexts.

Acknowledgments

The research reported in this paper was supported by the National Science Foundation (grant no. DRL-1419973). We would also like to thank Andrew Gatza, José Francisco Gutiérrez, Hamilton

Hardison, Brandon Singleton, Irma Stevens, Zack Reed, and Ryan Ziols for their assistance with collecting and analyzing the data presented in this paper.

MATHEMATICAL MODELING: CHALLENGING THE FIGURED WORLDS OF ELEMENTARY MATHEMATICS

Megan H. Wickstrom
Montana State University
megan.wickstrom@montana.edu

This article is a report on a teacher study group that focused on three elementary teachers' perceptions of mathematical modeling in contrast to typical mathematics instruction. Through the theoretical lens of figured worlds, I discuss how mathematics instruction was conceptualized across the classrooms in terms of artifacts, discourse, and identity. I then highlight, through four themes, how mathematical modeling challenged the ways in which both the teachers and students understood what it means to know and do mathematics. Findings suggest that the practice of mathematical modeling allowed for access, empowerment, and real world connections that were typically not present in classroom instruction. In addition, it challenged student positioning in the classroom in terms of who was framed as capable of doing mathematics.

Keywords: Elementary School Education, Equity and Diversity, Modeling

Introduction

Mathematical Modeling, a standard of mathematical practice in the Common Core State Standards, is a process in which students use mathematical tools to reason about, represent, and make decisions surrounding a real world scenario (Lesh & Doerr, 2003). The process of modeling is cyclic and it begins when the modeler translates the scenario into the mathematical world by posing a question. Using knowledge and mathematical tools, the modeler proposes solutions and translates them back to the real world to determine if they are appropriate or if modifications need to be made. In this paper, mathematical modeling refers to the entire process rather than the end product.

Although mathematical modeling has traditionally taken place in secondary and college classrooms, researchers (Carlson, Wickstrom, Burroughs, & Fulton, 2016) have argued that it is equally as important for elementary students to engage in the process. Modeling supports mathematical literacy (Steen, Turner, & Burkhardt, 2007) and allows students to draw on their own backgrounds and experiences in framing the mathematical problem (English & Watters, 2005). Modeling also promotes productive attitudes toward mathematics (Lesh & Yoon, 2007), and fosters integration across mathematical content and practices (Lehrer & Schauble, 2007).

The study of mathematical modeling in the elementary classroom is a relatively new field of study. The purpose of this paper is to add to existing literature by describing an elementary modeling task and the ways in which it challenged teachers' and students' perceptions of what mathematics is and what it means to do mathematics as well as the students' and teacher's roles within the classroom. Through the theoretical lens of figured worlds, in this paper I address the following research questions:

1. How does mathematical modeling press on or extend the boundaries of what it means to know and do mathematics in the elementary classroom?
2. In what ways, if any, does mathematical modeling challenge positionality and roles in the elementary classroom?

Theoretical Framework: The Mathematics Classroom as a Figured World

This work is framed through the theoretical lens of Holland, Skinner, Lachicotte, and Cain's (1998) concept of figured worlds. They define a figured world as, "a socially and culturally constructed realm of interpretation in which particular characters and actors are recognized, significance is assigned to certain acts, and particular outcomes are valued over others." (p.52) Holland et al.'s work addresses the idea that each individual's thoughts, behaviors, and ways of interpreting the world are often influenced by culture, power, and status. In addition everyday activities act as figured worlds that build, inform, and continually define individual's identities. In this paper, I argue that the mathematics classroom functions as a figured world. In the elementary classroom, there are routines that define what it means to know and do mathematics. In addition, both the teachers and students take on different roles and identities that are continually formed across the school year.

Figured worlds consist of three key elements: artifacts, discourse, and identity. I begin the paper by discussing a typical day in the teachers' classrooms in response to artifacts that contributed to the figured world of mathematics instruction, discourse surrounding how the three teacher's interpreted doing mathematics, and the identities and roles the teachers perceived in the classroom. Next, I identify and describe four themes that arose while mathematical modeling that challenged the established norms or figured worlds.

Methods

Participants

Three teachers participated into this study, Ms. A, Mr. B, and Ms. C. Ms. A was a fifth-grade teacher. Mr. B was a fourth-grade teacher and Ms. C was a third-grade teacher. The teachers were participants in a NSF-funded professional development on integrating mathematical modeling in the elementary classroom that took place in a school district in the Rocky Mountain West. As part of the professional development, the teachers attended a weeklong professional development on mathematical modeling and pedagogical practices in the summer. During the summer, they designed a modeling task to implement in their respective classrooms. Following summer professional development, the teachers participated in a teacher study group in which they met seven times across the fall semester to debrief and discuss the modeling task with a university faculty member. The three teachers were chosen for this study because they were grouped together in the same study group and enacted the same modeling task. I, the researcher, took on the role of their study group facilitator.

Modeling Task

This section is meant to give a brief overview of the task. Specific examples of students engaging in the task will be given in the results section. In designing the modeling task, each of the teachers discussed that they led some type of community-building lunch at the beginning of the school year for students to get to know one another. Instead of designing the activity themselves, they decided they would use this as a real-world scenario to engage students in mathematical modeling. Teachers presented the following scenario to students, "Building community in our classrooms is very important. The university has given us money to support a community building lunch." After presenting the scenario, they asked students to consider 1) What do we need to know? and 2) What tools could we use to help us? Students decided that they needed to address broad questions like "What should we have for lunch?", "What activities should be included to build community?", "Will what we want fit into our budget?". Students also discussed that there are other factors to consider like allergies and personal preferences in food selection.

The teachers worked with students on this task across 3-4 weeks, visiting the task a few times a week. Initially, the students worked on determining what should be served at lunch and quantity. Students primarily used surveys, multiplication, counting, and measurements as mathematical tools to aid them in making decisions. Once students had determined what should be served and how much, they needed to determine where the food would come from and if the meal was in budget. The teachers helped by providing grocery store and restaurant ads. Again, the students primarily used multiplication and repeated addition in determining the total cost.

Data Collection

I, the researcher, observed all three teachers across implementation of their modeling tasks visiting each teacher for 3-4 lessons. During observations, I took qualitative notes of what occurred in the classroom including what the teachers said or did, students' progress in the task, and students' remaining questions or concerns. In addition, I facilitated and video-recorded seven meetings in which the three teachers debriefed about the modeling task and their work as teachers. Following the fall teacher study groups, the teachers individually participated in a one-on-one interview that lasted for about 45 minutes. The purpose was for teachers to first describe the structure of a typical mathematics lessons including routines, student activities, and teacher activities. In the second half of the interview, the teachers were asked to describe their experiences enacting mathematical modeling. This included describing key features of and comparing mathematical modeling to a typical lesson. In addition, they were asked to describe what the process was like for their students and for them, as teachers. The primary data source for this article are the one-on-one interviews with observational notes used as triangulation.

Data Analysis

Interviews with teachers were audio recorded. Each of the interviews was transcribed verbatim resulting in about 10 pages of typed transcript per teacher. Classification and coding took place first related to the research questions and theoretical framework (Miles, Huberman, & Saldana 2014). I analyzed the transcripts first looking for statements that helped to contextualize and describe components of a typical mathematics lesson. Then, I analyzed the data looking for statements related to the three main components of figured worlds: artifacts, discourse, and identities. Finally, I looked for statements, in describing the modeling task, that were in contrast to the figured world of the mathematics classroom. I analyzed and grouped the statements to generate themes regarding the figured world of the mathematics classroom and the ways in which mathematical modeling challenged or reinforced this world.

Results

The Figured World of the Mathematics Classroom

Artifacts. Artifacts are objects that act as the "means by which figured worlds are evoked, collectively developed, individually learned, and personally powerful." (Holland et. al, 1998, p.61) Across the three classrooms, there were three artifacts that supported how mathematics instruction was conceptualized: group/carpet area, worksheets, and journals. Each of the teachers began the lesson by bringing the class together in a communal area or a carpet at the front of the classroom. The purpose was for the students to be able to express themselves in a communal environment. The teachers described that they first presented an idea or a problem to students in pairs or groups. Students were asked to compare and discuss their solutions with their partner and then solutions were shared allowed. In describing this part of the lesson, Mr. B stated:

> So they'll (the students) work independently, compare their answers with their learning partner and then I'll call, usually using the equity sticks, I will call several people up…often I just look and see a variety of different problem solving methods and always emphasize that the students learn more from each other than me.

Each of the teachers discussed this as time for students to voice multiple solution strategies, build community, and learn from one another.

The second artifact that shaped mathematics instruction was the worksheet. After students discussed and shared solution strategies, they moved back to their desks and were given different types of practice problems. All of the teachers used the worksheet as a way to individually assess if students understood the material as well as time to talk individually with students. Ms. C described, “I give them a few problems and I just want to see, I rotate from group to group to see if they are getting it.” The emphasis of this part of the lesson was for students to practice the mathematics and try out different strategies independently.

The journal was the final artifact that shaped mathematics instruction. All of the teachers either had students write in a journal or respond to a reflective prompt describing their learning and successes or challenges they faced. Ms. A described,

> After we have been doing any sort of activity…they open their journals and they reflect for a few minutes and I have them identify a success or a challenge that they had and we talk about it. Or sometimes I ask them to give advice to the next class on what they learned.

In examining the artifacts, students participated in mathematics through daily routines. Through the carpet space, mathematics was communal and open to discussion. Through the worksheets, mathematics became an individual endeavor in which teachers could examine students’ thinking and skills. Finally, mathematics became a reflective process through the mathematics journal.

Discourse. Discourse accounts for the ways in which people interact with one another and discuss a particular topic in their setting. Through classroom discourse, teachers and students are able to shape and define what it means to do mathematics. There were four themes that arose surround discourse from the teachers’ perspectives: student voice, multiple strategies, problem solving, and mistakes.

All of the teachers discussed student voice in defining what it means to do mathematics in their classrooms. The students were expected to share ideas with one another and this fostered the second theme of multiple strategies. When multiple students are able to share out, the teachers stressed that there are multiple ways to do a mathematics problem. For example, Ms. C described different student hand signals she employs so students can respectfully disagree or add to another students’ thought. She stated,

> As we talk we have different signals, like (one for) something to add when someone is explaining something or if they don’t think the answer is right. So there are different hand signals so that we establish a community that’s equitable and everyone’s voice is heard and we share different ways. So kids are prompted to think about if someone did in a different way and they can learn from each other.

For each of the teachers, mathematics was more than knowing facts or solving problems correctly, it was perseverance in problem solving. They each discussed that they wanted students to leave their classrooms with the confidence to attempt problems and apply what they knew. In addition, related to this theme, they also discussed making mistakes as part of problem solving. Mr. B stated,

> I want students to be sort of fearless. They don’t worry about failing. They just jump right in and, you know, my biggest thing is taking what you know, how can I approach a problem with what I know. So I want my students to be truly confident and believe that they can do this or don’t mind failing.

Across the four themes, mathematics was framed as an activity in which multiple voices should be heard and where multiple strategies could lead to a valid solution. In addition, students were encouraged to view mathematics as a problem solving activity in which it was normal to make mistakes.

Identity. Identity is the roles that teachers and students take on during mathematics instruction. The teachers each discussed that they expected students to take on different roles. They wanted students to learn from each other and be comfortable presenting mathematical strategies. Students took on roles of learner, presenter, and teacher with varying levels of engagement in each of these roles.

The teachers primarily envisioned themselves as facilitators rather than instructors. They discussed that they observed, listened to students, and had students explain their thinking rather than instructing students on how to solve the problem or having them complete several practice worksheets. Their role was to observe student reasoning over time and help students make progress both collectively and individually.

Pressing on and Extending the Boundaries of Mathematics through Modeling

As the three teachers engaged their students in the process of mathematical modeling, they described that the process was in contrast to typical mathematical instruction. Four themes emerged in relation to pressing on or extending boundaries: access, empowerment, real world connection, and positioning.

Access. Each of the three teachers discussed that the modeling task provided access and differentiation across the class that was not typically present during mathematics instruction. At the beginning of the modeling unit, when discussing the theme of a community luncheon, all students had questions and ideas that were important to them and they wanted to investigate. Based on past experiences, all students were able to contribute and posed broad ideas like we need to consider cost, likeability, and number of people but also more personal factors like food, allergies, and best places to shop. They each had experiences that they could draw from to start the conversation across multiple perspectives. In describing this, Mr. B stated,

> I think the thing that is most incredible about modeling is watching students use what they know to solve problems, you know? Watching each individual or each group come up with a completely unique way to solve a problem and bring their individual strengths to be part of the solution. That has been really powerful.

The teachers commented that the students, by grade level, determined the mathematics they would use and how far to pursue the task. For example, when planning the luncheon, the third-grade students decided to investigate the cost of a main and side dish while the fifth-grade students planned drinks, a main dish, a dessert, a game following lunch to help build community, and how they would allocate their time across each. Individually within grade levels, students could also access the task and apply mathematical concepts that were appropriate to their understanding. For example, in fourth-grade, students decided they wanted pizza for lunch. When determining the number of pizzas needed, some students used repeated addition while others used multiplication. In describing access, Ms. C stated, “It differentiates itself just by design and kids that are at different levels can be successful at it.”

Ownership and Empowerment. The second theme that emerged was the idea of ownership or empowerment. The teachers identified that the students were able to make choices in the process of modeling. For example, when determining what beverage(s) to serve at the lunch, students surveyed one another using Google documents and found that students wanted the following: 28% root beer, 25% orange soda, 17% lemonade, 10% Cool Aid, 10% apple juice, and 8% milk, and 2% Caprisun. At first, some students proposed that they should just serve root beer because it had the highest percentage. Other students disagreed and stated that less than half of the class wanted root beer, so they should have multiple choices. In the end, the class decided they would offer the top three choices so that more people would be happy in their beverage choice. In describing the process, Ms. A stated that she tries to give students choice, but the process of modeling provides greater opportunity for student choice and ownership. She stated,

> Well (modeling) it's all about choice. I mean they choose what path they want to do or take and how they go about solving it. I try to have a lot of choice in here (my classroom) but I can only have so much, right? And modeling is different because it (the choices made) are mostly theirs and when it wasn't theirs, they didn't know that. They had this empowerment that it was them controlling where they were going.

In addition to having choices, students understood that the choices they made mattered. Whatever they decided upon actually happened. For example, in the fifth-grade class, students decided on pizza for lunch, but ran out of Hawaiian pizza before everyone who ordered it was served. In describing the situation, Ms. A., stated,

> Like the little girl who didn't get her pizza. She just assumed her math was right and when I began to think about it, I just assumed that the kids had been sneaky, but maybe their math wasn't right and we didn't order enough of that kind of pizza?... It is pretty powerful and something that we could have a future discussion about.

Although this example highlights a negative outcome, through taking on the responsibility of planning, teachers commented that students felt confidence in making decisions and then seeing their decisions become reality.

Real World Connection. A third theme that emerged was the concept of math as reality. In describing the launch of the task, Ms. C stated, "I think a lot of them didn't realize they were doing math." Because the problem was situated in reality, all three teachers discussed that students engaged and related to the mathematics with more excitement and perseverance. Mr. B discussed that students were self-motivated when investigating the lunch problem. He stated, "for fourth-grade…our lunch was really successful, you know? It's been really motivating. There is no work I have to do, you know, no encouragement I mean. We just start the process and they are excited and want to attack the problem." It is interesting to note that the lunch modeling task took about a month to complete with students working on the task a few times a week. At no point did they loose motivation or interest to finish the project. Ms. C discussed that during a typical mathematics lesson there is limited connection to the real world. She felt that the process of modeling added an additional layer of meaning to the problem. She stated,

> The real worldliness of what we were doing was key. Because a lot of math that I teach on a daily basis I feel like has no connection to the real world. I mean, maybe you can stretch it to where we are talking about candy or in a story problem dividing it up, but it kind of loses something because it's not connected to a real-world thing that means something to the kids.

The process of modeling highlighted that mathematics is more than different strategies to a particular problem. It can be used to reason about issues students face.

Positioning. The three themes above, access, ownership, and real world connection, all involve how the students perceived and engaged with mathematical content. Mathematical modeling also served as a tool to question positioning in the classroom. All teachers described that it helped to challenge students who they labeled as gifted. The modeling process often takes time and there is no one right answer which was frustrating for some students. Ms. C. stated,

> I also like that it is challenging for the kids who are considered gifted. I have a couple (gifted) kids in my class that when they wrote their reflection, they were like, "I don't like this" because

> they are so used to, even though they are only third-graders, they are so used to being right and getting the right answer…and this was out of their comfort zone. I think that was a good thing.

The process helped to challenge the idea that mathematical thinking is not always about solving problems quickly and correctly. Mathematics can be interpretive. Some students commented that they usually did not like mathematics, but they enjoyed this process.

In addition, teachers commented that modeling fostered mathematics as a community activity. Everyone could feel included and that their ideas mattered. Students could bring knowledge and experiences from outside of the classroom in to help them make decisions about the task. In describing positioning in the classroom, Ms. A stated,

> The most amazing thing to me is that everybody is able, no matter who you are, can enter the (modeling) process where you need to enter it. I just, my entire life, as a person, I have always had a hard time not including everyone and not having everyone feel like they are valued and important. And, I've, when I decided to become a teacher, as much as we like to think public education is inclusive, it's not. We have groups, pullouts and things because we need to service everybody. I totally understand, but it has always made me a little uncomfortable because I see the dynamics because of that. Roles are created. Status is created within the classroom. It's just reality and so this was the first time that I had that that "aha" moment in the class this summer when we were reading those articles. If this is how math could be in my classroom where everyone was doing mathematics and didn't have a role in this or as the really smart kid or the not so smart kid. We would all just have a part in it.

All three teachers described that modeling allowed for all students to feel that they could actively contribute to solving the problem.

Discussion and Concluding Remarks

The teacher interviews and study group notes suggest that mathematical modeling can act as means to extend and redefine students' notions of what it means to know and do mathematics. In classrooms that already valued multiple solution strategies and community-based discussion, modeling acted as a means for all students to feel that they had something to contribute. This is similar to statements made by English and Watters (2015) that students draw on their own experiences to frame the problem. Students were also empowered to view mathematics as a tool rather than seeing mathematics as the practice of skills. The mathematical choices students made mattered. In addition, this study highlights that modeling pressed on the idea that mathematics is bound to classroom instruction. Students were able to see that mathematics could help them make choices about real world decisions. Lastly, modeling challenged perceptions regarding who was capable of doing mathematics and what it meant to be successful in solving a mathematical task. In closing, if mathematical modeling adds to students' understandings of what it means to know and do mathematics, it is important to investigate ways to provide opportunities for modeling across the k-12 system as well as investigate the impact from the student's perspective.

PROBLEM DRIFT: TEACHING CURRICULUM WITH(IN) A WORLD OF EMERGING SIGNIFICANCE

Nat Banting
University of Alberta
nbanting@ualberta.ca

Elaine Simmt
University of Alberta
esimmt@ualberta.ca

In this paper we frame our observations in enactivism, specifically problem posing, to propose the notion of problem drift as a method to analyze the curriculum generating actions of small group learning systems in relation to teacher interventions intended to trigger specific content goals. Teacher attentiveness to problem drift is suggested to be valuable in advancing the content goals in small group work.

Keywords: Problem Solving, Instructional Activities and Practices, Cognition

Small group problem solving has become a stalwart for classroom teachers attempting to occasion vibrant communities of mathematical communication and reasoning. Placing students in problem solving groups creates simultaneous short-range interactions, and results in a classroom ecology dense with opportunity for the teacher to curate productive mathematical insight. However, observing teaching and learning from an enactivist stance means a teacher cannot assume that the group will interact with the content goals of a lesson along a predictable pathway. Instead, cognition is a process of continually posing problems relevant in the moment (Varela, Thompson, & Rosch, 1991). A teacher may assign a task with specific content goals in mind, but, through their action with the task, groups bring forth multiple worlds of significance (Kieren & Simmt, 2009), each of which the teacher is then required to assess for relation to the original curriculum goals. After all, the ultimate responsibility of teaching any program of study is to deliberately impact learners. This leaves the teacher with the job of monitoring how a small group encounters targeted content outcomes within mathematically rich spaces during their course of interactivity as well as coupling with that interactivity with the intention of triggering interaction with targeted content outcomes.

Here, we suggest that the observation of the problem around which the group organizes their interactivity (the problem that is posed by the learners as relevant to addressing the task as currently understood by the group) can inform a teacher's intentional attempts to impact a group's mathematical action (Proulx & Simmt, 2016). This problem posing activity of a group signals the character of their knowing, of their world of mathematical significance. The ongoing re-posing of this relevant problem is termed *problem drift* (Banting, 2017), and can be thought of as a way of observing the emerging character of a group's curricular attention. We add to Proulx and Simmt's work by analyzing problem drift and its relation to the targeted content outcomes of a lesson. This frames our observations of the world of significance brought forth by a learning system (learners, teachers, and environment inclusive) in specific relation to the intended curricular outcomes. Doing so results in a pragmatic stance with(in) the learning system that includes more than just the interactions of the group surrounding content goals, but also the patterns of action in relation to the teacher interventions offered with content goals in mind.

In this paper we explore the notion of problem drift as a method for analyzing the dynamic bringing forth of meaning among members of small groups when given a mathematical task. We explore how problem drift can provide a focus for teachers (and researchers) whose goal it is to understand the nature of mathematical meaning and how they might be purposeful in their influence of it.

Establishing Problem Drift

For the enactivist, knowing is doing (Maturana & Varela, 1987); the process of knowing and its products are one in the same thing (Pirie & Kieren, 1994). The mathematical knowledge of a group (its knowing) is not a source through which the mathematical action (its doing) is resourced or initiated. Rather, knowing/doing emerges through interaction between a subject and their environment (Proulx & Simmt, 2016). Reciprocally, through these interactions from which knowing emerges, the environment is continually shaped (hence co-emerges), and, in return, triggers further possibilities for action. It is through this process that meaning is brought forth. Therefore, knowing emerges out of context. The coordination of learner and environment is not fully in the agent nor the environment, but emerging from the interaction between the two, constituting an emerging world of significance (Kieren & Simmt, 2009); this is the image of knowing and learning with(in) an environment. The learners do not interpret their context in multiple different ways, which would imply that the environment remains static as the learner constructs an impression of its character. Rather, through the mutual triggering of environment and agent, the learners' knowing—that is to say, doing—brings forth distinct worlds of significance. It is through this lens that content outcomes are recast in active terms. In other words, claiming that a specific skill (like "creating equivalent fractions") is *known* means that it must emerge as relevant; it must be enacted.

The mutual specification of problem (environment) and problem solver (learner) means that "we do not choose or take problems as if they were lying out there, independent of our actions, but we bring them forth" (Proulx, 2013). Action of a learner is not dictated or prescribed by the environment, but a learner's structure allows certain features of the environment to become problematic, curious, or interesting. These worlds are maintained through the ability of the learner, in this case, the learning group, to pose problems relevant to its needs at that moment (Varela et al., 1991), where that relevance is contextually and structurally determined (Maturana & Varela, 1987) and the action triggers a furtherance in the posing. In other words, for the enactivist, problems are not given (by the teacher); problems are posed (by the learner). It is through the posing of the problem deemed relevant in the moment that the problem environment and the learning action of the problem solver co-dependently arise. This evolution of the problem posing constitutes the problem drift of the learning system. Because problems are not ready-made, determining what problem has been posed as relevant provides the context in which the group is acting—what meaning they have brought forth. Problem drift details the relevant problem posed by a learning system in order to analyze its knowing action, a sort of trace of mathematical knowing.

It seems that we arrive at a fundamental tension between the responsibility (for the teacher) to provide problems pertaining to a specific set of outcomes as delineated by a curriculum document and the enactivist notion of problem posing—the recognition that learners enact the nature of the task by entering into interaction with it. It problematizes the role of problems to prescribe content outcomes. Rather, teachers design prompts in anticipation that the structure of the task will trigger action that is observed to be mathematical. Teachers then become fully complicit in bringing forth the world(s) of significance by participating in the meaning making (Proulx, 2010). In other words, the teacher does not stand aside and perturb the world of significance of the learners, the teacher participates in the becoming as a fully coupled agent. Conceptualizing knowing in this fashion co-implicates the teacher in the generation of significance. In this sense, the enactivist notion of problem posing does not consider the process of learning as helter-skelter and unbridled where the teacher has little-to-no influence. Such an image would be unapologetic to the project of schooling. Rather, enactivist cognition heightens the role of teacher as one who participates fully in the action—provoking, triggering, orienting, and influencing the learning system. The task of teaching becomes the tethering of the emergent problem posing the group undertakes to bring forth a world of significance to the anticipated content goals built into the task.

Problem drift sits at the crossroads between the enactment of a problem and the mathematical products required by a curriculum; it provides a method to analyze the curriculum a group brings forth. It allows an observer snapshots in the action that can be analyzed for the mathematical processes that were used to address the relevant issues that emerged through their interaction with the task. In short, problem drift allows us to observe the curricular outcomes emerge to address the problem(s) posed as relevant (Banting, 2017).

Methodology

The teacher participants for this study were recruited through previous professional relationships. Using a design research approach (Prediger, Gravemeijer, & Confrey, 2015) with specific attention on the tenants of enactivist methodology (Reid & Mgombelo, 2015), the daily instruction in two classrooms (belonging to two different teachers) was designed around small group tasks completed by students working in randomly-created groups of three. During the study, video data from the workstations of three randomly-chosen small groups was recorded on five separate occasions for a total of of fifteen accounts of group problem solving.

Three adults—a researcher, a classroom teacher, and a pre-service teacher partnered with the classroom teacher for the semester—took on the role of teacher during the classroom episode under analysis here. After each classroom session, a debriefing was audio recorded that included all three teachers. In it, they discussed what they observed in regards to the character of the groups, the interventions they offered, and the reasons behind their choices.

Portions of the action of Brock, Ria, and Sharla (pseudonyms used) is detailed as they worked together on the Tile Design task in their grade nine mathematics course which contained twenty-seven students, or nine groups of three. The Tile Design task asked students to create a series of shapes with colored square tiles to satisfy requirements given to them by a series of stage cards. The task was designed to provide occasions for students to work with two content outcomes:

- Creating equivalent fractions
- Comparing and reasoning about fractions in a part-whole model

Results

In what follows, we detail the action of Brock, Ria, and Sharla (along with the teachers) with interlacing dialogue, artefacts of their doing (images depicting the tile arrangements on their workspace), and description of teacher interventions with the intention of triggering interaction with the content outcomes of the task. For the sake of brevity, only a portion of their action (divided into three episodes) is provided.

In the first episode, the group was required to create a shape where one twentieth was yellow, one quarter was green, one half was blue, and the remaining was red. Dialogue begins after the group had arrived at an initial arrangement (Figure 1).

Teacher: Is that half blue?

After a quick glance of their arrangement, the group was unanimous that the shape was not half blue, and a student removed two blue tiles to leave the arrangement in Figure 2.

B	B	B	B	B	Y	G	G
B	B	B	B	B	G	G	G

Figure 1. Initial arrangement.

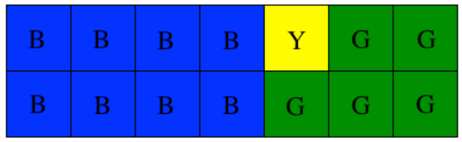

Figure 2. Altered arrangement.

Brock: This is only 14!
Ria: We need 20 tiles.
Sharla: Because the common denominator is 20?
Teacher: What were you going to say, Ria?
Ria: You need 20 tiles because the denominator, the common denominator is 20.
Brock: Yeah. It doesn't equal 20.
…
Ria: You add other blues.
Sharla: If you add, then you have to add in more. But then you have to add in another colour. Add another colour.
Brock: Wait, how many green do we have?
Sharla: We need to add in more green then if you added more blues.
Ria: Which means we have to add more yellow because it has to be equal.
…
Emma: Well, if blue is supposed to be one half, and green is supposed to be one-quarter, then green has to be half the size of blue because one half can be split up into two quarters and if this is one quarter it should be half the size of blue.

Shortly thereafter, a second episode was prompted when the group was provided with a new stage that required them to create a shape that was at least one half red, at least one quarter green, and no more than one sixth yellow.

Brock: At least means it has to at least be a half, right? Okay, so let's make it a common.
Ria: Let's just say this is half.
Brock: Let's do 12. Want to do 12?
Ria: Yeah, sure.
Brock: Okay. So half of 12 is 6. So we have to at least have 6 red.
Ria: Can I make the shape this time?
Brock: No more than one sixth is yellow. 2. And then at least one fourth is green.
Sharla: So that would be.
Ria: 3.
Brock: It has to be 3. Umm. Put one more yellow. It has to be like this. Make sure that's good.
Ria: So if its. We're using 12, then there can only be 2 yellow, right?
Brock: What?
Ria: We're using 12 and there can only be 2 yellow.
Brock: Yeah, but, at least. Oh yeah. K yeah, so that works.

The arrangement resulting from the second episode appears in Figure 3. The new stage did not trigger the group action away from the insistence of using a specific number of tiles, that equal to the lowest common denominator of the stage's requirements. In an attempt to trigger further action, a teacher removed a single green tile from the group’s arrangement (Figure 4) prompting a third episode.

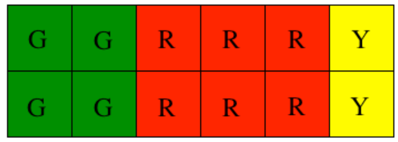

Figure 3. Initial arrangement.

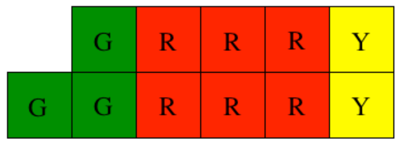

Figure 4. Teacher-altered arrangement.

Teacher: What if I did this? Does that still work?
Sharla: No, because he.
Ria: No, because this is less than a quarter now.
Sharla: No, it’s not.
Brock: No, it’s a quarter.
Ria: No, but it’s still not a quarter of this.
Brock: But it doesn’t equal 12.
Ria: Exactly, so you need that.

Analysis

The group’s action was analyzed using the notion of problem drift. That is, we, as observers, interpreted the relevant problem that was posed by the group as they worked through the stages of the Tile Design task. (For a more detailed explanation regarding the method of analysis, see Banting, 2017.) During the action detailed here, three relevant problems were determined to emerge and compose the group’s problem drift. In other words, we deciphered these episodes to each contain a unique problem posed as the group transformed—brought forth—mathematical meaning. The group’s action in the episodes detailed above was organized around the following pathway of problem drift:

- How can we meet the requirements by using 20 tiles?
- How does the *at least* requirement affect our 12-tile solution?
- Can we satisfy the requirements without using 12 tiles?

We now turn our attention to the important connection for the teaching of mathematics that emerged when the action of the group was analyzed by characterizing its problem drift. Analyzing problem drift allowed us to observe the group’s mathematical doing in relation to the teacher actions as they coupled with the learning system. Specifically, in the third episode detailed here, problem drift provides an explanation as to why a teacher intervention, while attempting to trigger mathematical action around a specific content goal, failed to do so.

Problem Drift Informs Content Goals

The problem drift reveals the group to be operating in a productive space with regards to the intended curricular outcomes. That is, the creation of equivalent fractions and the comparison and reasoning about the sections of a part-whole model have emerged as processes to address the problems posed as relevant in their context. We see this knowing/doing in two regards. First, the group consistently computes targeted common denominators. Specifically, they identify the lowest common multiple of the denominators in the stage's requirements, and execute the algorithm for creating equivalent fractions. This is how the group arrives at the 16-tile arrangement in Figure 1. The group converted one half, one quarter, and one twentieth into ten twentieths, five twentieths, and one twentieth respectively, only to lose focus on the size of the whole and assume that ten blue, five green, and one yellow would constitute the desired solution. We see it again in the 12-tile arrangement in Figure 3. These actions show that, when it is deemed to address a relevant problem, the group can execute this process.

Second, problem drift allows us to analyze the knowing at a deeper level by interpreting what problem caused the creation of common denominators to become relevant. The group calculation of equivalent fractions emerges while acting with the problem, "How can we meet the requirements by using 20 tiles?" The algorithm to create equivalent fractions is brought forth through a need to establish how many tiles they should use to create their arrangement. Before they begin to reason about the size of each part, they need to first establish the size of the whole.

Through the analysis of problem drift, we interpret that the group knows that equivalent fractions can be used to establish a whole because their doing surrounds the establishment of that whole. That is, the group understands the problem as one where a specific size of the whole (first twentieths and then twelfths) needs to be established. Creating equivalent fractions accomplishes that goal. The problem drift allows us to observe the curriculum outcome in the context from which it emerged as relevant (in active terms) and not simply as a skill that can be executed. It provides context as to why the group feels equivalent fractions are suitable; we begin to see the place of equivalent fractions in their emerging world of significance.

In the second episode the group was left with eleven of twelve tiles assigned a definite color after computing common denominators. They then began to address the remaining tile's worth of "empty space" by posing, "How does the *at least* requirement affect our 12-tile solution?" Throughout their action, there is no wavering in their understanding that they must work from a well-established whole. They reason about the possibilities of adding the different colors (attempting yellow, rejecting yellow, and eventually settling on the addition of a green) within the frame of the posed problem. In this sense, their reasoning about the size of fractions emerges within the context of filling in empty space left by the firm establishment of the 12-tile whole. The problem drift allows us to observe that the group knows that there are certain restraints in adding colors to an arrangement with a fixed whole. Throughout the episode here, analyzing the problem drift of the group allowed us to observe their dynamic mathematical doing tethered directly to content outcomes. Not only do we observe the direct execution of mathematical processes, but we also observe the world of mathematical significance in which these processes emerged as relevant.

Problem Drift Informs Teacher Action

The problem drift of the group in reaction to the teacher's decision to trigger action by removing one of the green tiles reveals the world of significance brought forth by the group. In the post-session interview, the teacher explained that they observed the group creating equivalent fractions, but their action never required them to compare the size of two fractions. With an eye to this content goal, the teacher hoped that removing a single green tile would trigger the group to compare the new fractions (now with a denominator of eleven) to the requirements of the stage. Having witnessed the group create equivalent fractions previously (creating equivalent fractions was a part of their structure), they assumed the intervention would result in a furtherance of this skill.

The third episode details how the group interacts with the intervention. The group not only fails to reason about the size of fractions using common denominators, they dismiss the new arrangement as impossible and the intervention as borderline nonsensical. Analyzing the group action through their problem drift reveals a possibility as to why. While the teacher assumed that the group would be triggered into further creation of equivalent fractions, they failed to take into account the context from which the creating of equivalent fractions initially emerged as relevant for the group. The group knows common denominators as an important process for establishing the whole; they do not know them as a process to compare unfamiliar fractions. This knowledge of equivalent fractions was never a part of their world of significance. In their understanding, equivalent fractions are a process to create the whole, not to compare sizes of constituent parts. That is why an intervention attempting to trigger action around such a concept was foreign. The teacher treated the creation of equivalent fractions as a skill held by the group, and did not interpret their action as brought forth with(in) a specific context. Problem drift allows us to re-conceptualize the reaction of the group to the trigger. They did not ignore the invitation because they were unable to execute the creation of a common denominator. As detailed previously, they do exactly this several times throughout the episodes. They ignore the invitation because the trigger was foreign to the world of significance they had brought forth.

For them, in their world of significance, the problem was one of establishing a whole and then assigning the parts to meet the requirements. This is evident through their problem drift. It is the symbolic equivalent to determining a fixed denominator and then adjusting the numerators of each section until the requirements are met. By removing a tile, the intervention asked the group to alter the established whole—to adjust the denominator instead of the numerator. Their reaction does not indicate a lack of skill, but rather that the anticipated interaction was not relevant to the problem they posed. The teacher’s anticipated vision was incompatible with the group’s world of significance. In other words, analyzing problem drift reveals the group’s preoccupation with establishing the whole, and why an intervention that suggests they do otherwise did not sponsor the desired action surrounding content outcomes. This does not suggest the intervention was an example of bad teaching (Towers & Proulx, 2013); it simply did not coordinate with their enactment of the problem—it was irrelevant.

Discussion

Problem drift is a method for analyzing the dynamic bringing forth of meaning. It provides a focus for teachers (and researchers) whose goal it is to understand the nature of mathematical meaning and how they might be purposeful in their influence of it. It focuses the search for emergent knowing on the nature of a learner’s doing.

The teaching intervention of removing a green tile did not have the desired curricular effect, but that is not to dismiss it as having no effect. Through their intervention, the teacher acting with(in) the world of significance provided a possibility by suggesting that shapes of different sizes could meet all the requirements of the stage. The structure of the group, and their world of significance evidenced through their problem drift, did not allow that possibility to become problematic, and it was treated as foreign or nonsensical. In order to trigger the desired content outcomes, the possibility of different sizes of shapes would need to first become relevant to their structure before becoming enacted into the group’s world of significance. Understanding this provides an avenue for the teacher to attempt further triggering.

We do not suggest that understanding problem drift will make the group response to a teacher intervention *predictable*. Instead, we suggest that identifying the problem that has focused action—

that is, become relevant—makes teacher interventions *accessible*. Problem drift speaks to what the group knows because it analyzes what they have done—what problems they have posed as relevant and their relation to the intended curricular outcomes. It is a way of viewing emerging knowing/doing and assessing whether the desired content outcomes have become a part of that action. It is a way of attuning to the group's structure and situating teacher inter-actions therein. Here, we propose that attuning to problem drift is a critical piece to inform teacher interventions designed to advance the content goals of a lesson. It switches the orienting question of teaching from "*How did they solve the problem?*" to "*What problem are they solving?*" The former assumes the problem was engineered to meet certain curricular requirements, while the latter sits at the crossroads between emerging meaning and curricular mandates—that which has become relevant in the moment.

REFORMULATION OF GEOMETRIC VALIDATIONS CREATED BY STUDENTS, REVEALED WHEN USING THE ACODESA METHODOLOGY

Álvaro Sebastián Bustos Rubilar
Cinvestav
abustos@cinvestav.mx

Gonzalo Zubieta Badillo
Cinvestav
gzubieta@cinvestav.mx

In this article, we report how a geometric task based on the ACODESA methodology (collaborative learning, scientific debate and self-reflection) promotes the reformulation of the students' validations and allows revealing the students' aims in each of the stages of the methodology. To do so, we present the case of a team and, particularly, one of its members who expresses the intention of reformulating validations for a mathematical conjecture besides showing evolution in the form of justifying.

Background and research problem

For some decades, the teaching and learning of proof have been studied by a number of mathematics education researchers to promote their learning (De Villiers, 2010; Hanna, 2000, among others) and identify and classify the procedures provided by the students when developing tasks in which they have to prove (Balacheff, 1987; Bell, 1976). The works by these authors consider that students in general show difficulties when they are asked to prove a mathematical statement or mathematically justify their statements. Proof is probably the only accepted way of validation among mathematics scholars. However, in a context of teaching and learning, students are not necessarily expert in the matter and will not become professional mathematicians (Legrand, 1993). This means that, when asking students to prove, we will probably find that what they consider will be far from what is accepted as proof by a professional or a scholar. Considering that, our research uses the term validation to refer to what a student may provide to justify a mathematical statement. We understand this validation as a dynamic process we expect to evolve according to the context in which the student works.

The aim of this work was to determine how the validation created individually by a student is reformulated and improved when working with tasks based on the ACODESA methodology proposed by Hitt (2007). To do so, we raise the following research question: How does a validation change from its written formulation by a student, its subsequent study by a team and debate by the class, to its final reconstruction in a process of self-reflection?

Theoretical References

In this study, we consider the term validation as a process through which a proposition or mathematical statement is validated, as Balacheff (1987) explains. He considers that proving is the intellectual activity, not entirely explicit, that deals with the manipulation of the given or acquired information to produce new one, aiming to ensure the truth of a proposition. The validation can be expressed in different ways: explanation, argumentation, proof or demonstration. All of them can vary or evolve, according to the context in which the student works. Therefore, as Brousseau (2002, p. 17) states:

> The didactical situation must lead them to evolve, to revise their opinions, to replace their false theory with a true one. This evolution has a dialectic character as well; a hypothesis must be sufficiently accepted—at least provisionally—even to show that it is false.

Accepting a form of validation will depend on the mastery of knowledge each student possesses as well as the social environment and how close he or she is to the validation criteria of the community where the validation occurs. This last element is of great importance since the validity of a proposition must be accepted by the student and his or her social environment. Above all, the validity must be guided by the validation criteria of the discipline—mathematics, in this case. The description of the different forms of validation, according to Balacheff (1987), are the following:

Explanation. Discourse with which the truth of a position or result previously acquired by the speaker is clarified.

Argumentation. Discourse aimed to obtain the listener's consent.

Proof. Explanation accepted by a community that can be rejected by another. It may simultaneously evolve with the advance of the knowledge on which it is based.

Demonstration. It is a series of statements organized according to a well-defined set of rules.

To identify and then categorize the validations produced by the students, we used the typology of levels and types of proof by Balacheff (1987):

Naive empiricism. It occurs when the student asserts the validity of a statement after verifying it in particular cases. The student's resistance to generalization is evident in this type of proof.

Crucial experiment. The student verifies with the least particular example he or she can manage. In this type of proof, the student explicitly generalizes from the example with which the statement is verified.

Generic example. The student provides an example representing the generality; that is, an example that is not considered a particular case but a representative of a type of cases for which the statement is true. In this type of proof, operations and transformations of the mathematical object explain why the statement is valid.

Thought experiment. The student explains the reasons through the analysis of the properties involved in the statement, decontextualizing it and taking it out from a particular representation.

Calculation on statements. Intellectual constructions based on more or less formalized or explicit theories, created in a definition or property. They are based on the transformation of symbolic expressions. This type of proof ranges from the thought experiment to the proof.

Balacheff (1987) groups the types of proofs, described above, in pragmatic and intellectual. On one hand, the naïve empiricism, the crucial experiment and the generic example are pragmatic proofs: they resort to action and concrete examples. On the other hand, the thought experiment and the calculation on statements correspond to intellectual proofs, given that they are supported by the formulation of mathematical properties set in play and the relationship between them.

Methodology

Students of a Master of Educational Mathematics participated in the study for two sessions of two hours each. In each session, two video cameras were used to record an overall view of the classroom and specific moments. Additionally, dialogs between the students were recorded using a voice recorder.

The task implemented was designed and organized according to the principles of the ACODESA methodology (Hitt, 2007), which allows promoting collaborative learning through social interaction and the use of technology. As a result, processes of conjecture, argumentation and validation are created in the classroom (Hitt, 2011; Hitt, Saboya, & Cortés, 2016). The ACODESA methodology has five stages:

1. Individual work. The student develops the task individually using paper and pencil.

2. Teamwork. The students work in teams of three or four members. Each member presents a solution and justifies the response to the problem in front of his or her peers to create a solution as a team.
3. Debate. Each team presents its proposal in front of all the class. The guidelines to the debate used in the ACODESA methodology must be in accordance with what Legrand (1993) stated.
4. Self-reflection. The students carry out a process of reconstruction of the task. This stage is important because, as Hitt y González-Martín (2014) and Hitt et al. (2016) state, the consensus obtained in the previous stage might be provisional for some students. Therefore, every student has to reconstruct the solution individually using paper and pencil, considering what has been done in previous stages.
5. Institutionalization. The teacher presents the institutional solution to the task in front of the students. To do so, the teacher summarizes what was done in previous stages and highlights the solutions proposed by each team.

The general aim of the task was to create a work environment in which the students could conjecture and then validate such conjectures both individually and in teams. With the activity, we sought to identify the types of validations provided by the students when working on the different stages of the ACODESA methodology. Then, we determined how their validations evolved from the individual formulation to the moment they were shared and discussed during teamwork in a plenary session and up to the moment when they were reconstructed by the student in the self-reflection stage. Due to space limitations, in this article we only report part of the results of the task. The statement in the task and the questions were as follows:

> A parallelogram is known to be a quadrilateral whose opposite sides are parallel. If you choose any given parallelogram and draw the respective diagonals, four triangles will be formed; then,
>
> - What can you say regarding the areas of the four triangles? Justify your response in detail and do not forget to mention which parallelogram you chose.
> - Are your responses above independent from the type of parallelogram you choose? Why? Justify your response in detail.

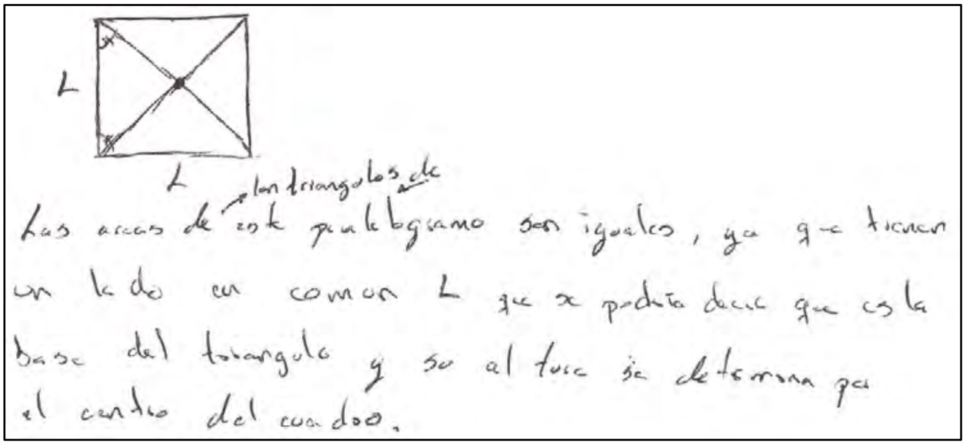
The first question aimed for the students to conjecture and validate for the particular case of a parallelogram. The objective of the second question was to make the students generalize their conjecture and then, validate it. To differentiate between their responses in the different stages, the students were asked to use a black ballpoint pen for the individual work, a red one for the teamwork and a blue one for the debate stage.

Analysis and Result Discussion

In this section, we present the case of Alex, a student whom we considered the most representative of the group in which the task was implemented. The analysis was carried out according to the stages of the ACODESA methodology.

Individual Work

Alex chose a square to formulate the response. To do so, he drew a general representative and assigned a measure L to each side (Figure 1). The student then conjectured that the areas of the four triangles formed randomly when drawing the diagonals were equal.

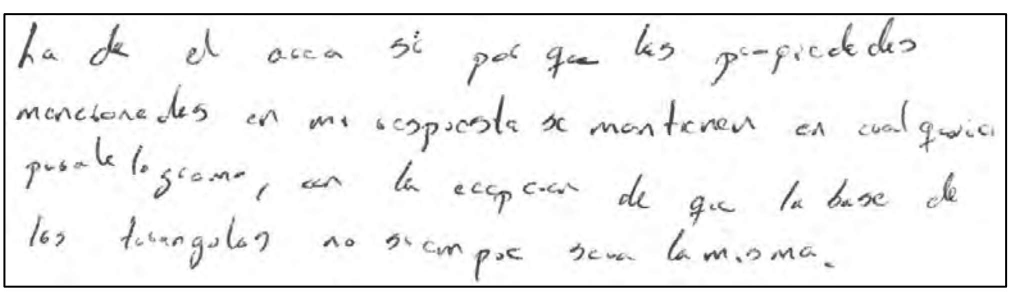


The areas of the triangles of this parallelogram are equal since they have a side L in common, which might be said to be the base of the triangle, and its height is determined by the center of the square.

Figure 1. Particular solution provided by Alex.

The student's strategy was to justify that the areas are equal because the four triangles have the same base and height. In his response, we identify two statements to achieve his objective: (1) the four triangles have equal base because L is a side of the square, and (2) the height of each triangle is determined by the center of the square.

The student justified the first statement through one of the properties of the square (equal sides). For the second statement, related to the congruency of the heights of the four triangles, Alex did not mention nor justified the property that allowed him to say the intersection point of the diagonals was the center of the square. Although his statements are valid, Alex omitted middle justifications (second statement). Regardless, we consider this validation to be a proof corresponding to the incomplete thought experiment, given that the student based the arguments on a general representation of the squares and presented (incomplete) justifications when he applied properties involved in the chosen parallelogram. In the response provided by the student for the second answer, in which he was induced to generalize, Alex claimed that his conjecture (regarding the square case) was independent from the type of parallelogram chosen; that is, the equality of the areas of the four triangles is met for any parallelogram (Figure 2).



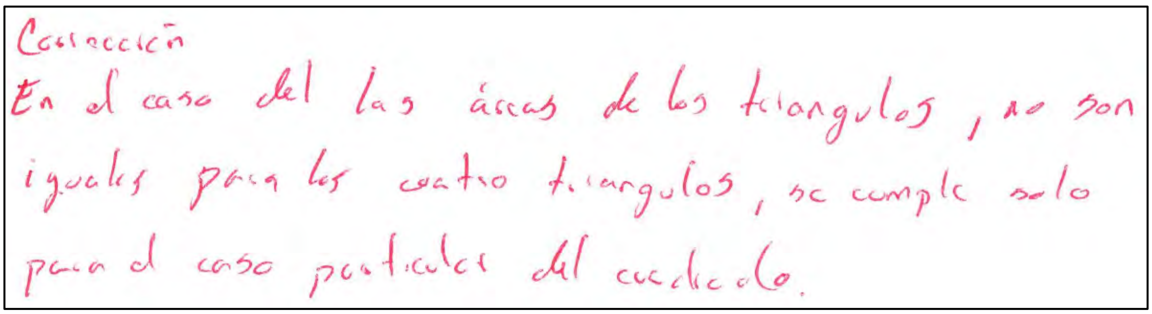
Yes to the one of the area because the properties mentioned in my response are maintained in any parallelogram, except that the base of the triangles is not always the same.

Figure 2. Generalization provided by Alex.

Alex correctly generalized the conjecture since the four triangles will always have the same area. However, when justifying the new conjecture—general conjecture, hereafter—we observe that the student supported his argument on the validation created for the case of the square. In consequence, we infer that the student believed that validation was also true for any parallelogram. Then, we have a generic example-type of proof because the validation of the general conjecture, which refers to all parallelograms, would be supported by the validation Alex created for the square case, which is only a representative of a type of the parallelogram family.

Teamwork

The other two members of the team, S1 and S2, created their own responses from a rectangle and a general parallelogram, respectively. Both students conjectured that only opposite triangles have equal areas and were adamant that the square is a particular case. Unlike Alex, they created thought experiment proofs based on the consistency of triangles. Although Alex conjectured that the four triangles would have equal areas in all parallelograms, he did not say so to his teammates and corrected his conjecture on the answer sheet (Figure 3), but did not create another validation.



Corrección
En el caso del las áreas de los triangulos, no son iguales para los cuatro triangulos, se cumple solo para el caso particular del cuadrado.

Correction
In the case of the areas of the triangles, they are not equal for the four triangles, it is met only for the particular case of the square.

Figure 3. Correction written by Alex during the teamwork stage.

Debate

During the debate, the students first discussed whether the four triangles or only opposite ones had equal areas. Once the teams presented their responses, the consensus of the debate was that, in any given parallelogram, the four triangles formed would always have the same area. The validation agreed on by all the students was based on congruency of triangles to justify the equality of the opposite triangles and the property of diagonals (the diagonals intersected each other) to justify the equality of the areas of adjacent triangles. After this, Alex corrected his response once more (Figure 4) and went back to his general conjecture—the one he had discarded during teamwork. He then expressed that the argumentation for such conjecture had to be changed. From his response, we infer that, after listening to different responses in this stage, Alex obtained more arguments to create a new validation for his general conjecture, although he only did so in the following stage: self-reflection.

Recorrección

La idea de que las areas eran iguales en los cuatro triangulos era correcta, (la argumentación cambia).

Se puede mostrar que son iguales tomando como base la parte de la diagonal de cada triangulo

Re-correction

The notion that the areas were equal in the four triangles was correct (the argumentation changes).

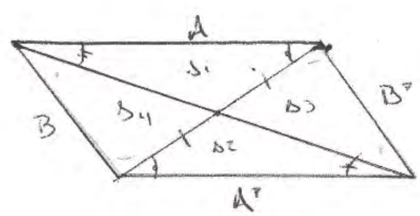
We can prove that they are equal based on the diagonal part of each triangle.

Figure 4. Correction created by Alex in the debate stage.

Self-Reflection

In this stage, we observed a more solid validation (Figure 5) than the one created by the student during the individual work stage.

Después de lo visto en clase, se puede considerar un paralelogramo general como el siguiente:



- Por intersección de paralelas tenemos que: $A = A'$ y $B = B'$
- Por el criterio de congruencia ALA (angulo lado angulo), concluimos que los triangulos Δ_1 y Δ_2 son congruentes. Es decir, $A\Delta_1 = A\Delta_2$.
- Análogamente se analizan los triangulos Δ_3 y Δ_4, concluyendo que $A\Delta_3 = A\Delta_4$.

Ahora bien, se sabe que el centro del paralelogramo divide a las diagonales en dos segmentos iguales, entonces, se observamos los triangulos Δ_2 y Δ_3 tienen la misma base y la misma altura por lo que $A\Delta_2 = A\Delta_3$

Por lo tanto $A\Delta_1 = A\Delta_2 = A\Delta_3 = A\Delta_4$ para cualquier paralelogramo

After what we checked in class, a general parallelogram can be considered as follows:

- By the intersection of parallels, we have that: $\boldsymbol{A} = \boldsymbol{A^T}$ and $\boldsymbol{B} = \boldsymbol{B^T}$.
- By the ASA (angle, side, angle) congruency criterion, we conclude that the triangles Δ_1 and Δ_2 are congruent, that is, $\boldsymbol{A}_{\Delta_1} = \boldsymbol{A}_{\Delta_2}$.
- Likewise, triangles Δ_3 and $\Delta_4$are analyzed, concluding that $\boldsymbol{A}_{\Delta_3} = \boldsymbol{A}_{\Delta_4}$.

That said, the center of the parallelogram is known to divide the diagonals in two equal segments, so, if we observe triangles Δ_2 y Δ_3, they have the same base and the same height, then $\boldsymbol{A}_{\Delta_2} = \boldsymbol{A}_{\Delta_3}$.

Therefore, $\boldsymbol{A}_{\Delta_1} = \boldsymbol{A}_{\Delta_2} = \boldsymbol{A}_{\Delta_3} = \boldsymbol{A}_{\Delta_4}$ for any parallelogram.

Figure 5. Validation created by Alex during the self-reflection stage.

Alex used triangle congruency as his first argument to justify the equality of the areas of opposite triangles ($A_1 = A_2$ and $A_3 = A_4$ in the parallelogram in Figure 5); such argument arose during the teamwork stage. The student then used the property of diagonals to justify the equality of the areas of adjacent triangles ($A_2 = A_3$ in the parallelogram in Figure 5); he built this argument during the debate stage. Alex returned to his general conjecture while his validation did not depend on a particular representation anymore. Then, it was a proof of the **type calculation on statements** since Alex based his statements on the definition and properties of the parallelogram.

Conclusions

In the individual work stage, we observed that the student created a thought experiment proof to validate his conjecture regarding the square case. However, when he generalized, his validation became a generic example proof. In the teamwork stage, Alex did not expressly wrote any reformulation to his validations, but did alter his general conjecture (Figure 3). During the debate stage, he went back to his general conjecture and gave indications that the validation had to change.

If we consider that the general conjecture created by the student (the four triangles have equal areas), the validation he created in the individual work stage corresponds to a generic example, a pragmatic proof. In contrast, during the self-reflection stage, the student built an intellectual proof for the same conjecture; it was a calculation on statements and included arguments that arose during the teamwork and debate stages. This revealed a noticeable change between his individual work and self-reflection to validate the same conjecture, given that his validation went from a pragmatic level to an intellectual one. We can credit this to the ACODESA methodology, as indicated by Hitt et al. (2016). An adequate environment was created for the students to conjecture and validate in a context of social interaction.

On the other hand, during the teamwork stage, Alex provisionally rejected his conjecture after listening to his classmates' arguments. This situation probably took place because Alex did not have the necessary arguments in that moment to persuade his team of the veracity of his conjecture. Regardless, this situation was overcome in the debate stage, during which all the students agreed that the four triangles would always have the same area despite the type of parallelogram used. In the previous chapter, we observed how the didactic situation led the students to evolve, as defined by Brousseau (2002), both in the initial conjecture and the arguments used for its validation.

Most of the students rationally justified their assertions, both in the individual and the group stages. Additionally, we observed an environment of discussion around the arguments used to defend the different statements that arose during the development of the task, especially in the debate stage.

THE INTERSECTION BETWEEN QUANTIFICATION AND AN ALL-ENCOMPASSING MEANING FOR A GRAPH

Irma E. Stevens
University of Georgia
istevens@uga.edu

Kevin C. Moore
University of Georgia
kvcmoore@uga.edu

Quantitative reasoning plays a crucial role in students' and teachers' successful modeling activities. In a semester-long teaching experiment with an undergraduate student, we explore how her conception of a graph plays a role in her ability to quantify and maintain quantitative structures. We characterize here Lydia's conception of a graph as one in which the graph entails several quantities she identified in a given dynamic situation, contradicting the conception of a graph as a representation of a multiplicative object consisting of only two quantities. We also discuss her thinking about her graph in terms of figurative and operative thought during a session in which we support her in disembedding and graphically representing quantities.

Keywords: Geometry and Geometrical and Spatial Thinking, Curriculum, Modeling, Teacher Education-Preservice

Introduction

Quantitative reasoning is a crucial component to students and teachers establishing productive meanings (Thompson, 2013). Researchers, however, have found that students' meanings for functions and their graphs lack reasoning about relationships or processes between quantities (Dubinsky & Wilson, 2013; Lobato & Siebert, 2002; Oehrtman, Carlson, & Thompson, 2008; Thompson, 1994b), which ultimately influences students' representational activities. For example, Moore and Thompson (Moore & Thompson, 2015; Thompson, 2016) characterized students' non-quantitative graphing activities in terms of *static shape thinking* (i.e., treating graph-as-wire and focusing on physical features of situations and graphs). During a semester-long teaching experiment, we noted that one of our participants, Lydia, seemed to have a particular meaning for graphs that not only entailed remnants of the static shape thinking discussed by Moore and Thompson, but also included thinking of a graph as containing an abundance of information she perceived in a situation. This latter meaning became problematic as Lydia progressed through the teaching experiment. In this paper, we explore how Lydia's meaning for graphs influenced her reasoning and how quantification and establishment of a graph as a representation of *two* quantities supported her in reasoning quantitatively about the sine and cosine relationship and their graphical representations.

Background and Theoretical Framework

This paper focuses on the intersection of quantification and the consideration of a graph as a multiplicative object. It is important to note that as we define these words, we are operating under the assumption that knowledge is actively constructed in ways idiosyncratic to the knower (von Glasersfeld, 1995). Because of this perspective, we view quantities—conceptions of a specific quality of an object that entails the quality's measurability (Thompson, 1994a)—as personally constructed measurable attributes (Steffe, 1991; Thompson, 2011). Moore and Carlson (2012) highlight the significance of this perspective by arguing that the relationships an individual constructs between quantities depends on her understanding of the quantities and, relatedly, the transformational nature of her image of how these quantities constitute a situation.

Before determining relationships between quantities, one must establish quantities through a process called quantification. Quantification is "the process of conceptualizing an object and an attribute of it so that the attribute has a unit of measure, and the attribute's measure entails a proportional relationship (linear, bi-linear, multi-linear) with its unit" (Thompson, 2011, p. 37). Consider the Ferris wheel in Figure 1; more specifically, let the object under consideration be the green cart (or more precisely, a point on the Ferris wheel that represents the location of the rider on the wheel). There are many attributes one could observe: colors, shapes, motions, etc. These attributes become a quantity when they are measurable; that is, a quantity is understood as a magnitude or amount-ness, such that it entails a unit or dimension and a way in which to assign numerical value to the magnitude or amount-ness. Note that the process of measuring does not need to be carried out in order for the attribute to be considered a quantity. Some quantities in the Ferris wheel situation include the distance the green cart is above the centerline, the arc length the rider is from the 3 o'clock position on the Ferris wheel, and the speed the rider has traveled. Reasoning about relationships between quantities is termed quantitative reasoning.

A graph is a way for students to represent the relationships between quantities they perceive in a situation. More specifically, a normative Cartesian graph defines a *pair* of quantities—directed lengths—via axes, and each point on the graph is a uniting of two quantity's magnitudes. A cognitive uniting of the two quantities in a given situation is necessary either to construct or to interpret a point on a graph in the aforementioned way. This cognitive uniting of magnitudes is what Saldanha and Thompson (1998) referred to as constructing a multiplicative object. This notion of a multiplicative object stems from Piaget's notion of "and" and as of a multiplicative operator (Piaget & Inhelder, 1963). For instance, the sine relationship can be considered as the cognitive uniting of the vertical distance above the horizontal diameter and the arc length traveled around a circle (both measured relative to the radius of that circle).

A conception of a graph as a multiplicative object along with a robust quantification process is necessary for thinking of graphs operatively (Moore, 2016). Piaget (2001) distinguished between two types of thought, figurative and operative thought. He characterized the former as thought constrained to sensorimotor experiences and perception and the latter as one that prioritizes the coordination of mental operations over figurative activity. For example, conceiving the sine graph as a multiplicative object is an example of operative thought due to the conception entailing the coordination of mental actions in the form of quantitative operations. Static shape thinking is an example of figurative thought, as such thinking is dominated by elements of sensorimotor experience and perception to the extent it does not necessarily entail a relation to Cartesian axes (Moore & Thompson, 2015).

Methods

The results of this study come from a teaching experiment (Steffe & Thompson, 2000), in which we worked with three students (two female, one male) across 10-11 videotaped teaching sessions lasting 1-2 hours. The sessions occurred over the course of a spring semester at a large public university in the southeastern U.S. We conducted two sessions with all three students present. All other sessions included one student with at least two research team members. The students were in their first semester of a four-semester secondary mathematics education program, enrolled in both a content course and a pedagogy course. The students had all completed at least two additional courses beyond a traditional calculus sequence with at least a C as their final grade. We selected students from their first content course based on the research group's analysis of their results on an adapted 1-hour version of Thompson's *Project Aspire* assessment, *Mathematical Meanings for Teaching Secondary Mathematics (MMTsm)* (Thompson, 2016), which focused primarily on questions related to rate of change, interpretation of graphs, symbolic notation, and proportion. The research group analyzed the assessments and identified three students who, from the researchers' perspectives, provided a range of responses and communicated their thinking clearly in their written responses. The three students then agreed to participate in the teaching experiment and were monetarily compensated for their time. The principal investigator of the project was the teacher-researcher at every interview. At least one other member of the research team served as the observer(s). The teacher-researcher and observers (heretofore referred to as researchers) took field notes and asked probing questions as necessary. All sessions and written work were videotaped and digitized.

The goal of the teaching experiment was to create models of individual's mathematics, specifically with regards to students' construction of graphs. Steffe and Thompson (2000) referred to these researcher models as the *mathematics of students* (cf. *students' mathematics*). In both ongoing and retrospective analyses efforts, we analyzed the students' actions using generative and axial approaches (Corbin & Strauss, 2008) in combination with conceptual analysis (Thompson, 2008). We first analyzed the students' observable and audible behaviors in order to develop tentative hypothetical models of their thinking. Then, we attempted to identify connections and consistencies across each student's activities with specific attention to her or his meanings for graphing and the extent to which these meaning entailed quantitative or covariational reasoning. Lastly, we made comparisons across students in order to construct more fine-grained models of the students' thinking. In this report, we focus on one student in the teaching experiment, Lydia, whose meaning for graphs enabled us to explore the intersection between the quantification process and her representational activity as we strived to support a conception of a point on a graph as a multiplicative object.

Results

We divide the results section into three parts: (a) Lydia's initial response to a graphing activity given a dynamic situation from her first interview, (b) a summary of our attempts to support quantitative and covariational reasoning of the sine and cosine relationships through reasoning about the relevant magnitudes in a simplified version of the Ferris wheel situation, and (c) Lydia's attempt to relate what she understood as the sine and cosine relationships in the situation and what she understood as the graph that represented those relationships.

The Ferris Wheel Task

One of the first tasks we presented Lydia was the Ferris Wheel Task, which includes a dynamic image of a Ferris wheel rider (green bucket) who travels at a constant speed clockwise from the bottom of the Ferris wheel (Figure 1) (Desmos, 2014). We first asked her to comment on what she observed in the situation, to which she stated there is "a function that would give us the shape of a circle." We subsequently gave her the prompt: "Graph the relationship between the total distance the rider has traveled *around* the Ferris wheel and the rider's distance from the ground." She then produced what she called her graph in Figure 2. When prompted, she indicated several different total distance and height pairs by pointing on a location on her drawn circle, tracing around her drawn circle from the bottom to indicate total distance, and motioning from the point to the denoted ground to indicate height. She also noted how the speed of the Ferris wheel would influence where along the circle she would be at a particular time, explaining "there has to be some physics formula for that, but I don't know it." Importantly, we inferred her drawn graph and comments to suggest that she conceived one particular curve to describe the Ferris wheel situation as a whole, and from that curve, she could isolate and discuss the quantities under question. As we describe below, this inference is important relative to her response to our prompting her to construct a graph in a normative Cartesian system.

Figure 1. Animation snapshots of the Ferris wheel task.

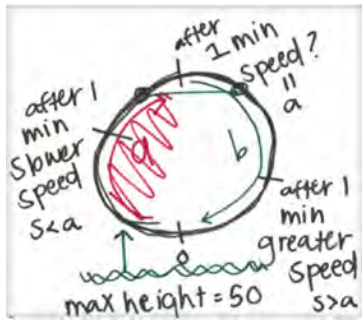

Figure 2. Lydia’s initial graph for the Ferris wheel task.

Partitioning Activities with Diagrams of Circles

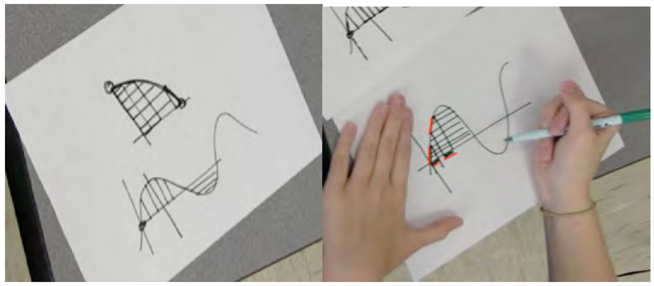
The teaching experiment tasks shifted away from constructing graphs shortly after this task in an effort to provide Lydia and the other participants of the teaching experiment with the opportunity to focus on reasoning together about the relationships between magnitudes in circular contexts. With considerable support from the researchers, the students engaged in partitioning activities (e.g., Figure 3) with a diagram of the circle to reason about amounts of change in horizontal/vertical distance from the vertical/horizontal diameter for equal changes in arc length. Lydia and another student related these quantities to sine and cosine graphs at the conclusion of the joint sessions. Lydia expressed the novelty of the partitioning activity to her, and it subsequently became a way for her to operate on images (diagrams or graphs) to explore relationships. However, as we argue in the following section, her conception of graphs described in the previous section constrained her ability to use this partitioning activity effectively to describe relationships between quantities.

Figure 3. Partitioning activities using a diagram of a circle from the joint sessions.

Sine Graph

In the next individual session, one week later, the researchers asked Lydia to return to the context of circular motion. Initially, they supported Lydia in drawing a diagram of a situation in which a point on a circle is traveling counterclockwise from the 3 o’clock to the 12 o’clock position (Figure 4a, top). She used her newly developed partitioning activities and constructed changes in horizontal distance for equal changes in arc length, and she compared these changes to conclude that the horizontal distance decreased by an increasing magnitude for an equal change in arc length as the point rotated from the 3 o’clock to the 12 o’clock positions (Figure 4a, top). Shortly after this description, we asked her to create a graph representing the relationship between the horizontal length and the arc length, with our intention being that she produce a normative graph for the cosine relationship. She produced the graph in Figure 4a (bottom), stating that the graph can be comparing “the *y*-height here [vertical segments in Figure 4a, bottom] and then also can be comparing the *x*-

distance [horizontal segments in Figure 4a, bottom].” In her initial description of her drawn graph, Lydia did not reference arc length. Thus, she seemed to indicate that the quantities she had conceived as “*y*-height and *x*-distance” in her diagram of the situation were both represented in her graph. This conclusion is consistent with her conception of her graph from the Ferris Wheel task in which she identified several quantities she thought were represented in her graph.



(a) (b)

Figure 4. (a) (top) Diagram of the situation highlighting amounts of change in “*x*-distance” and (bottom) resulting graph; (b) Equal changes in arc length denoted along curve and corresponding changes marked along horizontal axis.

The researchers subsequently asked Lydia to clarify how she was interpreting “*y*-height and *x*-distance” relative to her drawn graph. She first stated she would show the “*x*-distance” and then traced *along her curve* to indicate “increase in arc length.” Following this statement, she drew in horizontal line segments between the curve, starting nearest to the horizontal axis, and moving upwards (Figure 3b). She described these segments as decreasing as the “arc length” increased, which she argued was the same conclusion she had reached in the circular context. She made this statement while drawing in the vertical lines and motioning along two “arc length” and “*x*-distance” pairs, seemingly mimicking partitioning activities from a previous session (Figure 3). However, when asked to say more about how she was denoting “arc length” and “x-distance” on her graph, specifically about the vertical lines from and highlighted regions in Figure 4b, she questioned the efficacy of her actions. Soon afterwards, she switched from talking about horizontal distances to talking about height, stating, “[S]o we’re doing the arc length and height again [*labeling her axes with arc length on the horizontal axis and height on the vertical axis*]”. She then motioned along her horizontal axis, saying “and as I am going across my arc length” and shortly afterwards tracing along the curve starting from the first maximum in Figure 4b saying, “[O]ur arc length, as it increases, the height will decrease.” She then related this statement to her diagram by completing the first half of the full rotation on her diagram in Figure 4a (top).

To summarize, Lydia stated a directional covariational relationship between (i) “*x*-distance” and “arc length” and (ii) “height” and “arc length” using the same graph. Also, when referring to “*x*-distance”, she denoted horizontal segments that connected two points along her curve and conceived “arc length” as a distance along the curve. When referring to “height”, she conceived “arc length” as a magnitude along the horizontal axis and conceived height as vertical magnitudes between the curve and horizontal axis. After a researcher subsequently drew attention to Lydia’s reference to “arc length” as both a distance along the curve and a distance along the horizontal axis, she was perturbed and over the course of nearly 30 minutes attempted to rationalize the graph entailing the three quantities she had identified (“height”, “arc length”, and “*x*-distance/width”). About seven minutes into her efforts, she made the following statement:

Lydia: I don't know. I'm confused. That's what's going on. I like see the relationship, and I can explain it to a point, and then I get like – I confuse myself with the amount of information I know about a circle that I was just given to me by a teacher, and then what I've like discovered here [*referring to the teaching sessions*] and like how those – I'm like trying to find a connection, but I'm getting confused.

Her extended perturbation emphasizes the figurative conception she has of her graph, relying on perceptual features consistent with static shape thinking to relate it with her diagram. Due to the persistence of Lydia attempting to identify each of the three quantities in her drawn graph and the perturbations she experienced due to this attempt, the researchers decided to draw Lydia's attention back to the situation in hopes of isolating the three quantities she perceived in the situation. The researcher specifically asked Lydia to denote the three quantities (i.e., triple) she identified for various points along the circle (Figure 5).

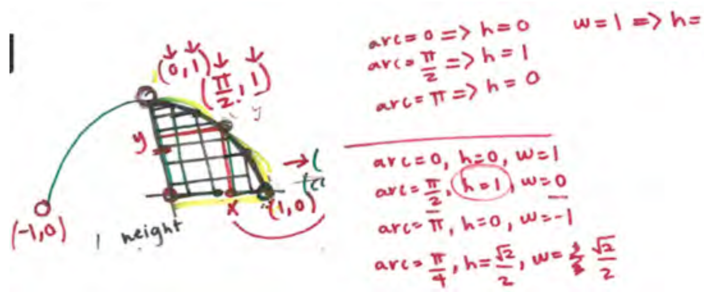


Figure 5. Lydia's diagram of the circle (left) and her triples for various points along the circle (*arc*= arc length, *h*= height, *w*= width).

Upon determining several triples (see Figure 5, bottom right), the researcher asked Lydia how the triples related to her graph (i.e., "[D]oes it represent all three [quantities]? Does it represent just two of them? Does it represent one of them?"). She then drew attention to the origin on her graph and explained:

Lydia: Because this is my – This is *x* – um, *x-y* plane, then here I'm saying at this point [*the origin*], my width is 0, my arc length is 0, and my height is 0.
Researcher: Width is 0, my arc length is 0 and my height is 0.
Lydia: Wait, but then I said at arc length 0, and [*laughs*] height is 0, then my width should be 1.
Researcher: And your width should be 1, right? What about at pi-halves? What should we have?
Lydia: Then I should have a height of 1 [*pointing to curve for an abscissa value of pi/2*].
Researcher: Okay.
Lydia: And then my width should be 0. So this graph does not do anything with the *x-y* plane.
[*Lydia summarizes this claim and then the researcher asks Lydia to consider an arc length of pi radians.*]
Lydia: Then my arc length on the *x*-axis [*motions across horizontal axis*] should be pi. My height should be 1 – or 0, and then my *x*-value should be negative 1. So this [*referring to her drawn graph*] just doesn't have – then this doesn't relate to the *x*, the width [*referring to width from the situation*], just this graph. So my whole circle talks about width and height and arc, but then this graph itself only talks about arc and height. [*speaking emphatically*] Done it. [*laughs*]

We infer that Lydia accommodated her meaning for her drawn graph, including how it related to the circle situation, during this interaction. Specifically, she came to understand that her drawn graph related two particular quantities—arc length and height directed horizontally and vertically, respectively—in a way compatible with the situation. She simultaneously held in mind that these two particular quantities were a subset of the three she understood to constitute the situation. We infer that her accommodation occurred when assimilating a point on the circle as containing a trio of information and then interpreting the point on her graph as entailing the three quantities' values as 0 (i.e., the arc along the curve, the abscissa value, and the ordinate value). This resulted in her experiencing a perturbation with her understanding of the situation (i.e., an arc length of 0, a height of 0, and a width of 1). Alleviating this perturbation required that she disembed two of the quantities from the situation, understand these quantities as represented orthogonally with respect to her drawn graph, and conceive a point on her graph as representing each quantity's value or magnitude simultaneously (i.e., as a multiplicative object). She tested the viability of this new model with two additional points before being confident in the efficacy of her actions; each point on her graph was a uniting of two, and only two, quantities. At this point, her thinking about her graph shifted from figurative to operative.

Discussion

We highlight four important findings from Lydia's activity. Firstly, we note the difficulty a student has in maintaining a consistent quantitative structure within and between a situation and its representation when (i) quantification and quantitative reasoning is a novel way of thinking and (ii) one has a conception of a graph as encompassing an abundance of quantities in a situation. For instance, Lydia had a graph on which she attempted to quantify based on the results of her partitioning activities in her diagram of the situation, but she did not maintain the quantities she believed the graph represented as evidenced by her switching arc length from axes to along the curve. Relatedly, the process of disembedding quantities was crucial for Lydia to view her graph as a representation of a multiplicative object, which was what shifted her thinking from figurative to operative. Thirdly, we have provided a more detailed example of Moore and Carlson (2012), who primarily characterized how the quantitative structure of the situation that the student constructed influenced their mathematical artifacts, including how the students conceived of a quantitative invariance between the two. We extend that work by providing a more detailed look into the students' activity by drawing figurative and operative distinctions, thus not presuming the students to have constructed and maintained quantities. Lastly, this study has important implications for the study of trigonometry in that students should understand the cosine (and sine) relationships as disembedding from the unit circle. Lydia's case shows that this disembedding process should not be taken as a given.

THE PROMISE AND PITFALLS OF MAKING CONNECTIONS IN MATHEMATICS

Emily R. Fyfe	Martha W. Alibali	Mitchell J. Nathan

Making connections during math instruction is a recommended practice, but may increase the difficulty of the lesson. We used an avatar video instructor to qualitatively examine the role of linking multiple representations for 24 middle school students learning algebra. Students were taught how to solve polynomial multiplication problems, such as (2x + 5)(x + 2), using two representations. Students who viewed an explicit linking episode were more likely to make important connections, but less likely to exhibit problem-solving success than students who did not view the linking episode. Further, the quality of the connections made by the students was negatively related to subsequent problem solving and transfer. Thus, although focusing on connections may support rich understanding, it may decrease learning of solution methods. The results showcase the promise and pitfalls of making connections in mathematics.

Keywords: Problem Solving, Algebra and Algebraic Thinking, Instructional Activities and Practices, Technology

Introduction

Making explicit connections during mathematics learning instruction is a recommended practice (e.g., NCTM, 2000; Pashler et al., 2007). In fact, some researchers have even defined mathematics understanding in terms of the number or kind of connections that have been constructed by the learner (see Crooks & Alibali, 2014). One important type of connection to make is between multiple representations of the same concept or procedure (e.g., the graph of a line and its equation). In the current study, we used an avatar video instructor to examine the role that linking multiple representations during an algebra lesson had on connection-making and problem-solving performance. Our goals were (1) to compare the effects of a lesson that included a linking episode versus a lesson that did not include a linking episode on students' connection-making and problem solving, and (2) to examine how students' connection-making related to subsequent learning and transfer. We selected the domain of algebra because it functions as a "gatekeeper" to future educational opportunities (Moses & Cobb, 2001). Further, algebra is a focal point of reform efforts in mathematics education (e.g., NMAP, 2008).

Theoretical Framework

Mathematical ideas and representations are connected to and build upon other mathematical ideas and representations. The new *Common Core State Standards for Mathematics* (National Governors Association Center for Best Practices, 2010) is explicit on this point: fundamentally, "mathematics is a connected subject" (p. 5). Understanding these connections is fundamental to having a deep, conceptual understanding of mathematics. Indeed, the notion of connecting mathematical ideas and representations emerges in many of the standards put forth by the National Council of Teachers of Mathematics (NCTM, 2000), one of which is the ability to "translate among mathematical representations" (p. 67).

The current study evaluated the influence of a lesson that explicitly linked multiple representations during instruction. We define *linking episodes* as segments of instruction during which the instructor seeks to make explicit links between ideas or representations (Alibali et al. 2014). For example, imagine instructing students on the concept of mathematical equivalence first using a balance scale, then using an equation, and finally by making the correspondences between the balance scale and equation explicit. Establishing the correspondences between the two representations would be considered a linking episode.

On the one hand, linking episodes during instruction should facilitate greater understanding for students because they point out conceptual links among ideas and representations (e.g., Crooks & Alibali, 2013; Rittle-Johnson & Alibali, 1999). For example, Hiebert and colleagues (1997) argue, "we understand something if we see how it is related or connected to other things we know" (p. 4). Further, there are many examples of students benefitting from connections made via a variety of instructional techniques, including direct comparison (Rittle-Johnson, Star, & Durkin, 2009), linking gestures (Alibali et al., 2013) and fading from concrete to abstract representations (Fyfe, McNeil, & Borjas, 2015).

On the other hand, making connections among representations can be cognitively demanding, requiring students to understand each representation as well as their correspondences (e.g., Gick & Holyoak, 1980; Nathan et al., 2011). For novices, this may overload their cognitive resources (e.g., Sweller et al., 1998). Indeed, learning from connections may be difficult for students with low background knowledge (e.g., Clark, Ayres, & Sweller, 2005; Kotovsky & Gentner, 1996). For example, one study found that making connections via comparison was beneficial for advanced students, but not for novices (Rittle-Johnson et al., 2009). Specifically, middle school students who did not know a method for solving the target equations benefitted more from studying two methods sequentially than from comparing two methods directly.

Thus, the inclusion of explicit linking episodes may help students focus on making rich connections between multiple representations. At the same time, it may detract from focusing on learning to work with each individual representation correctly, particularly for novice students.

Current Study

In the current study, we had two specific aims. Our first aim was to compare the effects of a lesson that included a linking episode versus a lesson that did not include a linking episode on students' connection-making and problem solving. Specifically, middle school students were taught how to solve polynomial multiplication problems, such as $(2x + 5)(x + 2)$, by an avatar instructor using an area-based representation and an equation-based representation (see Figure 1). Students in the *link* condition viewed a subsequent linking episode and students in the *no-link* condition did not. We expected students in the link condition to make more high-quality connections between the two representations than students in the no-link condition, but to have similar problem-solving performance. Our second aim was to examine how the quality of students' connection-making related to subsequent learning and transfer, regardless of condition. After the initial lesson and assessment, all students were exposed to an instructional linking episode and a posttest. This provided students an opportunity to use the knowledge they acquired from the initial lesson. We expected the quality of students' connection-making to be positively related to their performance on posttest items that tapped understanding of the links between the representations, but negatively related to their performance on posttest items that tapped understanding of individual representations. This work was part of a larger project that developed a teacher avatar (Anasingaraiu et al., 2016) and is investigating how variations in the avatar's behavior during linking episodes influences student learning. The present study focused on variations in the presence of linking episodes in the avatar lesson.

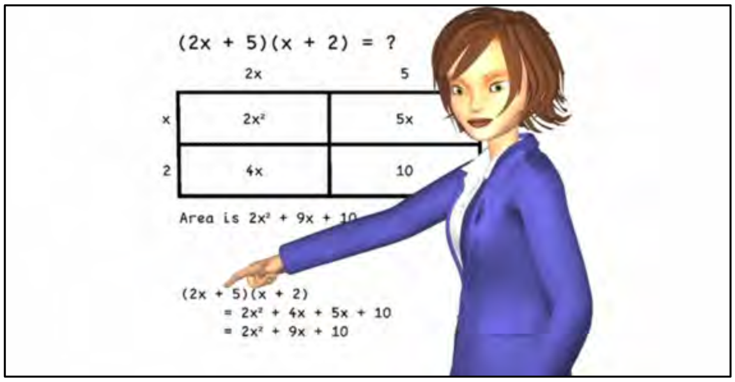

Figure 1. Image of the lesson with the area method (top) and equation method (bottom).

Method

Participants

Participants were 16 seventh-graders and 8 eighth-graders attending one of three middle schools in a mid-sized Midwestern city in the United States. Participants were predominantly White (75% White, 8% Asian, 4% Hispanic, 13% Other) and their mean age was 13.2 years (*min* = 11.5, *max* = 14.2). Sixty-two percent were male. An approved email was sent to all seventh- and eighth-grade students at the schools inviting them to participate in a project that would take place on the university's campus. Each student was compensated $15 for participating.

Design and Procedure

We used a pretest-lesson-posttest design. Each student participated in a single one-on-one session that lasted 45 minutes. Students completed a pretest to assess their background knowledge. Next, they viewed a lesson presented by an avatar video instructor. The lesson focused on multiplying binomials using a target problem: $(2x + 5)(x + 2)$. For the lesson, children were randomly assigned to one of two conditions (Figure 2): *link* (n = 12) or *no-link* (n = 12).

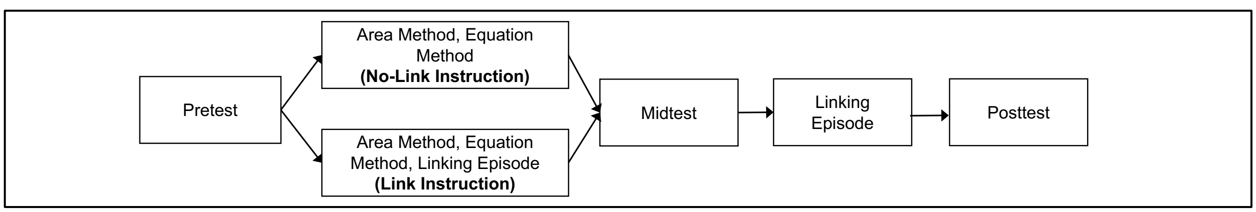

Figure 2. Sequence of activities in the experimental procedure.

The instructor described an area-based method and then described an equation-based method (Figure 1). In the *link* condition, the avatar instructor then provided a linking episode in which she delineated the correspondences between the two representations (e.g., "2x + 5 in the equation corresponds to the length 2x + 5 in the rectangle"). Students then engaged in an explanation of the target problem and solved the items on the midtest. The purpose of the explanation and midtest was to assess differences in learning between students who had viewed a linking episode and those who had not. After the midtest, all students in both conditions viewed the linking episode and completed a posttest. The purpose of the posttest was to evaluate how the quality of students' initial connection-making (as assessed on the explanation and midtest) related to their learning from subsequent instruction. Throughout the session, students were encouraged to think aloud so we could gain a richer account of their thought processes (Ericsson & Simon, 1993).

Materials and Measures

All items on all measures were presented one at a time on an interactive smart board.

Pretest. The pretest included six items (see Table 1 for examples). The first five items tapped students' background knowledge of operating with variables and calculating area. The sixth item was a target polynomial multiplication problem.

Explanation. After the avatar lesson, students were shown the instructional problem and asked: "Here is the same problem you just learned about. Imagine that another student is seeing this example for the first time. Can you explain how to solve this problem?" Explanations were coded for whether students (1) exhibited a "trouble spot," defined as indicating confusion or displaying incorrect understanding (Alibali et al., 2013), (2) referred to one or both representations, and (3) provided a general solution strategy rather than a step-by-step procedure.

Midtest. The midtest included two items (see Table 1 for examples). The first item was a polynomial multiplication problem. The second item was a linking item.

Posttest. The posttest included seven items (see Table 1 for examples). Two were polynomial multiplication problems. Three were linking items. The final two were transfer items that tapped whether students could apply what they learned about multiplying expressions with variables to multiplying whole numbers. Items were scored as correct or incorrect based on students' written answers and on the verbal think-aloud reports they provided while solving.

Table 1: Example Items Presented on the Pretest, Midtest, and Posttest

Item Type	Example Item	Instructions	Example Responses
Background Knowledge Item (five on pretest)	**X + X**	Simplify the expression.	Correct: 2x Incorrect: 1, 1x, x, 2, x^2
Solve Item (one on pretest, one on midtest, two on posttest)	**(6x + 3)(y + 7)**	Simplify the expression by multiplying the terms 6x plus 3 and y plus 7.	Correct: 6xy + 42x + 3y + 21 Incorrect: 6xy + 10, 21*6xy
Link Item (one on midtest, three on posttest)		Circle the term in the equation that represents the area of the shaded rectangle.	Correct: 8x Incorrect: 40
Transfer Item (two on posttest)		Which area model(s) correspond to the multiplication problem 57 x 32?	Correct: BC Incorrect: Only B, ABC, D

Results

Pretest

Students did moderately well on the five background knowledge items (percent correct ranged from 42% to 88%). However, only one student (out of 24) correctly solved the polynomial multiplication problem: $(x + 2)(x + 1)$. The two most common errors on that problem were to add the two x's and add the two integers to get $2x + 3$, or to combine terms within parentheses to get $2x * 1x$. Conditions were well matched at pretest (M_{link} = 58% vs. $M_{no\text{-}link}$ = 54%). A median split on total percent correct yielded a low-background-knowledge group (n = 12, M = 36%) and a high-background-knowledge group (n = 12, M = 77%). All students but one were unsuccessful on the target problem and were thus novices; the knowledge groups differed in terms of the background knowledge necessary to learn about the target problem.

Explanation

Following the lesson, students were asked to explain how to solve a polynomial multiplication problem. Consider the explanations presented below:

> Student 1 in the link condition: "Basically what you would do is multiply each number by every other number that's in the different set. So 2x times x [draws line connecting the 2x and the x in the equation] is $2x^2$ [circles $2x^2$ in the area model]. 2x times 2 [draws line connecting the 2x and the 2 in the equation] is 4x [circles 4x in the area model]. Both of these are one side [circles the 2x and 5 across the top of the area model] so you don't have to multiply these. Then you do 5 times x [draws line connecting the 5 and the x in the equation], which is 5x [circles 5x in area model]. And 5 times 2 [draws line connecting 5 and 2 in equation], which is 10 [circles 10 in area model]. Then you would take all those answers together [circles all four terms in bottom equation] and simplify them. So 4x plus 5x is 9x. Then 10, and $2x^2$."
>
> Student 2 in no-link condition: "So first you would do what's in parentheses…you do 2x plus 5 [points to 2x and 5 in equation], which I think would be 7x [writes 7x under the 2x + 5 in the equation]. Then you do x plus 2, which would be 2x [writes 2x under x + 2 in the equation]. Then you multiply them I think. So, it would be 14x."

Student 1 provides an accurate explanation, mentions a general solution strategy ("multiply each number by every other number that's in the different set"), and refers to both representations. In contrast, Student 2 exhibits a trouble spot (i.e., incorrect understanding), provides only a step-by-step procedure, and relies solely on the equation-based method.

To capture these differences, we created an *explanation quality score*. Explanations received one point for each of the following features: (1) did not contain a trouble spot, (2) offered a general solution method, and (3) referred to both representations. One third of students scored a maximum 3 out of 3, and across all students the average explanation quality score was 1.8 (out of 3; SD = 1.1). This suggests that typical explanations hit about two of the three criteria for being high-quality. It was most common to provide an explanation that was free from trouble spots (19 out of 24 explanations). It was less common to refer to both representations (12 out of 24 explanations) or to offer a general solution method (12 out of 24 explanations).

Students with low background knowledge had difficulty in explaining. Compared to the high-background-knowledge group, they were more likely to exhibit a trouble spot (42% vs. 0%), less likely to state a general solution method (33% vs. 67%), and less likely to refer to both representations (42% vs. 58%). As such, students with low background knowledge had lower quality scores (M = 1.3) than students with high background knowledge (M = 2.3), and there was little variability between the two conditions among low-background-knowledge students.

However, within the high-background-knowledge group, explanations varied by condition. Compared to students in the *no-link* condition, students in the *link* condition were more likely to provide a general solution method (83% vs. 50%) and more likely to refer to both representations (83% vs. 33%). Indeed, for the high-background knowledge group, students in the *link* condition had higher explanation-quality scores (M = 2.7) than students in the *no-link* condition (M = 1.8).

Midtest

Over half of the students solved the target polynomial multiplication problem correctly at midtest (54%) and all but three students (88%) solved the linking item correctly. Students with low background knowledge were less likely than their high-background-knowledge peers to correctly solve the multiplication item (33% vs. 75%), and the linking item (75% vs. 100%).

As with explanation quality scores, condition differences were minimal for the low-background-knowledge group. For the high-background-knowledge group, performance on the linking item was at ceiling, but performance on the multiplication item varied. Students in the *link* condition were *less* likely to solve the problem correctly than students in the *no-link* condition (50% vs. 100%). All the high-background-knowledge students who solved the multiplication problem incorrectly also provided explanations focused on both representations, suggesting that a focus on linking potentially interfered with learning at least one method well. Overall, regarding our first research goal, we found that a lesson with a linking episode resulted in higher-quality connection-making among students with sufficient background knowledge, but lower problem-solving success relative to a lesson without a linking episode.

Posttest

The posttest occurred after all students viewed a brief instructional linking episode. It allowed us to evaluate how students' initial connection-making related to subsequent learning and transfer. Overall, performance was moderate on the polynomial multiplication solve items (M = 60%, SD = 44%), high on the three linking items (M = 88%, SD = 26%), and moderate on the two transfer items (M = 52%, SD = 35%). Most students demonstrated some learning by the posttest. At pretest, only one student (4% of the sample) solved a polynomial multiplication problem correctly, but 17 out of the 24 students (71%) solved at least one correctly at posttest.

Recall that students explained a target problem after the initial instruction and received an explanation quality score. These explanation quality scores were related to posttest performance (see Table 2). The correlations in Table 2 suggest that explanation quality scores were positively related to posttest linking scores, weakly related to posttest problem-solving scores, and negatively related to posttest transfer scores. We also examined these associations by splitting students into a high-quality explanation group (n = 8, scored 3 out of 3 on explanation quality) and a low-quality explanation group (n = 16, scored 0, 1, or 2 out of 3). Among students with high background knowledge, there were clear differences based on explanation quality. Compared to students in the low-quality explanation group, students in the high-quality explanation group had higher posttest link scores (100% vs. 89%), similar posttest solve scores (75% vs. 75%) and lower posttest transfer scores (41% vs. 67%). These differences lend credence to the idea that students who focus on making connections (and therefore have higher-quality explanation scores) do well on items that tap their knowledge of links, but not as well on items that tap their knowledge of the individual solution methods or representations.

Table 2: Correlations Between Explanation Quality Scores and Posttest Performance

	Whole Sample	Low-Background-Knowledge Group	High-Background-Knowledge Group
Posttest Link Scores	$r_s = .43$	$r_s = .50$	$r_s = .14$
Posttest Solve Scores	$r_s = .22$	$r_s = .29$	$r_s = -.16$
Posttest Transfer Scores	$r_s = -.18$	$r_s = .00$	$r_s = -.42$

To look at this more directly, we made one additional comparison. The explanation quality scores took into account trouble spots, the provision of a general solution method, and references to both representations. To more directly consider connection-making, we compared students who differed only on this last criterion: students who referenced both representations ($n = 12$) vs. students who referenced only one representation ($n = 12$). Students who referenced both representations had slightly higher posttest link scores (89% vs. 86%), slightly lower posttest solve scores (58% vs. 63%) and lower posttest transfer scores (41% vs. 63%). These transfer differences were particularly pronounced for students with high background knowledge (36% vs. 80%). Overall, regarding our second research goal, we found that students' initial connection-making was related to their subsequent learning and transfer. Connection-making seemed to support students' understanding of the links between the representations, but not their ability to solve familiar or novel problems about the individual representations.

Discussion

Educational opportunities for all learners expand as we come to understand the conditions under which teachers' connection-making during instruction affects student learning. The current results highlight the promise and pitfalls of including linking episodes during algebra lessons. For middle school students with sufficient background knowledge, a lesson with a linking episode led to higher-quality explanations than a lesson without one. That is, students who saw the linking episode were more likely to provide a general solution method that applied to both representations and to refer to both representations rather than one. This suggests they were developing rich connections necessary for mathematics understanding (Hiebert et al., 1997).

However, students who saw the link were also less likely to solve a target problem correctly than students who did not see the link – potentially because they were focusing on processing the two representations and their correspondences rather than solidifying their knowledge of a correct solution method. Further, regardless of condition, students' engagement in connection-making was related to their learning and transfer from a subsequent instructional episode. Specifically, higher-quality connection-making appeared to be positively related to performance on posttest items that tapped understanding of the links between the representations, but negatively related to performance on posttest items that tapped understanding of individual solution methods. Thus, linking episodes may help students focus on making rich connections, but may also detract from their focusing on learning each solution method correctly, particularly for novice students (see also Clark et al., 2005; Rittle-Johnson et al., 2009). This may represent a trade-off in the development of conceptual versus procedural knowledge (e.g., Crooks & Alibali, 2014). Improvements in understanding conceptual links may come at the expense of improvements in understanding key procedures. Importantly, these results support the recommendation that instruction should include linking episodes that highlight connections among mathematics ideas. We find connection-making can be supported by a video-based avatar and we identify trade-offs between building rich conceptual connections and performing representation-specific solution procedures.

In this work we report on the findings of our ongoing study of fostering validation and refinement of mathematical models in classroom contexts. Drawing on an ethnomathematical perspective we examined interactions within mathematical modeling contexts in two 11th grade pre-calculus classes to identify and analyze instances where students drew on their contextual and mathematical knowledge when solving problems. Our analyses indicate that in presence of teacher's responsive comments students develop deeper learning and engage more intensely in tasks and across contexts.

Keywords: Modeling, Classroom Discourse, Equity and Diversity, High School Education

With the adoption of the National Governors Association (2010) Common Core Standards for Mathematics (CCSM) there has been an increased interest in mathematical modeling in the United States. Indeed, the CCSM lists mathematical modeling as both a High School content standard as well as a Standard for Mathematical Practice. While the CCSM describes the mathematical modeling process it offers little guidance in productive means for teaching mathematical modeling. The absence of research-based data on how this standard might be effectively implemented in ways that learners' own voices are considered is hugely problematic (Cai et al., 2016). Evidence exists that facilitating modeling cognition among school learners involves intricate attention to cultural backgrounds and life experiences of children in ways that the desired mathematics is treated not as the cherished prize but rather a humanizing capital that permit for deeper reflection on these experiences by both the teachers and learners. As such, the relationship among learners' use of mathematics in making sense of real life events, teachers' reflections on what they learn from children as they attempt to facilitate their modeling work, and ways in which gulfs of knowledge are bridged demands meticulous scholarly attention, an area rarely explored in mathematics education research. The overarching goal of this research study was to address this gap by examining the reflexive ways that learners and teachers navigate chasms between mathematical and life experiences within modeling contexts. This work will assist in building a theoretical model regarding unique features of instructional demands in presence of modeling as well as offer methodological implications for the teaching of mathematical modeling.

Background and Significance

Blum and Leiss (2007) offer an overview of the mathematical modeling process where a problem situation, couched in the real-world transitions into the mathematical world through the process of mathematization; is work on mathematically and mathematical results are produced. These results are then analyzed and interpreted against the context being modeled then finally validated with respect to the situation model and the cycle could be re-engaged (p. 226).

While there has been considerable research in examining the mathematization processes of students (Lesh, Galbraith, Haines, & Hurford, 2010); there has been significantly less research reports that examine how validation and refinement of models is mediated in the process of teaching mathematical modeling, a call voiced during the 2016 International Congress on Mathematical Education. Indeed, Cai et al. (2016) outlined a need for extensive research examining the nature of classroom discourse that supports students in becoming successful modelers and in particular examine and report on what mathematical modeling looks like during classroom instruction (p. 4).

Currently there is limited research on teachers' scaffolding practices in mathematical modeling contexts, and the current perspective in the literature seems to align with the view that instruction must shift students' views of problem contexts to an idealized solution (Tropper, Leiss & Hanze, 2015; Schukajlow, Kolter & Blum, 2015; Stender & Kaiser, 2015). Such an elitist view has been challenged by researchers for whom epistemological and ontological perspectives on learning are grounded in ethnomathematics, building a case for listening to the voices of the oppressed in designing instruction (Rosa & Orey, 2016). Primarily absent from the literature are cases where scaffolding involves sensitivity to students' views of particular contexts and formal mathematizations of those views. Previously we have argued (Manouchehri & Lewis, in press) that when engaged in mathematical modeling processes students rely heavily on their intuitions and personal experiences when working on such contexts, and these views impact both the perceived utility of their models and whether they consider the need to validate and refine them.

This ongoing study examines the nature of classroom interactions that occur during the implementation of mathematical modeling across two 11th grade pre-calculus classrooms and considers the particular ways that the teacher responds to students' interpretations of contexts, their solutions to their perceived problems in these contexts and ways that mutual negotiations take place when validating and refining models. In particular we examine the following research questions: (1) How do teachers and school learners co-construct practices associated with developing mathematical modeling over the course of an academic year? (2) What function do these practices serve in facilitating mathematical modeling process? How are these practices different from other mathematical practices?

Theoretical and Methodological Orientation

D'Ambrosio (1895) defines ethnomathematics as the "mathematics which is practiced among identifiable cultural groups" (p. 45) and distinguishes it from what he defines as academic mathematics, or the mathematics taught in school. Orey and Rosa (2016) outline "ethnomathematics embraces the mathematical ideas, thoughts and practices as developed by all cultures across time and space" (p. 6). This view of mathematics affords the ability to treat the experiences and views of a particular context as being viable, and unearth the mathematical validity of those statements in concert with those cultural ways of knowing. This affords a view where Western mathematical forms are not the only viable means of representing mathematical thinking. Further Orey and Rosa argue that when cultures meet, there are three possible outcomes: (1) that one culture eliminates the other completely, (2) that one culture is absorbed by the other, or (3) that the two cultures come together to produce a third distinct culture (p. 18), and as such argue for fruitful and equitable means of cultural merging as being aligned to the third view where both perspectives are honored.

We argue that a classroom in itself consists of multiple views motivated by the various cultural backgrounds of its members. Further we notice that the teacher serves as a representative of one cultural group with one mediating function being to bring learners into the practices of academic and curricular mathematics. Similarly we recognize that students across classrooms come from a variety of background and experiences and draw on various funds of knowledge (Moll et al. 1992) that that informs their intuitions. We argue that with these funds of knowledge informing interaction across tasks, it becomes paramount to consider the means by which these interactions frame the views of the teachers as well as their students, and examine how these experiences with contexts are treated in establishing the culture of the classroom and advancing learners' cognition.

Research Design and Methods

In examining the teacher's practices and interactions with students and their ideas in mathematical modeling contexts we employed a micro-ethnographic study (Bloome et al., 2010) to trace the types of interventions effective in fostering validation of these models. Bloome et al. (2010) articulates a relationship between theorizing, discourse analysis and the event in which analysis occurs where in triangulating of the generated theories they must be validated in the context of event through a discourse analysis, and validated by the members of the space. According to the authors, this process informs the overarching theory through these iterative processes in multiple cycles.

Data Collection

Preliminary data collection for this ongoing study commenced in the fall 2016 across two different pre-calculus classes taught by the same teacher. Our field site was a private academy in the Midwestern United States. Prior to formal classroom observations our cooperating teacher identified her primary instructional goal engaging her students in mathematical modeling on a regular basis, and to support them in both generating and answering their own contextual questions through mathematics.

Our cooperating teacher implements modeling tasks approximately once per week and focuses primarily on students generating and responding to questions about a particular context of interest. In addition to capturing these events through audio and video recording we also examined the nature of general classroom instruction to look for transfer of the mathematical modeling contexts used in class during the designated modeling time. In framing our analysis, we focused on the various ways that students drew on their funds of knowledge and intuitions over the course of instruction which became emergent through their interactions in the classroom.

Additionally a focus group of students was selected for additional audio recording to capture small-group interactions during classroom instruction and small-group/individual work. Written field notes were collected by the research team to identify points of interest for further analysis as well as serving as a log of instructional interactions. Regular reflective interviews were conducted with the teacher in order to get their perspective on classroom instruction for that particular day as well as capture in the moment thinking about the nature of the daily instruction. The research team also implemented daily reflection (either written or audio/video recorded) to help in identifying key events to analyze.

All video and audio records of the sessions are first transcribed. In our analysis we seek instances of interactions and methods that students use when solving problems. Particular attention is paid to the means by which learners' intuitive and experiential knowledge informs interaction with peers and contexts under study. Finally we look across these analyzed cases to seek productive ways that the teacher helps to scaffold students through this process, and where and how these interactions inform future interactions in other mathematical contexts. We characterized these experiences as meaningful instances of scaffolding.

Results and Conclusions

Our preliminary analysis of key events that occurred across five different modeling contexts over the course of three instructional units revealed that when the teacher was sensitive to students' interpretations of problems within each context that this triggered deep mathematical learning and intense engagement in these tasks. For example, in one instance during which students were considering the relationship between revenue, cost and profit models in an economic context, students challenged the viability of the particular model presented, and offered insights into optimizing the business growth potential, and drew on significant and robust mathematical ideas such as increasing revenue through raising prices, or evaluating staffing models of the business. We observed that it was through students drawing on their funds of knowledge and the teacher recognizing that these ideas had both contextual and mathematical merit that these issues were brought to bare in the classroom. Through the teachers responsiveness to these ideas the teacher was able to facilitate a mathematical discussion that helped the students gain insight into this context and unpack the mathematical ideas that they were considering.

In our session, drawing from event maps and illustrations of exemplary interactions, we will argue that in viewing student interpretations and ideas as viable sources of knowledge affords the ability for a responsive teacher to engage their students in deep mathematical and contextual learning that builds on these views. We offer that our analytical interpretations of these events provide a means for theorizing the types of teacher interventions that may be productive in developing a modeling disposition.

CHARACTERIZING SOPHISTICATION IN REPRESENTATIONAL FLUENCY

Nicole L. Fonger
Syracuse University
nfonger@wisc.edu

Representational fluency is key to understanding mathematical ideas is deeper ways. This research advances a framework for characterizing sophistication in representational fluency that builds on a structure of observed learning outcome (SOLO) taxonomy. Drawing on an analysis of interviews with 9th-grade algebra students solving equations using a computer algebra system and paper-and-pencil, I discuss four levels of sophistication: prestructural, multistructural, unistructural, and relational. This characterization is sensitive to the nature of students' creations, interpretations, and meanings. Future directions for research are noted.

Keywords: Problem Solving, Algebra and Algebraic Thinking, Technology

Introduction and Research Purpose

Representational fluency—"the ability to translate across representations, the ability to draw meaning about a mathematical entity from different representations of that mathematical entity, and the ability to generalize across different representations" (Zbiek, Heid, Blume, & Dick, 2007, p. 1192)—is key to understanding mathematical ideas in deeper ways. Modeling representational fluency is often approached through examinations of the number and type and representations student use (Dreyfus, 1991; Selling, 2016), and the nature of connections students make across representation types (Fonger, 2011). However, little research accounts for how to model early phases of students' learning and representing, including students' cursory use of representations to make progress in solving problems. For example, students may make progress toward solving identity or contradiction equations with multiple representations, yet struggle to articulate clear meanings of solution sets across symbolic, graphic, and numeric representation types (Huntley et al., 2007). Indeed, solving equations with multiple representations is cognitively complex, for "solution set" takes on differing forms when solving single-variable equations in symbols, as graphs of functions in a Cartesian plane, and as systems of equations in two variables. Examining students' equation solving with multiple representations with technology such as computer algebra systems (CAS) is especially important, for CAS can both afford and constrain students' activity and equation solving techniques.

The purpose of this research report is to advance characterizations of students' sophistication in representational fluency that are sensitive to the nature of students' mathematical activity and meaningful use of multiple representations in solving problems. I focus on the context of students' solving problems involving linear equations in a CAS environment.

Theoretical Framework and Background

A key theoretical assumption in this study is the notion that students' learning and representing are complexly intertwined processes. From this stance, Dreyfus (1991) advances four stages for learning processes from lesser to greater sophistication: using one representation, using more than one representation (in parallel with others), linking multiple representations, and integrating the use of multiple representations in a flexible way. Fonger (2011) elaborated the notion of connecting representations in an analytic frame that examines the number of representations connected and how. More recently, Selling (2016) modeled students' change in learning and representing as use of: use of a single type of representation, use of different types of representations, use of multiple representations for the same problem, and connects different representations of the same problem.

Across these studies, key components of learning, and arguably change in representational fluency, include: the number of representation types used to solve a problem (one or several), and how students reason about connections.

Building on this, and recalling the definition of representational fluency, in this study, I take translation and transposition as key indicators of representational fluency. A student *translates* among representations by creating and interpreting the meaning of a target representation from the source representation (e.g., symbolic to graphic); a *transposition* involves creating and interpreting a single representation type (Janiver, 1987). In students' interpretations, I focus on students' meaning of a mathematical scenario or entity (e.g., how a graph represents solution sets to equations). I take students' creation and interpretation of representations as the "assessed element" for examining representational fluency. With this unit of analysis, I followed an adapted version of the structure of observed learning outcomes (SOLO) taxonomy (Biggs & Collis, 1982) to articulate students' mathematical activity with respect to using one or more representations, connections between representations, and mathematical meanings students make in solving problems. I focused on four levels of the SOLO taxonomy: (a) *prestructural*—lacks knowledge of the element being assessed; (b) *unistructural*—focuses on only one element being assessed; (c) *multistructural*—focuses on several elements being assessed, may not be able to relate them; and (d) *relational*—correctly completes and relates more than one aspect of a task.

Methods

The data for this study are from two semi-structured task-based interviews I conducted at the close of a teaching experiment with 9th-grade algebra students (age 14-15). The participants included 2 students (of a class of 31) who participated in the 25-day collaborative teaching experiment taught by a ninth-grade teacher. Through this collaboration, we introduced equation solving with CAS and paper-and-pencil by building on students' experiences in comparing and justifying the equivalence of expressions. Students identified solutions to equations such as $ax + b = cx + d$ by comparing functions $f(x) = ax + b$ and $g(x) = cx + d$. Activities were designed to support students in creating and interpreting CAS graphs and tables as comparisons of functions before symbolic manipulations. Interview tasks involved solving linear equations given in symbols like $ax + b = cx + d$ for x (given integer parameter values for a, b, c, and d). Students solved equations with one, no, and infinite solutions. Additionally, students solved a set of two equations in two variables, $y = ax + b$ and $y = c$, solving for the variable x.

Data sources include one 45-minute video-recorded interview with each of Annie and Bryon (pseudonyms). I followed a constant comparative method of coding the video-recorded interviews (Glaser & Strauss, 1967). During a first round of coding, two external coders were trained using an adaptation of the analytic scheme for representational fluency as introduced by Fonger (2011). With 81% agreement across coders, all code disagreements were discussed until the discrepancy was resolved in either a re-assignment of a code or an adaptation to the framework. I drew on the initial round of analyses and additional literature to refine the framework, and recode all data. I again followed a constant comparative method of coding until a stabilized coding framework was established, and all data were coded consistently.

Results: Sophistication in Representational Fluency

In Table 1 I introduce an adaptation of a SOLO taxonomy for characterizing sophistication in representational fluency in four levels: prestructural, multistructural, unistructural, and relational.

Table 1: Levels of Sophistication in Representational Fluency

Level Definition	Data Example
Prestructural. Student demonstrates some procedural work within a given representation type but no understanding is conveyed. Student is not able to create and/or interpret representations of a given type with success to complete a task.	*Annie*: (Types $f3(x) = 3x - 2$ into CAS Graphs, moves cursor along the line,   moves horizontally to the y-axis, uses pen and hovers over quadrant one of graph drawn on her paper) [y=] four is right there. If only I could find that [solution] on my [paper] graph (Sighs).
Multistructural. Student moves between more than one representation type to make progress toward or successfully complete a task but demonstrates no or incomplete understanding of how these representation types are related or what they mean to solve the problem.	 *Annie*: [Starting from $9 + x = 6 + 4x$ Annie creates a split screen CAS graph and table relating $f4(x) = 9 + x$ and $f5(x) = 6 + 4x$] It tells me that it will intersect soon (gestures along positive *y*-axis of the CAS graph [below left]) and with my table it tells me right there (points to $f5(1) = 10$ in table [below right]). […] My solution is either ten or one. I'd have to find out, I really don't know right now.
Unistructural. Student creates and/or interprets representations within a single type to successfully complete a task but demonstrates no or limited understanding of connections to other representation types.	*Bryon*: [Task: Solve $x + 2 + 2x = 5 + 3x - 1$ for *x*. With paper-and-pencil Bryon wrote $3x + 2 = 4 + 3x$, subtracted 2 from both sides, wrote $3x = 2 + 3x$, subtracted $3x$ from both sides, and wrote $0 = 2$] *NF*: So, what's the solution to this equation? [$x + 2 + 2x = 5 + 3x - 1$] *Bryon*: Um, it's got none. Well there's zero *x*'s and it equals two, so it'd be, … if there's no *x*'s there's no solution. Unless it's a zero equals zero. But there isn't a zero equals zero, it's a zero equals two. So that's a no solution.
Relational. Student relates at least two different representation types together with a more sophisticated understanding of how they are related, what they mean, or of their significance to the whole. To *connect* multiple representations, a student gives a correct interpretation of an invariant feature across multiple representations or types.	 *Annie*: I need a graph for this. Because if I take both of them (points to $2 - 2x$ and $-2x + 2$ in the equation $2 - 2x = -2x + 2$) which is probably going to be equal in the graph, it may help (types the expressions into a graph $f6(x) = 2 - 2x$ and $f7(x) = -2x + 2$). (Looking at graph takes a deep inhalation) That's my problem! […] they have infinite solutions.

At the *prestructural* level, students may attempt to create or interpret representations to solve a problem without success. A typical prestructural level of representational fluency is characterized by either no attempt at the problem, or incorrect transpositions within one representation type. For example, asked to find the solution to $y = 3x - 2$ when $y = 4$, Annie struggled in working within the graphic representation type across CAS and paper-and-pencil. She found the point (2, 4) on a CAS graph, but could not identify that point as a solution on a hand-drawn graph. Second, students' *multistructural* level of representational fluency is characterized by students' movement between more than one representation type in either creation or interpretation of representations (but not both). At this level, the student makes progress toward successfully completing the task, but has difficulty conveying a relationship or connection between these representation types. For example, in solving $9 + x = 6 + 4x$ for *x*, Annie was successful in creating a split-screen graph and table, yet could not discern if the solution was 10 or 1. In this case, Annie's uncertainty about the solution being "ten" or "one" reflects a cognitive complexity in identifying solutions sets (i.e., $x = 1$ in a one-variable equation, or (1, 10) in a system of equations), and the meaning of solutions across representational forms.

At the *unistructural* level of representational fluency, students are successful at creating and interpreting multiple representations within one representation type, yet multiple representation types and the connections between them are not considered. For example, Bryon demonstrated a

Galindo, E., & Newton, J., (Eds.). (2017). *Proceedings of the 39th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* Indianapolis, IN: Hoosier Association of Mathematics Teacher Educators.

unistructural level of representational fluency, when given a one-variable equation in symbolic form, he wrote symbolic equations to reach 0 = 2, explaining "if there's no *x*'s there's no solution. Unless it's a zero equals zero. But there isn't a zero equals zero, it's a zero equals two. So that's a no solution." Here Bryon compared equations as equivalence relations. Finally, at the *relational* level, students correctly translate between representations to solve a problem, and may make a connection by correctly identify the solution as an invariant feature across representation types. For example, consider Annie's work. The task listed an original equation, $2 - x - x = x + 8 - 3x - 6$ with a next step of combining like terms ($2 - 2x = -2x + 2$), adding $2x$ to both sides ($2 = 2$) and subtracting 2 from both sides ($0 = 0$) with a solution of $x = 0$ and $x = 2$. In examining the truth of the claimed solution set Annie graphed the functions $f6(x) = 2 - 2x$ and $f7(x) = -2x + 2$ to claim "they have infinite solutions." Annie treated the equation as a relationship between expressions.

Discussion

In the proposed levels of sophistication, *prestructural* and *multistructural* denote lesser sophistication in representational fluency, while *unistructural* and *relational* convey greater sophistication. At the lower levels students conveyed cursory understandings of solution sets, while at higher levels students conveyed meanings of relational equality. It is notable that both students demonstrated sophistication across these levels, which varied by task type. Other frameworks that build on SOLO (e.g., Fonger, 2011) did not sufficiently account for the cursory understandings students expressed in this study at lower levels of sophistication, which may be important for developing greater sophistication over time. Characterizing students' sophistication in representational fluency with this lens can afford a window into students' emerging development of learning and representing. A fruitful direction for research on representational fluency is to investigate how students' meanings of mathematical ideas evolve over time in relation to how students create and interpret representations. The nature of the complex interplay between learning and representing with multiple representations is a rich area to investigate.

With attention on modeling in the Common Core State Standards for Mathematics (CCSSM), research has turned to supporting preservice teachers in preparing to teach mathematical modeling, especially addressing their diverse perspectives of modeling. This study explores conceptions of modeling, especially those not aligned with mathematical modeling as described in CCSSM, as reported by instructors of mathematics and mathematics education courses required by teacher preparation programs. With the analysis of interview data collected from five teacher preparation programs, we found varying modeling conceptions. Specific examples of the conceptions are described, as well as implications for mathematics education and the preparation of future secondary mathematics teachers.

Keywords: Modeling, Teacher Education-Preservice, High School Education

Engaging in mathematical modeling can enable students to learn mathematics as a complex, integrated, and coherent subject, as a powerful tool for making sense of the real world and everyday life, and as a critical numeracy lens for exploring embedded mathematics in media and political reports (Lesh & Doerr, 2003). Mathematical modeling is recommended by *Common Core State Standards for Mathematics (CCSSM)* as both a Content Standard and a Standard for Mathematical Practice (National Governor's Association Center for Best Practices [NGA] & Council of Chief State School Officers [CCSSO], 2010). This dual role of modeling – as a vehicle for learning mathematics as well as a mathematical goal on its own – has been noted by researchers, along with other potential meanings of modeling that may cause misunderstandings in both research and practice (e.g., Anhalt & Cortez, 2015; Smith, 2015).

Principles and Standards for School Mathematics [PSSM] (National Council of Teachers of Mathematics [NCTM], 2000) stated that "it is not surprising that the word [model] is used in many different ways in discussions about mathematics education" (p. 70). In addition to connecting mathematics to the real world, *PSSM* included the meanings: (1) physical materials, such as manipulatives, and (2) simulations in which a teacher shows how to solve a problem to students. Smith (2015) noted that language around modeling can be imprecise, and that care should be taken in distinguishing *instructional models* from *mathematical modeling*. Smith identified *instructional models* as "visible tools we all use to make invisible and abstract mathematical ideas accessible to students" (p. 8), but *mathematical modeling* as the process of making assumptions and simplifying an ill-formed situation to "where we can do some mathematics to answer our initial question" (p. 8). Smith cautioned that the distinction can be unclear. As an example, he explained that a numerical representation can be used both as an instructional model and as a tool supporting mathematical modeling. Similarly, Anhalt and Cortez (2015) described that their mathematics preservice secondary teachers (M-PSTs) expressed initial views of modeling in terms of instructional models, but their views developed to be closer to mathematical modeling after engaging with full modeling tasks.

CCSSM defined mathematical modeling as a complex, iterative process for "choosing and using appropriate mathematics and statistics to analyze empirical situations, to understand them better, and to improve decisions" (NGA & CCSSO, 2010, p. 72). Within the process of mathematical modeling, *CCSSM* recommended that students make assumptions to build a model, test the model mathematically, interpret the results, and then use the interpretations to validate the model or revise the model. *CCSSM* focused on students developing "expertise as well as creativity" as they engage in the modeling process, and focused on making and investigating conjectures as they make sense of the mathematics found within a given situation. M-PSTs need experiences developing their conceptions of mathematical modeling as they engage in modeling tasks and distinguish between the meanings of modeling (Anhalt & Cortez, 2015; Smith, 2015).

As we explore experiences that support M-PSTs in developing their own conceptions of mathematical modeling, we aim to answer the following research question: *What conceptions of modeling, different from those described in CCSSM, were reported by instructors who prepared secondary mathematics teachers to learn and teach algebra?*

Methods

Data used in this paper come from a larger research project *Preparing to Teach Algebra*. A part of the project investigated M-PSTs' opportunities to learn about mathematical modeling at five universities that we call Great Lakes University (GLU), Midwestern Research University (MRU), Midwestern Urban University (MUU), Southeastern Research University (SRU), and Western Urban University (WUU). We interviewed 48 instructors of required mathematics courses, mathematics for teachers courses, mathematics education courses and general education courses. We asked instructors to describe modeling opportunities they provided for students.

The interview data were transcribed and checked by another project team member. Two researchers individually coded the interview transcripts for instances when instructors described modeling in ways different from the conception of modeling described in *CCSSM*. They then met to compare coded transcripts to resolve discrepancies. The first author read all the coded data, summarized the main idea(s) of each coded item, and organized them by similar conception(s) of modeling. Two other authors then individually reviewed the categories and examples from the transcripts. Three authors met to discuss the coded items and categories until consensus was reached. Four themes emerged from this process: (a) generating mathematical notations, (b) constructing proofs, (c) using representations to solve non-contextualized problems, and (d) using manipulatives without solving a problem.

Findings

In considering instructors' examples of modeling opportunities that revealed conceptions different than those described in *CCSSM's* "Model with Mathematics" (NGA & CCSSO, 2010), we describe each theme below, using examples provided by instructors.

Generating Mathematical Notations

Linear Algebra and Abstract Algebra instructors described writing mathematical notations for algebraic concepts as examples of modeling. A Linear Algebra instructor at SRU provided an example of writing equations of spanning sets for $\mathbb{R}^n$. He compared physical representations of $\mathbb{R}^2$ or $\mathbb{R}^3$ with representations of $\mathbb{R}^7$ or $\mathbb{R}^n$ where M-PSTs looked for an abstract model of an abstract algebraic idea. Similarly, an Abstract Algebra instructor at MUU mentioned modeling as generating mathematical notation to describe certain properties. When she introduced an example of a group, she reported her students' struggle to use general mathematical notation describing properties in a specific context. Students either forgot to replace *G*, which represents an arbitrary group, or represented elements incorrectly, or used irrelevant operations. She concluded, "It's being able to interpret what these general statements mean from this particular example that they're looking at. In that sense, I think I'm using modeling." These examples of modeling tasks that rely on using mathematical notation to model abstract mathematical ideas, reveal a difference in conception from that described in *CCSSM* which focused more on mathematical application than abstraction; that is, on quantities and relationships in “physical, economic, public policy, social, and everyday situations” (NGA & CCSSO, 2010, p. 72).

Constructing Proofs

A Reasoning and Proof instructor at SRU and an Abstract Algebra instructor at MUU described constructing proofs as modeling. When the Reasoning and Proof instructor considered the *CCSSM* modeling process during the interview, he said, “Some modification of this goes into proof design.” He described several steps (e.g., identifying variables, formulating a model) of the *CCSSM* modeling process with respect to constructing and testing a proof. He explained, “This [modeling process] doesn't apply as much to formulating a specific problem, as it is to formulating and modeling the style of an argument.” Similarly, when an Abstract Algebra instructor at MUU considered the *CCSSM* modeling process, she mentioned that her students “had to formulate a model in terms of a proof by determining what representation worked.” She described students’ “validating the conclusions and possibly improving the model” in a classroom activity in which M-PSTs constructed a sketch of a proof and then exchanged their proof with another student in the class to receive feedback. These explanations revealed that the *CCSSM* modeling process can be interpreted as processes of proof for algebraic concepts.

Using Representations to Solve Non-Contextualized Problems

For geometry courses, instructors reported that M-PSTs learned about algebra as they learned geometry through modeling. The Geometry instructor at SRU demonstrated a modeling activity in which M-PSTs found the shortest distance between points on the surface of a sphere. This activity required M-PSTs to use a model of a sphere and consider the surface metric; he explained, “When we were first starting to talk about the idea of lines and originally thinking of it in terms of shortest distance… Here's a model that we did, it's sort of like spherical geometry [drawing], not quite so round…” Finding the distance between two points is often used in real-life situations, such as selecting the shortest path to go from one place to another. However, the focus in this model is representing abstract mathematical ideas using a more concrete model, without a specific real-life context. Without support, M-PSTs may struggle to connect these abstract ideas with the real-world, as needed to teach modeling as described in *CCSSM.*

Using Manipulatives without Solving a Problem

Another conception of modeling was the use of algebraic tools. The Student Teaching Seminar instructor at SRU provided an example of modeling where M-PSTs discussed the use of manipulatives, such as algebra tiles, pennies, and counters: “We talked about …models like using pennies or counters that were green and red, or something like that to talk about integers.” The instructor considered modeling as use of tools to discuss algebraic concepts, such as integers, but did not connect it with problem solving.

One major difference between these instructors’ modeling conceptions and those from *CCSSM* is that the instructors did not necessarily considered modeling as involving real-life problem solving. All the examples provided here, however, could be extended to include real-life contexts. For example, for the “Using Manipulatives” conception, if a real-life problem can be represented and solved using algebra tiles, pennies or counters, the problem could be considered as a modeling task described in *CCSSM*. Without such extensions, these reported conceptions entailed a distinct nature that is not evident in the description of modeling from *CCSSM*.

Discussion and Conclusions

It would be ideal if instructors of mathematics and mathematics education courses required by teacher preparation programs were supported in collaboratively sharing conceptions of modeling and preparing M-PSTs to learn about and to learn to teach modeling. It might not be realistic, though, to force all stakeholders to share a single conceptualization of modeling when the term *model* is interpreted in several ways. Along with (1) *using manipulatives*, which we described earlier as part of using instructional models (NCTM, 2000; Smith, 2015), and (2) engaging in mathematical modeling as described in *CCSSM* (NGA & CCSSO, 2010), participating instructors provided examples of three conceptions of modeling that differ from *CCSSM*: (3) generating mathematical notations, (4) constructing proofs, and (5) using representations to solve non-contextualized problems. It is worth recognizing these different meanings of a model or modeling when teacher educators discuss mathematical modeling in their classrooms because M-PSTs may possess varying conceptualizations of these terms either from previous mathematics or from mathematics education courses.

As we investigate several conceptions of a model or modeling from literature and additional meanings of these terms found from data collected from the teacher preparation programs, we conclude this paper by proposing a systematic way to interpret diverse meanings of a model or modeling. When we consider the term *model*, without mathematics in mind, it can be interpreted as manipulatives or imitation, as described in *PSSM* (NCTM, 2000) or by other researchers (Anhalt & Cortez, 2015; Smith, 2015). When we discuss *model with mathematics*, *CCSSM* started with the following statement in their Standards for Mathematical Practice: "Mathematically proficient students can apply the mathematics they know to solve problems arising in everyday life, society, and the workplace" and provided several real-world examples to support this idea. If connections to the real-world are necessary in *model with mathematics,* the first three conceptions reported by participating instructors are not necessarily consistent with this idea. They do, however, share mathematical processes (e.g., identify variables, interpret and validate results) that can be extended beyond modeling to generating mathematical notations, constructing proofs, or representing non-contextualized problem-solving. Connecting such mathematical processes can be an opportunity, not an obstacle, for M-PSTs if they have opportunities to learn from instructors who clarify ways in which these processes can be used for learning and doing mathematics; including, but not limited to, modeling. The various views of modeling held by instructors of teacher preparation programs have the ability to influence the way secondary M-PSTs learn to model with mathematics; therefore, instructors' awareness of these views need to be recognized and discussed in teacher preparation programs.

EDUCATIVE EXPERIENCES IN A GAMES CONTEXT: SUPPORTING EMERGING MATHEMATICAL REASONING

P. Janelle McFeetors
University of Alberta
janelle.mcfeetors@ualberta.ca

Kylie Palfy
University of Alberta & Muriel Martin School
kpalfy@ualberta.ca

Reasoning is critical to students' success in mathematics, yet reports on its development in elementary school are scarce. An action research project with grade 5 and 6 students investigated how growth in mathematical reasoning occurred within abstract strategy games. Results show that Dewey's educative experience emphasizes the importance of students' active engagement and noticing their own reasoning. Through characteristics of continuity and interaction, students analyzed moves, generalized toward strategies, and convincingly justified effective approaches through accepted structures of reasoning. Using educative experiences as practice/theory intersection demonstrates that all students could have equity in accessing high-level mathematics—such as proof and proving—later in school mathematics given opportunities in elementary school to engage in the verbs and strucutres of mathematical reasoning.

Keywords: Reasoning and Proof, Elementary School Education, Instructional Activities and Practices, Classroom Discourse

Reasoning is crucial to students' mathematical learning (Nunes et al., 2012). The possibility of abstract strategy games to support growth in reasoning is relatively unexplored (c.f. McFeetors & Palfy, 2017; Houssart & Sams, 2008). The research question was: How can we understand elementary school students' development of mathematical reasoning through commercial games? Our purpose is to offer a finely-nuanced understanding of a games-based context's contribution to students' foundational experiences of reasoning. Students' data illuminates an intersection between Dewey's theory and a novel classroom practice of using strategy games. The research at this intersection informs a potential practical route for the use of games in mathematics class and a potential theoretical route to understand how informal opportunities to learn impact students' interest and capabilities for future mathematical learning.

Perspectives: Experience and Reasoning

Dewey (1938/1997) saw experience as the essence of education. Experience is comprised of activity and reflection. Students learn by acting in and on the world around them. Reflective thought as an interpretive act is needed to transform activity into an experience. Educative experiences open up possibilities for further learning, determined through the characteristics of interaction and continuity. Interaction involves the interplay between the internalization of an individual and the situation. For situation, both context (ideas, physical environment that is material and natural) and other people are included. Continuity considers each experience as growing out of another experience and leading toward future experiences. Viewing interaction and continuity over a student's school mathematics learning could direct attention to earlier experiences as being foundational. *Foundational experiences* are students' (inter)actions and reflections that prepare them for future, more formalized mathematics learning opportunities.

We view mathematical reasoning as a systematic and logical pattern of behavior (Reid, 2002). Verbs characterizing this behavior include specializing, conjecturing, representing, generalizing, investigating, explaining, justifying, refuting, modifying, and convincing (Lannin, Ellis, & Elliott, 2011; Mason, Burton, & Stacey, 2010; NCTM, 2000). Reasoning structures include deductive and plausible, with subcategories of induction, generalization, specialization, and analogy (Polya, 1954), metaphor, metonymy, mental image (English, 1997); abductive (Conner et al., 2014); and transformational (Simon, 1996). Previous research has identified a developmental trajectory of mathematical reasoning across the grades which mirrors the development of conceptual understanding, moving from analysis of specific cases to systematic generalizations and proof (Stein & Burchartz, 2006; Tall, 2014). Contexts which promote the development of reasoning are familiar, stimulating, and motivating. Teachers' prompting for explanations (Mueller & Maher, 2009) and setting discursive contexts supports mathematical reasoning (Ko et al., 2016). Game play is familiar, motivating and social.

Mode of Inquiry

This report focuses on Pollard School, one of three schools in an action research project. Three grade 5/6 classes were cross-grouped for station-based learning in three micro-cycles. 45 of the 60 students and 3 teachers participated in data collection. Each week for one hour, over three months, one-third of the students participated in the classroom intervention with games. Four games were used: Gobblet Gobblers, Tic Stac Toe, Othello, and Go. The games contain no element of chance. Students played in pairs against another pair to encourage interaction.

While students played, and developed strategies the research collaborators (teachers, researcher, and assistants) prompted them to elicit reasoning. Data collection methods included: verbatim recording of student statements, student record sheets to explain their strategies and reasoning with words and drawings, field notes, photographs of students and game configurations, 20-minute student pair interviews and 30-minute teacher interviews.

We grouped data for analysis by individual student, and read through to develop a holistic view of each student's reasoning (McFeetors & Palfy, 2017). Data was first coded by reasoning structure used: inductive, deductive, indirect, metaphoric, analogic, imagistic, and informal and next by reasoning verbs: specializing, conjecturing, representing, generalizing, investigating, explaining, justifying, refuting, modifying, and convincing. After coding data individually in each phase, we compared data coded to maintain reliability to result in cohesive data sets within categories of both verbs and structures of reasoning. The high quality of students' reasoning caused a return to interrogate processes in which reasoning developed.

Results: Data Interpretation

Although initially students played with little justification for moves, they moved quickly to . conjecturing possibilities, generalizing strategies, and convincing others using varied reasoning structures. Reasoning developed in students through educative experiences, where continuity and interaction were present and contributed to mathematical learning.

Mathematical Reasoning and Interaction

The games were purposefully selected because the possibility of winning elicited a high degree of engagement which led to meaningful interactions. Students used the games to *investigate* moves, *explain* to a partner, *refute* other students' claims, and to *conjecture*. During play they *investigated* strategies and *explained* reasons for moves. In Othello, Renée and Eve *convinced* each other with whispered comments like "go here because we would get the side."

Partners also questioned as they *evaluated* each other's reasoning and *integrated* new strategies. In Gobblet Gobblers, Floyd developed a "checkmate" position, engaging in *analogic* reasoning by using a familiar term from chess. While Eric initially tried to *refute* the claim, he declared in a later match "I have Floyd in the checkmate position." Floyd *explained* "Because then if I put it here he can just go here. If I put it here he goes there. And if I put it over here then he can go there." Floyd's chains of if-then statements are indicative of *deductive* reasoning.

Frequently students *explored* opponents' strategies when their opponent won repeatedly. Students *analyzed* by noticing patterns in plays and moved toward *generalizations*. In Tic Stac Toe, Alex *analyzed* Robyn's moves and stated, "I'm trying to figure out a strategy to do a horizontal diagonal win, like Robyn." Robyn's wins were *convincing* enough for Alex to *investigate* why Robyn was effective and form a *conjecture* around a *modified* way to win.

Collaborators interacted with students' reasoning through verbal prompts to encourage them to enhance reasoning. Furthermore, Esme mentioned to her teacher, "The questions you asked me actually helped me play the game better. They made me think about the strategies."

Mathematical Reasoning and Continuity

The cyclical design of the study occasioned continuity of experiences from playing less complex games toward a highly strategic game by the end. Students' reasoning became more sophisticated as the complexity of the games increased, as well an increased eagerness to improve reasoning emerged. Continuity is best viewed by a focus on one student's development. We use Renee's thinking to illustrate how integral continuity was to students' progression.

Beginning with Gobblet Gobblers, Renee built on her prior Tic Tac Toe strategy of "playing in the middle of the board helps you because then any other place you go you can get two in a row." Renee *generalized* a middle position as a winning strategy and *justified* her answer using evidence from her previous experiences with Tic Tac Toe and Gobblet Gobblers. She combined *analogic* reasoning in connecting two games and *inductive* reasoning in moving from many specific instances to a global strategy.

For more complexity, Renee and her peers moved to *investigate* strategies in Othello. Renee quickly realized that both the sides and corners were powerful spots to control on the board: "I would put white in spot 13 because then I would get the side. The blak [sic] might then go on the side on square 12 and then I would sandwich them on the square to the left of square 12. I would then have 3 on the side". The importance signified by her chain of if-then statements indicates the development of a game tree of mental images or *imagistic* reasoning (Pirie & Kieren, 1994).

For the duration of the project, Renee challenged herself to learn a new game, Go. She demonstrated an emergent strategy after two matches to make an offensive move to "make a wall" in a diagonal line. Renée *conjectures* and *explains*, but does not justify her strategy of "making a wall". Her continued experiences gave her the confidence to advise others in the final class through the tips: "Making dimonds [sic] to capture the other player and marking territory" and "Making diagonal lines so that the other player has a hard time capturing you.

Renée *identifies* two strategies where naming board arrangements is an abstraction from *generalizing*, and now also *justifies* each strategy. The accompanying images point to her use of *imagistic* reasoning. Orally, Renee *justified* the first tip stating, "I like to make rhombus shapes…because it's my territory and nobody can put one in there. And, it's difficult to capture." Renee also commented on how game experiences opened up the possibility for further learning:

> It also helps learn how to make up your own strategy. So when you are doing problem solving–you use–what you did for learning a strategy and try to connect it to problem solving that you are doing. … I find it helps playing with other people. 'Cause then you can learn how their strategies affect the games. And also you get to know about the way that they think. And I think that it is important when you are with people, learning how they think so that you can use that to help you –

Renee sees connections to future experiences with problem solving. She identifies interpersonal learning in figuring out how others think. Finally, Renee introduced Go to her family, carrying forward learning from mathematics into familial, recreational activities outside of school.

Discussion: Significance and Conference Theme

As a potential new route to explore, commercial abstract strategy games like the ones used in this study can be used to support and investigate children's development of mathematical reasoning. What our research suggests is that the games were an authentic context, and what we observed were moments of reasoning that moved from nascent toward more robust. The verbs of mathematical reasoning students enacted while playing the games were broad and varied. Future research could include exploring more games and exploring a new site of parent-child interactions which could enrich home-school connections.

At the intersection of theory and practice, Dewey's notions of interaction and continuity are helpful in framing pedagogical decisions. Our research demonstrates that students can have educative experiences when teachers plan for interaction and continuity. These *foundational experiences* are required early in children's mathematical learning so that they can be consolidated over time and prepare them for success in secondary and post-secondary studies.

EFFECT OF QUANTITATIVE REASONING ON PROSPECTIVE MATHEMATICS TEACHERS' COMPREHENSION OF A PROOF ON REAL NUMBERS

Mervenur Belin

Gülseren Karagöz Akar
Boğaziçi University
gulseren.akar@boun.edu.tr

This study investigated the effect of quantitative reasoning on prospective mathematics teachers' comprehension of a proof on the decimal representation of real numbers. A proof comprehension test prepared according to the dimensions suggested by Mejia-Ramos, Fuller, Weber, Rhoads and Samkoff (2012) was used as both the pre-test prior to and the post-test upon completion of an instruction given to 19 prospective mathematics teachers. Also, one hour long post-clinical interviews were conducted with six of them. Wilcoxon Signed Rank Test results showed a significant difference between the pre and the post proof comprehension test on the performances of prospective teachers. Together, the results from the interviews suggest that once prospective teachers engage in quantitative reasoning during instruction their proof comprehension might develop.

Keywords: Reasoning and Proof, Rational Numbers, Number Concepts and Operations

Introduction

Proof and proving are the important branches of mathematics education. However, previous research showed that students face with difficulties related to proof and proving (Moore, 1994). Moore (1994) summarized the sources of difficulties considering proof practices: lack of knowledge about definitions of terms and statements and how to use them in the proof; lack of understanding the concepts and also mathematical language; inadequate concept images; and failure to generate or to use examples about the proof statement. For the elimination of these difficulties, researchers focused on different aspects during teaching using informal proofs such as visuals, diagrams, and generic examples (Gibson, 1998). As much the use of empirical examples are important, research also suggested that along with examples, the use of quantitative reasoning (Thompson, 2011) could be critical for students' thinking about proof (Weber, Ellis, Kulow & Özgür, 2014) since students who focus on generalizations through quantitative reasoning can perform better in constructing proofs than students who focus on empirical examples while obtaining generalizations (Ellis, 2007). Besides the importance of eliminating students' difficulties about proof and proving during teaching, it is essential to consider how to evaluate students' performances. Instead of using 'state and prove' format, Mejia-Ramos et.al. (2012) developed an assessment model of proof comprehension at undergraduate level with seven dimensions: **D1:** Meaning of terms and statements, **D2:** Justification of claims, **D3:** Logical status of statements and proof framework, **D4:** Summarizing via high-level ideas, **D5:** Transferring the general ideas or methods to another context, **D6:** Illustrating with examples, and **D7:** Identifying the modular structure. Considering research both on eliminating students' difficulties about proof and proving and using proof comprehension model, this study investigated the effect of quantitative reasoning on prospective teachers' comprehension of a proof about decimal representation of real numbers because research has shown that students have misconceptions and difficulties regarding real numbers (Voskoglou & Kosyvas, 2012), which is proposed to be taught through quantitative reasoning (Karagöz-Akar, 2016). The research questions of this study were as follows: What are the current levels of prospective mathematics teachers in the pre-and post-proof comprehension test according to the proof comprehension dimensions? Is there any significant difference between pre and post proof comprehension test results of prospective mathematics teachers who took an instruction about construction of real numbers as decimal expansion via quantitative reasoning? How do prospective mathematics teachers reason on the post-proof comprehension test upon completion of an instruction on the construction of real numbers as decimal expansion through quantitative reasoning?

Method

The sample of the study (N=19) was the prospective primary and secondary mathematics teachers* (from now on will be called as students) at a university in Turkey in which the medium of language was English. The design of the study was mixed methods, specifically an embedded experimental study since the quantitative data obtained from proof comprehension tests were supported by the qualitative data via conducting interviews. Quantitative part of the study was one group pre-test post-test design and the qualitative part consisted of semi-structured interviews conducted after the post-test.

For the data collection, a statement and its proof about the decimal representation of real numbers was used (Usiskin, Peressini, Marchisotto & Stanley, 2003) The authors individually developed the test questions considering the proof comprehension dimensions (Mejia-Ramos et.al., 2012). Eventually, the test consisted of 13 questions. After checking validity and reliability issues, the test was provided to students prior to and after the instruction. The instruction included two teaching sessions which focused on the decimal representations of real numbers via quantitative reasoning. Then, semi-structured interviews, with 6 students were conducted to collect further data on how students reasoned about and justified their answers to the proof comprehension test questions.

For the analysis of the data for research question 2, Wilcoxon-Signed Rank test was used due to the low number of participants. For the analysis of the data for research question 1, the percentages of correct, incorrect and partially correct responses for each dimension and each question were obtained. This informed whom to interview. Particularly, if the student answered all the questions in the dimensions correctly, his/her performance was classified as correct answer. If they could not answer or incorrectly answer all the questions in the dimensions, their performance was classified as no/incorrect answer. If they gave correct answer to one of the questions in the dimension and no answer or incorrect answer to the other question, the performance in the dimension was classified as partially correct. This classification was maintained both for the pre-test and the post-test performances. Then, the transitions between the answers from the pre-test and the post-test were illustrated (See Figure 2). For instance, for proof comprehension dimension 1, if a student was classified as partially correct in the pre-test and correct in the post-test, for the analysis, the case was taken as from partially correct to correct answer for Dimension 1. The focus of analysis for the interviews was students' reasoning quantitatively on the answers to the post-proof comprehension test questions.

Results

Quantitative Results

Regarding research question 1, when the percentages for correct, partially correct and incorrect answers in terms of dimensions were examined (See Figure 1), there is a decrease in the percentage of incorrect answers from the pre-test to the post-test. Therefore, percentages of partially correct and correct answers increased for almost all the dimensions, except for D3, asking about the method of the proof. For that, the percentage of incorrect answers in the post-test was higher and the percentage of the partially correct answers in the post-test was lower than the pre-test. For the research question 2, the Wilcoxon Signed rank test showed that there was a significant difference between the pre-and the post-proof comprehension test results ($z=-3.731$ and $p<0.05$). Additionally, 18 students' post-proof test scores were higher than the pre- test scores. One of the students' post-test score were the same as the pre-test score. Also, there were no students with a lower score in the post-test than the pre-test.

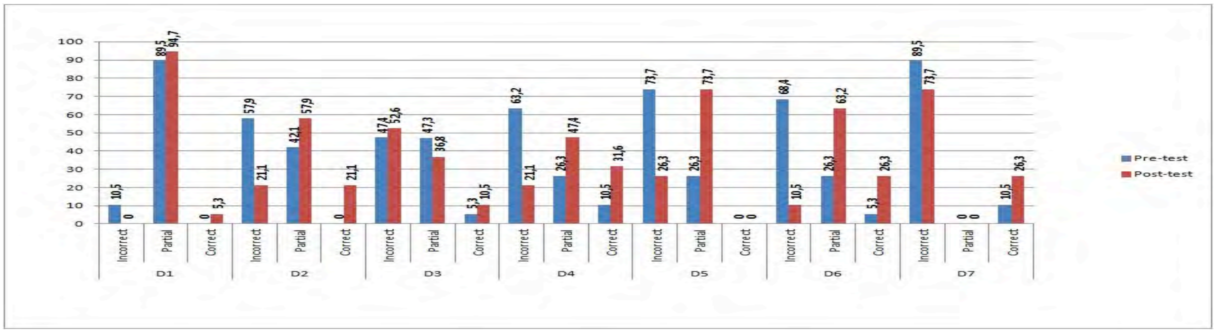

Figure 1. Response percentages for proof comprehension dimensions.

Qualitative Results

For research question 3, the following outline was used: As the data analyzed from 19 students, 5 different transitions from the pre-test to the post-test occurred (See Figure 2).

Interviewees	Pre-test D1	Pre-test D2	Pre-test D3	Pre-test D4	Pre-test D5	Pre-test D6	Pre-test D7	Post-test D1	Post-test D2	Post-test D3	Post-test D4	Post-test D5	Post-test D6	Post-test D7
S1	Partial	Partial	Correct	Partial	No/incorrect	Partial	Correct	Correct	Partial	Correct	Partial	Partial	Partial	Correct
S5	Partial	Partial	No/incorrect	No/incorrect	Partial	Partial	Correct	Partial	No/incorrect	Partial	Correct	Partial	Partial	Correct
S7	Partial	Partial	No/incorrect	No/incorrect	No/incorrect	Partial	No/incorrect	Partial	Correct	No/incorrect	Correct	Partial	Partial	Correct
S8	Partial	Partial	No/incorrect	Partial	No/incorrect	No/incorrect	No/incorrect	Partial	Correct	Partial	Partial	Partial	Partial	No/incorrect
S9	Partial	Partial	Partial	Partial	No/incorrect	No/incorrect	No/incorrect	Correct	Correct	Correct	Partial	Partial	Correct	Correct
S15	No/incorrec	Partial	No/incorrect	No/incorrect	Partial	No/incorrect	No/incorrect	Partial	Partial	No/incorrect	Correct	Partial	Partial	No/incorrect

Meanings of the colors		Transitions between pre-test and post-test		
(yellow)	There is no change	No/incorrect answer--> Partially correct answer	No/incorrect answer--> Correct answer	Partially correct answer --> No/incorrect answer
(green)	There is a positive change	Partially correct answer --> Correct answer	No change	
(pink)	There is a negative change			

Figure 2. Interviewees' profile.

For all of the five transitions, there was data showing that students used quantitative reasoning when needed. Yet, due to the page limitation, a sample data from Student 8 (S8) representing the transition from partially correct answer to correct answer in D2 was shared: S8 answered the Question 3(Q3) in both the pre and the post test correctly but he had no answer for Question 4(Q4) in the pre-test. Yet, in the post-test for Q4 (See Figure 3) he used both the diagrams and symbolic expressions to justify how he got the inequality asked in the question.

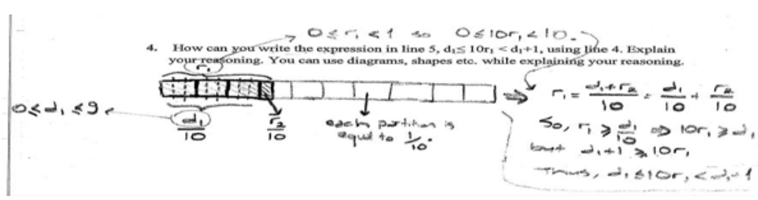

Figure 3. S8's answer for the Q4 in the post-test.

The data in the figure seems to suggest that he reasoned in the following way: S8 continued reasoning on the previous example he used in the test, 10/3, in question 1. He had divided 10 with 3 and came up with 3+ 1/3 using the division algorithm. Then, continuing with the remaining part, 1/3, he first partitioned a whole into 10 equal pieces. Then, he repartitioned each equal piece into 3 more equal pieces. Thinking 10 of those 1/30 th pieces, he obtained 10/30. This allowed him to determine the number of 1/10th s in 1/3 such that he grouped the pieces (each being equal to 1/30) by 3 and then counted how many of those 1/10 th there are in 1/3 rd. That is he measured 10/30 th with 1/10 th. In this way, he was able to find $d_1/10$ as being equal to 3/10 such that there were 3 times 1/10 th in

10/30 and $r_2/10$ was equal to 1/30. This way he was able to justify the inequality in the Q4. During the interview his reasoning supported his written work:

> S8: Now r_1 could be between zero and 1. I told you. For this reason, $10r_1$ is between 0 and 10. Now d_1 is $0 \leq d_1 \leq 9$ in this way. Now it is easier to define over the figure. We reach $r_1 = d_1/10 + r_2/10$. r_1 is greater than $d_1/10$. Why? we said here that from the piece of 10/30 that is 1/3 there are some remaining parts 1/30 portion, I mean. The non-terminating part I mean $r_2/10$. Here too. r_1 is greater than $d_1/10$. Therefore, $10r_1$ is bigger than d_1. d_1+1 is bigger than $10r_1$ because it is $r_1<(d_1+1)/10$.(He indicates the expression). That is d_1+1 means that. It exceeds this part (shows $r_2/10$ part). For this reason it (referring to 1/10) exceeds the portion 1/30.

As the data indicated S8 thought through an example using quantities and shifted to symbolic expressions to justify his answer through quantitative reasoning. Particularly, since r_1 was equal to the sum of $d_1/10$ and $r_2/10$, he was able to reason that r_1 had to be bigger than $d_1/10$. In this way, he reasoned that $10r_1$ was bigger than d_1. For the other side of the inequality, i.e. $10r_1$ is smaller than d_1+1, he again thought through the diagram such that he knew that the amount referring to $d_1/10+1/10$ exceeded the portion $r_2/10$.

Conclusion

The analysis of the results showed that once students reasoned quantitatively their comprehension of a proof on real numbers have developed: Particularly, not only there was a significant difference between the pre-and-post test results but also both in the post-test and during the interviews, for all dimensions students had a tendency to use diagrams and think through quantities while elaborating and justifying their answers. Specifically, descriptive results showed five different transitions from the pre-test to the post-test. Results showed that students had a development in proof comprehension dimensions, except for the D3, in which the name of the proof was asked. In fact, for all of the five transitions, data from the interviews showed that all students used quantitative reasoning while justifying their answers. These results align with Weber et.al. (2014) and Ellis' (2007) study arguing that quantitative reasoning is beneficial for proof and proving. Therefore, extending the earlier research results this study showed that students were able to make generalizations through quantities and even explain the abstract expressions in the proof comprehension test. Though, because of the number of students (N=19) participated in this study, we propose the effect of quantitative reasoning on proof comprehension regarding both the real numbers and other concepts to be investigated further.

LOGICAL IMPLICATION AS THE OBJECT OF MATHEMATICAL INDUCTION

Anderson Norton
Virginia Tech
norton3@vt.edu

Rachel Arnold
Virginia Tech
rlongley@vt.edu

Proof by mathematical induction poses persistent challenges for college mathematics students. We use an action-object framework to analyze ways that students might overcome these challenges. We conducted three pairs of interviews with students enrolled in a proofs course. Tasks were designed to elicit student understanding of logical implication and components of proof by induction. We report results from one student, Mike, who had constructed logical implication as an object, and who invented a quasi-inductive proof.

Keywords: Reasoning and Proof, Instructional Activities and Practices, Post-Secondary Education

Mathematical induction relies on two defining properties of the natural numbers: 1 is a natural number; and if k is a natural number, then k+1 is also a natural number. Any set with these two properties contains the natural numbers. In particular, if we define S as the set of natural numbers n for which an open proposition P(n) holds, then we can show S=N by showing the following: (1) P(0) is true, and (2) for any natural number k, if P(k) is true then P(k+1) is also true, written P(k)→P(k+1). In other words, P(n) holds for all natural numbers n if S satisfies the two defining properties of the natural numbers. The inductive implication P(k)→P(k+1) can be treated in one of two ways: as an inductive step from the inductive assumption, P(k); or, as an invariant relationship between P(k) and P(k+1) for any k. We apply an action-object framework to the study of logical implication and its use in proofs by induction.

Action-Object Theory

Piaget (1970) distinguished logico-mathematical knowledge from other forms of knowledge via its objects of study and, specifically, how they are created. Following Piaget, we define mathematical objects as coordinated mental actions. Our distinction between logical implication as a transformation and logical implication as an invariant relationship builds upon Piaget's action-object theory of mathematical development. Dubinsky made a similar distinction between actions and objects in APOS theory, which is also derived from Piaget's genetic epistemology (Dubinsky & McDonald, 2001). Within that framework, Dubinsky (1986) conjectured that understanding implication as an object could empower students in mastering proof by induction. Our study is an investigation of this claim within our own action-object framework.

Methods

The first author conducted clinical interviews with students from an Introduction to Proofs course taught by the second author. The course is a junior-level mathematics course designed to prepare mathematics majors for rigorous expectations in subsequent proofs-based courses. Three students volunteered for the study, and all three students were invited to participate in a pair of clinical interviews—one interview before mathematical induction was taught in class and one after. All of the interviews were video-recorded, and they lasted about 45 minutes. Each interview consisted of the students responding to tasks that were designed to elicit their reasoning and understanding. These tasks consisted of three types: logical implication, components of mathematical induction, and formal proof by induction (see Table 1).

Table 1: Sample Tasks

Task Type	Sample
A. Logical Implication	Suppose the statement is true: "If two topological spaces are homeomorphic, their homology groups are isomorphic." Evaluate whether the following statements are **true**, **false**, or **uncertain**. 1) [converse] 2) [contrapositive] 3) [negation]
B. Components of Mathematical Induction	Suppose P(n) is a statement about a positive integer n, and we want to prove that P(n) is true for all positive integers n. For each scenario, decide whether the given information is enough to prove P(n) *without induction*, *with induction*, or whether the given information is *not enough*. P(1) is true; there is an integer k≥1 such that P(k) implies P(k+1). P(1) is true; for all integers k≥1, P(k) implies P(k+1).
C. Formal Proof by Induction	Prove the following claim: For every positive integer n, $2 + 2^2 + 2^3 + \ldots + 2^n = 2^{n+1} - 2$.

Results

We report results for a student named Mike from his first interview. We focus on Mike because he seemed to possess an understanding of logical implication as an object. Mike quickly recognized the three transformed statements in Task A1 as the converse, contrapositive, and negation of the original statement. For example, in evaluating Task A3, he responded, "if the first statement is true, then that has to be false." When asked to justify his response, Mike replied, "it's the negation of the implication." He seemed to recognize how the original statement had been transformed into the three statements he was evaluating, and he did not have to rely on any formal notation in order to do so. We characterize this recognition as an assimilation of the statements within a single structure for comparing and transforming them.

In contrast, Mike did not seem to readily assimilate the scenarios in Task B1. However, he could make critical distinctions between them, particularly with regard to quantifiers like "there exists" and "for all." For example, consider his comparison of Tasks B1 and B3. Note that "M" refers to Mike, and "R" refers to the researcher (first author).

M: [reads Task B1 aloud, then pauses] That's interesting. I don't *think* it's enough because that's only the truth of two, unless you are meant to assume to know that that means that you could like replace that k+1 with some other integer--you know, j--that was… and then j+1 is also true, and so on. But I think it's just not enough.
R: Okay, so what *would* you know from this one?
M: I would know that there's at least... P(1) is true; P(k) and then P(k+1) is true. And that's all I really know, from this.
R: So you would know P(1) is true, P(k) is true, and P(k+1) is true.
M: Yeah.
R: But that's not enough to prove…?
M: That's not enough to prove all positive integers.
R: So, you know P(k) is true, for which k's?
M: Just, there is a k. Just one k.
R: Is that the problem, then?
M: I think that's the problem.
R: [shows Task B2 on paper]
M: [looks at statement and immediately responds] Yeah, I know this is what, this is what it would take. P(1) is true and for all integers, k, greater than 1, P(k) implies k+1 is true. So,

that is the like sort of recursive thing that I was talking about, up there, where like… If you know that, yeah, so… P(1) is true and for all integers greater than 1, P(k) implies P(k+1), so that just grows to encompass all reals.

R: How does this recursive thing work?

M: Well, recursive is the wrong word. I mean, it just like… If you know P(k). Let's say k is equal to 2. So then P(2) implies P(3). But since it's for all integers k greater than 1, then P(3) also implies P(4), and so on.

Despite having never seen proof by induction, Mike was able to engage in the cognitively demanding task of analyzing its components in Task B. His objectification of logical implication seemed to free up his cognitive resources for focusing on *where,* not *how,* to apply the inductive implication. However, Mike's struggle with the increased demands of Task B were evidenced by his numerous pauses and minor mis-statements (e.g., "k greater than 1").

Upon reading Task B2, Mike immediately recognized what had been missing in Task B1. The new scenario allowed the implication to be applied to all values greater than or equal to 1. Mike began to recursively apply the logical implication, P(k)→P(k+1), in a manner consistent with what Harel (2002) called "quasi-induction." In both Tasks B1 and B2, Mike was eager to successively apply the inductive implication to consecutive pairs of integers. After sorting through the cognitive demands of the tasks, he was able to do so correctly.

Mike subsequently applied his quasi-inductive reasoning to Task C. Although the task did not explicitly call for induction, Mike independently attempted to prove the claim that way.

M: Well, I'm sort of thinking here that like, start with n equals 1 because you know, the simplest to add all of them up. So, you have 2 is equal to 2 to the second minus 2, just… And I was thinking, if you could write it in sort of like a symbolic way where you have like the next one where n equals 2, then you have 2 plus 2 squared is equal to 8 minus 2. And then I was thinking maybe you could plug like the 2 squared minus 2 in for this initial 2 and get it to like [moves right hand in circular motion], you know, build on itself.

R: Oh. Okay. Um, I think that's a good idea. Um, does that relate to any of [the Task B scenarios]...

M: Yeah. Yeah, it does. That's what sort of gave me the idea... is like for the k+1.

R: Okay. These gave you the idea for doing that? Which of these scenarios would it best fit?

M: Well, hopefully [Task B2].

In Task C, P(n) is the statement "$2 + 2^2 + 2^3 + \ldots + 2^n = 2^{n+1} - 2$." Mike's approach was to use P(1) to build the equation in P(2) by substituting the right hand side (2^2-2) of the equation of P(1) for the initial 2 in the left hand expression in P(2). In this way, Mike used an inductive approach to show P(1)→P(2). Mike did not complete a formal proof by induction because he did not know how to write the inductive implication in a "symbolic way" that would generalize from any case, k, to the next case, k+1. However, Mike was conceivably on his way to generalizing his quasi-inductive argument into a formal proof by mathematical induction.

Conclusions

Piaget (1970) characterized logico-mathematical thought as grounded in composable and reversible mental actions. He described mathematical objects as coordinations of such actions. Dubinsky (1986) conjectured that treating logical implication as an object enables students to reason in more powerful ways, specifically with constructing proofs by mathematical induction. We investigated and affirmed Dubinsky's conjecture through our interviews with college mathematics students, like Mike.

Mike entered our study with an understanding of logical implication as an object. He coordinated actions on logical implications as objects to organize components of mathematical induction into inductive arguments. He used implication across particular pairs of cases (e.g. P(2) implies P(3)) in a manner that fits Harel's (2002) description of quasi-induction. Mike's struggles were limited to the following: (1) determining the cases in which the object applied; (2) symbolizing the inductive implication in a way that generalized to all valid cases.

Mike's first struggle relates to the role of (hidden) quantifiers and students' difficulties in differentiating between "there exist" and "for all" statements (Shipman, 2016). He recognized that Task B1 was existentially quantified, but struggled with the difference between an arbitrary variable and a fixed, unknown value. However, because Mike had logical implication as a mental object, he was able to resolve the details of the quantification. Mike's second struggle was apparent in his pre-interview in that he could not symbolically state the inductive implication for an arbitrary k. However, by the post-interview, he easily formalized a general inductive implication, possibly due to instruction on mathematical induction.

Mike did not seem to experience difficulty with other common challenges reported in prior research on mathematical induction. For example, he did not conflate the inductive assumption with assuming the proposition he was supposed to prove (cf. Avital & Libeskind, 1978; Ron & Dreyfus, 2004). We argue that students like Mike, who understand logical implication as an object, avoid this pitfall of conflation by treating the inductive assumption as a component of a larger object. For them, the inductive assumption is not an independent claim, rather it exists within the implication that must be established.

Piagetian theory offers a lens through which Dubinsky (1986) identified the objectification of logical implication as a potentially critical aspect of mastering proof by mathematical induction. Our results suggest ways that instruction can build upon such understanding. One such approach is the task sequence used in our study (Task A, Task B, and then Task C), which seemed to guide Mike to nearly invent mathematical induction. His independent formulation resembled Harel's (2002) quasi-induction, which Harel had recommended as an instructional approach. Instructional methods that separate the inductive hypothesis from the inductive step may inadvertently discourage students from engaging in quasi-inductive reasoning.

PUSHING TOWARD THE PINNACLE: SUGGESTIONS FOR ASSESSING PROOF UNDERSTANDING

Mark A. Creager
University of Southern Indiana
macreager@usi.edu

Zulfiye Zeyebek
Gaziosmanpasa University
zulfiye.zeybek@gop.edu.tr

Proof is considered the pinnacle of mathematics, but students commonly fail to understand proof. Research programs have sought to understand how students develop an understanding of proof and looked for ways to help improve students' understanding. Showing significant gains on measures of proof understanding is difficult. We suggest that the way proof assessments are scored is a cause. Namely, they focus on whether or not students can create acceptable proofs, and fail to capture students' informal means of reasoning. We describe three different proving practices we have observed that appear similar in their understanding of proof from the perspective of many rubrics, but when analyzed more closely show differences in understanding.

Keywords: Assessment and Evaluation, Reasoning and Proof

Proof has been called the pinnacle of mathematics, but most students fail to learn how to prove (see Harel & Sowder, 2007). Mathematics education researchers have posited several causes. No doubt a problem this widespread is likely the result of many factors. However, one issue we raise is that proof is often conceived of as a concept that one has either learned or not. Instead, we posit that proving is a complex process that even when understood well may not lead to success in all proving situations.

When proof understanding is assessed, students' proofs are often compared to teacher- or researcher- generated proofs. If we maintain the metaphor of proof being the pinnacle – the highest point – of mathematics, then it is clear there is an arduous journey from the bottom to the top. However, we are only measuring whether or not students have reached the mountain top and do not capture where they fall along this journey. We hope to provide insights into understanding students who are on their journey to the top.

Summary of Previous Research about Proof and Proof Understanding

In this section, we elaborate our meaning for proof and describe how various studies have attempted to assess proof understanding in order to highlight our critical issue. Namely, that these assessment rubrics focus on whether students have or have not developed deductive reasoning, and failed to parse the many diverse ways of reasoning informally.

Defining Proof and Proof Schemes

By proof we mean an argument that removes the doubts for a conjecture. In mathematics, proof is often reserved for specific types of arguments. To avoid confusion, we will clarify proofs by their types and allow others to decide if the arguments meet their definition for proof. Harel and Sowder (2007) described proof scheme as a way of thinking about proof. We have found their framework to be useful in categorizing the different types of thinking individuals use in proving situations. Harel and Sowder (1998) identified three kinds of proof schemes; external-conviction, empirical and deductive. Those who use the external-conviction proof scheme remove doubt by referring to an external source, such as a book, teacher, or form of an argument. Empirical proof schemes are marked by the use of examples, and deductive proof schemes meet three criteria: they prove for all cases, rely on valid forms of logical reasoning, and show operational thought (Harel & Sowder, 1998). Each proof scheme has many sub-schemes. Three are relevant to our discussion; the ritual proof scheme (external-conviction), the perceptual proof scheme (empirical), and the contextual proof scheme (deductive).

Assessing Understanding of Proof

The National Assessment of Educational Progress (NAEP) includes items that asked for a proof (National Assessment Governing Board, 2008). These items determine whether or not students understand deductive proof. For one released item students received full credit for including the full number of "statement-reason pairs" used in the assessor-generated proof, and varying degrees of partial credit for the number of statement-reason pairs they completed (NAEP Questions Tool, 2014). This rubric however would treat a student who reasoned empirically (demonstrating an understanding of the conjecture) and a student who left the item blank (demonstrating no understanding) as the same because both used zero statement-reason pairs.

More robust assessments, such as, Knuth and colleague's (2009) used a rubric broken into four categories. Level 0 included no attempt at proof, a proof based on an outside authority or based on an unsupported claim (external-conviction), Level 1 included empirical arguments, Level 2 included students who attempted to prove, but the arguments "fall short of being acceptable proofs" (p. 155), and Level 3 arguments were acceptable proofs – a term we adopt. Their rubric distinguishes students who no longer hold the empirical proof scheme, but still have not developed the deductive proof scheme. However, these students are all treated the same.

The most relevant evidence for our claim comes from Quinn (2009). As a result of breaking empirical arguments into two categories, she showed improvement in her students' ability to prove. Would similarly including more categories to Knuth and colleagues' Level 2 lead to a greater likelihood in showing interventions were effective? These studies all measured the differences between mathematicians' and students' views of proof. Weber and Mejia-Ramos (2015) suggested that one issue with these assessments is the ambiguity of the word "convince" because it has two interpretations, absolute and relative conviction. Absolute conviction occurs when someone "has a stable psychological feeling of indubitability about a claim" (p. 16). Students' inconsistent responses are a result of researchers' assumptions that participants have gained absolute conviction when they have only gained relative conviction..

Examples of Individuals Transitioning to Deductive Proof Schemes

We now highlight three different ways of reasoning we observed in our participants who would be considered as reasoning similarly by the many assessments for proof. Creager (2016) analyzed 13 pre-service secondary teachers (PSST) knowledge of geometric proof using a survey and two separate hour-long, cognitive interviews. Zeybek (2014) analyzed pre-service elementary teachers' (PSETs) conceptions of proof using a survey that consisted of open-ended proof items and cognitive interviews. Both studies asked participants to create, evaluate, and prove conjectures and evaluate researcher-generated proofs.

Proof Method

Ten out of 13 PSST in Creager's (2016) study appeared to have a procedural understanding of a method for proof in geometry. When asked to prove figures congruent, their method included the following steps; find two triangles that are congruent, prove those triangles congruent, then use triangle congruence to show the original figures congruent. These PSSTs used this method to create acceptable proofs, but there were five pieces of evidence that suggested they only had a procedural understanding of this method for proof.

First, this was the only method of proof that was used. For example, Mike said, "I don't know if I can [prove triangles similar]." Sadie said, "I don't remember how we prove lines parallel." Second, when they arrived at a point where they could not use their method, they either assumed an additional property was true (whether it was or was not) or claimed the conjecture was false. For the conjecture, “The median of a triangle creates two smaller triangles of equal area”, the PSSTs in this category could not use their proof method so, they said the conjecture was false. Third, they did not gain absolute conviction from their arguments. These PSSTs hedged their arguments by calling them “informal proofs” or “demonstrations”. Fourth, they focused on the form of the argument when asked to evaluate researcher-generated proofs. They preferred arguments that did not use examples and included “statements and reasons”. However, their meaning was not aligned with accepted uses. They accepted arguments that were based on examples that did not have any special characteristics (e.g. an acute triangle versus an isosceles triangle) and they felt that any reason was valid. Finally, in situations where proof would be a reasonable, but not explicit expectation, they relied on the empirical proof scheme. Mike for example, verified empirically that the diagonals of rectangles create two congruent triangles. When he was asked if he was absolutely certain, he agreed, but when asked how he would prove that he said, “Well, I guess I’d try to prove two triangles congruent.” Eight of the thirteen PSETs in Zeybek’s (2014) study held a similar procedural understanding of proof.

Interestingly though, the PSST and PSETs created several acceptable proofs. In a way, they are more like individuals with a ritual proof scheme. They seem to know what to do, but not why they would do it. However, they would be considered to have improved in their understanding of proof on many assessments. Our perspective however is that these students have learned to play their teachers’ game more effectively. Something we consider in the discussion.

Ritual Proof Scheme: The case of Alana and Elizabeth

Alana, a PSST, often reasoned similarly to those with a method for proof, but created arguments that were not “acceptable” proofs. To prove the diagonals of isosceles trapezoids are congruent, Alana marked the figure in a way that would suggest a proof, but claimed two different triangles were congruent. Thinking this was an error, she was asked for clarification. At this point Alana said, “Nope, nope, nope. Hold on here. No, I just know. I don’t know how to prove it but, I just know it’s diagonals are equal.” At that point she was okay with simply accepting the conjecture as true and moving on. Alana regularly displayed evidence of having the ritual proof scheme, but rejected empirical proofs regularly, despite the fact that she used them and found them convincing. Because of this, she would be considered as improving in her understanding of proof on many rubrics.

Zeybek (2014) similarly felt that PSET Elizabeth had a ritual proof scheme. She primarily created arguments to meet her perceived image of how proofs should look. When evaluating a false researcher-generated argument in the two-column format, Elizabeth claimed it was valid proof despite recognizing a flaw in the argument.

Contextual Proof Scheme: The Case of Lacy

Lacy, a PSST, worked on several conjectures about special segments of triangles (medians, altitudes, and angle bisectors). In every case, Lacy only considered the special segment that was drawn from the apex angle of a triangle drawn with a horizontal base. When Lacy used a Geometer’s Sketchpad to construct an isosceles triangle, the figure did not have a horizontal base, and she asked the researcher to fix the figure. Because this was a consistent behavior, it seems that Lacy’s conception of special segments of triangles was only those drawn from the apex angle. Because of this she “proved” several false conjectures.

Discussion

Lumping these types of student thinking into one category is problematic because it limits our ability to show gains in proof understanding. However, some rubrics seem too lenient. Are we to consider individuals like Alana or Elizabeth an improvement? Understanding the limitations of empirical reasoning could be a motivating factor in the search for more secure ways of justification. However, Alana consistently rejected empirical proofs, but gained absolute conviction by using the empirical proof scheme. Is it the case that she truly understands the limitations of empirical reasoning or is it that she has learned it is not part of the game called proof? Simply rejecting empirical arguments seems to be insufficient evidence to claim an improvement over those with the empirical proof scheme because it was Alana's dominant proof scheme. We have found success in differentiating between students like Alana and those who understand the limitations of empirical reasoning by asking participants to evaluate false proofs.

The differences in these students' thinking is probably best highlighted by the differences in actions one would take as their teacher. Lacy showed great skill at creating proofs, appreciated them, and even offered them spontaneously. It seems Lacy needs help in making sense of the segments of a triangle. We have found this type of thinking to be common. Proof might even be a vehicle to help these students develop concepts as it uniquely requires one to be explicit about their assumptions – Lacy's problem. Therefore, determining whether participants have knowledge of the concepts proofs rely on is a necessary part of assessing proof.

Is there an increase in sophistication in the reasoning of those with a proof method over people like Alana and Elizabeth? Consider for example a student who can set up a proportion, cross-multiply and solve. Few researchers would suggest this student has proportional reasoning. We can similarly argue that even though the students with the proof method were more successful than Alana and Elizabeth at creating proofs, the fact that they did not see those proofs as providing absolute conviction and only used proof when asked to do so suggests that these students have not developed a sufficient appreciation for proof. We hope our theoretical argument sparks a discussion about how to evaluate these students in terms of their understanding of proof.

In this report, we draw from a teaching experiment to report a prospective secondary mathematics teacher's reasoning within frames of reference in quantitative contexts. We pay specific attention to her graphing of relationships between two quantities within non-canonical coordinate systems and the interplay of figurative or operative thought in her committing to directionality of measure.

Keywords: Modeling, Geometry and Geometrical and Spatial Thinking, Teacher Education-Preservice, Cognition

Quantitative reasoning (Thompson, 2011) is important in the development of numerous K-16 mathematical ideas such as function and rate of change (Ellis, 2007; Confrey & Smith, 1995; Thompson, 2011; Moore & Carlson, 2012). Coordinate systems are used to coordinate sets of quantities by establishing frames of reference and obtaining a representational product space in which quantities are coordinated. Researchers and educators often assume students have internalized coordinate systems and thus—whether intentional or not—provide little attention to how students reason within frames of reference implied (to the observer) by a coordinate system (Lee, 2016). In this report, we draw from a teaching experiment to report how Lydia, a prospective secondary mathematics teacher, reasoned within frames of reference in quantitative contexts and engaged in graphing relationships between two quantities within non-canonical coordinate systems. Specifically, we present shifts in Lydia's commitment to directionality of measure across three tasks and provide implications and future research directions.

Theoretical Framework

We refer to *quantity* as a conceptual entity an individual constructs as a measurable attribute of an object (Thompson, 2011). Joshua, Musgrave, Hatfield, and Thompson (2015) offered a theoretical model of mental actions involved in conceptualizing a measurable attribute within a *frame of reference*: committing to a unit, committing to a reference point, and committing to a directionality of measure. We draw from this framework the notion of reasoning within quantitative frames of reference. Among the three mental actions involved, we narrow in on Lydia's committing to directionality of measure comparison.

We also draw from Piaget's distinction of figurative and operative thought. Figurative thought is based in, constrained to, and dominated by perceptual elements and sensorimotor experience; operative thought foregrounds the coordination and re-presentation of mental actions and the transformation of those actions (Montangero & Maurice-Naville, 1997). In developing models of students' graphing activity, Moore (2016) provided examples in which students' graphing activities are dominated by either figurative or operative thought. Drawing on Moore's work, we use figurative and operative distinctions to describe Lydia's graphing activity and her commitment to directionality of measure. In this paper, and emphasizing the notion of re-presentation, we use the term *graphing* to include both constructing graphs and determining whether a pre-constructed graph represents the appropriate relationship between two quantities.

Methodology

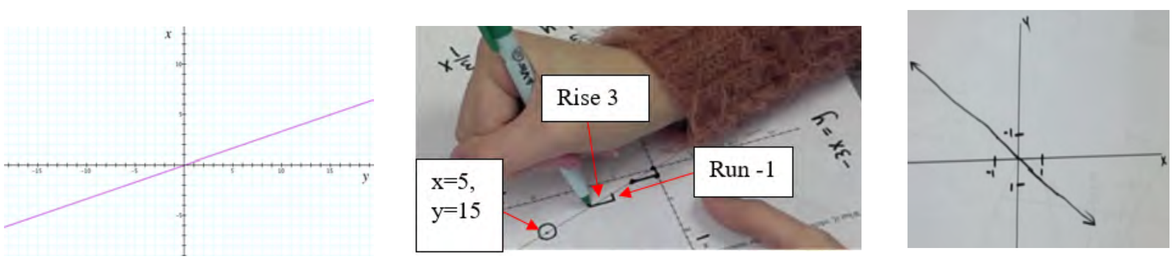
The data we present and analyze is from a semester-long teaching experiment (Steffe &

Thompson, 2000) at a large public university in the southeastern U.S. with three prospective secondary mathematics teachers. Our goal in the teaching experiment was to investigate how the participants conceived of situations quantitatively and represented quantitative relationships under particular coordinate system constraints. Among the three participants, we focus on Lydia, who participated in 12 videotaped sessions, each lasting approximately 1-2 hours. Through ongoing and retrospective analyses (Steffe & Thompson, 2000) we analyzed Lydia's activity graphing relationships between two quantities with specific attention to the interplay of figurative or operative thought in her committing to directionality of measure.

Analysis and Findings

Lydia's interplay of committing to directionality and figurative thought

In Task A, the teacher-researcher (TR) provided Lydia the following prompt: "You are working with a student who happens to be graphing $y = 3x$. He provides the following graph (Figure 1a). How might he be thinking about the situation?" As shown in Figure 1a, the student's graph was presented on a non-canonical coordinate system with the horizontal and vertical axes each representing y and x, respectively. Lydia rotated the paper clockwise 90-degrees such that the x-axis was horizontal from her perspective. She then concluded the "slope" of the line was "rising negative three." After picking two points on the line, Lydia drew a horizontal line segment left one unit and a vertical line segment up three units (Figure 1b). Lydia explained, "If I were to rise here…I'm rising this three…and then I'm running negative one, which would then [be] three over negative one x still equals negative three x." As such, Lydia related the amount of increase in the y-values to the amount of change in the x-values that she perceived of.



(a) (b) (c)

Figure 1. (a) Graph provided in Task A; (b) Lydia's actions on graph (a); (c) Lydia's $y = x$ graph.

Noticing that Lydia associated moving to the left with "running negative one," the TR asked Lydia the coordinates for the circled point on the line (Figure 1b). Lydia responded $x = 5$ and $y = 15$; she was aware the quadrant in which she was working entailed positive values for both x and y and thus held in mind a spatial orientation that entailed positive values compatible with that designed by the research team. Nonetheless, Lydia maintained her meaning for moving horizontally to the left with a decrease in the quantity's value. Her commitment was different from committing to the quantitative organization as we implied by the axis and the quantity's measures. From Task A, we inferred Lydia's committing to a directionality of measure to be figurative in that it was dominated by sensorimotor elements of graphical representations (e.g., moving to her left/right implying decrease/increase in values).

Rotating the Graph and Reconsidering Directionality

In Task B, Lydia revisited a task in which she had constructed the sine graph on a conventional Cartesian coordinate plane. We asked her to determine if that graph, when rotated (including axes) in different orientations, shows the appropriate relationship of how arc length and height change together. Lydia rotated the paper 90 degrees clockwise. Moving her finger from origin down along the vertically oriented arc length axis, Lydia said "And then here we're increasing in arc length." Moving her finger from origin to the right along the horizontally oriented height axis, Lydia explained "We're having a positive distance in arc length, having a positive distance in height" and concluded that the graph showed the appropriate relationship of how arc length and height change directionally together; Lydia attended to the direction of change in quantities along the axes of the coordinate system. This was different from her engagement in Task A in that her direction of change in magnitude was divorced from perceptual/physical orientations (e.g., going left/right implying increase/decrease in quantities). From this we infer that Lydia has shifted from committing to figurative directionality to committing to the quantitative organization as implied by the axes and quantities' measures.

We highlight, however, that Lydia continued to verify if graphs, when rotated, represented the same quantitative relationship in different orientations by purposefully and sequentially sweeping her finger/hand along the axes; when the TR asked her to predict for each case, Lydia was reluctant to conclude that the relationship was maintained without carrying out the physical activity of rotating the paper, moving her finger/hand along the axes, and considering how the displayed graph corresponded to increasing or decreasing values. As Lydia said, "If I'm being skeptical, I don't want to say it's going to get…guarantee that it's going to follow the pattern unless I rotate it and like can visualize…" We interpret this to mean that it was necessary for Lydia to carry out sensorimotor activity and instantiate each case using the perceptual material of the graph when the physical orientation of the axes changed. Lydia was yet to anticipate that each graph represented an invariant relationship no matter how rotated.

Lydia's Committing to Directionality Supported by Operative Thought

In Task C, after constructing the graph of $y = x$ on a non-canonical coordinate system in which the y coordinates decrease as one moves upward along a vertical axis (see Figure 1c), Lydia reasoned about the "slope" of the line and the relationship between the two quantities. In contrast to her activities in Task A, when determining the "slope" of the line, Lydia did not physically re-orient the graph such that the y-axis behaved in the conventional way, nor did she adhere to the visualization of "what we're used to a negative slope looking like." Instead, Lydia reasoned about the quantities and associated changes by maintaining an awareness of directionality in accordance with the axes as we designed them. For example, she explained, "So if x is 1, then y should be 1, which this looks like it has a negative slope, but it doesn't have a negative slope… Because if I rise one, then I'm like going down, but I'm rising a value, like a positive value." Further, Lydia explained, "even though [a graph] looks like a negative slope," for any linear function with positive slope "As an x increases, the y should increase" and vice versa. This stands in contrast with her activity in Task B, in which she engaged in sensorimotor activity to verify the invariance of the quantitative relationship for different orientations of the same graph. From this we infer that Lydia's directionality of measure has shifted from dominated by figurative thought to operative thought. That is, Lydia's directionality of measure and her claims of "slope" here were rooted in explicit attention to magnitudes organized in a directed, operative system and its transformations.

Discussion and Implications

Through our analysis, we presented how Lydia made sense of quantitative relationships represented on non-canonical coordinate systems. Specifically, we focused on Lydia's commitment to directionality of measure and its interplay with figurative and operative thought. Based on her activities, we found Lydia's notion of directionality to be critical in her reasoning within frames of reference and quantitative reasoning. Over the course of the teaching experiment, Lydia gradually attended to the direction of change in quantities along the axes of the coordinate system and established quantities in ways that sustained an awareness of directionality in accordance with the axes as were implied by the coordinate system.

We hypothesize that the questions from the TR to consider graphs in various orientations, her physical enactment of sweeping along axes, and her rotating graphs supported reorganizations in her notion of directionality. We also propose that the use of non-canonical coordinate systems afforded Lydia opportunities to operationalize directionality independent of the perceptual features of coordinate systems and particular sensorimotor activity. As suggested in Moore (2016), we emphasize the importance of opportunities that afford students engaging in and differentiating between figurative and operative frames of reference.

We envision that further investigations into students' conceptualization of frame of reference with attention to figurative and operative thought may provide insight into instructional support that afford powerful tools for reasoning about quantitative relationships independent of coordinate systems.

Mathematics problem solving has evolved significantly since Polya's and Schoenfeld's problem solving frameworks. This review examines research on strategy use during mathematics problem solving in terms of the strategies investigated, context in which problem solving occurs, characteristics of the participants, and efficacy of the strategy use on problem solving solutions. We are in the process of reviewing 164 studies that examined mathematics strategy use during problem solving. Preliminary findings indicate that domain-general strategies proliferate the current literature, contexts in which mathematics problem solving is investigated are diverse, studies mainly examine younger learners, and positive effects of strategy use on mathematics problem solving is conditional. We offer suggestions for future directions of research dealing with strategy use and mathematics problem solving.

Keywords: Problem Solving, Metacognition

The current study aims to review research related to mathematics problem solving in terms of: types of problem solving strategies investigated (e.g., pictorial, metacognitive); characteristics of the learners (e.g., grade level); methodologies of the study (e.g., naturalistic, controlled intervention); measures of strategy use; types of problem-solving tasks; and salient results of the strategy (ies) used and their impacts on problem solving. Using a systematic literature review process, this paper seeks to shed light on what contextual and individual characteristics lead to more effective problem solving. Additionally, this review will allow an examination of areas (e.g., pictorial mathematics strategies) that require further investigation.

Theoretical Framework

One influential framework for mathematics problem solving was Polya's (1957) *How to Solve It*. Polya proposed a general framework of mathematical problem solving which consisted of four steps: understanding the problem, devising a plan, carrying out the plan, and looking back. This framework showcased 67 heuristic strategies as general rules of discovering mathematical solutions which would guide their thinking and reasoning processes towards discovering of mathematically meaningful knowledge in mathematical problem solving.

Schoenfeld introduced his own framework (e.g., Schoenfeld, 1985; 1992) that retained many of the same elements of Polya's. Schoenfeld (1985) discussed two types of decision-making during problem solving: tactical decisions and strategic decisions. The former were similar in style to Polya's and included which algorithms and heuristics to implement, while strategic decisions referred to actions that guide, monitor, and control problem solving. The latter refers to metacognitive or self-regulatory processes. Schoenfeld (1985) indicated that the latter had received greater attention in the research literature. A study of students' cognitive processes in mathematical problem solving revealed that experts' use of monitoring and control processes to guide their use of heuristics lead to successful outcomes. In essence, while the use of heuristics played a significant role in mathematics problem solving, the importance of metacognitive processes seemed to dominate over that of heuristic thinking in mathematics problem solving.

Schoenfeld (1992) reframed mathematics knowledge as a science of patterns in place of the traditional view as a body of facts. To develop a broader framework of mathematical cognition for pattern-seeking, Schoenfeld defined mathematics as:

> …an inherently social activity, in which a community of trained practitioners (mathematical scientists) engages in the science of patterns – systematic attempts, based on observation, study, and experimentation, to determine the nature or principles of regularities in system defined axiomatically or theoretically ("pure mathematics") or models of systems abstracted from real world object ("applied mathematics"). (p. 335)

In this review, we sought to examine if these assumptions of mathematics, and mathematics problem solving more specifically, were evident in empirical investigations of strategy use (i.e., procedures that are "purposeful, effortful, willful, essential, and facilitative"; Alexander, Graham, & Harris, 1998, p. 130). We divided strategy use into two general categories: *domain general strategies* (i.e., processes invoked during problem-solving activities useful in any domain; Alexander & Judy, 1988) and *domain specific strategies* (i.e., processes invoked during problem solving that are specific to the relevant domain; Alexander & Judy, 1988). Domain general strategies consisted of *metacognitive strategies* (Flavell, 1979), *self-regulatory strategies* (Zimmerman 1989) and *heuristic strategies* (Polya, 1957). Domain specific strategies are comprised of *pictorial strategies* (Stylianou & Silver, 2004) and *symbolic strategies* (Zazkis, Dubinsky, & Dautermann, 1996) to represent mathematical relationships or patterns using visual-spatial properties or symbols.

According to Schoenfeld (1992), mathematics also involves social activity and tasks that allow pattern finding to occur. Hence, we decided to also investigate the context in which problem solving occurred, either in a more *naturalistic context* (i.e., study takes place in a typical learning context such as a classroom or museum) or a more *controlled context* such as a laboratory environment. Additionally, if the study included instruction or intervention we examined if it was: *one-on-one instruction*, *group instruction*, or *peer instruction*. We also examined whether the tasks were *well-structured tasks* (i.e., have a defined computational path with one acceptable solution; Simon, 1977) or *ill-structured tasks* (i.e., not well structured and may contain symbols with multiple acceptable solutions; Simon, 1977).

Finally, we are sensitive to the idea that low achieving students or students with disabilities may influence how effective these strategies are. Hence we also examined characteristic of the participants of each study that included age and if the participant were typically developing or if there were special development considerations (e.g., cognitive delay). Thus, with these issues in mind, four questions guided this review:

1. What types of strategies (i.e., metacognitive, self-regulatory, heuristic, pictorial, or symbolic) are most prevalent in empirical investigations of mathematics strategy use?
2. What contexts (i.e., settings, instruction types, and task types) are most prevalent in empirical investigations of mathematics strategy use?
3. What learner characteristics (i.e., age and typicality of development) are most prevalent in empirical investigations of mathematics strategy use?
4. What conditions or joint conditions regarding type of strategy, context, and learner characteristics promote the most effective problem solving outcomes?

Method and Data Sources

To investigate these questions we undertook a systematic literature review. First, we identified appropriate studies for the study pool by searching for the terms *mathematics*, *problem solving*, and *strateg** in the abstracts of the PsycInfo database. Further, we narrowed the results to peer reviewed empirical studies and English text between 1985 (when Schoenfeld's framework went to press) and 2013. A total of 164 studies met these criteria.

After the initial identification, we developed codes for the type of strategy, measure of strategy use, nature of the sample, type of development, context of the study, and the problem solving task discussed previously in the introduction. Additionally, in our table we decided to include descriptions of the strategy, the problem-solving outcome measure, and salient results of the study demonstrating a relation between the strategy under investigation and student outcomes on the problems given. All authors jointly coded five studies, then each independently coded 10 studies and compared the results. Once we were satisfied that the coding and descriptions were similar, the first author then coded the remainder of the studies (one-third of them currently).

During the coding process, we found and excluded studies that did not examine learners' strategy use during problem solving. Most of these studies examined teaching strategies during mathematics.

Results

Our preliminary findings indicate that studies have primarily: studied strategies that are domain general; encompassed both laboratory and naturalistic settings with diverse instructional approaches; involved typically developing elementary children; and, suggested fairly constrained findings on the effectiveness of the strategy on problem solving based on study conditions.

With regard to types of strategies, domain general strategies were the focus of 73% of the studies. Far fewer studies examined domain specific strategies on open sentence problems. With regard to settings, emphasis in the literature was much more evenly distributed among the categories. Approximately 45% of the studies were in a laboratory or laboratory type situation, whereas the rest where classroom based environment (48%) or computer-based environments (7%). Instructional approaches (one-on-one, group, or peer instruction) were also diverse. However, the types of tasks that students were asked to do were primarily well-structured (76%), with only 20% ill-structured and 4% that did not involve a task. With regard to learner characteristics, studies primarily focused on younger children. Elementary-aged students accounted for 52% of the studies, with 10% middle school, 7% high school, and 28% undergraduate or adult learners. 83% of studies focused exclusively on typically developing students, 14% with students with a cognitive impairment, and only one study of English language learners.

With regard to salient findings of the studies, a few common themes were found among these studies. First, strategy instruction did not always result in students' use of those strategies. Second, metacognitive and self-regulatory training can have positive effects on problem solving success. Last, success of strategy use is often subjected to certain prior conditions (typically aspects of the problem) in order to be effective.

Discussion

While the analysis is ongoing, it is apparent that the earlier focus on domain-specific strategies (Schoenfeld, 1985) has shifted more toward domain-general strategies. Certainly, metacognitive, self-regulatory, and more heuristic strategies are now the lion's share of the research agenda. This may be due in part to Schoenfeld's urging (among others who have echoed this since; e.g., De Corte et al., 2000) and also a broader reflection of the increasing trend in research on metacognition and self-regulation (Dinsmore et al., 2008).

Lastly, while we did not set out to examine how strategies were defined in each study, it was interesting to note what these strategies were called and how they were related to other constructs. For example, while each studied had something labeled "strategy", there were seemingly synonymous terms concurrently used such as skills (Davis et al., 2009), types of thinking (Groth, 2005), ways of thinking (Webb et al., 2009), and mathematical thinking (Wood et al., 2006). While we certainly would not expect identical use of terms, it may be helpful to clarify the differences in these constructs moving forward. It is our hope that an illumination of these and other issues and trends in this review can enable more strategic and coordinated research efforts moving forward.

UNDERGRADUATE STUDENTS' REASONING ABOUT MARGINAL CHANGE IN A PROFIT MAXIMIZATION CONTEXT: THE CASE OF CARLOS AND MARK

Thembinkosi P. Mkhatshwa
Miami University
mkhatstp@miamioh.edu

The purpose of this exploratory study was to investigate how business calculus students reason about marginal change (marginal cost, marginal revenue, and marginal profit) when solving optimization problems in an economic context. To carry out this investigation, task-based interviews were conducted with 12 pairs of students and this study reports on one of the pairs of students (Carlos and Mark). Analysis of Carlos and Mark's reasoning about marginal change in a profit maximization task (PMT) revealed that these students were able to define or even recall facts about the idea of marginal change and its relation to the fundamental principle of economics (FPE), which states that maximum/minimum profit occurs at a production and sales level where marginal cost equals marginal revenue. However, these students conflated marginal cost and marginal revenue with total cost and total revenue respectively in another PMT.

Keywords: Post-Secondary Education, Instructional Activities and Practices

Much of the existing research on students' reasoning about optimization problems has focused on problems that lack a real-world context (e.g., Borgen & Manu, 2002; Brijlal & Ndlovu, 2013; Heid, 1988, Swanagan, 2012) or problems that have a physics or life science context (e.g., Klymchuk et al., 2010; Maharaj, 2013; White & Mitchelmore, 1996). Research on students' reasoning about optimization problems that are situated in economic contexts are scarce, which is the motivation for this study. More specifically, there is a dearth of research on what students' reasoning about optimization problems in an economic context reveals about their understanding of marginal change, an important idea in economics. Marginal cost refers to the cost per additional unit produced, marginal revenue refers to the revenue generated per additional unit sold, and marginal profit refers to the profit per additional unit produced and sold. Mathematically, marginal change can be calculated as an average rate of change where the length of the interval of change is one unit. Marginal change can be approximated using the instantaneous rate of change. The importance of investigating what students' reasoning about optimization problems that are situated in economic contexts reveals about their understanding of marginal change cannot be overemphasized. First, there is a large number of students (more than 300,000) who enroll in business calculus nationwide every year (Gordon, 2008), and yet we do not know how these students reason about marginal change, an important idea in any business calculus course. Second, understanding optimization problems and marginal change in an economic context is vital in several fields such as marketing, managerial accounting, supply chain management, finance, and economics. The investigation of students' reasoning about optimization problems in an economic context reported in this study was guided by the following research question: What does business calculus students' reasoning about economic-based optimization problems reveal about their understanding of marginal change?

Evidence from research (e.g., Ärlebäck, Doerr, & O'Neil, 2013; Flynn, Davidson, & Dotger, 2014; White & Mitchelmore, 1996) shows that engaging students in solving mathematical problems that are situated in real-world contexts helps to reveal students' conceptual understandings and difficulties/misunderstandings of certain mathematical concepts and ideas. In their investigation of undergraduate students' understanding of average rates of change in the context of a discharging capacitor, Ärlebäck et al. (2013) found that "a focus on the context made visible students' reasoning about rates of change, including difficulties related to the use of language when describing changes in the negative direction" (p. 314). Flynn et al. (2014) reported on sophomore students who conflated rate of change with accumulation in an engineering context. More specifically, these students confused the rate flow of water into a roof drain with the total amount of water accumulated. The current study reports on what students' reasoning about economic-based optimization problems reveals about their understanding of marginal change.

Theoretical Framework

This study draws on the theory of realistic mathematics education (RME) which is both a theory of teaching and learning in mathematics education. As a theory of learning, RME emphasizes that students should be asked to solve problem situations that are not only realistic in the sense of being connected to a real-world context, but also "problem situations which they can imagine" (van den Heuvel-Panhuizen, 2000, p. 4). The economic context as it relates to optimization problems is not only realistic, but also experientially real for some students taking business calculus. This is especially true for students who take business calculus after having taken high school or college economics classes. Providing students with opportunities to reason about realistic optimization problems in an economic context has the potential to reveal their understanding of the idea of marginal change as it relates to the FPE, something that was fostered by the design of the study reported in this paper.

Methods

This study followed a qualitative design. A task-based interview was conducted with a pair of undergraduate students (Carlos and Mark) who had successfully completed a business calculus course in the spring semester of 2015 at a research university in the Unites States. In conducting the interview, I followed the principles and techniques (e.g., encouraging free problem solving) suggested by Goldin (2000). There were four tasks in total (Mkhatshwa, 2016). This study reports on the students' reasoning on one of those tasks:

> The following table shows the marginal revenue (MR) and marginal cost (MC) at various production and sales levels (q) for SciTech, a company that specializes in producing and selling computer chips. The company knows that total revenue is greater than total cost at all the production and sales levels shown on the table.

q	400	401	402	403	404	405
MR	58	56	55	54	53	51
MC	52	54	55	57	60	62

> What advice can you give to the management of the company about when to increase or decrease production and sales of computer chips?

Mark and Carlos were high achieving students. They both were management majors, sophomores, and had grade point averages (GPAs) over 3.5 in a 4.0 scale. Mark earned an A grade in the business calculus course while Carlos earned a B+ grade. While both students had previously taken a college economics course, herein referred to as ECN 200, Carlos had also taken two economics classes in high school (AP microeconomics and AP macroeconomics). The task-based interview was video-recorded and lasted for about one hour and 45 minutes. The interview was transcribed for analysis. Work written by students during the interview was also collected as part of the data. Analysis of the interview transcript and students' written work focused on students' understanding of the FPE. The findings of this analysis are presented in the next section.

Results

There are two findings from this study. First, drawing from their economics background, Carlos and Mark demonstrated a good understanding of the relationship between marginal cost and marginal revenue at a profit maximizing quantity, that is, the FPE. More specifically, when asked about the advice they would give to the management of the company mentioned in the task, Carlos indicated that "because marginal cost equals marginal revenue and at that point [402 units], that's the most profitable you going to be". Mark added, "that's where the marginal cost equals the marginal revenue so it doesn't make sense to create more just like in the skittles experiment where you keep eating them but you are not getting any satisfaction from them, so there is no point taking them." Prior to working on the task presented in this study, both students had recalled examples related to the FPE that were discussed in an economics class (ECN 200) they had previously taken together. In particular, Carlos recalled that a company has to produce until marginal cost equals marginal revenue. He went on to give an example, "like the example, which I kind of like going back to, if you have free pizza at the Cafeteria you will produce or eat pizza until the point of having like one more slice of pizza is not so appetizing or producing one more unit costs more than it would if you sold it." Mark recalled another example related to eating skittles, "same like eating skittles. That's the example that our professor [ECN 200] gave us." He added, "he [ECN 200 professor] was like he brings back a packet so there is a point where I just don't want to eat skittles and that's where …marginal cost equal marginal revenue." Carlos and Mark concluded by advising the management of the company mentioned in the task to increase production and sales of computer chips up to 402 units and then decrease production and sales of computer chips afterwards.

Second, I remark that although these students, especially Carlos, correctly explained what marginal cost and marginal revenue means, their understanding of these ideas are not robust. When asked to comment about marginal cost and marginal revenue (from a graph) at a break-even point in another profit maximizing task (Mkhatshwa, 2016), Carlos stated that "so marginal revenue, going back to economics, I know is the benefit or the revenue taken from producing one additional unit and marginal cost is the cost from producing one additional unit." On probing Carlos and Mark further about their understanding of the idea of marginal change, it appeared that their understanding of these ideas was vague. More specifically, Carlos and Mark incorrectly claimed that "marginal cost equals marginal revenue" at a break-even point: - a production and sales level where total cost equals total revenue. However, marginal revenue exceeded marginal cost at the break-even point. Thus, Carlos and Mark conflated marginal cost with total cost and marginal revenue with total revenue.

Discussion and Conclusion

This study makes a major contribution in what we know about students' learning of business calculus at the undergraduate level. More specifically, findings of this study indicate that while students can memorize the definition of marginal change, recall the FPE (relationship between marginal change and profit at a profit-maximizing quantity), their understanding of marginal change is not robust in that the students conflated rate with accumulation when they conflated marginal cost with total cost (and marginal revenue with total revenue). As noted earlier, undergraduate students' tendency to conflate rate with accumulation was reported by Flynn et al. (2014) in an engineering context. Given that the students reasoned correctly about marginal change from a numerical table but not so in a graphical task, it might be important for business calculus instructors (applied calculus in general) to provide sufficient opportunities for students to reason about marginal change in multiple function representations (algebraically, textually, graphically, and numerically) and in different real-world contexts. Future research might examine the opportunity to learn about marginal change via course lectures and business calculus textbooks.

CHALLENGES IN MODELING WORD PROBLEMS

Victoria Kofman
Stella Academy
drkofman@gmail.com

Sayonita Ghosh Hajra
Hamline University
sayonita@gmail.com

Keywords: Algebraic Reasoning, Modeling

In 2008, after the National Mathematics Advisory Panel of the U.S. Department of Education acknowledged the necessity of teaching early algebra, the focus in mathematics education shifted toward teaching students how to create models as tools for solving word-problems. Some educators concentrate on teaching students how to present word problems using symbols (Dougherty & Slovin, 2004), others teach *schemata* approach (Jitendra et al., 2015), which is not always mathematically strict. There is no agreement in approaches, which are necessary to increase students' ability to model word problems. We undertook research to analyze what challenges children have when creating simple models and what could be done to help them overcome those challenges.

Twenty elementary and middle school students attending a suburban learning center participated in this study. We taught participants schemata for creating (a) verbal model—the description of each value involved in word problems; (b) spatial-visual representations; (c) number equation model; (d) algebraic model, including defining symbols. We analyzed students' assignments and individual verbal responses. The mistakes of the students were thoroughly analyzed following an open and axial coding method.

Students demonstrated misconceptions when defining measurable attributes. Young students frequently mixed-up units with measurable attributes and had difficulties with verbal models for the problems involving difference. Many erroneously wrote, *3 is the difference between girls and boys*. Children demonstrated difficulties with interpreting symbols used in equations. They frequently identified symbols as equivalent to objects, units, or words, which was consistent with other studies (MacGregor & Stacey, 1997). Students benefited from a 4-model approach. This approach pinpointed weak areas for each student, helped create models for simple problems, and prepared students for modeling complex word problems.

CONSTRUCTING MATHEMATICAL HABITS OF MIND WITH LATTICE LAND

Christina (Yu) Pei
Northwestern University
cpei@u.northwestern.edu

Uri Wilensky
Northwestern University
uri@northwestern.edu

Keywords: Geometry and Geometrical and Spatial Thinking, Cognition, Technology, Curriculum

Wilensky and Papert proposed a theory of *restructurations*, where different computational representations can create new ways of thinking (2010). In this paper, we propose a *restructuration* of geometry that replaces the Cartesian plane with integer points on a square lattice. We created a constructionist environment called Lattice Land, a dynamic geometry system (DGS), and designed complementary activities for geometry classrooms (Sally & Sally, 2011). Now that new computational tools are reshaping the way scientists and mathematicians understand the world, we need to train students to learn and think in increasingly computational ways (Orton et al, 2016).

Cuoco and Goldenberg showed DGS have been used to shift the focus from low-level details to high-level thinking, to develop *mathematical habits of mind* (1996), but these DGS did not change the fundamental *structuration* of Euclidean geometry. Lattice Land curriculum tackles many of the same proof-based habits of mind we seek to develop, but with two key differences. (1) Using discrete geometry, Lattice Land taps into our earliest experiences with counting, making it a natural entryway into continuous geometry (Piaget, 1960). Additionally, discrete thinking resonates with computational thinking. (2) The curriculum uses empirically based inductive approaches to reasoning, which Schoenfeld has shown to strengthen deductive approaches to geometry, as well as helps to break students' tendencies to compartmentalize knowledge (1986).

Pei implemented and video recorded Lattice Land curriculum in 4 geometry classes at a large non-selective urban public high school: 81% Hispanic, 9% African American, 7% White, 2% Asian, 2% other, 94% low-income. Students in the study relied on a variety of techniques that demonstrated a range of mathematical habits of mind. They *tinkered* with the software and *experimented* to find multiple methods of dissection; built *definitions* from findings and their intuitions; *visualized* problems; *generated and collected data* about some subset of polygons; and used *inductive reasoning* to build sensible and testable formulas from *patterns*. Based on our analysis of 2 groups of 4 students, and pre/post-interviews, we show how the restructuration using an integer focus allowed students to build higher-order abstract thinking without requiring a well-developed sense of the density of real numbers. All students showed content gains. Based on the students' initial reticence and the teacher's surprise at their high levels of engagement and success, these habits of mind do not typically manifest themselves in everyday classroom practices. Because the teacher's role is critical—celebrating experimentation and mistake-making, steering conversation, summarizing—we plan to continue our study with classroom teachers facilitating.

For many students, experience with proof prior to college is limited (Jones, 2000). Students' prior competence (and interest) in mathematics is typically centered on producing accurate answers to easily recognized tasks. These abilities do not support, and may interfere with, students' work to conceptualize, write, or evaluate proofs. This study complements prior work that has focused on students' reasoning on specific problem-based tasks—typically proof construction and evaluation (Selden & Selden, 2003). We explored how students (n=14) describe their experiences in one "transition to proof" course at a mid-western university. In targeting students' experience, we have focused on what is different for students in elementary proof work and how students reorganize their learning to meet the challenge. These issues are important foci for all efforts to assist students in understanding the new challenges at this crossroads in their mathematical experience as well as supporting students in addressing them. The present study builds on Smith & Star (2007) in its focus on the following dimensions of students' experience of the introduction to proof course: (1) The nature of the course and how it differed from prior courses, (2) the reasoning involved in proving, and (3) the learning activities that support success. It also drew on that study's use of student-constructed graphs to assess changes in students' confidence.

Interviews were transcribed and coded using thematic codes based our interview protocol and the dimensions of Smith & Star (2007). We found that students were quite articulate about how the course differed from their prior mathematics course experiences, but their focus and emphasis varied. There were three main characterizations of difference: (1) Work in the transition to proof course explained why mathematics worked the way it did, where prior work had focused mainly on producing answers, (2) the course valued process over answers, and (3) the course changed students' conceptions about proof and writing in mathematics, noting that mathematical terms have more specific meanings than in everyday language. All but two students explained that they employed different practices in completing their homework than they had in prior courses (e.g., working with classmates, asking questions in mathematics class, using the university's mathematics learning center). The methodological technique of asking students to construct confidence graphs was fruitful, allowing us to uncover several contrasting profiles of students' affective experience over the course of the semester.

EFFECTS OF A MATHEMATICAL WRITING TREATMENT ON CHILDREN'S CONCEPTIONS OF EQUIVALENCE

Karl W. Kosko
Kent State University
kkosko1@kent.edu

Keywords: Elementary School Education, Number Concepts and Operations

Research suggests that students' engagement in writing in mathematics has a positive effect on mathematics achievement (e.g., Cross, 2009). Recently, evidence has emerged suggesting a relationship between elementary children's mathematical argumentative writing and their early algebraic reasoning (Kosko & Singh, 2016). To explore the phenomenon further, this study examines whether engagement in writing and early algebra tasks (i.e., equivalence) affects second grade students' mathematics achievement.

Data were collected from 46 second grade students across three teachers' classrooms. Students were assigned to one of three classroom conditions: writing and problem-solving (WPS), problem-solving (PS), and a control (C). The WPS and PS classrooms engaged in weekly tasks focusing on number relations (e.g., examining equations of the form $a+b=c+d$), with accompanying manipulatives (e.g., Cuisenaire rods). Students in WPS and PS conditions engaged in small group and whole class discussions, but students in WPS were also tasked with describing and justifying their mathematics in writing journals. Students in all conditions completed Rittle-Johnson et al.'s (2011) assessment on conception of equivalence at three time points across six months. Additional data collected includes classroom observations and teacher interviews across classroom conditions and over time. Data was examined using Helsel and Frans's (2006) Regional Kendall Trend Test (RKT). Applied to classroom comparisons, the RKT produces a tau coefficient representing the proportion of 'up moves' to 'down moves in time, adjusted by students within a condition. Results indicate statistically significant growth for students in WPS (τ=.66, p<.001) and PS (τ=.34, p=.02) classrooms, but not for students in MO classrooms (τ=-.04, p=1.00). Additionally, the WPS growth slope was statistically significant from both PS (Z=1.71, p=.09) and MO (Z=4.12, p<.001) classrooms, and the PS growth slope was statistically significant from MO (Z=2.41, p=.02).

These results indicate that students in the WPS classroom demonstrated larger gains in their conception of equivalence scores than students in both PS and MO classrooms. Further, while students across all conditions demonstrated statistically significant growth between the first and second assessment points, only students in WPS demonstrated growth between the second and third time points. This suggests that engaging in argumentative writing may have helped students to maintain and expand upon mathematical relationships developed early in the school year.

INSTRUMENTAL VS. CONCEPTUAL UNDERSTANDING IN CALCULUS

Karen Duseau
University of Massachusetts
kduseau@umassd.edu

Keywords: Cognition, Advanced Mathematical Thinking, Post-Secondary Education

Calculus is a gatekeeper for many aspiring STEM (science, technology, engineering, and mathematics) students. My overarching goal is to help students who are blocked from STEM fields due to limited ability in mathematics to find a pathway to achieve their goals. This exploratory study is the first step in understanding what knowledge of calculus students are constructing. Working from the assumption that students construct knowledge to make sense of their experiences (von Glasersfeld, 1992), I am exploring what kinds of procedural and conceptual knowledge (Hiebert & Lefevre, 1986) these students are able to construct. Many researchers and educators have been concerned that K-12 education is too heavily focused on rote, procedural teaching, learning, and assessment (Hiebert & Lefever, White & Mitchelmore, 1996).

My conjecture, in line with some of the past research (Engelbrecht, Bergsten, & Kagesten, 2009; White & Mitchelmmore, 1996) is that through traditional instruction, many students construct only procedural understanding at the expense of a conceptual understanding and that is problematic for students' continued participation in the STEM fields. My study is differentiated from the other studies in that I am looking specifically at non-mathematics majors, students who may have struggled with mathematics in the past and whose trajectory into the STEM fields may be blocked by their ineffective construction of calculus concepts. My research question is "What kind of procedural and conceptual knowledge do students in a college level Elements of Calculus class construct of the concept of the derivative."

Research Methodology

This study will employ a task-based clinical interview with undergraduate, non-math majors at a state university in New England. In describing the clinical interview, Ginsburg (1981) claims that there are "three basic aims: the discovery of cognitive processes; the identification of cognitive processes; and the evaluation of competence" (p. 10). It is appropriate then, to use a clinical interview to discover the cognitive process students use to make sense of calculus concepts.

Findings

In this study the vast majority of the data (about 70%) provided evidence of only procedural knowledge. Another finding worth discussion is the students' lack of precision, in particular, precision in verbal communication of mathematical concepts.

INTERPLAY OF REPRESENTATION, BELIEFS, AND PROBLEM SOLVING PERFORMANCE

Ji Hye Lee
The Ohio State University
lee.5250@osu.edu

Keywords: Problem Solving; Affect, Emotion, Beliefs, and Attitudes

Problem solving is regarded as a crucial aspect of mathematics learning (NCTM, 2000; Schoenfeld, 1985). Past research has clearly highlighted the paramount impact of affective factors on problem solving performance (Buchanan, 1987). Despite the close link between representations and mathematical cognition, less is known about the relationship among the use of mathematical representations and mathematical problem solving performance (Krawec, 2014). This study examined an individual's problem solving practices to explore the following research question: How do mathematical resources from which the individual draws when confronted with tasks impact their problem solving performance?

A college student not involved in STEM area served as the subject for the study. Since a major goal of the study was to trace the impact of the use of representations when solving problems, data collection consisted of two phases. First, the type of representations he accessed during the sequence of 4 different tasks from discrete mathematics, measurement, and geometry were documented through 4 problem solving interviews. During the second phase, to investigate the potential impact of additional representation on his work, a second set of 4 interviews took place during which the same tasks were used. During these second sequence of interviews, the researcher asked the participant to use a certain tool which included GeoGebra software, a calculator, a measuring cup, or a physical paper cylinder. A total of 8 sessions were observed and used as sources for data analysis to classify different modes of representation presented in past publications such as Applied Mathematical Problem Solving (Lesh, Post, & Behr, 1987). These modes are contextual, physical, visual, verbal, and symbolic representations. Interviews were transcribed and analyzed using open coding of 157 responses into 18 categories.

It was found that the individual's use of representations and overall performance were strongly influenced by his self-concept as a mathematics learner, persistence towards solving problems, beliefs about mathematics, the desire to be correct, and reliance on his preferred representations and heuristics. The individual's preference for verbal as well as symbolic representations using paper and pencil persisted although different tools, which could potentially assist in solving the problems, were offered. In most cases, the participant's performance was positively related with his use of verbal and symbolic modes of representations.

STUDENTS' CRITERIA WHEN EVALUATING SOLUTIONS FOR A PROOF TASK

Kimberly Conner
University of Missouri
kachz9@mail.missouri.edu

Keywords: Reasoning and Proof, High School Education

Despite the importance of proofs in mathematics, research has shown students are more likely to construct empirical arguments than deductive proofs when asked to prove a statement (e.g., Healy & Hoyles, 2000; Knuth, Choppin, & Bieda, 2009). One possible explanation is that the empirical arguments reflect what students are mathematically capable of producing, not what they believe constitutes a proof (Healy & Hoyles, 2000). However, both of the studies mentioned used written assessments as their primary data source, which did not allow for follow up questions to ascertain students' reasoning for their answers. To fill this gap, this study sought to uncover what criteria Algebra 1 students use when they evaluate given solutions for a proof task.Semi-structured interviews were conducted with 10 ninth graders enrolled in an accelerated Algebra 1 class. At the time of the study, no students had received formal instruction on mathematical proofs. In the interview, students were asked to prove that if you add any three odd numbers together, your answer will be odd. After students constructed a written argument, they evaluated five sample solutions for the previous task: a correct algebraic proof, an examples-based argument, a generic example/visual proof, a paragraph proof that drew on the definition of even and odd numbers, and a circular algebraic "argument". Students were asked to explain their evaluations for each solution and then select the solution they preferred the most.

Out of the five sample solutions, students overwhelmingly evaluated the paragraph proof and (correct) algebraic solution as being proofs (8/10 for each) and were least likely to consider the examples-based argument as a proof (2/10). However, of the eight students who thought the algebraic solution was a proof, half justified their response by saying the solution provided examples of why it worked. This criterion suggests that some students did not attend to the generality inherent in the algebraic argument when evaluating the solution. When justifying their responses, students consistently talked about whether the given solution "made sense". This was particularly true when explaining why they thought the paragraph argument was a proof. Even though none of the students had been formally introduced to proofs, 7/10 students preferred one of the deductive arguments (algebraic, visual, or paragraph) the most.

These findings extend those from prior studies in two ways. First, not all students who select algebraic proofs do so because they recognize the generality within the argument. Second, some students are able to recognize non-traditional deductive arguments as proofs when evaluating solutions based on whether they "make sense". One way that teachers can increase students' access to proofs is through leveraging their potential intuition to prefer mathematical arguments that make sense. This can be achieved by placing more instructional emphasis on making sense of the mathematical content in proofs than on writing proofs in the "proper" form.

STUDENTS' UNDERSTANDING OF PERIODICITY

Julia L. Berger
Syracuse University
jberge07@syr.edu

The New York State mathematics curriculum has not included extensive mention of periodicity, with it appearing only in the context of trigonometric functions (New York State Education Department, 2005; National Governors Association Center for Best Practices & Council of Chief State School Officers, 2010). Concepts of periodicity extend beyond trigonometry into other areas in mathematics and science. I designed a qualitative study, utilizing a questionnaire and interviews, to gather data on secondary students' broader understanding of periodicity. Specifically, I studied the characteristics students attend to when identifying representations as periodic and determining their periods, and how they reason about periodicity in a context.

Shama (1998) and Gerson (2010) studied student understanding of periodicity. The authors' studies demonstrate that secondary student conceptions of periodicity were situated in trigonometry, which led to limited conceptions of periodicity, such as periodic functions needing to be waves or symmetric. Shama concluded that students' conceptions of a period of a periodic phenomenon were restricted to the fundamental period. In Gerson's study, the precalculus student's "decisions about periodicity [were] not based on the formal definition, but instead upon properties he has generalized from prototypical functions in his concept image" (p. 33). Gerson further concluded that the student had an understanding of periodicity that was compartmentalized within graphs, meaning that the student "was able to make conjectures about periodicity only within the graphical representation" (p. 35). The findings from my study confirm and extend the findings of both of the above studies.

Three teachers in a small suburban high school administered my questionnaire in class to their students who agreed to participate – five classes of algebra 2/trigonometry students (n = 95) and one class of AP calculus students (n = 14). Two girls from the algebra 2/trigonometry classes and two girls from the AP calculus class volunteered to participate in the task-based interviews.

My analysis of the questionnaire data revealed that the majority of students had a basic understanding of periodicity as repetitive patterns. There were instances of misconceptions particularly for tabular representations and for discontinuous graphs. Overall, the calculus students had more robust understandings than the algebra 2/trigonometry students. All students expressed understandings of periods as exclusively fundamental periods; they did not demonstrate a conception of periodic phenomena as having multiple periods. My analysis of the interviews revealed that calculus students engaged in periodic reasoning in a context, but the algebra 2/trigonometry students did not. For all students, the task allowed use of contextual vocabulary to discuss periodic concepts, which made the concepts more accessible.

THE EFFECT OF ITEM MODIFICATION ON STUDENTS' STRATEGIES FOR NEGOTIATING LINGUISTIC CHALLENGES IN MATHEMATICS WORD PROBLEMS

Joanna O. Masingila
Syracuse University
jomasing@syr.edu

Victoria M. Wambua
Syracuse University
vmwambua@syr.edu

Louise C. Wilkinson
Syracuse University
lwilkin@syr.edu

Some researchers have recommended item modification as a means for accommodating English language learners in mathematics tests prepared in English (e.g., Kieffer, Lesaux, Rivera, & Francis, 2009). Item modification as a measure is based on the notion that complexity in the natural language is construct irrelevant (Messick, 1989). In other words, linguistic challenges resulting from the use of a natural language, such as English, are not part of the concepts a mathematics test is meant to measure. Indeed, "the fundamental notion of test validity is that low test scores should not occur because of factors that are irrelevant to the construct an instrument intends to measure" (Solano-Flores &Trumbull, 2003, p. 3).

Research has shown differentiated performance between students taking modified test items and those taking the original items (e.g., Abedi & Lord, 2001). In these research studies, students taking modified test items have performed better, and have expressed preference of the modified test items over their original counterparts. While many studies have investigated differences in performance between students taking modified and original mathematics test items, there seems to be no research investigating how the strategies students use to negotiate linguistic challenges may vary between students taking modified test items and those taking original ones. Knowing the differences and similarities in how students negotiate linguistic challenges while taking modified and original test items can help inform researchers about: (a) the effectiveness of item modification, (b) any additional linguistic challenges other than those emanating from the natural language, and, (c) how students' problem solving may be supported.

This poster will use data collected among eight Kenyan high school (ages 17 or 18) students who were assigned modified and original Kenya Certificate of Secondary Education (KCSE) mathematics test items. KCSE mathematics is a Kenyan high-stakes examination prepared in English, a foreign language, and taken by students completing high school. The original aim of this study was to investigate the linguistic challenges students face while solving selected KCSE word problems, and ways in which they negotiate these challenges. The findings of this study were presented at the 38th PME-NA conference. For this poster, we will compare the strategies students used to negotiate the linguistic challenges across the modified and original test items. This poster will thus present the salient differences and similarities between strategies students used while negotiating linguistic challenges in modified and original test items, as well as the implications for future research and practice.

AN EXPLORATION OF HOW ASPECTS OF A NOTICING INTERVENTION SUPPORTED PROSPECTIVE MATHEMATICS TEACHER NOTICING

Shari L. Stockero
Michigan Technological University
stockero@mtu.edu

Amanda D. Stenzelbarton
Michigan Technological University
adstenze@mtu.edu

Numerous studies, including our own, have documented that teacher noticing interventions can be effective in developing teachers' abilities to notice salient aspects of the mathematics classroom. In this study, we explore how specific aspects of one such intervention may have supported three prospective teachers in learning to notice high-potential instances of student mathematical thinking. The findings provide evidence that it was not one particular aspect of the intervention that was effective in supporting their noticing, but a combination of factors that include the use of a noticing framework, interactions with their peers and a facilitator, and targeted learning-to-notice activities.

Keywords: Classroom Discourse, Instructional Activities and Practices, Teacher Education-Preservice

The ability of a teacher to attend to and make sense of important events or aspects of the classroom – *teacher noticing* – is recognized as an important component of teaching expertise (Sherin, Jacobs, & Philipp, 2011). However, "the noticing required in teaching is specialized, it is not a natural extension of being observant in everyday life" (Ball, 2011, p. xx) and thus is a skill that must be learned. Fortunately, research has shown that noticing interventions, in a variety of forms, can be successful in helping teachers notice salient aspects of the classroom. For instance, interventions have been found to help prospective mathematics teachers become more focused on students' mathematical thinking (e.g., Mitchell & Marin, 2015), more discriminating about what is important to attend to in a classroom (e.g., Sherin & van Es, 2005), and better able to make connections between teacher actions and student learning (e.g., Roth McDuffie et al., 2014). In general, research suggests that teachers can become more attentive to whatever aspect of instruction is the focus of an intervention.

While it is clear that targeted interventions can be effective in scaffolding noticing, it is less clear why particular interventions work. Researchers have hypothesized a range of explanations, including the use of specific frameworks or targeted prompts (e.g., Roth McDuffie et al., 2014), discourse among participants (e.g., Mitchell & Marin, 2015), and multiple opportunities to engage in noticing activities (e.g., Santagata, Zannoni, & Stigler, 2007). Facilitation has been found to play a critical role in video analysis, a common feature of noticing interventions, since the facilitator must support teachers to "not only see what is worthwhile but how to dissect the details of the interactions represented in this video…to draw informed interpretations of teaching and learning" (e.g., van Es, Tunney, Goldsmith, & Seago, 2014, p. 352).

Our own work with prospective teachers (PTs) has documented that our noticing intervention has helped PTs become more focused on individual students' thinking, better able to articulate the specific mathematics underlying that thinking, and more capable of identifying instances of student thinking that have significant potential to be used to support students' learning (Stockero, Rupnow, & Pascoe, 2017). Like others, we have hypothesized aspects of the intervention that supported PT learning: using a framework, interacting with peers and a facilitator, and requiring a response template to structure PTs' reflections. We also suspect that some of the learning took place as a result of many opportunities to engage in noticing activities over time. The purpose of this study is to begin to explore how specific aspects of a noticing intervention may have supported the changes in noticing we have documented, and is thus at the crossroads of past teacher noticing research that focused on whether interventions can work and future research that is necessary to understand why such interventions work. To do so, we examine the cases of three PTs who formed one cohort that engaged in the noticing intervention. Specifically, this exploratory study focuses on the question: How do particular features of a noticing intervention support PTs' ability to notice high-potential instances of student mathematical thinking?

Theoretical Framework

Although teachers need to attend to a variety of classroom features while enacting a lesson, we focus our work on the noticing of students' mathematical thinking. This choice is grounded in our goal of helping teachers learn to enact *ambitious teaching* (Lampert, Beasley, Ghousseini, Kazemi, & Franke, 2010), teaching that is intentionally responsive to students' current thinking as a means of helping all students develop a deep mathematical understanding. We adopt Jacobs, Lamb and Philipp's (2010) definition of *professional noticing of [students'] mathematical thinking* to include the skills of attending, interpreting, and deciding how to respond. In this study, we focus specifically on the first two components. We hold the perspective that not all instances of student thinking should be given equal attention, however, since they do not all have the same potential to enhance student learning. We focus specifically on noticing instances of student thinking that have significant potential to be used during a lesson to support mathematical learning. We use the MOST Analytic Framework (Leatham, Peterson, Stockero, & Van Zoest, 2015) as a tool to identify such instances—those that occur at the intersection of student mathematical thinking, significant mathematics, and pedagogical opportunity. In the framework, each of these three characteristics has two criteria. Student mathematical thinking requires inferable *student mathematics* and an associated *mathematical point*; significant mathematics requires that the mathematical point is *appropriate* and *central* to student learning goals; and pedagogical opportunity requires that the instance of student thinking creates an *opening* to build on student thinking and that the *timing* is right to take advantage of the opening at the moment it occurs (for more detail about the framework, see Leatham et al., 2015). We prioritize the noticing of MOSTs because they are instances that have significant potential to advance students' mathematical understanding if built upon by a teacher – that is if made "the object of consideration by the class in order to engage the class in making sense of that thinking to better understand an important mathematical idea" (Van Zoest et al., 2017, p. 36).

Methodology

This study is part of a larger research project focused on supporting PTs' ability to notice MOSTs that surface during a classroom lesson. In this study, we focus on the last of five iterations of the intervention; this iteration was selected because it was found to be the most successful in supporting PT noticing (Stockero et al., 2017).

Intervention

The intervention took place during a one-semester early field experience course at a Midwestern US university. The participants were three PTs who comprised the fall 2014 cohort. Each PT completed weekly observations in a local, secondary school mathematics classroom, with the PTs taking turns recording a lesson in their classroom each week. The common full-length classroom video was analyzed individually by the PTs and by the research team each week. The research team used the PTs' and their own analyses to strategically select video instances to discuss at a weekly group meeting among the members of the cohort, facilitated by the first author (see Stockero et al., 2017, for more detail about the instance selection processes). The participants analyzed 9 different videos and attended 11 weekly meetings.

At the start, all of the PTs' video analyses focused on identifying "mathematically important moments that the teacher should notice"; they tagged such instances on a video timeline and annotated each instance with their reason for its selection. The PTs were introduced to the MOST Analytic Framework (Leatham et al., 2015) at the end of the Week 2 meeting to define important mathematical instances and provide focus for their video analysis. In Week 3, the PTs used the framework to re-analyze the two videos they had analyzed in the prior weeks. Subsequently, they used it to analyze each new video for MOSTs. In the Week 9 of the intervention, the PTs completed an activity focused on identifying in a set of statements those that represented a *mathematical point* that a given instance of student thinking could be used to work towards and rewriting those that did not. When analyzing the last two videos (Weeks 10 and 11), the PTs were provided a template to structure their video annotation by requiring them to address all six MOST criteria in their reasoning about instances.

Data Collection and Analysis

The data for the study include the PTs' individual video analysis timelines, the research team's weekly meeting plans, and video of each group meeting. In all of the data analysis, the data were first coded individually by two or three members of the research team. The team then met to compare coding and discuss coding differences until consensus was reached.

The unit of analysis for the PTs' video timelines was each instance marked by a PT, including their annotation. These instances were analyzed in two ways. First, each was coded according to three characteristics: *agent* (who was noticed), *specificity* (the level of detail with which the mathematics was discussed), and, for instances where the agent included student(s), *focus* (what about the student(s) was noticed) (adapted from van Es & Sherin, 2008; for more detail see Stockero et al., 2017). This coding was used to analyze changes in specific characteristics of the PTs' individual noticing in relation to our noticing goals: individual student agent, specific mathematics, and a focus on noting or analyzing student mathematics. Second, each instance was coded according to whether it aligned in the video with a MOST identified by the research team and whether the PTs' reasoning was consistent with what made it a MOST, an indication of whether the PTs were noticing high-leverage instances of student thinking.

The meeting videos were also analyzed in two ways. The first analysis focused on identifying instances of what we call *analytic discussion*. Here the unit of analysis was a segment of the meeting discussion that focused on a single topic; for example, making sense of the student mathematics in an instance. Informed by Lohwasser's (2013) concept of *accountable talk* in teacher professional learning communities, we focused on identifying segments of dialogue that were likely to advance the PTs' learning—those that went beyond sharing their thinking or agreeing with one another. Instead, analytic discussion included making sense of ideas, critiquing the thinking of others, and providing alternative perspectives. In short, it is discussion that has the potential for "developing and creating usable…knowledge for teaching" (Lohwasser, 2013, p. 141-142). In the second analysis, each individual facilitator move was coded according to its purpose, using a coding framework that was informed by the facilitation moves described by van Es et al. (2014). In the analysis reported here, we focus specifically on *probing* and *challenging* moves—the moves that were most likely to directly influence PT learning. In a probing move, the facilitator pushes for more detail or specificity about a PTs' thinking. In a challenging move, the facilitator may point out a discrepancy in reasoning, or push the PTs to consider an alternative explanation or point of view, critique another PTs' explanation, or make a firm decision about the value of an instance.

The data analysis involved analyzing the coding to compare changes in the PT's individual noticing to key features of the intervention as documented in the meeting notes and group meetings. This analysis focused on determining whether changes in the PTs' noticing could be explained by particular aspects of the intervention.

Results

In the following, we first briefly describe the cases of the three participants – Claire, Aaron, and Ruth – in terms of the overall trajectory of changes in their noticing. We then use these cases as background for considering the extent to which particular aspects of the intervention appeared to support the PTs' noticing.

Cases of Learning to Notice

Claire's baseline noticing data showed that she was focused on the important mathematical ideas in the lesson, but in isolation from the students. For example, her annotation of one instance said, "Opposites added together always equal zero." None of her instances in the baseline data were coded as being consistent with MOSTs. After the introduction of the MOST framework, Claire quickly changed her focus and was able to maintain a productive focus throughout the remainder of the intervention. Beginning from the first week she used the framework, Claire consistently focused on the students' mathematics, discussed this mathematics in a specific and often analytical way, and noticed instances that satisfied at least some of the MOST criteria. Claire is a case of a PT who was quickly able to make sense of the framework she was provided and use it to identify high-potential instances of student thinking.

Aaron's initial noticing was focused on the teacher and non-mathematical issues, such as "getting everyone involved". It was thus inconsistent with MOSTs. After the introduction of the MOST framework, Aaron began to focus more on students, but moved back and forth between a teacher and a student focus for several weeks. Aaron was similar to Claire in that he began displaying analytical behavior early on. His noticing generally focused on instances that satisfied some of the MOST criteria beginning in Week 5, and his noticing became entirely aligned with MOSTs by the last two weeks. Aaron is a case of a student who took some time to make sense of the framework, but at the end of the intervention was displaying productive noticing skills.

Ruth's baseline noticing had a mixed focus on the students as a collective and on the teacher. Over half of her noticing was non-mathematical in nature and all of it was inconsistent with MOSTs. The introduction of the framework allowed Ruth to shift her focus to the students in the video and thus allowed her noticing to become more consistent with MOSTs. She also began to discuss some of the mathematics in a specific way, although much of such discussion was still at a very general level. She was slower than Claire in developing the ability to identify MOSTs; it was not until Week 8 that the majority of Ruth's noticing consistently focused on MOSTs. Ruth had the most difficulty with the interpreting aspect of noticing, as she only had instances coded as analyzing student mathematics in the last two weeks of the intervention, and even then only a single instance in each video reached this level. Ruth is a case of slow growth over time and of a student who may have benefitted from a longer intervention.

Supports for Noticing

Noticing framework. We first considered how the use of a framework supported the PTs' noticing. To understand its immediate impact, we analyzed the PTs' noticing in Week 3, when the MOST framework was used to reanalyze the videos from the first two weeks, and Week 4 when the framework was used to analyze a new classroom video.

The data suggests that the MOST framework immediately and effectively supported Claire's noticing. During her first use of the framework, her noticing shifted from teacher to students, and to instances that were MOSTs. Impressively, Claire's annotations were coded as analyzing student mathematics in over two-thirds of the instances she identified in Weeks 3 and 4, and nine of her ten identified instances were MOSTs. To give a sense of the type of noticing Claire engaged in during her early use of the MOST framework, consider her annotation of an instance that occurred when students were being introduced to Pythagorean Triples:

Student: ‘Times 13^2’. One student thought that $5^2 + 12^2$ should be multiplied by 13^2 to find out the hypotenuse length. [T]his concept is not especially difficult, that it should [be] equal to 13^2, but when this is just being introduced, it might be difficult for a student to understand how to know if a 5, 12, 13 triangle is a Pythagorean triple. At this point it is important to understand that they just need to plug the values into the equation $a^2 + b^2 = c^2$.

In this instance, Claire not only noticed an important error made by a student, she also hypothesized why the concept might be difficult (Pythagoreans triples have just been introduced) and explained what mathematical idea she would want the student to understand.

Aaron and Ruth, on the other hand, seemed to take more time and need more support to make effective use of the framework. Although about half of their noticing was focused on MOSTs in Weeks 3 and 4, each displayed key inhibitors to their noticing. Aaron’s was his continued focus on the teacher, despite the fact that the first MOST criteria is student mathematics (e.g., “The question is how to compute the hypotenuse given two legs. The goal is to be able to use the Pythagorean Theorem to do this. [The teacher] explains the central goal in detail so the students will understand this concept”). For Ruth, it was her vague explanations that lacked evidence that she was engaging in analysis and interpretation of the student’s thinking (e.g., “The students are all getting the problem wrong, and you can tell what they are thinking mathematically by their misspeaking or wrong answers.”). Thus, although the framework provided some focus to Aaron and Ruth’s noticing, it was not sufficient to focus them on noticing and interpreting MOSTs.

Group discussions. The data indicated that, on average, the PTs engaged in 14 episodes of analytical discussion in each weekly meeting, with a range from 8 to 19 episodes. The PTs’ participation in these discussions was found to be evenly distributed, so they all had equal opportunity to engage in discussions that were likely to promote their growth in noticing.

The Week 1 and 2 analytical discussions focused largely on distinguishing between teachers’ noticing and their use of prior knowledge to make instructional decisions, as well as on making sense of what it means for something to be mathematically important (versus important for some other reason). Inferring the student mathematics (SM) in the video was a primary focus of analytical discussions nearly every week, as was articulating a mathematical point (MP) that the student mathematics could be used to work towards, after this concept was introduced with the MOST framework. Other topics that were the object of analytical discussion were definitions of specific MOST criteria and considering these criteria within specific contexts (such as what it means for an idea to be central to student learning if it is not the focus of the current lesson, or what the SM is if two competing student solutions have been shared). During the second half of the intervention, proposing building moves was also a significant topic of discussion, although not the focus of our current analysis.

The SM and MP criteria are the most mathematical of the MOST criteria and are typically the components that require the deepest level of analysis to identify whether an instance is a MOST. They appear to be the components that were most challenging to Ruth and Aaron and thus affected the advancement of their noticing skill. There is evidence that a sustained focus on these topics during the meetings was effective, however, since Ruth and Aaron both continually increased in their focus on noting and analyzing the student mathematics and their ability to identify MOSTs. Aaron did so more quickly than Ruth as his noticing was coded as either noting or analyzing the student mathematics in nearly all instances beginning in Week 5, and by Week 6 he noticed mostly MOSTs. Ruth gradually increased in the percentage of instances coded as noting student mathematics and that were MOSTs, but only showed evidence of analyzing student mathematics in the last two weeks of the intervention. To give a sense of how the analytical discussion may have supported the PTs in learning to infer the SM, consider an excerpt from the Week 5 meeting in which the PTs were discussing a video instance in which a student said that the coordinates of the x- and y-intercepts of a graph "both have a zero":

Facilitator: What do you think the student is saying there?
Claire: I think she is noticing that the x-intercept is when y is zero and the y-intercept is when x is zero. That's not what she says. She says they both have a zero, but I think that's what she's getting at.
Aaron: She just didn't find the right way to explain it, a way that everyone else would understand what she meant by saying it, which is why [the teacher] later went into explaining when looking for the x-intercept, it's when y=0, when it crosses the x-axis. She goes over a few ways to explain it. Actually explaining it in a way that everyone else would understand makes sense. It makes sense for her to interject there.
Facilitator: I heard Claire say that she didn't really say that. Is there enough there to infer the student math?
Ruth: I feel like she wasn't entirely clear on what the correct answer was. She just made the observation that each coordinate has a zero. That's what I thought.
Facilitator: So that's all you're willing to infer, then? That each one has a zero in it.
Ruth: Yeah, she was just making that observation and the teacher then elaborated on it.

In this excerpt, we see Claire and Aaron make an inference about the SM that went beyond what should be reasonably inferred based on the student's brief statement. Ruth contradicted their inference, however, providing the opportunity for them to reconsider their assertion about the SM. In fact, later in the discussion Claire noted that, "We've kind of thought that she made an observation that might or might not be correct, so [the teacher] needs to elaborate or figure out what she really means before it can be opened up to the class to discuss," indicating that Ruth's comments had caused Claire to reconsider her original inference.

The meeting data showed that Ruth struggled to articulate MPs related to the students' ideas through much of the intervention. For example, a Week 7 meeting discussion focused on an instance in which a student had suggested that to convert the fraction 1/10 to a percent, you could just use the denominator, so it would be 10%. When the facilitator asked, "Is there a mathematical point associated with that? In other words, what would you want him to understand?", Ruth replied "That's not how you do it,"—a response that typified her articulation of MPs and lacked the level of interpretation that was our goal. Despite participating in numerous discussions where the other PTs had articulated MPs, Ruth struggled to do so. This was a primary reason that she was unable to reach what we considered the most advanced level of noticing, where she was able to identify and also make sense of students' mathematics.

Facilitation. Related to the *analytic discussion* findings, an examination of the role of the facilitator suggests that the meeting facilitation was also important to the PTs' learning. In the ten meetings that focused on analyzing video instances (all except Week 9), 84% (119/155) of all analytic discussions were supported by either *probing* (79) or *challenging* (6) facilitator moves, or by both (34). This was relatively consistent across meetings, with between 69% and 92% of analytic discussion supported by such moves. Additionally, 77% (40/52) of all *challenging* facilitator moves during the intervention meetings coincided with analytic discussion, indicating that such moves were effective in causing the PTs to grapple with ideas. Together, these results suggest that the meeting facilitation played a key role in supporting changes in the PTs' noticing during the intervention; in particular, the facilitator's moves appeared to support discussion among the PTs that was likely to advance their learning.

Targeted activity and template. Prompted largely by the observation that Ruth was having difficulty advancing her noticing due to her inability to articulate MPs—an important part of the identification of MOSTs—in Week 9 we engaged the PTs in an activity where they worked on articulating MPs associated with instances of student mathematical thinking that they were provided. Following this activity, we also provided a template that prompted the PTs to address all six of the MOST criteria in their instance annotation beginning with the Week 10 analysis. Because these activities occurred simultaneously, it is difficult to separate their impact on Ruth's noticing. There is evidence, however, that together they had a positive effect on her noticing.

In Week 8, a typical annotation by Ruth addressed the SM and the MP as follows: "The student math is that she discovered what the pattern is for getting the inverse [of a matrix]. Her point was closely related to what they're learning because it was the teacher's next part of the lesson." Note that this response alludes to the SM and to a MP, but does not precisely articulate either. In Week 10, however, her response addressed the same two criteria as follows:

> Student Math: She said the absolute value of -5 was 5 because it's the opposite of 5.
> Mathematical Point: The absolute value of a number is always the distance that number is away from 0. This is because absolute value is a measure of distance and distance is always positive.

Here, the level of detail and precision are both much improved from the prior example. Thus, it seems that the Week 9 activities and template did advance Ruth's noticing. Even at the end of the intervention, however, she did not display the same level of analysis of student mathematics as her peers, with only a total of two coded instances reaching this level. In this case, a longer intervention may have allowed Ruth to continue to develop her noticing skill.

Conclusions

This exploratory study—at the crossroads of past teacher noticing research that focused on whether teacher noticing interventions could work to future research focused on understanding why they work—examined how various aspects of a noticing intervention that have been hypothesized to support teacher noticing appeared to help three PTs learn to recognize and interpret MOSTs in classroom video. As hypothesized, a provided framework did in fact support changes in their noticing, although the changes for two of the PTs were neither immediate nor drastic; in other words, the framework did not serve as an 'answer key' and was not by itself sufficient to support noticing. Rather, the PTs' noticing appeared to develop over time though participation in regular group discussions that allowed them to grapple with components of the framework. Moreover, the evidence suggests that facilitation that probed or challenged the PTs' thinking was important in supporting their engagement in analytic discussions that pushed their thinking and thus promoted learning. In the case of one PT, a direct intervention to support her in becoming more analytical of the mathematics underlying the student thinking was necessary to improve her noticing, but even then there was room for improvement. The results of this study highlight the significant effort required to develop skills in a practice as complex as noticing student mathematical thinking. Consistent with research on teacher professional development (e.g., Loucks-Horsley, Stiles, Mundry, Love, & Hewson, 2010), this study suggests that brief or minimally supported interventions are unlikely to fully develop such a practice.

We discuss affordances and liabilities of using a storyboard to depict a written case of a teacher's dilemma that involves race, opportunity to learn, and student community. We rely on reflections by the teacher educator who authored the written case and later depicted it as a storyboard to use it with his preservice teachers (PSTs). The analysis involved, first, organizing the signifiers in each of the two representations of practice into what we call concentric spheres of stratification, and secondly, contrasting the various meanings attributed to signifiers by both the author and his PSTs. We suggest that the resources of storyboard allow for more inquiry and alternative narratives than is available from the single modality of text in the written case.

Keywords: Equity and Diversity, Teacher Education-Preservice, Technology

Introduction

Motivated by the increasing use of multimodal representations of practice (e.g., video, animations, storyboards) in mathematics teacher education, we discuss affordances and constraints of such media and propose a framework for analyzing them. This contribution helps address the challenge of anticipating what meaning a group of preservice teachers (PSTs) will attribute to the complex system of signifiers included in a representation. The framework addresses this issue by offering a way of organizing those signifiers and suggesting that teacher educators could consider where and how the meanings that they and their PSTs attribute to a given representation might differ. To demonstrate the value of the framework, we use it to analyze a teacher educator's use of a written case and a storyboard representation of the same classroom scenario. The scenario was used to discuss a teaching dilemma that involves race, opportunity to learn, and student community – the decision to move a student to a more advanced mathematics class. The data comes in the form of the reflections by the teacher educator (and co-author) who initially wrote the case and then created a storyboard for use with his PSTs. We examine issues of representation illustrated by that data and that concern the use of representations of practice to support practice-based and inquiry-oriented teacher education.

Perspectives and Theoretical Framework

The notion of *representation of practice* has been a key in developing a practice-based approach to professional education (Grossman, et al., 2009). Representations of practice using the written narrative modality have been common in professional development (e.g., Stein, Smith, & Silver, 1999). Written cases are useful because they can help focus attention on important aspects of practice. But inasmuch as written cases use abstract symbols (words!) to represent individuals,

Galindo, E., & Newton, J., (Eds.). (2017). *Proceedings of the 39th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* Indianapolis, IN: Hoosier Association of Mathematics Teacher Educators.

settings, and actions of practice, they are less effective in immersing their audience into key aspects of classrooms such as the simultaneity and temporality of classroom events (Doyle, 1986; see also Herbst et al., 2011). As video technology became more accessible and approaches to teacher education as inquiry more common, teacher educators have been using video records to immerse novices in practice (Brophy, 2004; Lampert & Ball, 1998). Much has been written describing the affordances of having teachers watch and discuss classroom video to promote noticing and reflection (Rich & Hannafin, 2009; Sherin, Philipp, & Jacob, 2011). The capacity of video to record simultaneous multimodal communication (gesture, inscription, voice, movement, etc.) by a diversity of individuals has been noted as advantageous for creating an increased sense of presence (e.g., in comparison with text; see Kim & Sundar, 2016). That capacity also provides key affordances to allow for expanded inquiry pursuing a variety of foci, though the camera always directs attention in some way (Hall, 2000). This is not always what teacher educators need or prefer, as quite often their students latch onto aspects of a video not particularly germane to the goals of their instructors (Star & Strickland, 2008).

To bridge the gap between the capacity of video to immerse and the capacity of text to focus, professional educators have started to explore other media (e.g., animations and storyboards with cartoon characters) to represent practice (see Herbst et al., 2011; Tettegah, 2005). Art critics and scholars of visual communication have for long used language as a metaphor in examining visuals (Barthes, 1972). But more recent progress extending the systemic functional linguistics approach to language (Halliday & Matthiessen, 2004) to a variety of sign systems (Kress & van Leeuwen; 1996) and levels of realization (including the register of classrooms; Christie, 2002) has brought us closer to actually being able to examine the affordances of the comics medium as a language using similar approaches and resources as how SFL examines the uses of language. This paper contributes to an examination of how the multimodal resources in the comics and animation medium permit the production of complex messages about classrooms and the way in which they also enable a degree of openness (Weiss, 2011) that allows for inquiry and alternative narratives. Some of these features of comics will be exemplified through a comparison of a comics-based representation and a written representation of a classroom story.

Mode of Inquiry

We collaboratively examined the interaction of a teacher educator (Lawrence Clark) with successive versions of a technology for depicting classroom interaction in an effort to translate a written case to a storyboard. This examination allows our field to learn about affordances of storyboard technology for the representation of teaching practice. *Depict* (a tool included in Lesson*Sketch*; www.lessonsketch.org), allows users to upload and manipulate graphics and provides cartoon characters designed to create classroom visual meanings. Just as language has the words *student* and *teacher* to represent roles in a classroom, and other linguistic resources to describe how people feel (e.g., the student was *happy*), where they are (e.g., the student was *at the board*), or what they are doing (e.g., the student was *solving an equation*), *Depict*'s graphic language has resources to represent those meanings (e.g., see Figure 1).

Notably, if words report simultaneous happenings, the graphic medium allow us to show this simultaneity. Video can also do that, but it might also include other messages about the action that might be less relevant to convey (e.g., the style of clothes popular at the time the video was captured). In designing a semiotic system for representing classrooms, the developers of *Depict* wanted to make available graphic elements and software features that help communicate classroom meanings of particular relevance for the study of teaching practice. One important set of considerations has been the dimension Herbst et al. (2011) called *individuality*, or the extent to which the set of graphic resources enables distinguishing individual differences among classroom participants and settings. In this regard, it is worth distinguishing between *enacted* individual differences (e.g., the possibility that one student would do or express something that others would not) and *enduring* individual differences (e.g., based on individual characteristics that recur across enactments, such as body size, race, class, or gender). While *Depict*'s character set (Figure 1) was originally conceptualized as a cast of characters with some resources to express enacted individual differences (e.g., facial expressions, body orientation), very few resources were originally provided for enduring individual differences (e.g., no affordances for body size, hairstyle, or skin color). *Depict*'s characters were nondescript characters whose role was to depict practice rather than individuals. In that context, Chazan and Herbst (2011) had described the affordances of the cartoon characters as comparable to variables in algebra and distinct from diagrams in geometry: As Laborde (2005) has noted, diagrams have the liability that they spatiographically assert properties that are not always theoretically necessary—e.g., a diagram of a rectangle will likely show two sides longer than the other two sides. Other properties of rectangles, however, are not only visible but also necessarily true (e.g., opposite sides are congruent). Students often latch onto spatiographical properties as they use diagrams to learn geometry. While video is like diagrams in geometry in that it enables the observation of ancillary events, Chazan and Herbst (2011) argued that *Depict*'s cartoon language is like the generic language of algebra in its capacity to make assertions about practice, as opposed to assertions about specific individuals. Yet they also thought of the graphic resources as a developing language that would progressively incorporate new semiotic systems to represent more aspects of practice. The extent to which considerations of race enter in the way teachers relate to students in practice offered an important opportunity to further explore the possibilities of phasing in new graphic resources to increase the representation of individuality.

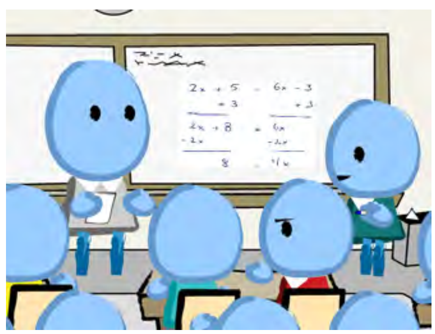

Figure 1. A frame from a storyboard using Depict.

New resources have been recently added to *Depict*'s graphic language to allow representation of some enduring individual differences. The *complexion* system, operationalized by color wheels that enable the user to pick skin tones for characters, affords the user the ability to choose whether to use the default blue skin or to choose freely from the color wheels. We wondered whether this particular affordance supported the work of a teacher educator in representing a case that he wanted to bring to his PSTs, and the extent to which the depicted representation allows for alternative inquiries and narrative. We examine the use of *Depict* by comparing Clark's Case of Mya (see Chazan, et al., 2016, p. 1059) and a storyboard Clark constructed to represent the case. The comparison is of interest because the storyboard demanded more graphic resources than were prescribed in the text (e.g., things unsaid in the text needed to be depicted to visualize the classroom scene) although it was created after the written case; generating the possibility that alternative stories could emerge from the engagement of the readers with the media.

The Case of Mya

The Case of Mya describes a dilemma faced by a middle school mathematics teacher, Scott Johnston, in his effort to provide a more rigorous and challenging mathematical learning environment for one of his students, Mya. Johnston was employed in a middle school and district where 8th graders were assigned to one of four mathematics courses (from lowest to highest level of rigor): Math 8, Pre-Algebra, Algebra, and Advanced Algebra. A potential byproduct of grouping students by performance is grouping students by race and social class: Racial and class gaps in performance have persisted throughout the history of mathematics education in the U.S. The Case of Mya acknowledges and incorporates these complexities. Scott Johnston commits his efforts to providing Mya, an African American female eighth grade student enrolled in one of his lower level mathematics classes, a more rigorous school mathematics experience. Based on Mya's social and intellectual performance in the course she is currently enrolled in, Scott takes on the work of enrolling her in a higher-level course.

Clark was also recruited as a fellow for a project that supported the creation of multimedia representations of practice for use in teacher education. He took on the challenge to represent the Case of Mya as a storyboard. He describes his challenge thus:

> When faced with moving the written Case of Mya to a storyboard, numerous considerations came into play. The first consideration revolved around how I might illustrate the complexities of the case context. I grappled with questions like
>
> - How can I depict the larger forces at play (context) that shape and direct a mathematics teacher's classroom decision-making and instructional practice?
> - As race and class are 'in the mix' of students' access to mathematics opportunity, how can the storyboarding tools serve to illustrate these phenomena?
>
> For example, in the written case, I had stated:
>
> > [S]he (Mya) was unquestionably the most engaged, inquisitive, and mathematically confident student in the entire [Pre-Algebra] class, and she consistently outperformed her classmates on tasks and assessments. She thrived in her position as one who I could call on to assist struggling students. Her ability to communicate her mathematical thinking and problem solving approaches in front of the entire class was unmatched. Mya fared less well in other academic areas, but it was evident to everyone, including herself, that she was comfortable and in her element when interacting in the [Pre-Algebra] class. (Chazan, Herbst, & Clark, 2016, p. 1059)
>
> I had not gone into the specifics of her mathematical thinking in the written case. But I did go into specifics of her mathematical thinking when afforded the opportunity to create the storyboard. I designed the following scenes in the depiction and asked readers to explore and comment about Mya's mathematical thinking in the lower level class:

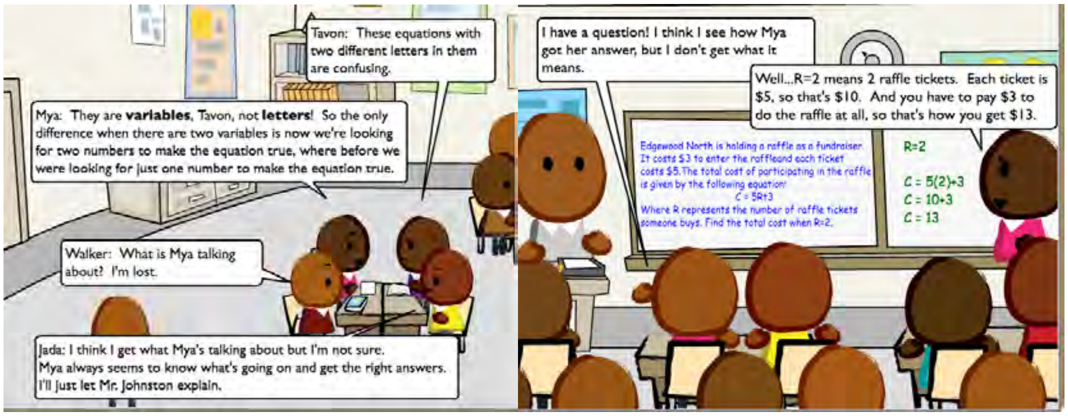

Figure 2. Mya's mathematical ideas, represented by speech and boardwork.

It was also important that both depictions of Scott and Mya reflect their African descent through skin tone, so I chose to depict Scott and Mya using dark skin tones. The written text of the Case of Mya explicitly refers to Mya as African American, however the text does not explicitly refer to Scott as African American, so the reader of the case may (or may not) see both Scott and Mya as African American. This shared racial characteristic can be explored in the discussion of the depiction to gauge the reader's perception of Scott and Mya's shared racial characteristic as relevant or salient to Scott's decisions. For some readers, Scott and Mya's shared racial characteristic may suggest some form of connection, allegiance, and loyalty. In the written case I described the Advanced Algebra class to which Mya transferred as being populated predominantly by Caucasian students. Identification of skin tones on the color wheel that represent Caucasian students was challenging. I tended to rely on pinkish or creamy skin tone shades. I had to create multiple pilot scenes to determine if pilot viewers saw the Advanced Algebra classroom as populated predominantly by Caucasian students. In some cases, viewers mentioned that the students in Advanced Algebra were unnaturally pink. Furthermore, when choosing pinkish or creamy tones for skin color, the color of the outline edge of the character created confusion in the viewer. For example, a light pink character possessed a dark pink edge. A creamy character possessed a brown or tan outline edge. During depiction design, I incorporated scenes of small group work in the Advanced Algebra class that showed Mya as the only student of color in the group. In these scenes, Mya's mathematical ability is questioned and challenged by others. The purpose of including these scenes is to further explore viewers' perspectives on whether race could be a salient and relevant influence on student-student interaction around the mathematics task at hand.

Results and Discussion

From the above example, one may see affordances of a semiotic system embedded in the storyboarding environment. While building a storyboard the availability of the empty, but editable, whiteboard may make the creator wonder what should be written on the whiteboard in the case of Mya. It is more difficult to see those opportunities while writing a case. Similarly to the first example described earlier, from this second example one may generalize the affordances that a semiotic system could offer in the storyboarding environment. When creating a storyboard in *Depict*, the default skin tone of the students is blue (see Figure 1). One can change the skin tone of one character, but then it is likely that one will feel the need to assign skin tones to all characters. The teacher educator felt compelled to represent Scott's skin tone – which, as he suggests, might motivate a reader to infer social relationships between Mya and the teacher.

Table 1. Meanings attributed to the written and depicted case of Mya.

Excerpt from representation	Author meaning/intent	Reader/viewer interpretation (E) - expected; (U) - unexpected
Written case: *Excerpts from written case transcribed above (p. 4)*	Mya is successful when completing complex mathematics tasks and assessments in the pre-algebra classroom Mya has a strong mathematics identity in the Pre-Algebra course, yet may not possess a strong general academic identity (across all subjects). Unlike the majority of her peers in the Pre-Algebra class, Mya possesses confidence and comfort in communicating her mathematical thinking publicly. Mya may be viewed as a peer resource by other students. Mya's explanations may support the development of other students' understanding.	PSTs remarked that Mya possesses power and agency in the Pre-Algebra course. (E) PSTs remarked that Mya is a resource for other students in the Pre-Algebra course. (E) Some PSTs felt that the teacher should not move Mya from the Pre-Algebra course to the Advanced Algebra course. (U)
Depiction: See Figure 2	The Pre-Algebra class is composed predominantly of students of African descent as signified by student skintone; the Advanced Algebra class is composed predominantly of Caucasian students. Mya's demonstrates an understanding of the concept of variable. Mya's demonstrates the ability to solve equations in one variable and equations in two variables given a value for one of the variables. Mya may be able to reason through identifying a set of values of the two variables that solve the equation without being given one of the values.	PSTs focused on many classroom signifiers when describing differences between the two classrooms (seating arrangements, calculator use, etc.), yet were hesitant to mention racial differences between the two classes. (U) A PST interpreted Scott Johnston's physical distance from students in the Pre-Algebra class as a classroom management strategy ('he needs to be able to see all students at all times due to behavior problems') (U) PSTs remarked that Mya understood that parallel lines have the same slope. (E) PSTs remarked that Mya would be able to solve equations in two variables only when given a value for one of the variables. (U) PSTs remarked that Mya would be able to solve systems of equations. (U) When asked how Mya is perceived by her peers, a PST remarked that her peers may view Mya as unrelatable, intimidating, and a 'know it all'. (U)

The case of Mya provides the grounds for a distinction in the kind of storytelling afforded by the storyboarding tool. While originally developed to represent practice, *Depict* also permits to tell character-centered stories that happen in practice; indeed, to some extent it uses the latter to flesh out the former, much in the way that specific diagrams can represent generic figures – diagrams convey important intuitions that help generate geometric theory, might scenes with cartoon characters do the same for teaching? By character-centered stories we refer to stories that are focused on the individualities of one or more characters and what happens to them as they go through episodes in their lives; this contrasts with environment-centered stories that are focused on what happens in specific places as different characters interact. The original design of *Depict* supported the representation of practice in classroom-centered stories. The storyboarding of the case of Mya challenged *Depict*'s graphic language and required the development of a framework for us to examine character-centered stories.

The Framework

We suggest that one can think of the signifiers in a representation of a character-centered story as developed in concentric spheres, each of which includes a stratum of graphical elements available to choose from in order to graphically communicate strata-specific meanings. The innermost sphere in such representations consists of signifiers associated to the characterization of the protagonist(s) of the story. These could include signifiers of physical, cognitive, or emotional individual traits. The second sphere consists of signifiers of the immediate context of the protagonist(s) at various points in the story--resources to represent relations to other characters or to the immediate physical environment. A third sphere consists of signifiers of the more general environment in which the whole story takes place. Earlier, we described and compared the author's textual and storyboard representation of the case of Mya in which Scott proposes that Mya be moved from the Pre-Algebra class to the Advanced Algebra class. In that story, the second sphere will consist of characteristics of those classrooms and the third sphere consists of characteristics of the school community. These different strata form the first dimension of the framework. We argue that the value of the first dimension of this framework is that it helps one organize the many signifiers in a (character-centered) representation of practice.

A second dimension includes consideration of whose meanings one is attending to. The value of the second dimension of this framework is that it encourages considering what meanings different people attribute to a representation, in particular those attributed by the author and by readers, which we suggest are the source of alternative inquiries and narratives. As suggested earlier, we argue that storyboards allow for more alternatives, as they include not only text, but also other communication modalities. A comparison of Clark's intended interpretations of various signifiers in the two representations of the case of Mya and those made by his PSTs is used as example. In some instances, PSTs interpretations were aligned with Clark's meaning or intent; in other instances PSTs generated interpretations that were unexpected (see Table 1). We focused here on signifiers in the innermost sphere of the representation, similar such tables could be used to consider and compare interpretations of the signifiers at each sphere of stratification.

Conclusion

The multimodal resources in the comics medium permit creation of complex messages about classrooms that allow for inquiry and alternative narratives by different readers (Weiss, 2011). These alternative forms of representation also have liabilities. A main gleaning from this paper is that the graphics communicate as a system, both for the author and for the reader. The creation of materials for the study of teaching is not only a creative endeavor but also an analytic one that involves composing with a language and examining the systems of choice with which that language is built. The *individuality* dimension (Herbst et al, 2011) in representations of teaching is one aspect in which this semiotic system can be built, and complexion is one subsystem that contains affordances both for focusing the message and for enabling inquiry.

Indeed while written cases can focus attention on important aspects of practice and video can immerse students in the complexity of practice, a graphics-based semiotic system can be used to scaffold this complexity, combining inquiry with direction. The case of Mya shows that the translation from written case to storyboard included the opportunity to show some interesting nuances in the visibility of race, all of which have a lot to do with mathematics education if we think of mathematics education as an institutionalized practice: Students are learning mathematics in classes and with other students with whom they have particular kinds of social relationships, they are being taught by teachers who could be their advocates or mentors, and these relationships are mediated by race as well as other factors.

EVALUATING PROOFS AND CONJECTURES CONSTRUCTED BY PRE-SERVICE MATHEMATICS TEACHERS

Zulfiye Zeybek
Gaziosmanpasa University
zulfiye.zeybek@gop.edu.tr

This study focused on investigating the ability of 58 pre-service mathematics teachers' (PSMTs) to construct-evaluate mathematical conjectures-proofs in a mathematics course. The combined construction-evaluation activity of conjectures-and-proofs helps illuminate pre-service mathematics teachers' understanding of proof. The result of the study demonstrated that the number of instances where the PSMTs constructed conjectures were less than the number of instances where they constructed arguments to prove/disprove assertions during the semester. Additionally, the PSMTs usually constructed conjectures when they were explicitly asked to do so. The majority of the arguments that were constructed by the PSMTs attempted to provide an explanation for why the assertion held true which may show that the explanatory role of arguments indeed held an essential criterion for the PSMTs.

Keywords: Teacher Education-Preservice

Proof is viewed as a cornerstone of mathematics and an essential element for developing deep understanding (e.g., Ball & Bass, 2000; NCTM, 2000). Yet, research indicates that students of all levels tend to have limited understanding of proof and struggle with constructing proofs (e.g. Harel & Sowder, 1998). Many researchers demonstrated that the empirical reasoning is pervasive among school students including advanced or high-attaining secondary students (e.g. Coe & Ruthven, 1994; Healy & Hoyles, 2000), university students including mathematics majors (e.g., Goetting, 1995) as well as prospective and in-service teachers (e.g. Morris, 2002; Simon &Bume, 1996).

Despite the importance of teachers' understanding of proof, relatively little research has investigated aspects of prospective or practicing teachers' understanding of proofs (Goetting, 1995; Morris, 2002; Stylianides, Stylianides, & Philippou, 2007). Furthermore, previous studies focus solely on teachers' understanding of the distinction between deductive and empirical arguments by asking them to evaluate researcher generated arguments. Stylianides and Stylianides (2009) criticized that there has been limited research about how instructions can help pre-service teachers' develop their understanding of proof. Thus, this study aims to contribute to literature on pre-service teachers' understanding of proof by reporting on pre-service mathematics teachers' (PSMTs)processes of constructing-evaluating mathematical conjectures-proofs during a course in which PSMTs specifically engaged in proving tasks.

Functions of Proof in Classrooms

Traditionally the function of proof has been seen almost exclusively as being to verify or justify the correctness of mathematical statements (e.g. Ball & Bass, 2000). The "verification" function of proof is often interpreted in subjective terms, establishing the truth of a statement with an individual's belief in the truth of a statement and thus allocating proof a role in the subjective acquisition of such belief. However, as Bell (1976) argues, proof is not necessarily a prerequisite for conviction; proof is essentially a social activity of validation or establishing results, which follows reaching a conviction. Duval (2002) argues that a proof can change the logical value as well as epistemic value of a statement. That is, a proof may logically validate a statement, but it can also affect the belief of the cognizing subject as to the truth of the statement. These two functions of

Galindo, E., & Newton, J., (Eds.). (2017). *Proceedings of the 39th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* Indianapolis, IN: Hoosier Association of Mathematics Teacher Educators.

proof—to convince individuals and to establish results in the field—are by no means the only functions of proof in mathematical activity.

Researchers have contributed to such elaboration on the functions of proof both by reflecting on its many roles in the discipline of mathematics and by identifying its roles in mathematical understanding. These roles are identified by de Villiers by building on the work of others (Balacheff, 1988; Bell, 1976; Hanna, 1990; Hersh, 1993) as follows: (a) verification (concerned with the truth of a statement), (b) explanation (providing insight into why it is true), (c) systematization (the organization of various results into a deductive system of axioms, major concepts and theorems), (d) discovery (invention of new results), (e) communication (the transmission of mathematical knowledge), and (f) intellectual challenge (de Villiers, 1990, p.18).

Hersh (1993) argues that the role of proof in the classroom and the role of proof in mathematical discipline could be different, stating that the purpose of proof in mathematical discipline to be to convince, while in a classroom it should be to explain. Knuth (2002) has echoed this theme, arguing to teachers that proofs are valuable because they can help students understand mathematics. Hanna (1990) distinguishes between “proofs that prove” and “proofs that explain”.Thus, the development of proofs in the course where the study took place served two related functions: (a) as means for explaining why an assertion was true or false by showing how the statement of a theorem coheres and connects with the key properties of the concepts involved in the proof, which will be referred as Type P_1proof and (b) as a means for justifying that an assertion was true thereby promoting conviction, which will be referred as Type P_2 proof in the study.

Methodology

In this section, the context in which the research reported here took place, the research participants and the data collection and analysis processes will be described.

Participants

Participants of the study were 58 pre-service mathematics teachers (PSMTs) who are certified to teach mathematics in grade 5- 8. The PSMTs enrolled in a mathematics course during the semester of spring of 2016. The course was worth three university credits, and so the class met 3 hours per week for a semester. The course was designed to cover a wide range of mathematical topics in three major mathematical domains (algebra, geometry and number theory). The PSMTs were offered various opportunities to engage with mathematical proofs including constructing-evaluating proofs, representing them in different ways (using everyday language, algebra, or pictures), and examining the correspondences among different representations.

Tasks

A sample of proof tasks in which PSMTs were engaged in during the semester will be presented here in order for readers to better conceptualize PSMTs’ conjecture/proof construction and evaluation processes (see Table 1).

Data Collection Process

The participants were engaged in a course where they were required to work in groups of 6. The participants were engaged in solving tasks that were adopted from existing literature (see Table 1). All instructions were videotaped during three hours of the instruction time for 14 weeks in the semester. The video camera was located at the corner of the classroom where the board was captured. These videos served as the main data source for the study. In addition to the class videos, the PSMTs’ written responses to some of the tasks and their class assignments were also collected.

Table 1: Sample of the Tasks

Task A was adopted from Wilburne (2014). The task was as follow: A fast food restaurant sells chicken nuggets in packs of 4 and 7. What is the largest number of nuggets you cannot buy? How do you know this is the largest number you cannot buy?	**Task B** was adopted from (Weber, 2003). The task was as follows: For every odd integer n, n^2 - 1 is divisible by 8.
Task C was as follows: Justify that the area formula of a kite is $\frac{d_1 d_2}{2}$, where $d_1$and d_2 are the diagonals of the kite.	**Task D** was adopted from Boaler and Humphreys (2005). The task was as follows: 
Data Analysis

The data analysis started with reviewing the videos of the instructions first. After the first review of the videos, the parts where the PSMTs were engaged in construction-and-evaluation of mathematical conjectures-and-proofs were selected and transcribed. Later, the selected segments and the transcript of these segments were viewed again and the PSMTs' proof constructions were coded in one of the following categories: Type P_1: valid general argument that explains why an assertion was true by standing of the underlying mathematical concepts, Type P_2: valid general argument that proves that an assertion was true but did not provide any insight into why it might hold true, Type P_3: general argument that fall short of being acceptable proofs , and Type P_4: unsuccessful attempt for a valid general argument (invalid, unfinished, or irrelevant responses (or potentially relevant response but the relevance was not made evident). Categories TypeP_1 through TypeP_4 represent four different arguments constructed by the PSMTs in decreasing levels of sophistication (from a mathematical stand point), with Type P_4 representing the least sophisticated argument. The construction of conjectures was coded in one of the following categories: Type C_1: conjecture that was constructed as a response to a requested wish (usually by the instructor) in a given context, Type C_2: conjecture that was constructed spontaneously as a natural extension of a task, and TypeC_3: incorrect conjectures. As opposed to categories for proofs, categories Type C_1 through Type C_3 for coding PSMTs' conjectures were not listed in hierarchical levels of sophistication.

Results

General Findings

Table 2 summarizes the distribution of proof-conjecture constructions during the semester. As it was evident in the table, the majority of the proofs constructed during the class were Type P_1 proof, valid general argument that explains why an assertion was true or false by showing how the statement of a theorem coheres and connects with the key properties of the concepts involved in the proof. Of the remaining 29 proving occurrences, 18 of them were Type P_2 proofs, valid general arguments that established that an assertion was true thereby promoted conviction, but provided little or no explanation for why it held true.

Type P_4 proofs, unsuccessful attempt for a valid general argument (i.e. incorrect, invalid, unfinished, or irrelevant responses-or potentially relevant response but the relevance was not made evident in the argument), were proposed 8 times during the semester; however, it should be noted that the PSMTs were aware of the limitations of these arguments. Therefore, they were able to evaluate those arguments as not proofs or as not correct argument during the class discussions. Of these 8 unsuccessful attempts to prove the class tasks, 2 arguments were empirical arguments. The PSMTs who proposed these empirical arguments as well as the others in the class were able to state the fact that generalizing from specific cases was not a valid mode of argumentation.

The number of the cases where conjectures were constructed during the class happened significantly less than the number of cases where proofs were proposed (13 vs. 57). Additionally, the majority of the cases where the conjectures were constructed occurred as a response to a request made usually by the instructor (Type C_1 conjecture). Incorrect conjectures were proposed 3 times during the instructions and after these conjectures were proposed the other PSMTs in the class were able to refute these conjectures by providing a valid counterexample.

Table 2: Distribution of Proof-Conjecture Constructions During the Class

Proofs				Conjectures		
Type P_1	Type P_2	Type P_3	Type P_4	Type C_1	Type C_2	Type C_3
28 (49%)	18 (31%)	3 (5%)	8 (14%)	6 (46%)	4 (30%)	3 (23%)

Classroom Episodes That Represent Different Types of Proof-Conjecture Constructions

In this part two classroom episodes will be shared to exemplify some of the codes used to codify the PSMTs' proof –and-conjecture conjectures.

Episode 1: Chicken tender task. In this episode, the PSMTs were engaged in working on chicken tender task in their groups.

Orhan: Our group has decided that the numbers that can be represented as 28k+27, where k is an integer, cannot be bought in the packets of 7 and/or 4.
Instructor: Ok. Where did 28 and 27 come from?
Orhan: 7 times 4 is 28, so 28 can be bought in packets of either 7 or 4 or its multiples.
Instructor: OK, if k=1 then how many nuggets do you think you cannot buy, umm, 55?
Orhan: Yes
Instructor: Can we have 55 nuggets in the packets of 7 and/or 4?

Merve: Yes. We can have 5 packets of 7s and 5 packets of 4s. So, we can get 55 nuggetsin total.
Instructor: Ok, so the numbers that are represented as 28k+27 can be bought in packets of 7 and 4. Anybody else have an argument? Selman?
Selman: (Writing numbers on the board). You can represent all numbers by adding 4. For instance, if you add 4 to 11, you will get 15; if you add 4 to 12 you will get 16; if you add 4 to 14 you will get 18 and it will continue like this. These numbers cannot be bought in packets of 7 or 4 (highlighting the numbers underlined below). Umm, I needed to check 21 because it is to add 4 to 17 and I know 17 cannot be represented as addends of 4 (or multiples of 4) and 7 (or multiples of 7). However, I have found that 21 is 3 times 7, so it is okay too. Now you will continue this pattern for all numbers 21+4=25, 22+4=26,23+4=27,24+4=28...etc.

1	2	3	4	5	6	7	8	9	10
11	12	<u>13</u>	14	15	16	<u>17</u>	18	19	20
21	22	23	24	25	26	27	28	29	30

Ayse: When you get modulo 7, the residue classes will be 1,2,3,5,or 6 (4 cannot be counted here because we can get the packets of four). When you get modulo 4, the residue classes will be 1,2,and 3. When you add all residue classes up you will get the answer-17.

In this episode, the conjecture proposed by Orhan was coded as Type C_3: incorrect conjecture. The instructor posed a counterexample as a necessary condition for the realization of falsity of the conjecture. The PSMTs were able to explain how the example 55 contradicted the conjecture and refuted Orhan's conjecture. Selman's argument was coded as Type P_1 since it was built on the properties of numbers. It was a correct argument to justify that 17 was the highest number of chicken tenders that could not be bought in packets of 4 and/or 7. Ayse identified all residue classes of modulo 7 except 4 (since it could be a possible answer) and added them up to reach the answer of 17. However, her argument did not include a justification for the assertion that the residues would always be the highest number that could not be bought in the packets of 4 or 7. Indeed, when her argument was applied to different numbers such as packets of 6 and 4, it would not give the correct response. Therefore, her argument was coded as Type P_4.

Episode 2: Area perimeter task. In this episode, the PSMTs were engaged in working on geometry task-investigating the relationship between area and perimeter of rectangles. The instructor asked the PSMTs to construct conjectures about area and perimeter of rectangles. Cihat proposed the following conjecture: "With *the same perimeter, the smaller the difference between the side lengths of a rectangle, the biggest the area*". The instructor asked the PSMTs to evaluate the conjecture and prove whether it was correct.

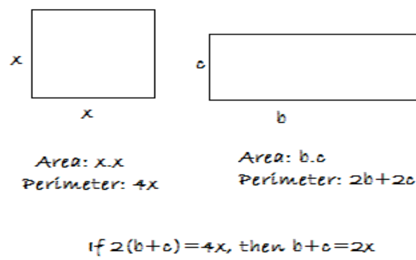
Merve:(Drew three rectangles with the side lengths of 12 by 6, 15 by 3, and 9 by 9). It is true. These rectangles have the same perimeter, 36. But, the area of the square is bigger than the other two rectangles.
Instructor: Do you think that Merve proved Cihat's conjecture?
PST: No, she just demonstrated for those rectangles.
Instructor: What is missing in her argument?
PSTs: It is not general
Instructor: We mentioned that providing examples do not suffice as mathematical proofs. How many examples can I draw with a perimeter of 36?
PSTs: 5? (Said as if they were asking if it was true). Infinitely many?

Cihat: Infinitely many, because in between whole numbers, there are infinitely many rational numbers

Instructor: So we can draw infinitely many rectangles with the perimeter of 36, will you be able to try all of these rectangles out like Merve attempted to do here?

PSTs: No!

Yılmaz: (Volunteered to share his argument). Now we have the lengths of b,c (referring to the long and short sides of a rectangle in this order) and x (referring to a side length of a square). They should have the following relationships: b>x>c. Thus, x^2>b.c. Let's assume that x=n and c=n-1 and b=n+1. Therefore, $x^2=n^2>b.c=n^2-1$



Instructor: Why does b have to be bigger than x and x has to be bigger than c?

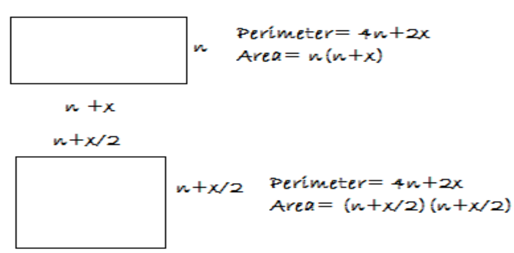
PSTs: If these two rectangles have the same perimeter, than this relationship should hold.

Instructor: Ok, but why should x between b and c?

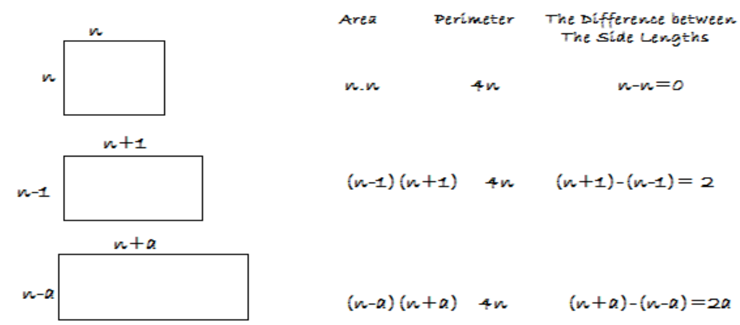
Cihat: b and c should be different in lengths, because we consider the rectangles that are not squares, so b≠c. Then, we know that $x=\frac{b+c}{2}$ since the perimeter of the two shapes should be equal. Thus x should be between b and c. We know that $x=\frac{b+c}{2}$ so, $x^2=\frac{b^2+c^2+2bc}{4}$. We know that b-c>0, so $(b-c)^2>0.b^2-2bc+c^2>0 \Rightarrow b^2+c^2>2bc$. If $b^2+c^2>2bc$, Then $\frac{b^2+c^2+2bc}{4}$ should be bigger than b.c (the area of the rectangle).

Instructor: Ok, great.Zeynep, would you like to share your method with us?

Zeynep: (Writing her argument on the board).The perimeters of these rectangles should be the same.$A_1= n^2+nx$ and $A_2= n^2+nx+x^2/4$. Thus, it is obvious that A_2 should be bigger than A_1 since x≠0.



Aysegul: (Writing her argument on the board).



Cihat's conjecture was constructed as a response to the Instructor's request. Therefore, it was coded as Type C_1. Merve provided three examples that demonstrated that Cihat's conjecture was true. Since Merve used an invalid mode of argumentation-inductive argument-, her argument was coded as Type P_4. Stylianides (2007) argues that the main difference between empirical arguments and proofs lies in the modes of argumentation: invalid versus valid modes of argumentation. Empirical arguments provide inconclusive evidence by verifying the statement's truth only for a proper subset of all covered by the generalization, whereas proofs provide conclusive evidence truth by treating appropriately all cases covered by the generalization. When asked to evaluate the argument, both Merve and the other PSMTs in the class were able to state this limitation of the argument. Stylianides & Stylianides (2009) argued that construction-evaluation tasks can better identify prospective teachers' who seem to posses the empirical justification scheme. Unlike Merve, Yilmaz attempted to construct a deductive argument. However, his argument did not provide justification for some of the assertions he used in his argument (i.e. $b>x>c$). Additionally, Yilmaz's argument was constructed based on a condition- the side lengths of the rectangle and the square should be consecutive. Yilmaz's argument was coded as Type P_3. Cihatwas able to provide the justifications for each step of his argument. Thus, his argument as well as Zeynep's and Aysegul's arguments was coded as Type P_1.

Conclusion and Discussion

Given that teachers' ability to teach mathematics depends on the quality of their subjectmatter knowledge, a necessary condition for the realization of the importance of mathematical proofs as stated in the current curriculum reforms (NGA/CCSSO, 2010; NCTM,2000) is that teachers of all levels have good understanding of proofs (Stylianides & Ball, 2008). This study reported pre-service mathematics teachers' engagement with proof-and-conjecture tasks.The results of the study demonstrated that the number of instances where the PSMTs constructed conjectures, which isreferred as one of the essential parts of the process of making sense of and establishing mathematical knowledge (Stylianides, 2008), were limited and usually occurred when asked explicitly. Constructing arguments to prove and/or disprove assertions, on the other hand, occurred more often. Furthermore, the majority of the arguments constructed highlighted the explanatory aspect, which is consistent with the results of many studies that claimed that in mathematics classrooms, it would be more useful to use proof as a tool to explain than to convince (Hanna, 1990; Knuth, 2002).

EXPLORING ELEMENTARY MATHEMATICS TEACHERS' OPPORTUNITIES TO LEARN TO TEACH

Mathematics teacher education is faced with the challenge of preparing new teachers for ambitious instruction, but we have limited understandings of what happens within the courses where this preparation occurs. This paper draws on interview data from of a larger investigation of novices' enactment of ambitious instruction in elementary mathematics and language arts across six teacher preparation programs. Findings describe the application of the framework developed by Grossman et al. (2009) to opportunities to learn to teach in elementary mathematics methods courses and associated field experiences, focusing on the range of activities described and their relation to the framework.

Keywords: Teacher Education-Preservice

A current challenge facing teacher educators is preparing new teachers to engage in ambitious mathematics instruction (Lampert et al., 2013). Yet, despite recent research related to specific pedagogies for mathematics teacher education (e.g., Lampert et al., 2013), we still know very little about the range of instruction and opportunities available to teacher candidates in methods courses (e.g., Clift & Brady, 2005). In response to these challenges, as part of a larger study seeking to understand the relationships among teacher characteristics, features of teacher preparation programs, and novice teachers' enactment of ambitious instruction, we interviewed elementary mathematics methods instructors and program coordinators across multiple teacher preparation programs. Our goal is to characterize the opportunities to learn provided through methods courses. Specifically, we focus our investigation on the opportunities teacher candidates have to learn to teach, as compared to opportunities to learn mathematics content (Schmidt, Bloemeke, & Tatto, 2011).

Grossman and colleagues (Grossman et al., 2009) developed a framework based on *pedagogies of practice* "to describe and analyze the teaching of practice in professional education programs…" (p. 2055). Here, we use their framework to continue that same work. Specifically, in this paper we share findings from our efforts to use the Grossman et al. framework (2009) to categorize the activities described by instructors and coordinators. In so doing, we explore the range of activities shared, note the ways in which these activities do and do not fit the Grossman et al. (2009) framework, and consider the importance of variations in the enactment and sequencing of activities in terms of the opportunities to learn they might offer.

Theoretical Framework

We frame our study of opportunities to learn in elementary mathematics methods courses using Grossman and colleagues' (2009) framework that established three primary pedagogies for teaching relational practices, including teaching, to novices – representation, decomposition, and approximation. In this paper, we are focusing specifically on representation and approximation, both of which we see as also involving aspects of decomposition. Grossman and colleagues define *representations* as, "the different ways that practice is represented in professional education and what these various representations make visible to novices," (Grossman et al., 2009, p. 2058). They noted that representations can vary not only in what they do and do not make visible for teacher candidates, but also in their "comprehensiveness and authenticity" (p. 2065). *Approximations* are defined by Grossman and colleagues as, "opportunities for novices to engage in practices that are more or less proximal to the practices of a profession," (p. 2058). They suggest that, similar to representations, approximations can vary along a number of dimensions, including the nature of the aspect of teaching practice being approximated, "how closely the activity approximates actual practice", and "the role of the [teacher] educator" (p. 2079). This framework focuses attention not only on how novices learn to enact teaching practices, but also on how novices learn the knowledge and skills that underlie those practices.

More recent studies have taken up this framework to design and characterize pedagogical interventions in methods courses and to understand the relationship between these pedagogies and novices' learning outcomes. For example, Amador and colleagues (2016) explored the differences in teacher candidate noticing of teacher practices in the context of a representation and an approximation of practice. Ghousseini and Herbst (2016) focused on the importance of sequences of representations and multiple approximations for teacher candidates' opportunities to learn to lead classroom discussions. Here, rather than focusing on a specific activity or series of activities, we are investigating the range and sequences of activities across multiple teacher preparation programs, with a specific focus in this paper on those activities involving teacher educators' enactment of representation and approximation pedagogies.

Methods

The findings reported here are part of a larger study of novices' enactment of ambitious instructional practices in elementary mathematics and language arts. The larger study investigates (a) how a purposively sampled set of six teacher preparation programs in three states supports elementary teacher candidates to develop ambitious math and language arts instruction and (b) factors that are associated with how graduates of these programs enact math and language arts instruction as first- and second-year teachers. This investigation includes surveys of approximately 150 teacher candidates from the set of six teacher preparation programs during their final year of the program and their first two years of teaching. Additionally, we observe these graduates multiple times as they teach mathematics and language arts as first-and second-year teachers.

For this specific study, we focused on interviews with 12 elementary methods instructors and 9 program coordinators to better understand their perspectives on the opportunities to learn to teach provided in elementary mathematics methods courses and associated field experiences across the a subset of three of the six teacher preparation programs in the study. Each participant was interviewed once during 2015-2016 for approximately 45-60 minutes. Data was audio recorded and later transcribed. Interviews were semi-structured based on a protocol designed to solicit information about the backgrounds, instructional activities, and philosophies of method instructors and their respective programs. Questions asked included the following:

1. How would you characterize the overall approach to teaching that you seek to develop among the teacher candidates through the course?
2. What major instructional strategies do you want teacher candidates to learn and know how to enact? Why do you focus on these strategies?
3. How do you engage teacher candidates in learning these strategies? What kinds of activities do you use to help them learn about these strategies?

Analysis

Our analyses focused on making sense of the interview data from methods instructors and program coordinators. Our process involved iterative cycles of coding during which we both developed emergent codes from the data and built from theory. Specifically, we began by applying grounded theory techniques of initial coding (Saldaña, 2015) to examine a broad sample of our interview data looking for common issues discussed across the group of methods instructors and program coordinators. Next, we refined our initial codes by looking for similarities and differences across the codes and comparing our emergent ideas to those categories present in existing theoretical frameworks (e.g., Darling-Hammond & Bransford, 2005; Grossman et al., 2009). Subsequently, we continued multiple rounds of this iterative process to clarify our codes. In particular, we sought out examples of interview excerpts that were not well captured by previous versions of codes in order to identify those features of opportunities to learn to teach that our codes did not yet capture. Finally, we generated code definitions and selected representative examples.

Ultimately, our analyses resulted in a multi-leveled codebook that distinguishes: (a) what knowledge, practices, or content teacher candidates have opportunities to learn, (b) how those opportunities to learn are made available to teacher candidates, (c) who provides the opportunities to learn, (d) teacher preparation program capacity for opportunities to learn, (e) teacher preparation program structure, (e) program and teacher candidate evaluation, and (f) reasoning behind particular opportunities. Here we focus on a subset of the codes related to *how* opportunities to learn are made available to teacher candidates.

Findings

In the following sections we share initial findings from our early coding work focused on interviews with methods instructors and program coordinators. Broadly, we found the theoretical constructs of approximations and representations to be a useful starting point to interpret the opportunities teacher candidates have to learn to teach during methods courses. Additionally, we identify a number of interesting dilemmas with regards to parsing the work of methods instructors into these discrete categories. Here we share our codes, summarized in Table 1, along with representative excerpts of interview data to illustrate these dilemmas and describe what we have learned.

Table 1: Codes for How Opportunities to Learn are Provided to Teacher Candidates

Code Name	Description
Representations	Opportunities for teacher candidates to watch examples of the work of teaching
Approximations	Opportunities for teacher candidates to experience deliberate practice immersed in activities of actual teaching.
Do a math or literacy task	Opportunities for teacher candidates to engage with specific content knowledge through tasks
Learning to learn from teaching	Opportunities for teacher candidates to learn how to be reflective of their work as teachers and to use their teaching experiences as a means to grow as professionals
Reflection	Opportunities for teacher candidates to reflect about their teaching in writing or aloud
Formative feedback	Opportunities for teacher candidates to receive formal or informal feedback about their work
Problems of practice	Opportunities for teacher candidates to learn from challenges that arise during instruction.
Examining classroom artifacts	Opportunities to examine samples of student work or other classroom artifacts (generated or authentic) as a specific focal point for reflection.
Connect to other coursework/ knowledge	Opportunities for teacher candidates to build on work from previous classes or to connect to ideas that will be the focus of courses later in the teacher preparation program
Field Experiences	Opportunities for teacher candidates to learn to teach through field experiences (e.g., practicum placements, student teaching)

This paper explores only our findings related to the codes *representations* and *approximations*. In our efforts to understand how to organize and apply these two constructs, however, we identified a number of additional ways in which methods courses provide opportunities for teacher candidates to learn to teach. Thus, an important initial finding is that representations, approximations (and decomposition) as proposed by Grossman and colleagues (Grossman et al., 2009) are not sufficient to address of all of the opportunities provided in methods courses. Although this paper focuses on applying and clarifying definitions of the constructs of representations and approximations, we note that there exists an important course of future research to explore the nuances of opportunities to learn to teach presented through our other codes in Table 1, especially learning to learn from teaching and field experiences.

Representations

Following Grossman et al. (2009), we define representations as opportunities for teacher candidates to observe examples of the work of teaching. A classic representation of teaching practice might be a video recording of a teacher teaching a lesson to a class of students. In our initial analyses we did find some discussion of instructors using videos of practicing teachers as representations of quality practice. Early coding revealed, however, that instructors more often discussed representations of practice other than those involving video, including teacher candidates observing their cooperating teachers in action and observing their methods instructors modeling particular instructional practices.

For example, the following excerpt, from an interview with a mathematics methods instructor, is representative of some of the issues we encountered related to identifying representations of teaching practice.

> Instructor: Part of the modeling is that I model. If we're going to do something, like for example, we have a giant number line that I made and they had to put decimals and fractions on it. And one of them facilitated it. But, I made the materials and then we said, how does this help to model?
> Interviewer: Oh, to model a concept or something?
> Instructor: Yes, model a concept… but modeling how you model a concept. [laughs]
> Interviewer: Right
> Instructor: And so that's another thing that, in terms of conversation, a lot – I always have them sit in groups. And if there's something that I think is important, I will either model it or I'll set it up so someone else [a teacher candidate] can help to model it. […] So I try to set up experiences for them to experience things like modeling and then *they* talk about it. And I will facilitate their discussion or I will say to somebody else [a teacher candidate], could you please facilitate the discussion on… So, that they are doing as much as possible.

In this excerpt the methods instructor described her strategy of using her own instruction during the methods course to model the kinds of teaching activities and strategies she was presenting to the teacher candidates. That is, she used her own instruction as a representation of the kind of ambitious instruction that she would like her teaching candidates to learn.

This excerpt also highlights some of the complexity we found in determining the boundaries of representations in methods courses. It was not always clear when teacher candidates were engaging in opportunities to observe representation of practice as compared to other opportunities to learn, such as approximation of practice, or developing content knowledge. For example, in the excerpt above, the instructor described how she represented quality teaching practice while simultaneously engaging students with mathematical content (e.g., locating decimals and fractions on the number line) and providing opportunities for teaching candidates to try out pedagogical strategies (e.g., facilitating discussion). This was typical across our data set, and thus a dilemma arose for us as to how to bound the idea of a representation of teaching practice. Could we consider any teaching the method instructor does (e.g., share PowerPoint lectures, ask thoughtful questions) a representation of teaching practice? Since not all interactions with teaching are necessarily supportive of learning to teach (e.g., Lortie 1975) nor intended to serve as representations of teaching, we limited considerations of representations to only those instances in which the interviewee explicitly discussed the pedagogical reasoning related to the representation. For example, to be considered a representation, a methods instructor would need to explicitly describe how their actions provided an opportunity for teacher candidates to learn about teaching practice. Additionally, in instances where teacher candidates had opportunities to observe the work of teaching in the field (e.g., practicum, student teaching) without explicit discussion of the pedagogical purpose, we coded those instances as opportunities to learn through *field experience*, not representations.

Approximations

Building from the work of Grossman and colleagues (2009), we define approximations as opportunities for candidates to experience *deliberate practice* (Ericsson, 2002) as they engage in activities of actual teaching practice. Through approximations, teacher candidates can experiment with their new teaching skills, knowledge, and ways of thinking. Unlike representations, which focus on observing practice, approximations necessarily involve teaching candidates in doing aspects of the work of teaching. As described by Grossman and colleagues (2009), approximations may be simplified or scaffolded versions of practice (e.g., only facilitating a small group discussion instead of the whole class, analyzing assessment results with extensive instructor support), or they might engage teacher candidates in more explicitly elaborated versions of practice (e.g., detailed unit plans). Since approximations are filtered version of reality, they typically involve intervention from instructors and/or cooperating teachers.

A typical example of an approximation we observed in the data was related to engaging teacher candidates in planning for a lesson. The following excerpt was from a mathematics methods instructor describing how she engaged her teacher candidates in learning teaching strategies. She explained,

> So, they will do lesson planning, and they will present a lesson, and they will create an assessment that they use with students in their field site and then reflect on that. So, you know, reflection is a big part of it. They do journal writings and the journal writings are specific to the students in their field sites, whether it be just observing what the teacher does and reflecting on that, or when you work with the students, what happens there.

The instructor described a characteristic methods course activity in which teacher candidates plan a lesson, teach that lesson to a small group of students, assess students' learning, and then reflect on what they learned from the experience. This type of activity was pervasive throughout our interviews with methods instructors. Lesson planning could be considered a canonical approximation of teaching practice. It was simplified in that teacher candidates had to only prepare a single lesson plan, usually with extensive feedback from instructors, and often the lesson was taught to only a single class or a small group of students.

Methods instructors also described such lesson planning activities as involving more details and complexity than might otherwise occur in a regular classroom. For example, another mathematics methods instructor described the major assignment in her course in the following way,

> And even though in some ways it feels silly to have one lesson plan count so much, we really, I feel like we use that as a vehicle for learning all kinds of other things. Because we use it as a vehicle – it's essentially an annotated lesson plan, with a lot more required than would be typical,

> and I continue to tell them that. You will never write this much in a lesson plan as long as you live.

This quote highlights one of our findings that opportunities to learn through approximations, even typical lesson planning activities, do not always follow a clear trajectory of moving from simplified to more complex activities. Our interviews with methods instructors revealed that the purposes instructors have for engaging teacher candidates in an approximation affect how complex or simplified that approximation of practice might be. For example, the instructor in the preceding excerpt explained that she used the lesson planning approximation to support nearly all of the learning to teach activities that occurred throughout her course over an entire semester. Teacher candidates were expected to examine content and practice standards, consider student development, plan for thoughtful pedagogy and intentionally use instructional strategies. Subsequently, teacher candidates also taught the lesson to a group of students, video recorded their teaching, and then later reflected on the video recording of their instruction. This level of detail and time commitment to a single lesson would likely be impossible in the real world of a classroom teacher. The approximation of practice, however, allowed the methods instructor the space to support teacher candidates to deeply explore a range of components that go into a single lesson.

Grossman and colleagues (2009) noted "approximations may require more elaborated versions of practice than what novices will enact in their careers" (p. 2077) citing detailed unit plans as an example. In addition to more elaborated versions of planning activities, our initial analyses also revealed additional examples of approximations with added complexity, including elaborated investigations of students' communities. For example, a mathematics methods instructor described an assignment that required teacher candidates to immerse themselves in the community of their teaching placement to better understand the specific challenges and resources of their placement location. The methods instructor explained,

> [teacher candidates are] not just talking to their mentor teacher. They're talking to parents. They're talking to shop owners. They're exploring the space around school and spending time in coffee shops and groceries stores and the community where their school's situated, despite the fact that they might live in [another town].

Practicing teachers may not always immerse themselves in the community where their students live; however, an important part of ambitious instruction involves building on students' knowledge and experiences. This example of an elaborated approximation of practice illustrates another way methods instructors provided opportunities for teacher candidates to learn about teaching in ways that might have been more complex than their counter-parts outside a methods course.

Another interesting complexity we found related to approximations was the ways they juxtaposed with representations of practice. The illustrative excerpt below was taken from an interview with a program coordinator, during which the coordinator described the opportunities to learn to teach provided to teacher candidates during their student teaching placements.

> Mentors are trying to help them learn to teach, but I think that they are helping them learn to teach in the way that they teach their district teachers. So we do encourage them to do co-planning, co-teaching, but in terms of the philosophy of teaching, this year we talked about our own visions of teaching, how those match with their mentors. But I worry sometimes our interns go out and just try to imitate with what they are seeing the mentor doing and consider that good teaching or not good teaching.

The coordinator described opportunities for teacher candidates to learn from their mentor teachers, including opportunities to co-plan and co-teach.

By engaging in co-planning and co-teaching, teacher candidates have the opportunity to actively participate in the work of teaching, engaging collaboratively alongside their mentor teachers. Thus, we would consider opportunities to co-plan and co-teach as approximations. This quote highlights, however, that participating in co-planning and co-teaching also provides opportunities for teacher candidates to observe a representation of practice, the practice of their mentor teacher. In this case, the coordinator emphasized the authenticity of this representation, in that mentor teachers teach in the ways supported by their district, not necessarily in the model suggested by the university teacher preparation program.

Although co-planning and co-teaching fit within the category of a scaffolded approximation of teaching practice, we found that the opportunities to learn provided to teacher candidates are not easily delineated to separate an approximation from a representation. When in the field, any interactions teacher candidates have with practicing teachers offer potential representations of practice. The ways in which teacher candidates interact and engage with those examples of practice offer potential approximations of practice. Methods instructors and mentor teachers make use of these opportunities to learn in specific and sometimes overlapping ways.

Discussion and Implications

We found that methods courses provide a range of opportunities for teacher candidates to learn to teach, and Grossman and colleagues' (2009) framework provided a useful starting place to interpret and organize these opportunities. These findings reveal that applying the constructs of representations and approximations methods course data is not straightforward and that we needed to refine and supplement the definitions. Likewise, these findings build on literature that encourages interrelationships between pedagogies (e.g., Darling-Hammond & Bransford, 2005) by illustrating how methods instructors and mentor teachers use representations and approximations intertwined with one another.

Additionally, this paper highlights the need for a more detailed taxonomy of methods course activities as they fit within the broad pedagogies of practices. Thus, we seek to identify possible sequences of learning activities within methods courses. One model of using approximations to learn to teach might be that methods instructors move teacher candidates from more distal examples of practice, with more scaffolds, to more proximal examples of practice, dropping the scaffolds as they progress. For example, teacher candidates might move from facilitating a single small group discussion to facilitating a full class discussion. Alternatively, we found that approximations of practice do not necessarily progress along a trajectory of complexity, but rather the degree of complexity of an approximation may be tied to an instructor's learning goals for a specific activity. For example, some methods instructors discussed how they used a variety of approximations within the course to support teachers' candidates learning of specific instructional practices (e.g., asking higher-order thinking questions; learning about students' communities), but did not discuss the progression of these approximations from one activity to the next, suggesting that they may be thinking more closely about the alignment of individual approximations to instructional goals than the progression of approximations over time. Given the similarities we observed across the methods courses, we wonder then if there are also underlying trajectories of particular pedagogical activities that support learning to teach, as found by Ghousseini and Herbst (2016) with respect to learning to teach through discussion. Relatedly, we seek to explore instructors' rationales for using particular pedagogies with teacher candidates. Additional research is warranted into opportunities to learn to teach including further exploration of approximations and representations, as well as additional opportunities we identified beyond the scope of the Grossman et al. framework (2009).

INTERPRETING AND REPRESENTING STUDENTS' THINKING IN THE MOMENT: PRESERVICE TEACHERS' INITIAL NUMBER STRING LESSONS

Lizhen Chen
Purdue University
chen1905@purdue.edu

Laura Bofferding
Purdue University
lbofferd@purdue.edu

Being able to effectively interpret students' thinking and respond effectively in the moment are important skills that preservice teachers (PSTs) need to learn. This study zooms in on 14 PSTs' planning, teaching, and reflections involved in number string lessons, and investigates to what extent PSTs anticipate their students' strategies and incorrect answers. Further, through a lens focused on PSTs' talk moves, we explore how PSTs supported students' understanding of the strategies and concepts, and handled incorrect answers and unanticipated responses (strategies). Results show that PSTs were capable of anticipating many answers and strategies but need more improvement in making full use of various talk moves in their questioning. Implications are provided for mathematics methods instructors to plan activities to better support PSTs.

Keywords: Teacher Education - Preservice, Classroom Discourse, Instructional Activities and Practices

The ability to know students' thinking is a key factor in mathematics teachers' ability to conduct group discussions and improve their classroom teaching (Stein, Engle, Smith, & Hughes, 2008). Especially when teaching practices emphasize students' freedom of exploration and use of mathematical processes, the importance of facilitating discussion around students' solutions to problems are paramount (NCTM, 2006). Teachers' roles in facilitating discussion rely on being able to anticipate what students will say and have strategies for dealing with unanticipated responses. Our study helps characterize this process with preservice elementary teachers during number string lessons, which involve presenting a series of related arithmetic problems that highlight an overarching strategy or pattern (Stein et al., 2008).

Theoretical Framework

Responding to Students' Thinking in the Moment

Even though much literature focusing on PSTs offers teacher educators resources to educate PSTs before they actually teach, responding to students' spontaneous thinking during number string lessons is a challenge for PSTs and a demanding task for teacher educators (Bofferding & Kemmerle, 2015). Responding to students' spontaneous thinking is complex, involving PSTs' mathematics knowledge, students' mathematics knowledge, the classroom learning culture, teacher-student interactions, and instructional representations (Ghousseini, 2015). Further, PSTs must make quick actions to respond to students' ideas, especially when unanticipated (Stein et al., 2008), under the condition where they lack a rich knowledge-and-experience base to handle everything in the classroom (Jacobs, Lamb, & Phillip, 2010). Because of this complexity, there are no textbooks to tell PSTs how to anticipate or determine the best way to respond to the variety of situations they might encounter (Zeichner, 2012).

Before responding to students' thinking in the moment, PSTs must unpack and interpret students' reasoning, a process that is aided by the use of restatement and other talk moves to ensure mutual understanding among the class (Chapin, O'Connor, & Anderson, 2009). They make use of symbols, pictures, gestures and mathematical discourses to represent chosen students' thinking and assess students' strategies (Leinhardt & Steele, 2005). During this process, PSTs must judge the relative importance of different ideas. The judgment is particularly pertinent to what Ghousseini (2015) defined as "mathematical sensibilities" (p. 343), i.e., PSTs' mathematical knowledge and abilities to attend to what proper interpretations to make and how representations are selected and used.

Anticipating Students' Problem-solving Strategies

There are a few steps PSTs should take before engaging students in solving a mathematics problem. They should know the correct answer (or answers) and should at least solve the problem themselves. However, knowing only one solution to a problem is insufficient to teach students with a wide array of answers and strategies for the same problems (Stein et al., 2008). Full preparation for possible emergent student thinking is beneficial (Jacobs, Lamb, & Philipp, 2010); without such preparation, PSTs might be inclined to feel unprepared and have limited ideas about ways how to handle unanticipated answers (Smith, 1996). Therefore, it is important for PSTs to anticipate multiple student strategies (both correct and incorrect), different reasoning supporting those strategies, and representations utilized by students at different levels of mathematical understanding (Stein et al., 2008).

Talk Moves

Aside from anticipating possible student strategies and reasoning, PSTs also need to utilize this knowledge together with appropriate questioning prompts in order to structure the sharing of students' mathematical thinking to the class (Stein et al., 2008). To solicit students' thinking in the moment, PSTs have access to some discursive tools that are helpful in encouraging students to say more about their ideas, support positive teacher-student interactions, and align with instructional goals. Much literature has documented such discursive tools. Chapin, O'Connor, and Anderson (2009) presented five talk moves that support students' thinking and help maintain a collective learning environment, i.e. teacher revoicing, student restating, applying one's own reasoning to someone else's, further prompting opportunities and using of wait time. In a similar vein, Ghousseini (2015) elaborated the discursive tools from a perspective of discourse routines and divided them into five categories, which serve as our lens for analysis. These categories are revoicing (the teacher repeats, rephrases and translates students' saying), orienting (the teacher puts someone's idea on the spot and asks other students to comment on and contribute to that idea), pressing (the teacher pushes students to talk more about their reasoning), negotiating (the teacher connects different students' strategies and tries to involve students in the discussion about the similarities and differences), and making certain aspects of the discourse explicit.

In the face of errors or mistakes, many teachers cannot help correcting students (Stein et al., 2008) and tend to use show-and-tell discourse (Ball, 2001). Especially when these errors are unanticipated, PSTs might feel out of control and at a loss for how to appropriately respond to students' ideas (Son, 2016). This study is aimed to contribute to the literature by looking at the intersection of PSTs anticipating and use of talk moves in number string lessons. Investigating PSTs' actual and spontaneous responses to students' strategies and identifying what discursive tools PSTs usually fall back on when encountering unanticipated student errors will advance our understanding of this intersection. The following research questions guide us in this exploration.

1. To what extent do PSTs anticipate their students' mathematical strategies and incorrect answers during number string lessons?
2. What talk moves do PSTs use, and what potential do they have for supporting students' understanding of the mathematical strategies and concepts?
3. How do PSTs handle incorrect answers and unanticipated responses (strategies), if they occur?

Methods

Participants and Setting

Participants in the study included 17 female PSTs taking an elementary mathematics methods course at a Midwestern university. Of these, we selected 14 for further analysis by excluding PSTs who worked with only one student, a life skills class, or did a topic besides addition, subtraction, or multiplication. Between two sections of the methods course, twelve PSTs came from one section and two came from the other. As part of their course, the PSTs each spent nine afternoons teaching, doing interviews with students, helping out, and teaching three mathematics lessons and two to three science lessons at an elementary school. Our focus—a number string lesson—was one of the three mathematics lessons. All but two of these PSTs shared a classroom with a second PST, and their placements varied from Kindergarten to Grade 5.

Design and Materials

The methods course aimed to raise PSTs' awareness of students' strategies and attune them to ways of building on students' mathematical strategies through talk moves and the use of representations. In the class, PSTs were asked to read chapters from two books to help them think about students' arithmetic strategies: Fosnot and Dolk's (2001) Young Mathematicians at Work: Constructing Multiplication and Division and Wright, Stanger, Stafford and Martland's (2006) Teaching Numbers in the Classroom with 4-8 Year Olds. With the purpose of interpreting and representing students' thinking in number strings, PSTs read about students' strategies for solving addition, subtraction, and multiplication problems. Drawing on these reading materials, PSTs designed their number string teaching plans (as negotiated with their placement teachers in the elementary schools).

Their plans, which were co-written if they shared a classroom with another PST, required them to identify the targeted strategies they hoped students would use in the lesson or pattern they hoped students would notice, list the problems they would pose, anticipate strategies and answers (both correct and incorrect) for each problem, draw possible representations PSTs would use to illustrate students' thinking, and list connections they anticipated making among students' strategies. Given PSTs' instructor's written feedback to the teaching plans, some PSTs also revised their plans. PSTs' teaching plans and revised versions serve as one data source.

Then PSTs implemented their teaching plans in elementary schools, and lessons lasted around 15-20 minutes. They audio-recorded their lessons and took pictures of any representations they made on the board during their lessons. The course instructor (the second author) was on site with PSTs and noted down their representations and students' uses of strategies. Together, the transcripts of PSTs' teaching and the course instructor's notes served as a second data source. Finally, PSTs each wrote a teaching reflection focused on the actual strategies students used, how the PSTs handled errors, how they used representations, and any changes they would make to the lesson. Therefore, the data includes 8 lesson plans, some with revisions, audio and pictures of the representations used from the lessons, and 14 lesson reflections.

Expected Take-Away from Course Readings

Fosnot and Dolk (2001) and Wright et al. (2006) discussed in depth strategies of solving addition, subtraction and multiplication used by K-5 students (see Table 1 for addition examples). We expected PSTs to think about these strategies when they anticipated what their students would do as part of their teaching plans and draw on them during their number string lessons as well as their reflections. Aside from the strategies discussed in the readings, PSTs also had their own strategies, such as the use of standard algorithms, to use.

Table 1: Strategies of Solving Addition Mentioned in Course Readings

Strategies	Explanations
Counting by ones	14 + 5: Count all or count on starting at either number.
Doubling	7 + 7: Double same numbers
Jump Strategies	14 + 7: Start at one number and make strategic jumps to add on, e.g., 14 + 6 = 20, 20 + 1 = 21.
Split Strategies	24 + 13: Split apart the numbers into tens and ones and add similar place values, then add the results together, e.g., 20+10=30, 4+3=7, 30+7=37.
Split-jump	24 + 13: Split apart the numbers into tens and ones, add the tens, and then make jumps to add on the ones, i.e. 20+10 = 30, 30+4=34, 34+3=37.
Compensation	26 + 17: Change one number to make the addition easier, and then adjust for it later, e.g., change 17 to 20, then do 26 + 20 = 46, 46 – 3 = 43.
Manipulatives/tools	Use ten frame, double ten frame, fingers, cubes, pictures, number line, etc. to help counting

Analysis

With PSTs' teaching plans and actual teaching transcripts available, we began our analyses by identifying the anticipated vs. unanticipated strategies and answers. We looked at PSTs' planning documents for answers and strategies they anticipated students would have for each problem, and compared these to the answers and strategies students used in the lessons. We organized these by anticipated answers (anticipated strategies or unanticipated strategies) and unanticipated answers (anticipated strategies or unanticipated strategies) with the purpose of revealing the consistency between PSTs' anticipation and actual student action. We looked at totals for each category as well as how many of the anticipated and unanticipated answers generated were incorrect. Correct answers were assumed as anticipated if not explicitly discussed in PSTs' lesson plans.

To better understand PSTs' talk moves around anticipated and unanticipated answers and strategies, we focused on two addition number strings and coded each talk turn within each lesson episode using Ghousseini's (2015) framework. An episode is defined as a round of teacher-student exchanges (talk turns) in which a student's reasoning for his/her answer is sought out in detail. Episodes occurred after initial answers were elicited, and certain problems had more episodes if there was more variety in how students solved the problems (i.e., the teacher asked several students how they solved the problem). If a PST asked a student a question, the student responded, and the PST followed up before moving onto a different strategy, that was three talk turns and one episode. Some talk turns had no codes if no talk moves were used, and some had multiple codes if more than one talk was used. One researcher completed the coding, and a second researcher checked a portion of the codes; disagreements were discussed until there was agreement. Finally, we compared and contrasted the frequency of different talk moves in order to get a general profile of PSTs' discourse when they responded to students' ideas.

Results

Discrepancies Between PSTs' Anticipated and Unanticipated Answers and Strategies

First of all, we focus on the results of PSTs' anticipation of students' answers and strategies across the addition, subtraction and multiplication lessons. As Table 2 shows, 53.5% of students' strategies (54 out of 101) were anticipated by PSTs while 33.7% (34 out of 101) were not anticipated by the PSTs' regardless of their successful anticipation of students' answers. PSTs were able to anticipate answers most of the time but missed out on the variety of strategies students used to get the same answer. In other words, the PSTs focused mainly on one way to get an answer, even though thinking about multiple ways was modeled heavily in their methods course. For instance, for 8+8+4+4, PSTs in the 3rd grade addition class succeeded in anticipating that students might use doubles to get 16 and 8 and then add 16 to 8 to get the final answer; however, the PSTs did not anticipate a popular strategy, 8x3, arising from the third graders' recent focus on multiplication. Even though PSTs could anticipate a general strategy, they did not typically anticipate all variants of the strategy. In the case of 19+21, PSTs expected students to use a compensation strategy, i.e. 20+21-1=41; 41-1=40. One student, nevertheless, knew the answer of 19+22 and thus compensated differently.

Table 2: Anticipated Answers versus Unanticipated Answers

Strategies / Grade Levels	Anticipated Answers		Unanticipated Answers	
	Anticipated	Unanticipated	Anticipated	Unanticipated
2nd Addition	8 (1) *	2	1 (1)	3 (3)
3rd Addition	6	9	3 (3)	0
Kinder Subtraction 1	3	3 (3)	0	1 (1)
Kinder Subtraction 2	6	7	0	1 (1)
Kinder Subtraction 3	5	2	0	2 (2)
3rd Subtraction	0	7	0	0
3rd Multiplication	16 (1)	1	1 (1)	1 (1)
5th Multiplication	10 (1)	3	0	0
Overall	54	34	5	8

Note:
*: "8" means the number of student strategies PSTs anticipated; the number "1" in the bracket refers to the number of those that were incorrect answers.

In consideration of PSTs' different responses to correct and incorrect answers, we found that they mostly anticipated correct answers. A plausible explanation might be that PSTs applied the strategies they had learned in the methods class to their teaching plans. When predicting the split-jump strategy, PSTs in the second grade addition class anticipated two different usages of this strategy and were able to smoothly handle students' reasoning. By contrast, PSTs without a perception of students' strategies in advance had a more difficult time making connections when questioning students. For example, in the third grade addition class, two co-teaching PSTs did not expect students to use multiplication (or arrays) in addition problems. When four students claimed that they used arrays in three addition problems, PSTs took a lot more talk turns to figure out what students' arrays looked like. For example, given 16+16+4+4, a student claimed to use an array of 8 down, 5 across, i.e. 5x8. PSTs repeatedly asked questions about this to ensure they understood what the array looked like. Once getting the idea of 8 down, 5 across, PSTs concluded the conversation and moved to the next one without making a reasonable connection between the addition and the multiplication. The

PSTs later reflected, “Arrays are a drawing strategy taught by teachers to encourage multiplication.” Overall, PSTs only anticipated 6 out of 19 incorrect answers. Another 5 incorrect answers resulted from students’ improper uses of PSTs’ anticipated strategies and the remaining 8 were unanticipated answers preceded by unanticipated strategies.

PSTs’ Talk Moves in Addition Problems

PSTs had to utilize different talk moves for anticipated versus unanticipated answers and strategies. The two groups that did addition number strings demonstrated an overwhelming use of revoicing and pressing talk moves in both classes, i.e. 29 in the 2nd grade class and 62 in the 3rd grade class (see Table 3). Also PSTs used more talk moves all together in situations of anticipated answers than those in situations of unanticipated answers (2nd: 19>16, 3rd: 45>22). Since the number string lessons were meant for PSTs to elicit and represent students’ mathematical thinking, PSTs were advised not to tell students how to solve the problems. Consequently, they often repeated students’ answers or strategies and pressed for more information to get clarity from students. This is consistent with Baxter and Williams’ (2010) results that PSTs deprived of their most familiar show-and-tell teaching mode likely lean toward silence and avoid telling students anything, expecting students can make use of their questioning to discover the right way to correctness.

Table 3: PSTs’ Talk Moves in Two Addition Classes

		Anticipated Answers		Unanticipated Answers		Total
Strategies		**Anticipated**	**Unanticipated**	**Anticipated**	**Unanticipated**	
2nd Addition	revoicing	10	1	3	5	19
	pressing	4	2	3	1	10
	orienting	0	0	0	0	0
	negotiating	2	0	2	2	6
	Total	**19**		**16**		**35**
3rd Addition	revoicing	11	16	7	0	34
	pressing	5	12	11	0	28
	orienting	0	1	2	0	3
	negotiating	0	0	2	0	2
	Total	**45**		**22**		**67**

The aforementioned situation was applicable when students themselves could clearly articulate their reasoning. Then PSTs could pretend not to know the strategy and press students to articulate their reasoning. In the 3rd grade addition class, for example, a student proposed multiplication (8x3) to solve 8+8+4+4 because of three “8’s.” A PST argued that she did not see three 8’s, pressing the student into saying more about the strategy. The student then made it clear that two 4s were put together first in his strategy. This is a successful episode where the PST used pressing to make the student’s reasoning clearly accessible to the whole class. On the other hand, revoicing and pressing did not move students’ reasoning forward when their reasoning was ambiguous. Students with difficulty presenting their strategies logically and meaningfully often revealed more helpful information when PSTs oriented the class to these students’ ideas or negotiated with them around alternative strategies. Solving 4+4+4+4+2+2, one student relied on “8 times 3” to get his 24 but could not offer where three 8’s came from. Then the PST negotiated by asking, “So you thought it was like the last problem (8+8+8)?” A “yes” answer was given. Under such a circumstance, the PST was able to look far beyond students’ reasoning and associate possible mathematical evidence with students’ reasoning so that more information was elicited from the student through the PST’s appropriate questioning.

Similar to the function of negotiation mentioned above, PSTs were inclined to turn to orienting and negotiating talk moves when they addressed students' mistakes. In the 3rd grade addition class, there were three episodes dealing with wrong answers and PSTs either invited the involvement of the class to discuss the problems in question, negotiated an alternative with students, or negotiated by soliciting other students' explanations.

Conclusions & Implications

Overall, most PSTs did anticipate a majority of students' answers and strategies after the instructional reading in their methods course. But there were still many alternative strategies to the same problem that PSTs failed to anticipate. Therefore, we as teacher educators need to guide students to try out various solutions to a problem, in particular multiple ways to get the same answer, especially considering students' knowledge at different grade levels (i.e., such as the third graders knowing multiplication). The results from this study also indicate that the revoicing and pressing talk moves prevailed in PSTs' classroom discourse. PSTs need to analyze the benefits and use cases of the talk moves in more depth; students' problem-solving procedures were well explored by means of revoicing and pressing but student reasoning was ignored to some extent. Admittedly, revoicing and pressing helped PSTs continue on in the exploration of student reasoning when they encountered something unexpected; but these strategies are far from being sufficient to elicit students' thinking and create learning opportunities that students can take up later. In this regard, the negotiating and orienting talk moves provide students with opportunities to reconsider and compare their strategies with others.

In the case of errors, the fact that most incorrect answers were not anticipated by the PSTs during their planning called our attention to the need for PSTs to think more about common incorrect answers, especially how students might make mistakes using strategies they anticipated. When students presented incorrect strategies, they could not easily jump out of their reasoning and discover the expected path to correct strategies when the only talk moves PSTs used were revoicing and pressing. One possible way to better support students is for PSTs to use negotiating and orienting question prompts to target students' reasoning, and bring students face to face with their emerging strategies. These discursive interactions with students allow PSTs to help students notice unproductive steps in their strategies. Further, an important next step is to support PSTs in helping students move beyond addressing their mistakes to building on their mistakes (e.g, when a student did 19+19 by adding only 9 to 9, PSTs should move beyond eliciting what the student was thinking when making the mistake, have students build on what they did successfully (9+9), push students to fix their mistakes (help them figure out how to make use of the tens).

When we delve further into PSTs' interpretations and representations of students' thinking, it is evident that there is room for teacher educators to orient the methods course with how to build on student mistakes and encourage PSTs to try the orienting and negotiating talk moves. Therefore, teacher educators can encourage PSTs to embrace the uncertainty of what students will say and see if the class can collectively make sense of and build on places where students' strategies are breaking down. This could be done through such pedagogical approaches as rehearsals (Grossman, Hammerness, & McDonald, 2009), creating opportunities of modeling real classroom teaching to help PSTs practice dealing with some specific mathematical topics like unanticipated strategies and student mistakes. By means of these rehearsals, PSTs could possibly enhance their teaching skills and mathematics expertise when teacher educators focus PSTs' attention on those specifics of teaching as well as those "variations of the practice as it relates to particular students and mathematical goals" (Lampert, et al., 2013, p. 238).

MATHEMATICAL MAKING IN TEACHER PREPARATION: WHAT KNOWLEDGE IS BROUGHT TO BEAR?

Steven Greenstein
Montclair State University
greensteins@montclair.edu

Justin Seventko
Montclair State University
seventkoj1@montclair.edu

In this paper, we describe an experience within mathematics teacher preparation that engages pre-service teachers (PSTs) in Making and design practices that we hypothesized would inform their conceptual and pedagogical thinking. With a focus on the design of new tools to support mathematics teaching and learning, this Learning by Design experience has PSTs exploring at the crossroads of content, pedagogy, and Making. We report our findings of the variety of forms of knowledge that PSTs brought to bear on their design work. As the engagement and advancement of these forms of knowledge is essential to effective mathematics teaching, these findings suggest the promise of a making-oriented experience within mathematics teacher preparation coursework.

Keywords: Technology, Teacher Education-Preservice, Teacher Knowledge

Preservice elementary teachers typically come to teacher preparation with limited conceptions of mathematics (Association of Mathematics Teacher Educators, 2013) and a model of mathematics teaching based solely on their own classroom experiences as students (Lortie, 1975). These models can be characterized by appeals to rules and procedures (Ball, 1990; Ma, 1999; Thompson, 1984), problems whose solutions are predetermined and predictable (Schoenfeld, 1992; Thompson, 1984), and teaching in which mathematical information is imparted from teacher to student with unquestioning acceptance (Lampert, 1990; McDiarmid, Ball, & Anderson, 1989). This is a problem because this model of mathematics teaching is not consistent with a pedagogy that is viable for learning mathematics with understanding. Consequently, as part of their preparation for elementary teaching, prospective elementary teachers must be presented with opportunities to challenge their current models of mathematics teaching and learning that engage them with both the problems of mathematics and the problems of children's learning of mathematics.

At the same time, the proliferation of spaces for digital design and fabrication suggests new opportunities to teach and learn new mathematical things in new ways and to even think in new ways about what teaching and learning mathematics might look like. However, research is only beginning to identify the mathematical thinking and reasoning that these technologies might make possible. And there is no research that explores what these technologies might offer to support the preparation and professional development of teachers. As such, this proposal presents a novel Making-oriented experience within mathematics teacher preparation that tasks pre-service elementary teachers with designing, fabricating, and evaluating new manipulatives (Post, 1981) aimed at engaging and advancing learners' mathematical thinking and reasoning. Thus, this project addresses the need for better preparation of elementary mathematics teachers through education research that seeks to understand the processes and potential benefits of teacher learning in a Maker context.

Proceeding from the hypothesis that Making and doing lead to new ideas and experiments in embodied (Johnson, 2007), networked (Latour, 2005), and tool-centric (Vygotsky, 1978) engagement that, in turn, will lead to powerful innovation in mathematics teaching and learning, this project seeks to address the following question: *What forms of knowledge are brought to bear on pre-service elementary teachers' design work as they make new manipulatives to support the teaching and learning of mathematics?*

Theoretical Framework

In the context of math-focused exhibitions in the designed informal learning environments (National Research Council, 2009) of science centers and museums, investigators have identified evidence of visitors engaging in algebraic (Pattison, Ewing, & Frey, 2012) and spatial reasoning (Danctep, Gutwill, & Sindorf, 2015), and also demonstrating qualitative, intuitive understandings of slope (Nemirovsky & Gyllenhall, 2006; Wright & Parkes, 2015). Within Makerspaces (Peppler, Halverson, & Kafai, 2016), where activities are designed with a variety of learning goals in mind, some research suggests that in order to see and support opportunities for mathematical activity, it is necessary to look beyond the content and use a more broadened conception of mathematics – "including mathematical dispositions, habits of mind and identity" – to identify the mathematics in which learners engage (Author et al., 2016a). These findings of mathematical engagement in informal settings point to the possibilities that semi-structured design-centered experiences can offer in relation to mathematics teaching and learning.

As for K-12 educational settings, Shaffer's (2005) use of design tasks in a microworld (Papert, 1980) to teach transformational geometry, and Cochran and colleagues' (2016) suggestions about how middle school teachers can use 3D printing as a context to promote geometry understanding, lend further credence to the proposition that Making can provide a gateway to meaningful interaction and deepened understanding of both content and pedagogy by engaging preservice teachers (PSTs) in the design of new manipulatives and corresponding tasks that generate environments for mathematical thinking and learning. Research can shed light on the creative and participatory practices associated with teachers' Making experiences and how those experiences inform their knowledge and their identities as elementary mathematics teachers.

Teachers as Designers

In investigating the experiences of PSTs designing for mathematical learning, we connect with other researchers' conceptions of *teachers as designers* (Kalantzis & Cope, 2010; Maher, 1987). Svihla et al. (2015) refer to "teachers as designers of learning experiences to emphasize teacher involvement in designing from pre-instructional designing of lessons, activities, units and learning environments to their design work that continues into the classroom" (p. 284). When teachers are given agency to craft their own manipulatives and corresponding curricular materials, they assume ownership over these materials and the learning environments they generate, thereby coming to see themselves as agents of curricular and pedagogical reform (Leander & Osborne, 2008; Priestley, Edwards, Priestley, & Miller, 2012). In doing so, they find themselves moving toward more legitimate forms of participation (Lave & Wenger, 1998) as they develop their identities as designers of mathematical instruction.

Learning Teaching by Design

The premise of this project follows from the proposition that it is productive to develop teacher knowledge within a context that honors the connections between its constituent forms of knowledge. Accordingly, we took somewhat of a Learning by Design approach (Koehler & Mishra, 2005; Koehler, Mishra, Hershey, & Peruski, 2004; Mishra & Koehler, 2003), a methodology that was developed as a means to advance teachers' technological pedagogical knowledge, or TPCK (Koehler & Mishra, 2010). An environment is created in which teachers naturally confront content, pedagogy, and technology so that the connections between are honored and maintained. Within this environment teachers assume the role of designers of technology and work collaboratively in small groups to develop technological solutions to authentic pedagogical problems. "By participating in design, [they] build something that is sensitive to the subject matter (instead of learning the technology in general) and the specific instructional goals (instead of general ones). Therefore, every act of design is always a process of weaving together components of technology, content, and pedagogy" (Koehler & Mishra, 2005, p. 95).

Our own Learning by Design approach to mathematics teacher preparation is grounded in several principles. First, constructionism (Harel & Papert, 1991) is the theory of learning that undergirds the Maker movement's focus on problem solving and digital and physical fabrication (Halverson & Sheridan, 2014, p. 497). Second, Piagetian constructivism, a theory of learning that is well suited to the way learning works in an environment of mathematical inquiry (Author et al. 2016b), informs the pedagogy. Indeed, the power of manipulatives lies in their capacity to support the construction of abstract mathematical concepts from sensorimotor engagement with concrete tools (Kamii & Housman, 2000; Piaget, 1970; Vygotsky, 1978), a process grounded in the theory of constructivism. Third, knowledge of the content to be taught and a variety of ways in which that content may be presented, represented, and experienced (Ball & Bass, 2009; Ball, Thames, & Phelps, 2008; Shulman, 1986) informs the mathematics. Finally, Dewey's (1938) and Pinar's (2012) broadened conceptions of curriculum that frame learning as the product of play, experimentation, and authentic inquiry align with our conception of curriculum. Still, the rich scholarship devoted to teacher knowledge reflects the complexity of the question of precisely what forms of knowledge might actually be brought to bear on PSTs' design work (Ball, 1990; Borko & Livingston, 1989, 1990; K. F. Cochran, DeRuiter, & King, 1993; Grossman, Wilson, & Shulman, 1989; Hill, Ball, & Schilling, 2008; Ma, 1999; Shulman, 1986).

Methods

The study took place in two sections of the first of two required specialized mathematics content courses for pre-service elementary teachers at a large public university in the northeastern United States. Our Making-oriented experience began with PSTs' inquiries into the principles that ground our Learning by Design approach and that are among the standard course goals and objectives for this course. Specifically, these include providing PSTs with opportunities to reconceptualize the content of K-6 school mathematics (including number, arithmetic, and algebraic thinking) while also promoting an inquiry-oriented pedagogy by fostering an understanding of the nature of mathematics, assimilating a constructivist theory of learning mathematics, acquiring a model of how learning works in interaction with manipulatives and other technologies, designing instructional tasks that both promote and reveal students' understanding of mathematics, and developing an understanding of the way in which students' content knowledge develops over time, as well as the struggles they're likely encounter. Concurrently, as PSTs learned to use 3D design and fabrication technologies, they engaged in an iterative "Design Thinking Process" (Stanford University Institute of Design, 2004).

As students were permitted to work either individually or in groups on a design project, the twenty-six students who consented to participate in the study comprised a total of twenty-one groups. The data corpus consists of the following three components of each group's "design case" (Boling, 2010): 1) a "Project Idea Assignment," which describes the group's initial thoughts about a manipulative they want to work on; 2) a "Project Rationale Assignment," which provides an account of why and how a group thinks their project should work from a mathematical learning point of view as well as how their design reflects an understanding of what mathematics is and of how learning happens; and 3) a "Final Paper and Design Show," which includes a short research paper about the project and a PowerPoint that describes the intended purpose of the manipulative, the corresponding tasks that were created, and the group's findings from an intended user's manipulative-mediated engagement with those tasks.

To initiate the analysis of that data, we chose three design cases at random. Three researchers individually analyzed the components of those cases and generated codes (Corbin & Strauss, 2008) that identify forms of knowledge that were revealed in the elements of PSTs' written work. Then, the three researchers got together to generate a cumulative list of codes and clarifying definitions (Table 1). Next, each of the researchers used those codes to analyze all of the remaining design cases. As the analysis continued, new codes were also introduced and then shared among the researchers.

Table 1: Analytical Framework for Coding Knowledge Types

Code (Knowledge of…)	Description
Mathematics Content	Common content knowledge of mathematics.
Specialized Mathematical Knowledge	Variety of ways mathematical ideas can be expressed and explained.
Content and Students	Common student struggles and misconceptions; planning for student thinking.
Standards and/or Curriculum	Acknowledgement of Common Core and/or curricular materials as an important aspect driving instruction; knowledge at the mathematical horizon.
Distinction between Concrete & Abstract	Abstract ideas are abstracted from concrete representations.
Constructivism	Knowledge is constructed; model of knowing as understanding; role of exploration and experimentation; relevance of prior knowledge.
Research on Student Learning	Use of mathematics education research literature.
Task Design for Problem Solving and/or Assessment	Tasks designed for use with a manipulative require challenge/productive struggle, but can also play a dual role of learning and assessing.
Personal Experiences	Students' personal mathematical experiences (both as learner and teacher) inform their design.
Student Affect	Importance of designing tools and tasks that make learning engaging and fun.
Mathematical Tools	Knowledge of currently available tools (e.g., integer chips, base ten blocks, number lines).
Manipulatives	General comments about how learning works with manipulatives; as embedded representations of mathematical ideas.

Intercoder reliability was calculated using percentage of agreement. Since three coders participated in the analysis, each coder was compared to one another in a pairwise manner. Thus, every coding decision had a total number of three pairs to check for agreement. The number of agreements was noted, and ultimately divided by the total number of possible agreements in order to calculate the percentage of agreement. The data presented here had a percentage of agreement of .82, well within the standard put forth by Neuendorf (2002).

Results

Our analysis showed that students used a variety of forms of knowledge in the course of their "Design Thinking Process," as demonstrated in the table of codes provided above. These knowledge types ranged in frequency of occurrence from 68% to 100% (see Table 2).

Table 2. Code Frequencies and Match Percentages

	Mathematics	Specialized Mathematical	Content & Students	Standards and/or Curriculum	Concrete/ Abstract	Constructivism
Coder 1	21	12	20	12	11	19
Coder 2	20	20	20	17	20	20
Coder 3	21	20	19	14	19	20
Total	62	52	59	43	50	59
Match %	0.97	0.75	0.97	0.78	0.71	0.87

	Research on Student Learning	Tasks for Problem Solving & Assessment	Personal Experience	Student Affect	Mathemati cal Tools	Manipulatives
Coder 1	17	12	11	7	11	21
Coder 2	13	19	19	9	12	21
Coder 3	14	18	17	8	14	21
Total	44	49	47	24	37	63
Match %	0.78	0.71	0.68	0.87	0.75	1.00

From this analysis, we see that every group drew on both Knowledge of Mathematics and Knowledge of Manipulatives in their design process. Comments such as "the manipulative will aid students in learning geometry because they will be able to turn, rotate, and reflect on the shapes that they will make" and "the main idea behind the design of our tool… is to help students determine the area and perimeter of two similar figures" demonstrate that knowledge of mathematics content was an extremely important aspect of their design thinking. In particular, these excerpts demonstrate some of the ways the groups expressed their knowledge of manipulatives as embedding mathematical principles.

In the course of thinking about content in this way, each of the groups also leveraged their Knowledge of Manipulatives. We saw a diversity of thinking about manipulatives, ranging from the more generic ("Manipulatives are defined as concrete objects that aid in classification.") to the more sophisticated ("Manipulatives not only allow students to construct their own cognitive abilities for abstract mathematical ideas and processes, but they also provide a concept and common language behind it."). Other students professed a more nuanced understanding of the role of manipulatives in instruction, acknowledging they are best used with other teaching techniques: "Fraction circles are a simple, clear 'physical tool' for teaching this challenging concept, and when used in conjunction with other [fraction contexts] (equal sharing, part-whole, etc.) can be very illustrative." One group drew on their own review of the research literature to inform and support their thinking about manipulatives, writing that "These concrete materials are meant to assist children at all levels of education including understanding processes, communicating their mathematical thinking, and extending their ideas to higher order thinking levels (Balka, 1993)."

Evident in the PSTs' Knowledge of Manipulatives is the related Knowledge of Constructivism as a learning theory that can inform design decisions. Phrases such as "help students construct the idea," "children can tinker with the board and the pieces to find the relationships between the pieces and the groups," and "create a way to teach even and odd numbers that does not revolve around memorizing," all demonstrate the ways the groups were thinking about making tools that allowed for exploration and discovery, both hallmarks of the pedagogical implications of a constructivist theory of learning. In this way, students began to seriously consider not only features of an inquiry-based pedagogy, but also the ways in which tools can be seen to support those implications in classrooms.

Although their design assignments hadn't explicitly called for students to make connections between their design ideas and the coursework, almost every group conceived of their design and the learning it aimed to promote through the lens of their Knowledge of Content and Students. They drew on class readings, the math education literature, and their own experiences as learners of mathematics to anticipate concepts that students would be likely to struggle with. These considerations were evident in statements like, "Since some children have non-anticipatory coordination between groups and shares, my manipulative serves as a way for students to utilize the pieces to see the distribution of shares to each group."

We also saw evidence of other knowledge categories, though with less frequency than those elaborated above. These forms of knowledge include considerations of the relationship between concrete and abstract representations, knowledge of task design for problem solving and/or assessment, knowledge of currently available mathematical tools, and the importance of considering student affect in their designs.

Conclusion

At the crossroads of digital fabrication technologies, human-centered design practices, and constructivist orientations to mathematical thinking and learning, students and teachers are afforded a host of new possibilities. As researchers exploring how these technologies might be used to engage teachers and students in new forms of learning, we hypothesized that a making-oriented approach to pedagogical and curricular change aligned with the kind of progressive, inquiry-oriented pedagogy we aim to cultivate in students preparing to teach mathematics. Accordingly, we developed an approach to nurturing students' inquiry-oriented pedagogy that leverages design practices and digital fabrication technologies as a resource for their learning. While we recognize that teacher preparation is complex and that pedagogical change is difficult, that we identified in PSTs' design work a variety of forms of knowledge whose advancement is essential to mathematics teaching, these findings suggest the promise of a making-oriented experience within mathematics teacher preparation.

ROLE OF REPRESENTATION IN PROSPECTIVE TEACHERS' FRACTIONS SCHEMES

Steven Boyce

mossdl@appstate.edu

This research report explores relationships between fractions' task representations (discrete, rectangular, or circular) and elementary prospective teachers' (PTs) fractions conceptions. Studies show PTs' conceptions of fractions are centered on a part-whole understanding, which may be problematic when teaching children about improper fractions. We studied PTs' conceptions of fractions using a task-based written assessment. The assessment also included PTs' rankings of task difficulty. We found that PTs' responses involving circles representations aligned best with the empirical trajectory of children's developing understandings of fractions. We discuss implications for supporting PTs in conceptualizing fractions as measures.

Keywords: Rational Numbers, Teacher Education-Preservice, Teacher Knowledge

Introduction

Although the conception of a fraction as a *measure* (Lamon, 2007) is emphasized early in the Common Core State Standards (CCSSM, 2010), many middle grades students and prospective teachers (PTs) remain focused on *part-whole* meanings of fractions (Newton, 2008; Norton & Wilkins, 2010; Olanoff, Lo, & Tobias, 2014). In this research project, we build off the learning trajectory for PTs' understandings of fractions as measures described by Lovin, Stevens, Siegfried, Norton, & Wilkins (2016). Our study aligns well with the PME-NA Conference Theme of "Synergy at the Crossroads" because our approach involves looking across both fraction representation and fraction task structure to better understand the role of each in understanding and supporting PTs' understanding of fractions.

Background and Purpose

Norton and Wilkins (2010) designed written assessments of middle grades students' fractions' schemes using rectangular and circular representations of fractions. A subset of these (rectangular) items were validated via clinical interviews with sixth-grade students (Wilkins, Norton, & Boyce, 2013). Lovin et al. (2016) used the written items to assess the fractions schemes of PTs before and after instruction in mathematics courses for elementary PTs. In examining PTs' written responses, Lovin et al. (2016) noted that PTs often set up proportions and used division to correctly solve fractions tasks in ways that would not be available to elementary or middle grades students. They mentioned that PTs' use of such procedures to find equivalent ratios may have been confounding researchers' assessments of some of the PTs' fractions understandings (potentially producing both false positives and false negatives). This could lead to difficulty in assessing and supporting PTs' learning, particularly for fostering PTs' self-monitoring of their understanding of the mathematical goals and constraints that their prospective students may face.

In this paper, we report on results of modifying Norton and Wilkins' (2010) items and methods to explore relationships between the form of fractions' task representations (discrete, rectangular, or circular) and elementary PTs' fractions conceptions prior to instruction in their college course. Our aim in this study is to understand how PTs' ways of operating with fractions in different representations are connected, so that we, as mathematics educators, can plan to introduce and moderate perturbation (von Glasersfeld, 1995) that will help them to construct more powerful fractions schemes. With this aim, we modified the assessment approach of Norton and Wilkins (2010) and Lovin et al. (2016) to isolate differences in PTs' responses to fractions tasks.

Theoretical Framework

We adopt a radical constructivist epistemology in modeling PTs' fractions meanings as the product of their organizing mental structures (schemes) to fit their experiences (von Glasersfeld, 1995). The construct of scheme refers generally to the way researchers model how individuals operate mentally in service of a goal. A scheme consists of three parts – recognition of a situation, operations (mental actions), and an expected outcome. Individuals' schemes become established as they become refined and generalized through their use, via processes of assimilation and accommodation (Piaget, 1970). When a scheme is interiorized, the situation, operations, and anticipated result of operating are experienced altogether as a unified and connected structure (a concept) that can itself be operated upon (Piaget, 1970).

Fractions Schemes

We focus on four specific schemes pertaining to fractions identified by Steffe and Olive (2010) – the parts-out-of-wholes fraction scheme (PWS), the partitive unit fraction scheme (PUFS), the general partitive fraction scheme (PFS), and the iterative fraction scheme (IFS). The PWS involves *partitioning* a whole into discrete pieces that can be disembedded (removed from the whole without modifying the whole) and double-counted to form a numerosity of part(s) within a numerosity of a whole. The PUFS builds upon the PWS as the individual conceives of the *size* of a disembedded part and its relation to the size of the whole (i.e., that *iterating* the amount of $1/n$ n times results in the size of 1). The PFS extends this notion to the size of a composite (but proper) fraction. An individual with an iterative fraction scheme (IFS) understands the size of an (im)proper fraction (m/n) as the result of coordinating mental operations to include partitioning the size of '1', disembedding a unit fractional size ($1/n$), and iterating the disembedded fractional unit m times.

In order for an individual's fraction scheme to become interiorized as a fraction concept, his or her fraction scheme must be *reversible*. For instance, an individual with a *reversible* IFS could reverse his or her ways of operating to determine the size of '1' from a given improper fraction size. Reversing the PFS involves forming the size of '1' from a given (composite) proper fraction size, and reversing the PUFS involves forming the size of '1' from a given unit fraction size. Reversing the PWS involves forming the numerosity of the whole from a given proper fraction (e.g., reasoning that if three parts represents the fraction 3/7, then the whole must be 7 parts). In the next section we describe specific examples of these four fractions schemes.

Task Structures

Figure 1 displays four task structures, two involving proper fractions (Task PFS1 and Task PFS2) and two involving improper fractions (Task IFS1 and Task IFS2). Consider that if a task involves a discrete representation for a unit fraction (e.g., a dot or a chip) then forming a size (via a counting measure) is often indistinguishable from forming a numerosity. Thus, Task PFS1 theoretically requires a PWS in the discrete representation and a PFS in the bar and circular representations. In each of the three representations, the correct response is 2/5, but an individual with a PFS might instead respond with a slightly different fraction (such as 4/7 or 3/8) in the bar and circle models if rulers or protractors are not available to make precise measurements.

Task PFS2 theoretically requires a *reversible* PFS in the bar and circle representations. To form the size of a unit fraction from the proper fraction requires intermediately forming the size of the whole. In the dots representation, the task requires a reversible PWS.

Theoretically, Task IFS1 requires a reversible IFS, as it asks for the size of '1' from a given improper size. To form this size, one could partition the given amount into nine equivalent one-fourths and then iterate that amount four times. However, a PT could potentially solve the task in the discrete representation using a ratio understanding. A PT might coordinate partitioning and iterating to solve the task in the bar representation, but not the circular representation, because of an established understanding of a circle as necessarily the size of ‘1’.

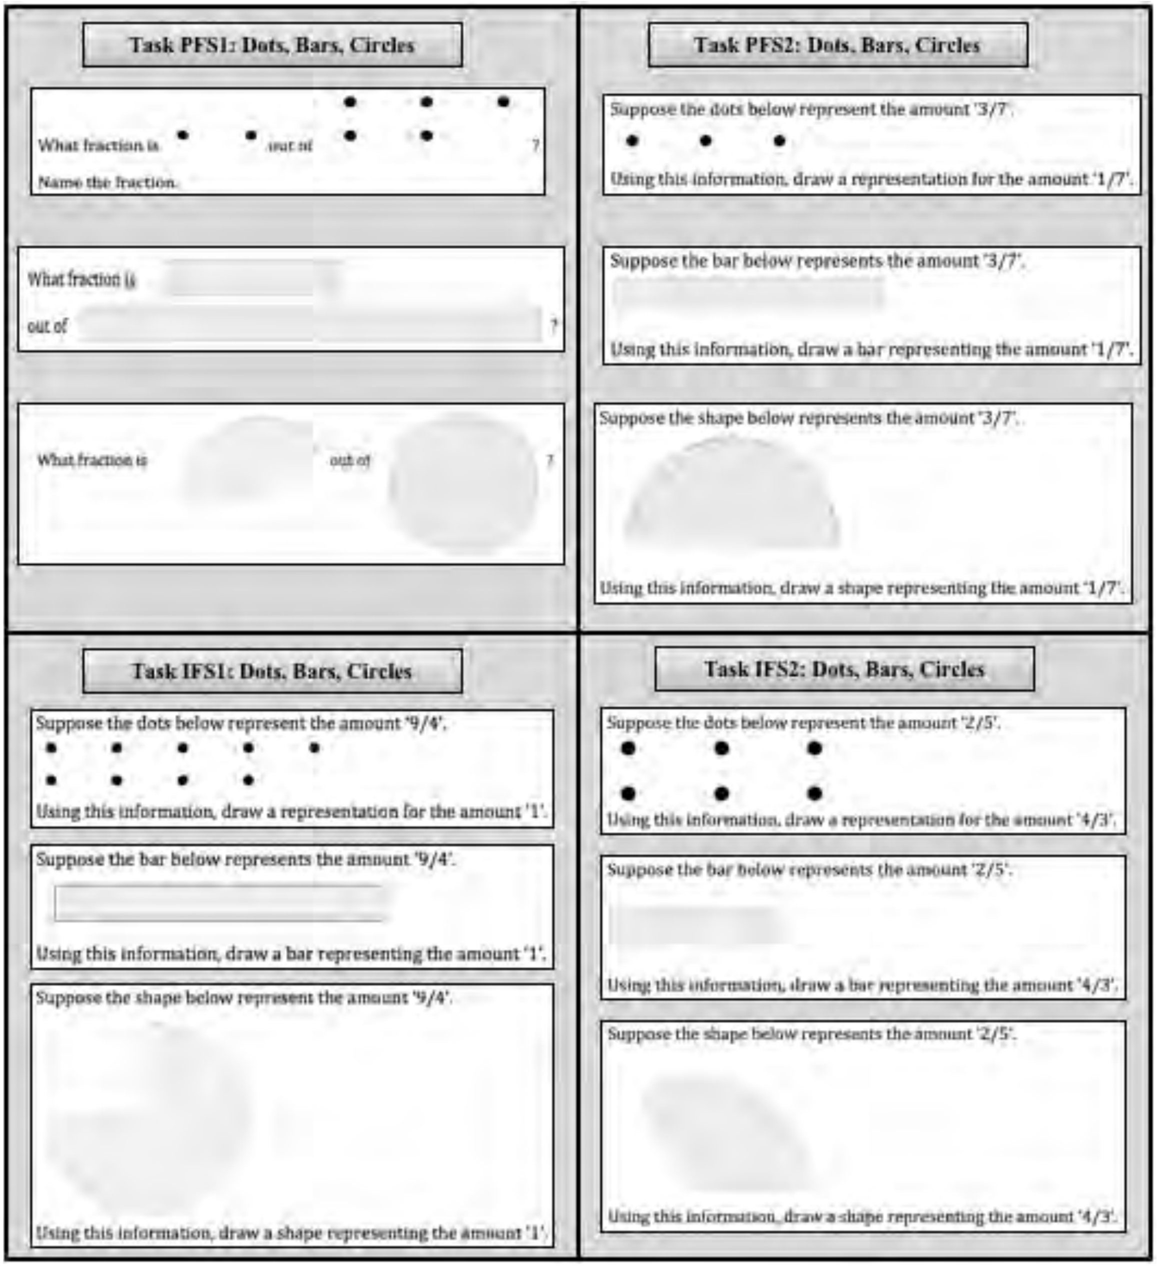

Figure 1. Four fractions task structures with dots, bars, and circles.

Task IFS2 theoretically requires recursive use of an IFS. One could solve the task by first partitioning and iterating to form the size of 1 (using a reversible IFS) and then partitioning and iterating to form an improper fractional size (using an IFS). PTs might instead approach the task by finding a common denominator by which to determine equivalent fractions without forming the size of 1. Lovin et al. (2016) noted that PTs may rely on such procedures when encountering improper fractions because they have yet to coordinate three levels of units: the unit fraction, the improper fraction, and the whole–when attempting to iterate a unit fraction beyond the whole, they lose track of the size of the whole (Steffe & Olive, 2010).

Methods

We administered a written assessment to 76 PTs in an Elementary Math Methods course at a U.S. university, prior to class discussion of fractions. To reduce the length of the assessment and to isolate differences in task representation, each of the PTs completed one of three forms. On the first form, there were four tasks with dots followed by four structurally identical tasks with bars. On the second form, the four dots tasks were followed by four circles tasks, and on the third form, the four bars tasks were followed by four circles tasks (see Figure 1). The four tasks in each representation were consistently given in the sequence: IFS1, PFS2, PFS1, IFS2.

These tasks use the same wording and form of items from Norton and Wilkins (2010), and our process for scoring items also followed their approach. First, a graduate assistant blinded and reorganized scanned pages of the assessments so that the two raters (authors) could not identify PTs' names or assessment forms. If there was strong indication that a PT had constructed a scheme, we scored it '1', and if there was strong counter-indication that a PT had constructed a scheme, we scored it '0'.

Figure 2 displays sample responses scored as '0' or '1' for two items in the bars and circles representations. For instance, for Task PFS2, to assign a score of '1', we were looking for evidence that the individual had partitioned the given size into three equally-sized pieces and drawn one of those pieces. Indication that the individual had instead partitioned the given amount into seven pieces would suggest assigning a score of '0' for Task PFS2. Note that we coded Task IFS2 with '1' if the PT determined the (approximately) correct fractional size by first using a procedure to determine equivalent fractions.

We calibrated our scoring by discussing our inferences and interpretations of ten randomly selected responses to each of the 12 items. As we independently coded the remaining responses, we also assigned '0.6' and '0.4' to indicate "leaning" toward indication or counter-indication, respectively. The (linear) kappa scores for the two raters across the 12 items ranged between .44 and 1, with a mean kappa score of .75, suggesting substantial inter-rater agreement (Landis & Koch, 1977). Agreement was strongest for the dots tasks, for which the PTs' responses were less ambiguous (kappa > .9 for each of the four tasks). The bars and circles tasks had the lower kappa values, as we had to make inferences from the PTs' markings about their intent to create a correct fractional size because they were not provided with a ruler or protractor with which to make exact measurements.

After computing a satisfactory kappa, we reconciled our scores. We assigned a reconciled score of '1' if we had each marked either a '1' or a '0.6', and we assigned a reconciled score of '0' if we had each marked either a '0' or a '0.4'. If one rater had marked '0.4' and the other '0.6', then we assigned a reconciled score of '0.5'. For the remaining responses, we returned to the data to decide on a score of either '0' or '1' for each item. Whereas Lovin et al. (2016) further used the sum of four reconciled scores on similar items to assign an overall '1' or '0' regarding an individual's construction of a fractions scheme, our item scoring remained focused at the item level.

We used the Wilcoxon rank sum (Wilcoxon, 1945) to test whether there were significant pairwise differences in mean scores for each item for this group of PTs. The null hypotheses were that there would not be significant pairwise differences in mean scores across task types or representations. We tested for differences in mean scores across task representations (dots, bars, and circles), controlling for the task types (PFS1, PFS2, IFS1, and IFS2), and we also tested for pairwise differences in mean scores across items within each of the three representations.

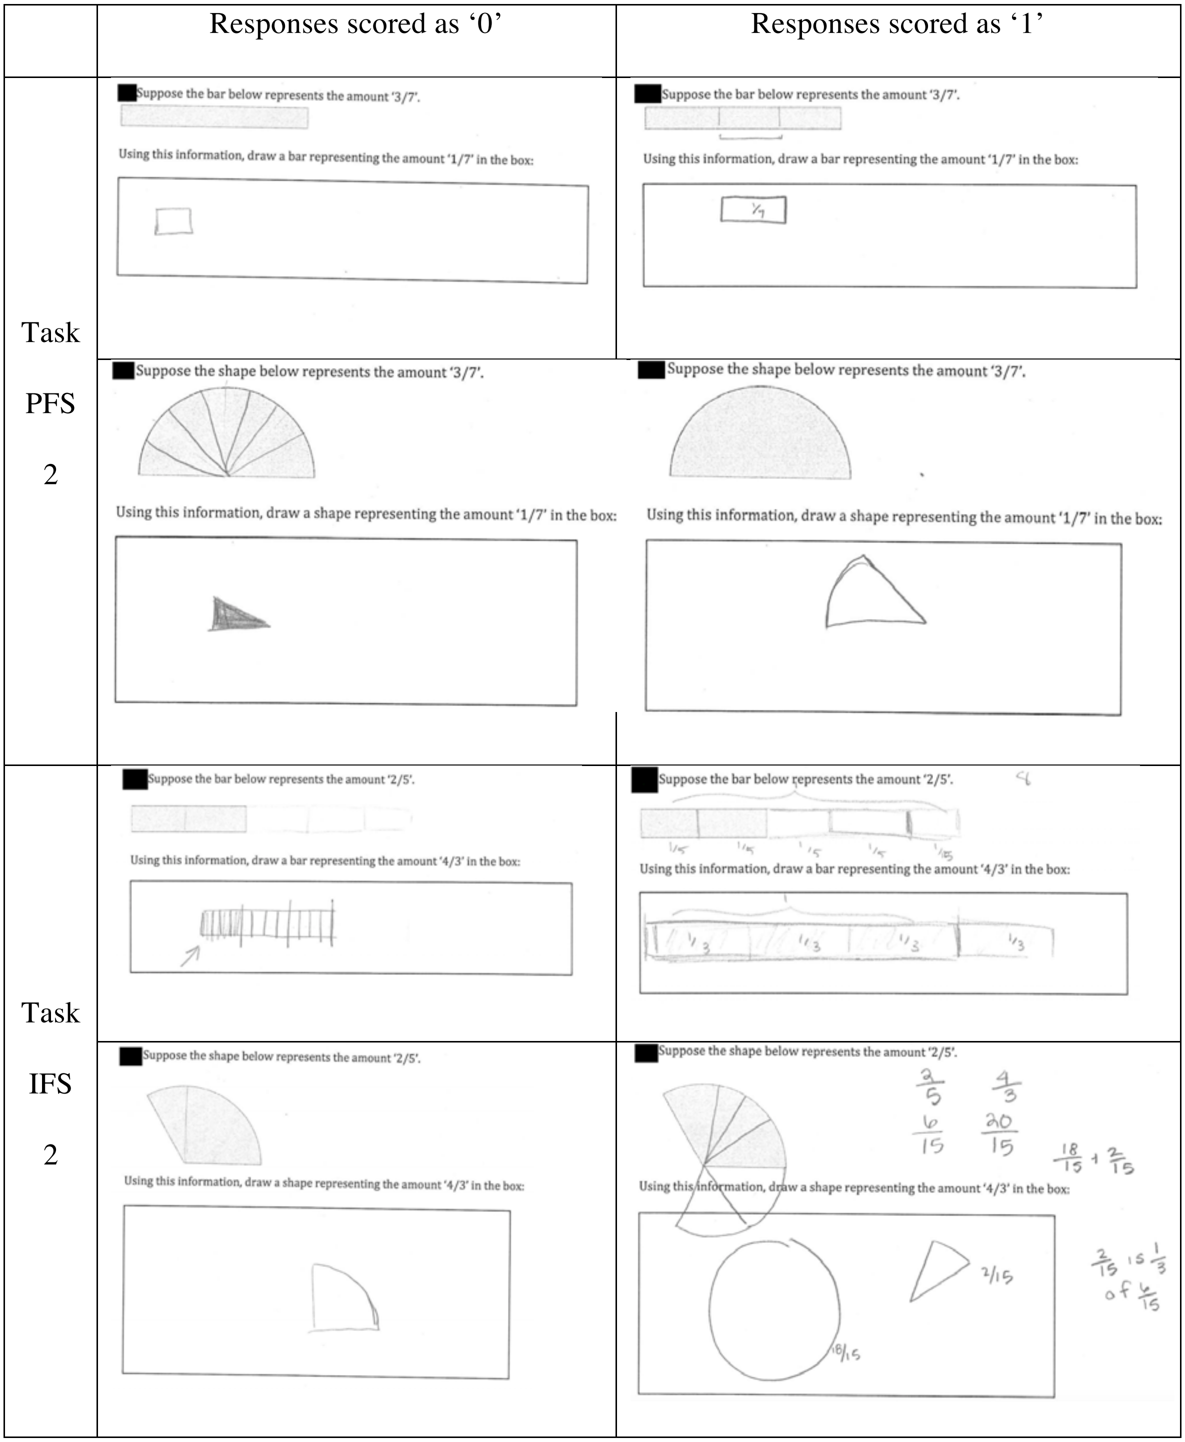

Figure 2. Sample responses coded with '0' or '1' in the bars and circles representations.

PTs' Rankings of Task Demands

Each of the three forms included an identical ninth question, intended to assess PTs experiences of the cognitive demands of their previous eight tasks. The PTs were asked to rank the previous eight tasks they had completed in order from least difficult (1) to most difficult (8) and to then explain their ranking decisions. The instructions emphasized that each of the numbers '1' through '8' were to be used exactly once in the rankings. We discarded PTs' responses to the ninth question in the analysis if they repeated more than one of the numbers 1-8, which resulted in including 71 of the 76 responses. We repeated the Wilcoxon rank sum tests with the PTs' difficulty rankings to test where there were pairwise differences in the PTs' experiences of difficulty across task type or task representation.

Results

Table 1 displays the the mean scores and difficulty rankings for each of the 12 tasks. Within each of the three representation types, the Wilcoxon rank sum test indicated significant differences (at alpha = .05 level) between both the mean performance and difficulty rankings on the two IFS items. Task IFS2 was more difficult than Task IFS1 (and was also more difficult than either PFS1 or PFS2), and this was in concordance with the PTs' rankings of the two items' difficulty. The difference in performance was not significant for the two PFS items across all three representations (p=.500 for dots, p=.355 for bars, and p=.232 for circles). For dots and bars, the ranking of the difficulty of Task PFS2 was significantly greater than Task PFS1; for circles the difference in difficulty was marginally insignificant (p = .012, p=.009, and p=.073, respectively). Across each of the four items, scores on dots tasks were significantly higher than circles tasks. One PT expressed, "The dots make no logical sense to me, and the shapes [bars] are easy until a fraction is more than a whole. What is that supposed to look like?" This response affirms that both task structure and task representation are important considerations for assessing PTs' fractions knowledge.

Table 1: Results Across Task Representation

	PFS1	PFS2	IFS1	IFS2
Dots Mean Score (Mean Dots Difficulty Rank)	.906[a] (2.062)[ab]	.937[ab] (2.917)[b]	.760[b] (3.771)[b]	.344[b] (5.833)[b]
Bars Means Score (Mean Bars Difficulty Rank)	.522[ac] (4.467)[a]	.622[a] (3.333)[c]	.656 (4.467)[c]	.300[c] (6.333)
Circles Mean Score (Mean Circles Difficulty Rank)	.766[c] (4.553)[b]	.681[b] (4.021)[bc]	.457[b] (5.553)[bc]	.128[bc] (6.745)[b]

Notes. Score was from 0 (counter-indication of scheme) to 1 (indication of scheme). Difficulty ranking was from 1 (easiest) to 8 (hardest). Using Wilcoxon signed rank test, with alpha = .05.
[a] Denotes significant difference between dots and bars. [b] Denotes significant difference between dots and circles. [c] Denotes significant difference between bars and circles.

Though Task IFS2 was ranked as the most difficult across all three representations, it was significantly less likely to be answered correctly in the circles representation than in the bars or dots representations. A common explanation for the PTs' assignment of difficulty rankings was that PTs found Task IFS2 "confusing" – particularly in the circles representation. We infer that this was often because the PTs were unfamiliar with a whole circle not representing the size of '1' (see Figure 3 for a sample response).

Supporting this inference, PTs were more likely to correctly answer Task PFS1 (in which the whole circle represented the amount 1) as representing 2/5 in the circles representation than in the bars representation. They more often incorrectly responded with '1/3' or '1/2' in the bars representation. This also explains why the difficulty ranking and score were each lower for Task

PFS2 in the bars representation than in the circles representation. For instance, one PT mentioned that "we didn't really know what a bar represented, so I just had to divide them up equally and go with it."

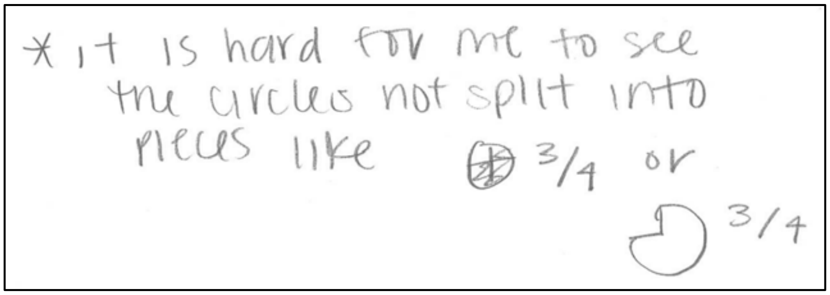

Figure 3. One PT's explanation of her difficulty rankings.

Conclusions

The results of our study generally concur with the learning trajectory described by Norton and Wilkins (2010) and Lovin et al. (2016), in that the PTs in our study were more likely to make sense of PFS tasks than IFS tasks. However, some PTs' familiarity with part-whole interpretations of fractions and proportions resulted in their being able to correctly solve tasks with dots but not structurally identical tasks with bars or circles, even though bars and circles tasks followed the dots tasks in their written assessments. PTs' ranking of task difficulty aligned best with the empirical trajectory of middle grades students' fractions schemes in the circle representation. This suggests that PTs enter their elementary mathematics course well-suited to appreciate the challenges elementary students face in constructing fractions schemes, and that instructors can support PTs by introducing non-standard circular representations of fractions.

We believe more investigation is necessary for the disentanglement of differences between PTs' fractions schemes across representations to inform instructional practice. Anecdotally, we have found in our teaching that focusing on non-standard circular representations early in a course can be frustrating and temporarily reduce some PTs' confidence, but eventually result in their reorganization of their fractions concepts. Future research may investigate the influence of varying the introduction of task structures and representations in elementary math courses. Important considerations include PTs' resilience, motivation, and self-efficacy for teaching mathematics.

SCHOLARLY PRACTICE AND INQUIRY: DYNAMIC INTERACTIONS IN AN ELEMENTARY MATHEMATICS METHODS COURSE

Andrew M. Tyminski
Clemson University
amt23@clemson.edu

McKenzie H. Brittain
Clemson University
mhoxit@clemson.edu

This paper represents research that exists at the crossroad of scholarly practice and scholarly inquiry. We share the design, enactment and empirical examination of an elementary methods course activity, Exploring and Supporting Student Thinking (ESST) which engaged 18 prospective teachers in two sessions of one on one problem posing with 3rd grade students. Results mirror outcomes from existing literature on student interviews and letter exchanges.

Keywords: Teacher Education-Preservice, Teacher Knowledge

Research suggests that teachers who understand how students think about particular mathematical ideas will be better positioned to recognize, interpret and support these ideas in their instruction (Brown and Borko, 1992; Fenema and Franke, 1992). Research on Cognitively Guided Instruction (CGI) has demonstrated teacher knowledge of student thinking, reasoning and strategies can lead to gains in student achievement (Carpenter & Fennema, 1992; Carpenter, Fennema, Franke et al., 2000). Ball and her colleagues' work on mathematical knowledge for teaching identified knowledge of content and students as a crucial facet of pedagogical content knowledge necessary for teaching mathematics effectively (e.g. Hill, Ball & Schilling, 2008).

In light of these findings it has become increasingly important for mathematics teacher educators (MTEs) to assist prospective elementary mathematics teachers (PTs) in developing knowledge of children's thinking. Jacobs, Lamb and Phillip's (2010) work on professional noticing of children's mathematics has become a popular framework to explore the ways in which teachers attend to, interpret and respond to students' mathematical thinking. Mathematics methods course activities sometimes provide PTs opportunities to examine and interpret authentic (and/or instructor-generated) samples of student work depicting invented computational strategies or mathematical reasoning as a means to gain experience interpreting and responding to student thinking (e.g. Tyminski, Land, et al., 2014). We term these types of interactions as static, in that there is no student to interact with during the process of interpreting the work, and once PTs have done so, there is no opportunity to respond authentically to students and observe the result. Although we see value in these types of interactions in developing PTs' knowledge of students' mathematical thinking and include examples of them in our methods courses, we sought to design and enact an activity in our early field experience that would foster PTs' understanding of how to elicit and support student's mathematical thinking and which would be dynamic in nature; allowing for a sustained exchange between the PTs and the student.

This paper represents research that exists at the crossroad of scholarly practice and scholarly inquiry. We outline the process in the design, enactment and empirical examination of an elementary methods course activity, Exploring and Supporting Student Thinking (ESST), and answer the question, "What are the experiences of PTs within the ESST activity?"

Literature Review

Scholarly Inquiry and Practice

In methods course activity design and enactment, the authors seek to leverage the interplay between research and practice thorough the processes of scholarly inquiry and scholarly practice (Lee

& Mewborn, 2009). Scholarly inquiry is the exploration of "issues and practices through systematic data collection and analysis that yields theoretically-grounded and empirically-based findings" (p. 3), while scholarly practices are "adapted from empirical studies of the teaching and learning of mathematics and the preparation of mathematics teachers" (Lee & Mewborn, 2009, p. 3). "Scholarly inquiry and practices are interrelated in that MTEs use empirical studies in mathematics education to build practices that are labeled scholarly. In addition, scholarly practices can inform directions for scholarly inquiry regarding PSTs' mathematics teaching and learning" (Kastberg, Tyminski & Sanchez, in press). In order to create the ESST Activity as an example of scholarly practice, we reviewed the literature on existing scholarly inquiry on dynamic interactions in a methods course in order to: 1) synthesize knowledge on the potential impact of these activities on PTs' learning and 2) inform the activity's design by understanding the variation and commonalities of activities described in other researchers' scholarly inquiry.

Dynamic Interactions

Examples of dynamic interaction activities found within the research literature included asynchronous activities such as letter writing exchanges (e.g. Crespo, 2000; 2003; Norton & Kastberg, 2012), as well as face-to-face activities such as interviews with learners (e.g. Ambrose, 2004; Jenkins, 2010), scripted interview protocols (Moyer & Milewicz, 2002), and PTs work with small group of learners (e.g. Nicol, 1998). A brief summary of the activity, context and findings are presented for each example of scholarly inquiry.

In Ambrose (2004), Elementary PSTs worked in pairs to pose open-ended problem solving activities focused on whole number operations and fractions to children. The goal was to impact PSTs' beliefs about teaching, potentially shifting beliefs from teaching as explaining, by leveraging their current beliefs as caregivers. Ambrose concluded PSTs developed new beliefs that were incorporated in existing belief structures.

Jenkins (2010) intervention involved six middle grades PTs working in pairs in alternating roles to pose open-ended tasks focused on patterns and proportions to students. Jenkins searched for evidence of PTs' "interpretive listening skills and awareness of the different ways that middle school students make sense of mathematics" (p. 147). Jenkins reported "the structured interview process fosters an interpretive orientation to listening and initial awareness of the variety of ways that middle school students think about mathematics" (p. 147).

Moyer and Milewicz (2002) engaged 48 PTs in using scripted diagnostic interview protocols focused on rational number tasks to guide their interactions with children. The PTs conducted interviews with children throughout the semester. The final interview was recorded, transcribed, analyzed and reflected upon by the PTs and served as evidence of PTs' experiences and use of questioning. Analysis of the interviews revealed a beginning classification for the types of questioning: 1)"check listing," asking the questions in the protocol with little regard for student responses; 2) "instructing vs. assessing," in which PTs explained mathematics directly to the student with little regard for students' reasoning; and 3) "probing and follow up questions," characterized as PTs genuinely listening to student responses and generating follow-up questions meant to elicit further student thinking.

In Nicol's (1998) activity, 14 PTs were engaged in weekly interactions with small groups of 6th and 7th grade students. The PTs solved problems involving multiplicative reasoning in class and then posed adapted or extended versions of these tasks to students. Nicol examined PTs' abilities to question, listen and respond to students using prospective teachers' journal reflections as sources of evidence for these behaviors. Across the weekly implementations of the activity, PTs began to shift their approaches from those that focused on arriving at a correct answer toward an inquiry-based approach focused on eliciting and understanding student thinking.

Crespo (2000) examined the ways in which elementary PTs listened to the responses of the fourth-grade students in a series of six interactive letter exchanges. PTs' initial interpretations of student work focused on correctness and tended to contain conclusive claims about student understanding based upon small samples of student thinking. Reflective journals were used by PTs to explore their interactions with students. PTs' interpretations began to focus on what the student intended or meant in a solution by the fifth week of the course. Crespo (2003) used the same letter writing activity and data to explore PTs' abilities to pose problems. Initially, PTs attempted to "make their problems less problematic and more attainable to their pupils" (p.251). PTs' questions were worded to avoid student errors or confusion rather than to generate learning opportunities for students or themselves as teachers. Problems included in the last three letters "were puzzle-like and open-ended, encouraged exploration, extended beyond topics of arithmetic, and required more than computational facility" (p. 257). These questions were posed to challenge or extend student thinking and often asked for multiple solutions and explanations.

Methods

Participants and Context

This study examined the experiences of 18 junior-level PTs enrolled in the required elementary mathematics methods course for their university program as they engaged in the ESST Activity. Prior to this course, PTs had completed four mathematics content courses designed for elementary mathematics teachers, including a course on problem solving, and were concurrently enrolled in a fifth content course addressing middle grades mathematics topics. Prior to engaging in this activity, PTs had engaged in activities involving standards documents, CGI problem types and student strategies, responding to students through questioning, number choice and number choice progressions, and opening routines in the grade 2-6 mathematics classroom (Drake, Land, et al., in press).

Exploring and Supporting Student Thinking Activity

The design of the ESST Activity was developed as an example of scholarly practice informed by the literature described above on dynamic interactions. From the literature we identified four contextual factors as potentially supportive in the design and enactment of such an activity: 1) PTs should have opportunities to solve challenging mathematical problems prior to posing them to students; 2) PTs should pose the same problems to students in order to give PTs common experiences to discuss; 3) PTs require opportunities to reflect on their experiences both in a whole group setting as well as through individual, targeted reflection; and 4) MTEs must consistently respond to PTs' reflections.

The ESST activity engaged PTs in solving, planning, and posing a series of 5 tasks. As the instructor of the methods course, the first author provided PTs with 5 tasks designed for use with 3rd grade students. As a class, the PTs and the instructor planned for the enactment of each task using an adaptation of the Thinking Through a Lesson Protocol (Smith, Bill, & Hughes, 2008). During week 5 of our course, PTs visited our partner school where each was paired with a student from a third grade class. During a half-hour session, PTs were asked to pose as many of the five problems as their student could work through, employing extensions and scaffolds as they saw fit. PTs video recorded their session and posted them on the Edthena video tool. PTs were asked to reflect on their own video in terms of their student's solution path and their interactions with the student. They watched and provided feedback for three of their peers, commenting on similar ideas. The instructor also provided feedback on these foci. Following this process, PT synthesized their reflection and feedback into a written plan of ways to improve their facilitation of each task. In week 7 of our course, the PTs returned to our partner school and enacted the same five tasks with a student from a different third grade class. As before, PTs recorded, uploaded, reflected and commented on the videos of this session. The first author provided feedback on these sessions as well. To complete the activity, PTs wrote a reflection paper summarizing their work and what they learned through their enactment and observations. We utilized their reflection papers to make sense of PTs' experience with the activity.

Theoretical Frame

The synthesis of the above examples of scholarly inquiry suggested PTs' dynamic interactions with student thinking can potentially: 1) develop PSTs' knowledge of students' mathematics and strategies (Ambrose, 2004; Crespo, 2000); 2) encourage PSTs to shift their focus in working with students from attaining correct answers to eliciting and understanding student thinking (Crespo, 2000; Jenkins, 2010; Moyer & Milewicz, 2002); and 3) develop PSTs' emerging abilities to use student thinking in crafting responses and posing new problems (Crespo, 2003). We expanded the first code to include not only knowledge of student thinking but any example of what has been defined as knowledge of content and students (Hill, Ball, & Schilling, 2008). We utilized these potential outcomes as our lens as we examined PTs' experiences with the ESST activity, as described in their reflections.

Data Analysis

The authors began the process of data analysis by individually coding the written reflections of the 18 PTs using the three *a priori* codes identified within the theoretical frame. Through several readings of the data and discussion of our existing codes, these three main codes were refined and operationalized using descriptions and sub-codes into our final coding scheme. Excerpts of PTs' written reflection at the conclusion of the activity were taken as the unit of analysis and were coded with both a main code and a sub-code if applicable (Table 1). Inter-rater reliability for the coding was completed demonstrating 74% agreement across 285 units coded. Disagreements were resolved through discussion.

Table 1: Coding Scheme and Number of Coded Units (N = 285)

Knowledge of Content and Students (n = 48)	Attain Correct Answers or Support Student Thinking (n = 120)	Learning to Respond Using Student Thinking (n = 117)
Anticipating possible student solution paths 14	Aware – focused on student obtaining correct answer 13	
Conceptions and misconceptions 27	Unaware – focused on student obtaining correct answer 12	
Task difficulty for students 7	Action -- eliciting and understanding student thinking 42	
	Reflection - the goal of the interaction is to focus on student thinking 53	

Beyond the codes developed from our examination of prior scholarly inquiry, we also employed open and emergent coding techniques (Strauss & Corbin 1998) in order to identify other themes within the data. Two main themes emerged from within the PTs' reflection on their experiences: "the importance of unpacking a task for students" and "PTs' tendency to label or evaluate students based on minimal evidence".

Results

In this section we present our findings related to our five main codes and their applicable sub-codes. We include illustrative examples of each in order to demonstrate our analysis process.

Code 1 - Knowledge of Content and Students (KCS)

As anticipated based upon pour literature search, our analysis of the data revealed a number of instances where PTs identified specific mathematics in their student's work and potentially developed knowledge of content and students from those interactions. There were 48 such examples out of the 285 units. To distinguish among the interactions where PTs seemed to sub-codes were developed and utilized to identify three specific categories of KCS (See Table 1).

Anticipating possible student solution paths was utilized when PTs developed new perspectives on how a student might solve a problem. Susan (all PTs and student names are pseudonyms) provided the following evidence of developing such knowledge while interacting with her first student: "Madison struggled with the coin problem trying to use five coins to make 51 cents. I thought it was very interesting while watching the videos that so many students started with putting out five dimes and a penny. My first reaction is always to make 50 cents with two quarters. Perhaps they all started this way because it would get them closer to five coins total." Of the 48 units identified as Knowledge of Content and Students, 14 involved anticipating possible student solution paths.

Instances where preservice teachers described conceptions or misconceptions of students' mathematical thinking were coded as such. There were 27 units within PTs' reflections identifying their attention to student conceptions or misconceptions. In the following quote from Georgia, we see an example of this code.

> I noticed that my student thought in a different way than I was used to and had some misconceptions about regrouping while doing the standard algorithm for subtraction. In the candy problem, she didn't seem to fully understand how to count up by ones. She was counting by 5's and passed the number she was "counting up to." Then, when she started to count by ones she started at 5 then jumped to 10, 11,12,13.

Anna, as another example, discussed the following misconception when working with her student: "I also found it interesting that once he got a new answer from subtracting, he didn't realize or understand what number he needed to change in the addition problem that was suppose to check his answer."

In 7 instances, PTs demonstrated developing KCS through recognizing, most always in retrospect, the potential difficulty of a task for students. Anna's comment was typical of these responses, "This problem was the hardest for me as a teacher because although he comprehended that each person got 9 brownies, he didn't understand that the last brownie got divided into four pieces and became a fraction".

Code 2 –Obtain Correct Answers or Support Student Thinking

Our examination of the existing literature suggested when working with students can support PTs shift from a focus on students attaining correct answers to eliciting and understanding student thinking. There were 120 units coded as examples of these two mindsets. Within these, we categorized PTs' experiences further using sub-codes. In instances where PTs were focused on their student obtaining a correct answer, we differentiated between PTs who were aware of this focus and those who did not seem to recognize it. For units coded as examples of PTs supporting student thinking, we identified two categories: PTs moves we viewed as supporting student thinking and PTs reflections restating the goal of the activity was to elicit, interpret and support student thinking.

The code "obtain correct answers – aware" was utilized when PTs self-identified their tendency to focus on students arriving at a correct answer. Riley's reflection serves as a typical example of this sub-code. "For the second task, the student struggled in understanding how to approach the problem. I made the mistake of telling him that he should possibly add up. Because of the goal of this assignment, I should not have suggested a strategy to him. Then, I guided him too much through that strategy. Instead I needed to let him approach the problem on his own." Of the 120 units within Code 2, 13 received this code.

The code "obtain correct answers – unaware" was assigned when PTs seemed unaware of their decision or unconscious tendency to lead the student to the correct answer. Marisa's reflection provides an illustrative example, "She had much more trouble with the Brownie Problem and the Coin Problem. I may have prompted her more through these two problems, but she eventually got to the right answer." There were 12 units identified in which PTs were unaware of their actions leading a student to the correct answer.

Action focused on eliciting and understanding student thinking was assigned when PTs' posed tasks or questions intended to help them to better understand the student's thinking. For instance, Heather discussed the following steps she took when interacting with her student: "For example, I created a road map to follow for each problem depending on the child's responses: whether she chose a successful solution path but could not explain the procedure, struggled and needed scaffolding, or completed the problem successfully and explained her thinking. The questions were not random, but rather flowed with her responses." Kim's reflection also exhibited evidence of her actions intended to focus on student thinking. "When Maggie was answering the problems, I would ask her throughout each one what her thinking was, what ideas she was using and how she was sure that her answers to the problems were correct". There were 42 of 120 instances where PTs focused on eliciting or understanding student thinking.

Reflection stating the goal of the interaction is to focus on student thinking was assigned in instances where PTs reflected on the interaction with their student and reminded themselves to keep their focus on the student's thinking. "This was, and still is, an improvement I need to continue to work on so I am able to better explore and support student thinking, assess what strategies a child knows, and determine a child's overall cognitive ability" (Leah). Heather also commented, "Throughout the coin problem, I did not provide enough wait time and found myself explaining too much instead of letting her explore for a longer period of time". There were 53 of 120 instances where preservice teachers reflected on their interaction with the student and stated that the goal was to focus on student thinking.

Code 3 – Learning to Respond Using Student Thinking

We posited our PTs would have the opportunity to develop their abilities in using student thinking to craft responses and pose new problems based on their interactions with students. There were 117 instances where PTs reflected and offered examples of how they might respond if faced with a similar situation in the future. Georgia discussed her interaction with a student: "I also, could have had him do an extension problem with harder numbers to be able to observe his thinking with more difficult numbers." Georgia's thought to pose an extension problem based on the interaction she had with the student is one example of how PTs considered responses as a result of the activity. Landon shared a similar consideration on based on his interaction with a student: "Instead of saying 'take away the smaller number form the bigger number', which is why he put the smaller number on top of the bigger number in his solution path, I could have said 'you have the bigger number and you want to take away the smaller number from it.' This could have prompted him to complete his solution path without any confusion." Landon reflects on his interaction with the student and how he could have responded differently to help the student better understand the problem. Lawson provided an example of responding using student thinking: "Next I decided that in order to help my next student through the problems that I would need to provide my student opportunities to work with 2 digit numbers if they struggled with 3 digit numbers like my first student did. I also would give my student opportunities to work with 1 digit numbers as well if they needed to." Lawson discusses his responses during the interaction with the student and his goal of helping the student when he or she was stuck or struggling.

Code 4 – The Importance of "Unpacking" a Task for Students

Preservice teachers often discussed the concept of unpacking the problem for their student before allowing the student to explore the problem. The unpacking theme was discovered after many preservice teachers reflected on their interactions with the students. For instance, Haley discussed her goal of unpacking the problem: "Unpacking the problem is one thing that I could have done significantly better - making sure the students understood what the story was about and then the method used to solve it. I worked with two students and found that one was on a much higher math level than the other student causing me to work and speak toward the upper level student in the beginning and the lower student as we began working. When I saw that the higher student understood the problem I was quick to move on without checking the lower students understanding. Although I moved on from unpacking the story quickly I think that both could have benefitted from a more in-depth explanation." Eloise provided an example of her goal of unpacking the problem for her student: "Lastly, I want to work on 'unpacking the problem' more. I think it's beneficial for students because it really sets them up correctly for the problem and gives them the most help to complete the problem." There were 58 instances of PT's commenting on unpacking problems for students.

Code 5 - Evaluating or Labeling Students Based on Minimal Evidence

Preservice teachers also had a tendency to evaluate or label students after a minimal time of working with the student. There were several instances where preservice teachers broadly evaluated a student based on minimum experience. For example, Anna wrote, "I would classify Landon as an above average math student who understands most concepts but gets through problems by going through the motions and performing the standard algorithm." Anna had minimal experience working with Landon, but was quick to classify him as an above average math student based off of a small observation. Margaret evaluated her student after working through a few problems: "I think one of the reasons for this was the fact that my student was very smart and she knew how to do all of the problems, and she for the most part solved them all correctly on the first try." There were 16 instances where preservice teachers worked with their student on a problem and then labeled the student based off their ability of a single interaction.

Discussion and Implications

As we examine PTs' experiences with the ESST activity, we can draw several conclusions about the design of the activity and its potential to foster the types of outcomes suggested by the literature. As presently constituted the ESST activity did not seem to afford PTs the opportunity to develop KCS. Perhaps extending the activity beyond two sessions and utilizing a variety of different problems would be necessary in order to support this development. The activity did seem to provide opportunity for PTs to consider their role of listening to and supporting student thinking as well as to provide opportunity for reflection on the ways in which they did and might respond to students. The additional themes of unpacking and labeling students imply these are areas of our course we need to pay explicit attention to prior to our PTs working with students. The continuing cycle of scholarly inquiry and practice will allow us to further refine and empirically examine this activity.

SEEKING THE INFLUENCE OF COONEY, SHEALY, AND ARVOLD'S (1998) BELIEF STRUCTURES

Carlos Nicolas Gomez

AnnaMarie Conner
University of Georgia
aconner@uga.edu

Cooney, Shealy, and Arvold (1998) wrote a widely-cited paper that described four belief structures of prospective teachers and argued the structures can aid in describing the ways beliefs change and the influence of authority on the individual. In this paper, we investigate the impact of this manuscript on the field. We first conducted a literature review (n = 48) of journal articles and proceedings published since 1998 covering the same population and goals of Cooney et al. (changing prospective teachers' beliefs). We then conducted an analysis of 106 journal articles citing Cooney et al. to see why the author(s) cited the piece. We conclude the impact of Cooney, et al.'s article differs from that of their results and suggest belief structures should be more carefully investigated by the field.

Keywords: Teacher Beliefs, Affect, Emotion, Beliefs, and Attitudes

There is a long history of studies focusing on the beliefs about mathematics and mathematics teaching and learning of students, prospective teachers, and inservice teachers (Philipp, 2007). These studies have argued that being informed about the beliefs of these populations is helpful in designing appropriate interventions for shifting beliefs (Philipp et al., 2007) and evaluating the success of a teacher preparation program (Charalambous, Panaoura, & Philippou, 2009). Cooney, Shealy, and Arvold (1998) sought to understand the development of and opportunities to change prospective teachers' beliefs and the structure of their beliefs. Cooney et al. (1998) concluded with four belief structures: isolationist, naïve idealist, naïve connectionist, and reflective connectionist. Each of these described the ways the beliefs of the individual were held and could help in explaining the changes in beliefs of the individuals. "We posit the notions of naïve idealist, isolationist, and connectionist with the intent that a description of preservice teachers can enhance our understanding of the ways preservice teachers construct meanings as they progress through their teacher education programs" (Cooney et al., 1998, p. 331).

Although Cooney et al. (1998) is cited frequently in the field (382 times according to Google Scholar as of Jan. 2, 2017), we could not find many studies that used their belief structures as an explanatory tool to shifts in beliefs. Studies have shown the strength of using Cooney el al.'s belief structures: "One of the strengths of the Cooney et al. construct of belief structures is its explanatory power with respect to propensity to change and success in changing" (Conner, Edenfield, Gleason, & Ersoz, 2011, p. 501) We investigated the influence of Cooney et al.'s belief structures by reviewing literature with the same focus, changing beliefs of preservice teachers, and the ways Cooney et al. has been referenced since its publication. We provide a summary of Cooney et al.'s report followed by the methods used to investigate the influence of the article. We then present our results of both investigations and conclude by discussing future research trajectories and issues to be addressed by mathematics education researchers.

Background: Summary of Cooney, Shealy, and Arvold (1998)

Cooney et al. (1998) conceptualized their study through a constructivist perspective influenced by the cognitive and social construction of knowledge. They desired to the students in their secondary mathematics methods course to see themselves as participants in a community of mathematics educators. Cooney et al. used multiple theoretical frameworks to make sense of the beliefs of the prospective teachers. These frameworks helped them to consider the influence of context and reflection (Bauersfeld, 1988; Dewey, 1933), how beliefs are held (Green, 1971), and one's orientation to authority (Belenky, Clinchy, Goldberger, and Tarule, 1986; Perry, 1970). Bauersfeld (1988) provided a way to consider the sociocultural aspects within cognitive interactions with his description of how communities construct knowledge. This was important to Cooney et al.: "Because much of what an individual learns about teaching is through interactions within various communities, it seems reasonable to assume that those contexts are important influencing factors in what is learned" (1998, p. 307). Dewey (1933) aided in operationalizing reflection and how reflection influences the changes of beliefs because reflection is necessary to resolve problematic experiences. Green (1971) described the metaphor of a beliefs systems to emphasize how beliefs are held. He described three characteristics of a belief system: (a) There is a quasi-logical relationship between beliefs; (b) Beliefs are both peripheral or central and derivative or primary; and (c) Beliefs exist within clusters that are isolated from one another (thereby allowing the possibility of an individual having contradictory beliefs). Finally, Belenky et al. (1986) and Perry (1970) were "two schemes that address one's reliance on authority for knowing… These two schemes are similar in that they describe individuals who range from those for whom an authority dictates truth to those for whom truth is seen as contextual" (Cooney et al., 1998, p. 311). To Cooney and colleagues these frameworks collectively provided a way for them to investigate the beliefs about mathematics and mathematics teaching and learning of prospective teachers and gave new insight into the ways prospective teacher hold their beliefs.

Cooney et al. (1998) purposefully selected four participants from a cohort of 15 prospective secondary mathematics teachers. The cohort was in the final year of the teacher preparation program and all students were enrolled in a mathematics methods course. The participants were selected based on survey results as well as observations and assignments completed in the methods course. Each participant was interviewed 5 times during the course and student teaching, and Cooney et al. used a constant comparison procedure (Strauss, 1987) to identify themes that emerged from the data. They reported on four cases.

Based on the four cases, Cooney and colleagues described four possible belief structures: naïve idealist (characterized by uncritical acceptance of ideas presented by authority figures resulting in clusters of contradictory beliefs), isolationist (belief are held strongly and nonevidentially so contradictory ideas are rejected without reflection), and naïve or reflective connectionist (characterized by attempts to incorporate new ideas meaningfully into already present belief structure more or less critically and coherently). Cooney and colleagues end the paper with comments on the importance of considering belief structures in teacher education. "An analysis of belief structures… can provide a forum by which our teacher education programs will be better able to address issues of reform" (Cooney et al., 1998, p. 331). Cooney et al. claimed the goal of teacher education is to develop reflective connectionists, though they admit to having difficulty imagining how to do so with isolationists and naïve idealists. They call for future research to investigate these possible shifts. Based on Cooney et al.'s call to action, we sought to see how researchers had responded after 18 years.

Methodology

We set out to explore the ways Cooney et al. (1998) may have influenced the field. The first exploration entailed conducting a literature review of studies published from 1999 to 2016 with a similar focus as Cooney et al.'s investigation, changing beliefs of prospective teachers. We began by conducting searches in both ERIC and EBSCO using the words beliefs, preservice teacher, change, and mathematics, focusing on peer-reviewed hits. The initial search had over 700 hits. As we began to look through the 700 publications, we realized many of the pieces found did not match our criteria but instead had within the article the searched for words. To aid in focusing specifically on studies about beliefs, we choose to change the search criteria. The second time, we searched both ERIC and EBSCO databases for manuscripts with belief in the title, and including the words preservice, mathematics, and change anywhere in the text from 1999 to 2016. We repeated the searches replacing belief with conceptions and then orientation as we found these words could potentially be synonymous with beliefs. Finally, we repeated the previously mentioned searches in both databases, replacing preservice with prospective. After duplicates were removed, we had 86 peer-reviewed journal articles and proceedings. For this first part the publication was the unit of analysis. In a spreadsheet, we collected information from each publication such as: (a) author; (b) title; (c) abstract; (d) intervention described to change beliefs; (e) beliefs attempting to influence; (f) grade band of prospective teachers; and (g) did they cite Cooney et al. and if yes, then did they use belief structures as an explanatory tool. As we read through the 86 publications we found only 48 pieces fit the search criteria (empirical studies about prospective mathematics teachers' shift in beliefs). Those excluded either focused on the wrong population (e.g. students in mathematics content courses, prospective science teachers, etc.), wrong phenomenon (e.g. content knowledge) or were not empirical.

The second investigation required us to do a citation analysis similar to Leatham and Winiecke's (2014). Using a Google Scholar citation report for Cooney et al. (1998), of the 382 citations listed, we located 106 peer-reviewed English language articles. We then sought out in each article the line of text or statement that was a direct citation to Cooney et al. (1998). Four articles did not have proper citations and were excluded. For this part of the investigation, the unit of analysis was the citation instance in each article (n = 142). We used a constant comparative method (Strauss, 1987) to identify categories of the purposes of citing Cooney et al.

Results

The results of our investigation are reported in two parts. The first part focuses on the 48 manuscripts in which the authors investigated aspects of beliefs similar to Cooney et al.'s (1998) study. We then report on the citation analysis conducted. Overall, Cooney et al.'s construct of belief structures has minimally been used in the field. Two of the 102 manuscripts examined used belief structures as an explanatory mechanism for the change in beliefs of the participants. The citation analysis revealed the purpose of citing Cooney et al. (1998) was to justify claims of the impact of beliefs on teacher perspectives or practices, statements about the influences on beliefs and the difficulty in changing them or to describe how beliefs are held.

Nature of the 48 Publications on Changing Beliefs of Prospective Mathematics Teachers

Cooney et al. (1998) was focused on changing prospective mathematics teachers' beliefs about mathematics and mathematics teaching and learning. The majority of the studies (n = 29) were focused on changing the same beliefs. A number of studies, however, focused on other kinds of influential beliefs, for example, teacher efficacy, epistemological beliefs, the incorporation of a concept, skill, or philosophy (e.g. social justice), and others on specific mathematical constructs (e.g. proof). Table 1 enumerates foci of the beliefs publications. Some publications considered multiple beliefs categories, such as Charalambous et al. (2009) who investigated the change of epistemological and efficacy beliefs of prospective elementary teachers, thus the total number of pieces in the table is greater than 48.

Table 1: Foci of Beliefs Publications

Focus	# of Pieces
Mathematics, Mathematics Teaching and Learning	29
Teacher Efficacy	8
Epistemological Beliefs about Mathematics	4
Technology Use in Mathematics Education	4
Equity/Social Justice Issues in the Mathematics Classroom	3
Proof	2
Confidence in Teaching Mathematics	2
Mathematics Teaching Incorporating Arts	1
STEM Incorporation	1
The Role of Teachers and the Learners	1
Mathematical Knowledge	1

A number of studies used beliefs to evaluate their teacher education programs (e.g. Charalambous et al., 2009). The shift of prospective teachers' beliefs toward more reform-oriented (NCTM, 2014) beliefs provided evidence of success of the content, methods, or general program. This was true for both studies focused on beliefs about mathematics and mathematics teaching and learning, and those focused on teacher efficacy and epistemology. Cooney et al. did not explicitly seek out to evaluate the teacher education program or course in which the prospective teachers were enrolled. Their focus was on the beliefs about mathematics and mathematics teaching and learning. This matched the majority of studies found.

Cooney et al. (1998) did not examine the influence of a particular intervention. Instead, the intervention was more implicit as the catalyst to change beliefs was the teacher education program itself. This can be seen as a macro level intervention because the planned intervention was at the group level. This matched the majority of the studies on prospective teachers. Table 2 lists the categories of interventions used in the 48 publications. Some studies (Philipp et al., 2007) used multiple interventions in different sections of a mathematics methods course for prospective elementary teachers. Each intervention in these cases was counted separately.

Most interventions were more at a macro level or did not intervene at an individual level. The intervention was the teacher education program or course (n = 13), a course or program with a specific philosophy informing the make-up of the course or program (n = 14), or the inclusion of a field component (n = 5). These interventions are not guided towards individuals but instead at the group of individuals. This is different from more micro or individualistic interventions like specific activities conducted in the course (n = 11), or the addition of a technology component (n = 5). These interventions were targeted to individuals to participate in the intervention. A few studies combined both micro and macro level interventions (Philipp et al., 2007).

Finally, Table 3 shows some other characteristics of the 48 publications. Out of the 48 pieces about changing beliefs of prospective mathematics teachers, the majority of the studies focused on elementary teachers (n = 38). Only three studies focused on secondary mathematics teachers, while the remaining seven had a combination of secondary and elementary teachers. The lack of secondary investigations could potentially be due to the methods used to investigate beliefs. Quantitative studies (n = 25) along with heavily quantitative mixed studies (n = 6) represented about 65% of the publications. The use of quantitative methods requires a large number of participants. Secondary mathematics programs typically have fewer students than elementary teacher preparation programs. Additionally, research has shown prospective elementary teacher programs have a high percentage of students with negative dispositions towards mathematics (Szydlik, Szydlik, & Benson, 2003). Therefore, changing beliefs of prospective elementary teachers may seem more relevant to producing reform-oriented mathematics teachers.

Table 2: Interventions Used to Change Prospective Teachers' Beliefs

Type of Intervention (Micro/Macro)	Description of Intervention	# of Pieces
Philosophy Informing Course/Program (Macro)	Describes a theory, construct, or philosophy guiding the structure, activity, and/or goals of the course	14
Teacher Education Program (Macro)	Goal is to evaluate or see the changes incurred by the current teacher education program or course.	13
Specific Activity (Micro)	Describes a specific activity or intervention (observations during field placement, or pedagogical activity) as catalyst for change.	11
Field Component (Macro)	The addition of a field component to course	5
Technology Component (Micro)	The addition of a technological tool to the course (e.g. use of wikis, online discussion boards; online workshops)	5
Program Addition (Micro)	The addition of activities outside of courses (mentoring by experts, monthly seminar, small discussion groups, etc.)	2
Student Teaching (Macro)	Goal is to evaluate or describe the changes incurred by the student teaching experience.	2

Table 3: Characteristics of Manuscripts by Grade Level Focus of Participants

	Elementary	Secondary	Elementary & Middle	Elementary & Secondary	Not Specified
Qualitative	13	2	0	2	0
Quantitative	20	1	1	1	2
Mixed	5	0	0	1	0
Cited Cooney et al. (1998)	7	2	0	0	0
Used Belief Structures for Analysis	1	1	0	0	0

Of the 48 publications, only nine cited Cooney et al. (1998), although all publications were reporting on similar populations and phenomena. Of those nine, two studies (Conner et al., 2011; Mewborn, 2000) used belief structures as described by Cooney et al. This demonstrates the construct of beliefs structures has not been taken up by the field, at least when investigating similar phenomena. Cooney et al.'s study required multiple sources of data and deep qualitative investigation. Most of the studies found were quantitative in nature and therefore would not have the data necessary to use belief structures. If only 9 of the 48 publications cited Cooney et al., then what explains the 382 publications found in the Google Scholar citation report? This finding led us to conduct the citation analysis described below.

Nature of the 102 Publications Citing Cooney et al. (1998)

Following Leatham and Winiecke (2014), we conducted an analysis of the 142 citation instances collected from 102 journal articles. Using a constant comparative method (Strauss, 1987), we found eight categories reflecting the reasons Cooney et al. (1998) has been cited. In this section we briefly describe each category and provide examples. These categories represent the impact Cooney et al. has had on the field. Table 4 summarizes the primary purposes for citing Cooney et al.

Table 4: Summary of the Primary Reasons for Citing Cooney Et Al. (1998)

Reason Cited	Percent (n)
Impact of beliefs on perspective or practice of teachers	25% (n=35)
Influences on beliefs and difficulty in changing them	18% (n=25)
How beliefs are held	13% (n=18)
No mention of beliefs (content knowledge, role of teacher education, etc.)	12% (n=17)
Casual citation (no specific content of article referenced)	11% (n=15)
Potential of reflection	8% (n=12)
Methodology	8% (n=11)
Different types of beliefs exist	6% (n=9)

The most common reason for citing Cooney et al. (1998) (35 or 25%) was to support claims about the ways beliefs influence teachers' perspectives or classroom practice. These included descriptions of the general relationship between beliefs and practice and the way beliefs act like a filter when making sense of a situation. Furthermore, some publications used Cooney et al. to highlight how beliefs influence certain actions in the classroom. For example, Philipp et al. (2007) stated: "Beliefs might be thought of as dispositions toward action, having a motivational force (Cooney et al., 1998…)" (p. 450). Although, Cooney et al. discussed the impact of beliefs on teachers, the focus of their study was not on these relationships. They conjectured how beliefs structures may influence the actions of the prospective teachers, but the relationship between practice and beliefs was part of the rationale for the study.

Researchers also cited Cooney et al. (1998) to describe experiences influencing the development of beliefs of teachers (25 or 18%). Claims included the impact of context on beliefs and how the background of the individual impacts beliefs about mathematics and mathematics teaching and learning. "Beliefs tend to be context specific, arising in situations with specific features (Cooney et al., 1998)" (Philipp et al., 2007, p. 450). As before, Cooney et al. justified their work based on these conceptualizations of beliefs; these statements were not part of their results.

The next largest group of statements described how beliefs are held (18 or 13%). This is the group that is closest to the main focus of Cooney et al.'s (1998) study. Cooney and colleagues were interested in how beliefs are structured and how those structures influence prospective teachers' beliefs about mathematics and mathematics teaching and learning. These statements focused on the use of Green's (1971) metaphor of belief systems, the use of Perry's (1970) discussion about authority and knowing, and in-depth descriptions of belief structures. Discussions of Green and Perry were included in Cooney et al.'s theoretical framework, while in-depth descriptions of belief structures comprised their findings.

The next two groups cited Cooney et al. (1998), but they made no specific link to the conducted research. The category of no mention of beliefs was made up of a collection of statements that cited suggestions or other aspects of teacher education Cooney refers too. For example, Conner et al. (2011) stated: "Cooney et al. (1998) suggest that one goal of teacher education is to help teachers become reflective connectionists" (p. 500). Many of these statements were used to back up claims about the role of teacher education, characteristics of teachers, or prospective teachers' mathematical content knowledge. The collection of casual citations (15 or 11%) cited Cooney et al. in a generic way: "Many studies have been designed to bring about changes in the conceptions of preservice and inservice teachers (e.g. Cooney, Shealy & Arvold, 1998…)" (Steele, 2001, p. 140).

Cooney et al. (1998) emphasized the importance of reflection as a way to change beliefs of prospective teachers, and this was highlighted by a number of publications (12 or 8%). Cooney et al.'s argument about reflection followed their conceptualization of beliefs and how beliefs are held. The claims made focused on the power of reflection to change beliefs or the importance of reflection in teacher education. Philipp et al. (2007) highlighted Cooney et al.'s study to stress the importance of reflection, "Researchers studying teacher education have added to our understanding of the role that reflection plays in teacher education. Cooney et al. (1998) found that…" (p. 471). Many of the researchers built on Cooney et al.'s conceptualization of reflection's role in changing beliefs.

The final two categories cited Cooney et al. (1998), usually in a list of other researchers, either to justify or describe the chosen methods (11 or 8%) or to emphasize the existence of different kinds of beliefs (9 or 6%). Though these are valuable contributions, neither of these reasons for citing Cooney et al. are explicitly about the results of the study.

Discussion and Conclusion

Our results show Cooney et al. (1998), although widely cited, has not significantly impacted research on changing beliefs. The most common reasons to cite Cooney et al. demonstrate the usefulness of Cooney et al.' conceptualization of beliefs and beliefs change. Cooney et al.'s belief structures, however, are minimally considered by those in the field. Only two publications (Conner et al., 2011; Mewborn, 2000) that cited Cooney et al. explicitly used belief structures as an analytical tool. A slightly bigger impact was shown by the 18 citation statements (from 14 publications) that discussed how beliefs are held. We considered statements about how beliefs change to be potentially referencing ideas close to Cooney et al.'s belief structures. The remaining 124 citations cited Cooney et al. without reference to their major results. These researchers cited Cooney et al.'s theories and interpretations of other researchers, often without clarifying their intention, rather than citing the theory resulting from the empirical results of the study. We found this to be problematic. Depending on the citation statement, Cooney et al. could be seen as either a study about the relationship between beliefs and practice, a study about prospective teachers' content knowledge, or a study about the role of teacher education.

Cooney et al.'s conceptualization of belief structures and the studies that explicitly use beliefs structures suggest more focus on beliefs structures could be a powerful direction for future research. Our review of 48 peer-reviewed publications addressing beliefs change in prospective teachers demonstrated that trends in research on changing prospective teachers' beliefs aligns with Cooney et al.'s (1998) chosen intervention and focus on beliefs about mathematics and mathematics teaching and learning. Studies examining beliefs and beliefs change have established that while change is slow, it can happen. However, little is known about why and how beliefs change. That is, researchers have established that reflection and particular interventions within coursework and field experiences can promote change, but little is known about the mechanisms for that change. Cooney et al.'s beliefs structures potentially provide insight into those mechanisms for change. The use of beliefs structures as an analytical tool could move forward beliefs research by providing a deeper understanding of how beliefs shift over time. This will require the development of instruments and possible ways of collecting more pointed data for identifying the belief structures of teachers. Furthermore, specific interventions for different belief structures need to be developed if the goal of teacher education, as stated by Cooney et al., is to develop reflective connectionists.

Most teacher preparation programs require prospective teachers (PTs) to engage in early field experiences (EFEs) prior to completing required coursework. These EFEs, however, may lack meaningful connections to course content and provide limited opportunities to experience the demands of classroom teaching. In this paper, we share evidence from the implementation of a novel kind of EFE, the "University Teaching Experience" (UTE) model, where secondary mathematics PTs receive mentoring from teacher educators (TEs) as they teach in a undergraduate mathematics course Findings reveal the importance of both guidance from TEs and observations of peer teaching for PTs learning in EFEs.

Keywords: Teacher Education-Preservice

Field experience is an essential part of teacher preparation (Dewey, 1938; Zeichner, 2010). While all certification programs require PTs to complete a capstone field experience (typically called "student teaching"), *early* field experiences (EFEs) emerged around the time of laboratory schools with the premise that PTs should have opportunities to work in K-12 classrooms before and/or during their professional coursework to ground their understanding of pedagogical theory with practice (Dewey, 1938). Typical EFEs involve PTs in observing students in classroom environments during or conducting short episodes of instruction (Cruickshank & Metcalf, 1993).

Recent research indicates that the quality of field experiences matters; having more field experience in a teacher preparation program does not necessarily lead to better prepared PTs (Ronfeldt & Reininger, 2012). Current opportunities for PTs to gain teaching experience each have specific limitations. PTs that only observe in K-12 classrooms for their EFE have limited access to understanding the scope of teaching. Activities like microteaching segments of lessons with peers in a methods course may offer better opportunities for PTs to practice innovative methods than simply observing, as they can receive feedback from a university-based teacher educator. Microteaching is limited, however, in that teaching to one's peers is inherently an artificial instructional situation. School-based EFEs where PTs are engaged in instruction provide authentic opportunities for learning about the complexity of teaching in school settings. However, research documents a disconnect between what PTs see and experience in K-12 classrooms and what they learn about effective teaching in on-campus methods courses (Allsopp, DeMarie, Alvarez-McHatton & Doone, 2006; Zeichner, 2010). Additionally, school-based EFEs can involve some risk for the mentor teacher if the mentor teacher's performance evaluations are based on value-added measures, not to mention risk for students' learning.

In this paper, we report results from the implementation of a novel type of EFE that addresses some of the typical shortcomings of early field experiences in its design. The University Teaching Experience (UTE) model involves an undergraduate remedial, or non-credit, algebra course as a site for an EFE. The UTE model entails four components. One component (inquiry-oriented curriculum and task design) involves mathematics teacher educators (MTEs) as the methods course instructors collaborating with mathematics faculty responsible for the remedial mathematics course curriculum to design curricular sequences for the course that feature tasks (individual or series of problems) requiring a high level of cognitive demand (Stein, Grover & Henningsen, 1996). A second component (plan and implement) features PTs planning and teaching lessons in the remedial mathematics class while enrolled in their initial mathematics pedagogy course (hereafter referred to as the "methods course"). A third component of the UTE is the mentoring that is provided by MTEs during the planning, implementation, and reflection stages of lead PTs' teaching in the developmental mathematics course. The MTEs include the faculty course instructor and graduate assistants with secondary mathematics teaching background. The MTEs also model teaching practices and provide in-the-moment coaching, if needed, during PTs' teaching episodes. Finally, MTEs orchestrate a debrief discussion after the lesson with the lead PTs for each lesson and their peer PT observers to discuss the development of mathematics students' thinking and react to the decision making of the lead PTs. In addition, the debrief discussion offers an opportunity for PTs preparing to teach subsequent lessons to rehearse the beginning, or task set-up, phase of the lesson prior to actual enactment in the developmental mathematics course.

Initial research during the early-stage implementation of the UTE model established the viability of the model for ensuring an effective learning experience for the undergraduate students enrolled in the remedial mathematics course (Bieda, Wolf & McCrory, 2013; Bieda, McCrory & Wolf, 2014). The second phase of the project attended to the viability of this kind of EFE for PTs' learning. In this phase, we analyzed data from several sources to address the following research questions: *To what extent does the UTE support the development of PTs' planning for attending to student thinking as evidenced in their written lesson plans for UTE lessons? To what extent do PTs teach in the remedial math course in ways consistent with the methods and strategies to promote mathematical proficiency, (i.e.,* recognizing and building on students' prior knowledge, anticipating and responding to student thinking, selecting and sequencing students responses to achieve specific mathematical goals, pressing for justification and explanation, and maintaining a high level of cognitive demand during task enactment)? *Finally, how do PTs evaluate the opportunities to learn in the UTE and how do they compare those experiences to their work in a school-based placement during the second semester?*

Theoretical Framework

We use *transformative learning theory* (Mezirow, 1997) as a frame for thinking about how PTs' knowledge about teaching develops through their interactions with activities and experiences in their teacher preparation program. According to Mezirow, transformative learning is the "process of effecting change in a *frame of reference*" (p. 5; italics in original). PTs' frames of reference with regards to teaching practice are composed of both *habits of mind* and a *point of view* (Mezirow, 1997). *Habits of mind* are "broad, abstract, orienting, habitual ways of thinking…" (Mezirow, 1997, p. 5) that are informed by the years of experience PTs have as students in classrooms (Lortie, 1975); by participating in the norms of school as students, PTs have absorbed a "set of codes" (Mezirow, 1997, p.6) that frame their understanding of what teachers do and what they did, as students of mathematics, in response. Similarly, Cuoco, Goldenberg and Mark (1996) talk about *mathematical habits of mind* as the "methods by which mathematics is created and techniques used by [mathematical] researchers" (p. 376) and, as such, are the ways that mathematicians think when solving problems.

Mezirow (1997) argues that points of view are responsive to feedback and shift as we reflect on the outcomes of our actions in the environment. A person's point of view can shift whenever we try to make sense of why something has happened in a way we did not anticipate (Mezirow, 1997). This is precisely the state of novice teaching at the K-12 level; by trying out teaching practices in authentic settings, teachers get feedback in the form of students' responses that they can compare to their assumptions about what they intended to happen. Their reflection upon this experience can change their points of view on what it takes to achieve the kind of learning outcomes they are intending.

Hence, the feedback that PTs receive from a teaching experience - both intrinsically as they react to the setting in the moment and extrinsically as they receive feedback from a mentor or peer – is critical to changing their point of view. Yet the kind of feedback they receive is largely dependent upon the context in which they teach. For example, in a microteaching setting involving teaching to one's peers, PTs are more likely to accurately anticipate the outcome of their teaching moves, and, thus, the intrinsic feedback will be affirmative. Thus, if mathematics teacher educators want to shift PTs' points of view on what it takes to teach in ambitious ways for all learners (Lampert, Boerst & Graziani, 2011), we need to ensure that the context in which they practice ambitious teaching offers an opportunity to get feedback that is representative of the kind of student responses they would receive in K-12 instructional settings.

The emerging research on rehearsals, where PTs rehearse scripted teaching moves in short instructional episodes (Kazemi, Ghousseini, Cunard & Turrou, 2015; Kazemi, Franke & Lampert, 2009; Lampert, Franke, Kazemi, Ghousseini, Turrou, Beasley, Cunard & Crowe, 2013), is moving the field forward in developing teacher education that helps PTs to enact particular teaching practices. Our claim is that the UTE model, like rehearsals, offer PTs an opportunity to ground their learning of how to do particular teaching practices, but in a setting that helps them develop an understanding of what it will take to carry out those practices in live classrooms. A key driver for this situated understanding is the involvement of mathematics teacher educators in providing ongoing instructional support to the PTs in the UTE. Although this support may be more involved than what PTs would normally receive from a mentor teacher in a school-based placement, it is critical support at this stage in their preparation to help them to reflect upon their instructional decision making as they grapple with multiple competing obligations.

Methods

Participants were 19 PTs enrolled in their first semester-long course on mathematics pedagogy (Methods I) in a large teacher preparation program at a Midwestern University. The Methods I course included a three-hour seminar meeting per week, a four-hour school-based placement experience per week, and a two-hour commitment to participating in the UTE per week. Each PT co-taught a lesson in the UTE twice during the course of the semester. Prior to UTE teaching, each pair received a packet with tasks to be completed during the lesson. Then, each pair submitted three drafts of their lesson plan: (1) initial draft completed using the Thinking through a Lesson Protocol (Smith, Bill & Hughes, 2008); (2) revised draft based on feedback from MTE a week before teaching; and (3) revised draft after teaching the lesson in the UTE. To address the research questions, we collected video-recordings of PTs' teaching in the UTE, along with the lesson plan drafts they completed related to their UTE teaching. The results we share in this paper focus on analyses of the first and revised drafts of the lesson plan. We also conducted semi-structured interviews with 11 PTs, who volunteered to be interviewed from the larger sample of 24 PTs, to learn about their perceptions of the value of the UTE for their learning to teach, as well as their reflections on its affordances and constraints as compared to their school-based placement experience. Additional information about the analyses of these data sources will be presented in the Results section.

Results

We will present the results in three parts, with each part corresponding to one of our three research questions: (1) *To what extent does the UTE support the development of PTs' planning for attending to student thinking as evidenced in their written lesson plans for UTE lessons?* (2) *To what* *extent do PTs teach in the remedial math course in ways consistent with the methods and strategies to promote mathematical proficiency?* and (3) *How do PTs evaluate the opportunities to learn in the UTE and how do they compare those experiences to their work in a school-based placement during the second semester?*

Quality of PTs' Teaching in the UTE

To assess the overall quality of PTs' instruction with respect to promoting mathematical proficiency, we rated the video-recorded observations using the Instructional Quality Assessment (IQA, Boston, 2012) across two dimensions: Implementation of the Task and Student Discussion Following the Task. The rating scale for the Implementation of the Task dimension is based on the levels of cognitive demand (Stein, Grover & Henningsen, 1996), with ratings from 0 to 4 where a 4 rating indicates that:

> "Students engaged in exploring and understanding the nature of mathematical concepts, procedures, and/or relationships, such as: Doing mathematics: using complex and non-algorithmic thinking (i.e., there is not a predictable, well-rehearsed approach or pathway explicitly suggested by the task, task instructions, or a worked-out example); OR Procedures with connections: applying a broad general procedure that remains closely connected to mathematical concepts." (Boston, 2012, pg. 9)

The Student Discussion Following the Task rubric complements the Implementation of the Task rubric by focusing in on the question: "To what extent did students show their work and explain their thinking about the important mathematical content?" (Boston, 2012, p.10). Similarly to the Implementation of the Task rubric, the scale ranges from 0 to 4 with a Level 4 rating indicating:

> "Students show/describe written work for solving a task and/or engage in a discussion of the important mathematical ideas in the task. During the discussion, students provide complete and thorough explanations of why their strategy, idea, or procedure is valid; students explain why their strategy works and/or is appropriate for the problem; students make connections to the underlying mathematical ideas (e.g., "I divided because we needed equal groups"). OR Students show/discuss more than one strategy or representation for solving the task, provide explanations of why the different strategies/representations were used to solve the task, *and/or make connections between strategies or representations."* (Boston, 2012, p. 10)

Raters were trained to use the IQA rubric prior to rating, and achieved an inter-rater reliability in their scoring (within .5 rating points) of 95% on a sample of 5 lessons of 17 total lessons collected. The rating rubric follows a scale from 1-4, without half-point increments. As there were 19 PTs, there were a total of 8 pairs and one team of 3 PTs. Because some pairs were reorganized during the second round of UTE teaching, we selected only the first and second UTE teaching episodes that were taught by the same pairs of students each time. Thus, a total of 6 pairs of teaching episodes, or 12 total lessons, were analyzed for these results.

Table 1: Aggregated Mean IQA Rating

	Pair 1	Pair 2	Pair 3	Pair 4	Pair 5	Pair 6
First UTE	2	3.5	4	2	2	4
Second UTE	4	3	3.5	2.5	2	3

Table 1 provides the aggregated mean scores for each episode, combining ratings for Implementation of the Task and Student Discussion Following the Task. The aggregated score is appropriate as no episode had a difference greater than 1 point in the ratings for each dimension. The table shows two findings of interest. First, for the majority of episodes, PTs' instruction rated at least at a level of 3, indicative of teaching that promotes some level of conceptual understanding. Second, there are no significant patterns in the ratings from the first UTE to the second UTE observation. While two of the pairs improved in their aggregate scores, four pairs either remained the same or received lower ratings.

Growth in PTs' Planning to Attend to Student Thinking

Given that the likelihood of PTs' teaching significantly improving over the course of several weeks during the semester is low, we also analyzed PTs' lesson plan drafts for their first and second UTE teaching to determine whether specific lesson planning practices were improving as a result of the UTE mentoring. We focused our analysis on how PTs planned to attend and respond to student thinking as evidenced in their lesson plan drafts. Table 2 provides the coding scheme we developed from an iterative coding process (Strauss & Corbin, 1998) as well as examples for each of the codes. Two researchers coded a sample of lesson plan drafts for IRR. The agreement of what was to be coded from the lesson plans was 89%, whereas agreement regarding the assignment of the categories reached 65%.

After category codes were assigned to the text, the text was also scored for quality using a 4-point rubric (0 = is not mentioned; 1 = vague/generic, 2 = somewhat specific, and 3 = mathematically specific). We used three values to summarize the data. The *total quantity* was determined by counting the total number of coded instances. The *total quality* was calculated by adding the individual scores of codes. The *quality average* was computed by dividing the quality total for the lesson by the quantity to get an "average" response across all instances. In this paper, we focus on reporting the quality average.

Table 2: Categories Coded in Lesson Plan Drafts

Category	Example text from a PT Lesson Plan
Predictions of students' mathematical thinking	*seeing them write f(x)=???? will be how I know they're putting the pieces together*
Students' mathematical talk	*hearing students talk about inputs of functions and outputs of functions related to my, or their, examples*
Questions students might ask	*students may ask how these extraneous solutions affect the equation's graph*
Student misconception/difficulty	*students may not realize that 'consecutive odd integers' means that the unknown has to be defined as x and x+2*
Student prior knowledge	*students should be familiar and comfortable with the box method for factoring.*
Student learning outcomes	*I want students to walk away from this lesson looking at mathematical functions like they're operations and tasks rather than random grouping of numbers/letters/symbols*

Figure 1 below shows results in the form of average quality scores for the entire sample, across lesson plan drafts and disaggregated by category type. Across nearly all categories, quality scores increased from the first UTE to the second UTE teaching experience. And, not surprisingly, the final drafts for each UTE teaching (Lesson Plan 2 and 4, respectively) had higher quality instances of planning related to attending to student thinking than initial drafts (Lesson Plans 1 and 3). However, it is interesting to note that the quality of evidence linked to predictions of students' mathematical thinking and questions students might ask decreased, somewhat, from Lesson Plan 3 to Lesson Plan 4. This may have happened because, as the math became more challenging in the remedial class, PTs downgraded their expectations in the revised drafts based on experiences with students during the lesson enactment.

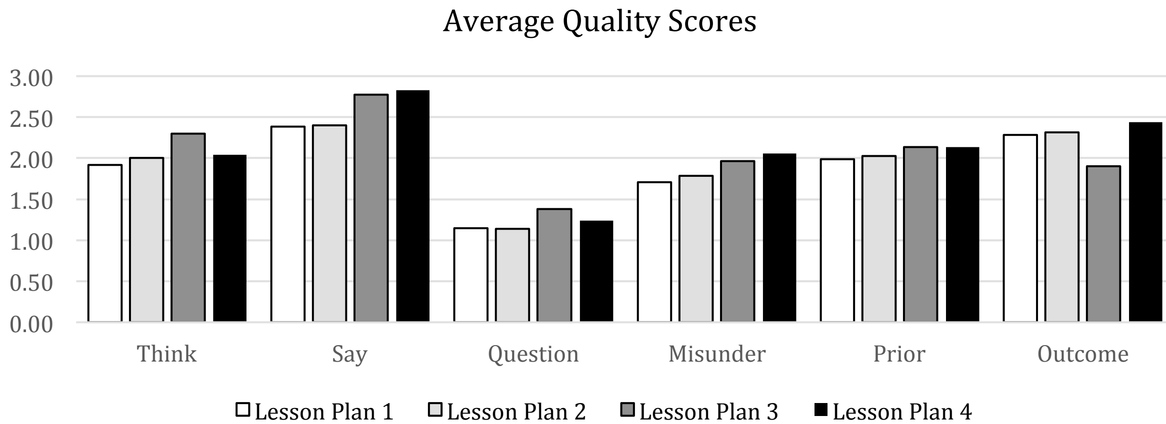

Figure 1. Average quality scores for each category across drafts.

PTs' Perceptions of Learning to Teach in the UTE

Finally, we share results from analyses of interviews with PTs who voluntarily agreed to participate in semi-structured interviews to learn more about their experiences in the UTE. We asked questions such as*: What aspects of the experience did you find useful? What did you learn from observing others teach and taking observation notes? Did the MTL experience influence your work in doing the slices of teaching and lesson studies in your placement classroom?* The interviews were audiorecorded and then transcribed. For select questions, the transcribed responses were coded at the phrase level to capture what participants stated they had learned from participating in the MTL experience (a "what" code) and for how participants stated they had learned these lessons (a "how" code). Using an iterative coding process following methods of grounded theory (Strauss & Corbin, 1998), four codes emerged for "what" was learned (teacher moves, comfort in the classroom, specific discussion strategies, and lesson planning) and four codes emerged for "how" those aspects of teaching were learned (UTE teaching, observing peers in UTE, lesson planning in UTE, peer feedback after UTE).

Not surprisingly, participants most commonly reported that doing teaching in the UTE was the most beneficial aspect for their learning to teach. But, when asked why they felt teaching in the UTE was beneficial, many acknowledged the importance of the support they received while teaching in the UTE. As one participant pointed out, the UTE allowed her to teach "with the guidance of someone there you know well enough to jump in and save you if needed." Another pointed out that working with undergraduate students allowed her to teach "real life students" that "aren't gonna fail if you mess up." However, this pointing to the supportive environment was not universal; other participants stated that they saw any teaching as beneficial to them, and the UTE was just another place to practice teaching, with no special emphasis on the environment. As one participant put it, "the benefit of UTE is getting some experience under you belt, um, kind of getting to know a little bit about yourself as a teacher."

The two most common aspects of teaching the PTs reported learning in UTE were comfort in the classroom and specific discussion strategies. Because teaching in the UTE was among the first teaching experience for most of the PTs, many reported that teaching in the UTE helped them gain some confidence in the classroom. PTs also reported learning how to facilitate whole-class discussions by implementing them while teaching in the UTE. This aspect was discussed as an affordance that the UTE provided that the school-based placement did not. As a PT stated: “in my placement class, um, I don’t think the teacher would have stepped in unless it was a real like, um, train wreck, I guess? Um, meanwhile [Kristen] or the TAs in the UTE would be willing to step in for smaller things, just like, hey, think about this, or whisper in our ears, hey, think about this.” Most of the participants reported similar positive gains in learning to implement discussion-based lessons from the help and support given by instructors during their teaching experiences in the UTE, including the modeling of discussion-based practices by the MTEs early in the semester. This opportunity in implement discussion-based instruction was especially valuable for participants who were later placed in classrooms with teachers who were resistant to using discussion-based instructional practices.

Finally, most PTs reported learning about teaching strategies from watching their peers in UTE, an affordance of the model that school-based placements are unable to offer. Of the 19 instances of participants reporting having learned some sort of teaching strategy, 15 reported learning them from peer feedback or from observation peers. Participants reported favorable on observing and being observed by peers primarily because of the various teaching skills they learned from each other. In looking at the times participants reported learning something from either observing peers or receiving peer feedback, there were only 2 out of the 17 combined instances that participants did not report learning teaching skills.

Concluding Remarks

Taken together, the analyses of data sources suggest that the UTE experience affords PTs with an opportunity to learn about the complexities of teaching in a supportive environment where they can attempt practices such as facilitating whole-class discussions. Findings from our analyses of the quality of PTs’ instruction show that, on average, the quality of instruction is often better than what the literature typically characterizes the nature of teaching in remedial, non-credit, mathematics courses (Larnell, 2016). While the observation ratings show that overall quality does not markedly improve for PTs over the course of the semester, the analysis of lesson planning artifacts reveals that PTs do improve over time in their preparation to attend to student thinking – a high-leverage teaching practice (NCTM, 2014).

Does the UTE model provide better opportunities for PTs to learn from, and within, teaching (Lampert, 2010) than school-based EFEs? Evidence from participants’ reflections about both EFEs in the interviews suggests that the curriculum of the UTE, the structure of the setting, and the mentoring provided by MTEs may provide better access for all PTs to engage in student-centered teaching practices such as leading whole-class discussions. Moreover, the PTs mentioned that opportunities to reflect on their peers’ instruction, which rarely happens in typical EFEs where PTs are placed one-on-one or as a pair with a mentor teacher, was an important aspect of their learning in the UTE. Although the design of this initial study into the effectiveness of the UTE model as a EFE cannot definitively address whether the UTE model provides better opportunities for learning about teaching practice than school-based EFEs, the evidence suggests it is a promising model that would benefit from wider implementation to assess its impact on PTs preparation for the challenges of teaching mathematics in school settings.

TOWARDS A HYPOTHETICAL LEARNING TRAJECTORY FOR QUESTIONING

We report on efforts to better understand the questioning practices used by preservice elementary teachers (PSTs), including the range of preferred question types and the values they invoke when evaluating their questions. We sought to determine whether teachers exhibited consistent patterns in selecting questions with certain features, such as funneling students to a particular strategy or eliciting student thinking, across different instructional situations. We found that such patterns did exist; in this paper we use the patterns to propose a trajectory for developing the skill of asking questions that elicit and build on student thinking. The trajectory describes the beliefs, values, and questioning practices associated with PSTs at each stage.

Keywords: Learning Trajectories (or Progressions), Teacher Education-Preservice

Introduction

Asking questions is central to the work of teaching. Yet research (e.g., Franke et al., 2009) has demonstrated that some questions are more likely than others to provide opportunities for students to make their thinking explicit. More research is needed to better understand how teachers might improve the types of questions they ask in the classroom. This study was conducted to learn more about ways to support preservice teachers (PSTs) in developing the skill of asking questions that elicit or build on students' thinking.

Theoretical Framework and Literature Review

We view knowledge for teaching as situated in the context of teaching (Borko et al., 2000), which means that it should be developed through experiences that approximate, to some extent, the practice of teaching (Grossman, Hammerness, & McDonald, 2009). Approximations of practice provide opportunities to learn through the decomposition of teaching into components, which can then be studied and practiced (Baldinger, Selling, & Virmani, 2016). The learning experiences described in this paper use cartoon representations of teaching, developed using the online program Lesson*Sketch*, that provide opportunities for PSTs to choose from specific pedagogical actions (that is, questions), see their (pre-established) impact, and then reflect on those choices (Herbst, Chazan, Chen, Chieu, & Weiss, 2011).

Although this project focuses on developing knowledge about teaching through action and reflection (Ball & Forzani, 2009), we also acknowledge the role of beliefs and values in influencing teachers' practice. In particular, values, which involve teachers' views about what is *important*, have particularly strong impact on teachers' decisions (Bishop, 2012). Efforts to influence the teaching practice of novices must acknowledge and contend with the incoming values of PSTs. In this paper, we explore some interactions between PSTs questioning practices and their stated values with regard to questioning in mathematics teaching.

Features of Questions

The National Council of Teachers of Mathematics' Principles to Actions (2014) advocates teacher questions that "build on, but do not take over or funnel, student thinking," and those that "make mathematical thinking visible" (p. 41). Other productive questioning practices include pressing for mathematical justifications, asking students to make explicit connections between different strategies, and probing errors (Kazemi & Stipek, 2001). These features are in contrast to questions that invalidate students' thinking or impose a way of thinking onto the students. For example, funneling questions are a sequence of closed questions intended to direct students through a series of procedural steps until they obtain the correct answer (Herbel-Eisenmann & Breyfogle, 2005; Wood, 1998). These questions reduce students' opportunities to build on their own understanding because the teacher ends up doing much of the cognitive work and the student merely answers with the expected response (Franke et al., 2009). Although these categories are helpful, more research is needed to articulate how novices improve their questioning practice and what their learning might look like as they transition from asking less productive to more productive questions.

Hypothetical Learning Trajectories

Hypothetical learning trajectories (HLTs) are constructed to represent a possible progression of student learning in a format that is useful for teachers and curriculum designers (Empson, 2011). While some researchers draw solely from existing literature to develop their HLT, others also use insights developed from the analysis of data collected in the first of two research phases (e.g., Meletiou-Mavrotheris & Paparistodemou, 2015). Our study aligns with the latter approach to developing HLTs. Once the HLT is developed, researchers then conduct multiple iterations of their experiment in order to refine their trajectory until it closely mirrors participants' actual progressions of learning (Cobb, Confrey, DiSessa, Lehrer, & Schauble, 2003). Complete HLTs consist of three main elements: "the learning goal, developmental progressions of thinking and learning, and sequence of instructional tasks." (Clements & Sarama, 2004, p. 84). In this study, we examined the patterns in features of questions selected by PSTs in response to student thinking across multiple Lesson*Sketch* experiences and sought to characterize these patterns in terms of a hypothetical learning trajectory. We will focus primarily on the first two elements of the HLT in this paper.

Methods

Participants were 86 elementary preservice teachers (PSTs) in their second of two method courses at a university in the Midwestern United States. Data consisted of PSTs' typed responses to prompts within five online Lesson*Sketch* experiences, two of which we classified as the pre and posttest. In this paper, we will focus on the last three experiences; namely, the Brandon and Cedric experiences and the posttest. In the pre and posttest, PSTs were initially presented with a mathematical task and one simulated student's solution to the provided task. PSTs composed and gave a rationale for a question they would like to ask the student (e.g., Brandon) and then selected all of the questions from a provided list they thought would be good questions to ask the student. In the remaining three Lesson*Sketch* experiences, PSTs were again presented with a mathematical task and one student's solution to the task; this time, they went through two rounds of selecting a question and seeing the student's (pre-determined) response, evaluating the question after each round. At the end of the experience, PSTs decided which of their two selected questions they thought was more effective and explained why. See Table 1 for examples of the questions used in the different experiences, classified according to their question feature. We developed the categories of question types drawing on the literature on effective questions described earlier.

Table 1: Classifications of Question Types

Category	Examples
Suggest a specific alternate strategy (not eliciting)	• (Brandon experience) "Do you know what you need to do to the denominators before you can add fractions?" • (posttest) "Why don't you try dividing each sub into three parts?"
Specific to student's work, but invalidates and funnels	• (Cedric experience) "If it is 4 SQUARE yards, can you just multiply by 3?" • (posttest) "When you are comparing fractions, don't you need to use the same whole?"
Funnels	• (Brandon experience) "In the problem it says that there are three fourths and three sixths. Are fourths the same as sixths?" • (Cedric experience) "Are we talking about one-dimensional units or two-dimensions?" • (posttest) "Is it 1/3 of a sub, or 1/3 of half of a sub?"
Elicits student's thinking	• (Brandon experience) "Can you tell me more about where the fourths, the sixths and the tenths are in your picture?" • (Cedric experience) "Can you show me the square yards in your picture?" • (posttest) "Can you tell me more about how you were thinking about the 1/3?"
Help students build on their own thinking	• (posttest) "Let's look at your pictures for Car A and Car C. Based on the picture, who would get the most?"

Analysis

We began constructing the hypothetical learning trajectory by describing the learning goal, drawing on features of effective questions cited in literature, and hypothesizing which features of questions might be more difficult for students to adopt based on our findings from the Phase 1 data. Next, we looked for patterns among the types of questions PSTs selected and composed in response to student thinking on the posttest and then examined their responses in the earlier experiences to determine whether these groups of PSTs were more likely to select questions with similar features (e.g., funneling or eliciting) in the earlier experiences. As the patterns arose, we identified ways to categorize the different groups of PSTs and adjusted our learning trajectory as needed. During this process, we hypothesized what values and beliefs about teaching might be motivating different types of questions. For example, we conjectured that PSTs would be more likely to ask questions that reference students' work if they valued understanding students' current thinking. In order to gain insight into the PSTs' values, we analyzed their evaluations of selected questions using open codes, which we later condensed into the categories shown below:

- **Building on student thinking:** PST claims that the question provided an opportunity for Brandon to come to a new realization on his own
- **Understanding student thinking:** PST claims that the question helped the teacher to better understand Brandon's thinking or allowed the student to explain his thinking
- **Addressing misconceptions:** PST claims that the question helped the student understand, focused on a misconception, or failed to "fix" a misconception
- **Leading to correct answer:** PST claims that the question helped get the student to the correct procedure or answer

Finally, we investigated the links between PSTs' values (what PSTs believe is important) and practices by examining the relationships between the criteria they used to evaluate questions (i.e., the value codes just described) and the types of questions they tended to prefer (Table 1).

Findings

Patterns of Features of Questions PSTs Selected

After examining the questions PSTs composed and selected on the posttest, we formed groups of participants according to specific features of these questions. We initially classified PSTs as "funnelers" if they a) selected both of the funneling questions **or** b) composed a funneling question. We used similar criteria to create an initial "eliciters" group. These criteria yielded 51 funnelers and 54 eliciters, including 29 PSTs who were listed in both groups. We reclassified these 29 PSTs as "funnelers-eliciters." This resulted in three distinct groups: 22 funnelers, 29 funnelers-eliciters, and 25 eliciters.

A chi squared test of independence showed that in neither the Brandon experience (X^2 (2) = 7.08, p = .029) nor the Cedric experience (X^2 (2) = 5.95, p = .051) were the question types independent of the group. Overall, PSTs tended to select a question that funneled or directed the student in the Brandon experience and a question that elicited or built on student thinking in the Cedric experience (see Figure 1). However, an examination of the standardized residuals revealed that in the Brandon experience, *fewer* funnelers (std. res. = -1.92) and *more* eliciters (std. res. = 1.1) selected the question that elicited or built on student thinking than statistically expected. In the Cedric experience, the inverse was true: namely, *more* funnelers (std. res. = 1.45) and *fewer* eliciters (std. res. = -1.56) selected a question that funneled or directed the student than statistically expected. Figure 1 shows the percentage of PSTs within each group who selected the eliciting and funneling questions in the Brandon and Cedric experiences. Notice that the percent of funneling questions decreases and the percent of eliciting questions increases between each group in both experiences.

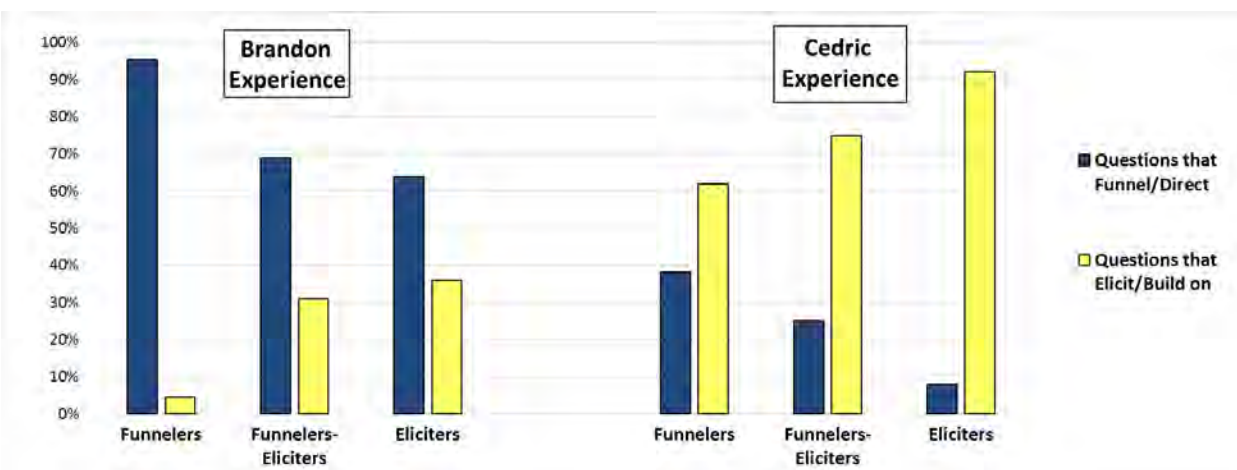

Figure 1. Percent of PSTs in each group who selected either a question that funneled/directed students or elicited/built on student thinking in the Brandon and Cedric experiences.

Criteria for Evaluating Selected Questions

Recall that after viewing the simulated student's responses to two questions they selected, PSTs indicated which question they preferred and why, which we analyzed in order to characterize the PSTs' values underlying their question selection. Over three-fourths of the PSTs in the funneler category gave justifications that focused on whether or not their question resolved Brandon's misconception, compared to less than half of the funneler-eliciters or eliciters (see Figure 2). One PST in the funneler group stated that she preferred the funnel question, “because it made [Brandon] realize that the pieces were not able to be added because they were not the same. He is not realizing it with [the eliciting question], he just keeps labeling his picture and justifying his original answer.” Notice that the PST is evaluating both the funneling and eliciting questions based on whether or not they resolved Brandon’s misconception. Additionally, her negative evaluation of the eliciting question suggests that the PST does not realize that Brandon could have discovered the error on his own in the process of justifying his original answer.

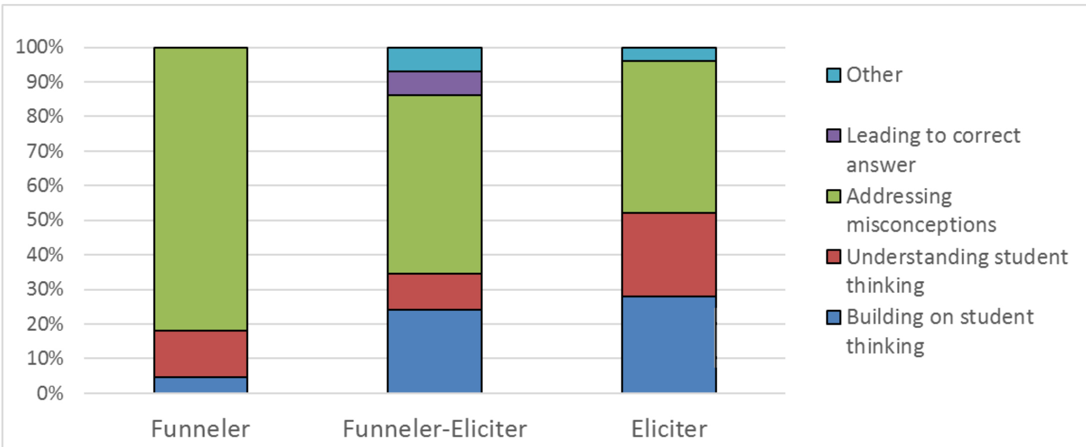

Figure 2. Percent of PSTs who focused on each criterion when evaluating questions in the Brandon experience.

PSTs in the eliciters group were more likely to evaluate their questions based on whether it allowed them to understand or build on the student’s thinking. For example, one eliciter stated that she liked the eliciting question “because we actually get the chance to observe Brandon's thinking and strategies. He is able to explain his thought process for us. The other [funneling] question was more of the teacher telling Brandon what is right and what is wrong.” Here, the PST appears to recognize the value in understanding Brandon’s current thinking before seeking to move his thinking forward. Overall, patterns in the types of evaluations given suggest that not only were PSTs in different groups more likely to select different types of questions, but they also valued different things when asking Brandon a question. We looked for similar patterns in the Cedric experience, but in this case, the differences were not statistically significant. Despite this, the consistency individuals exhibited in the questions they selected and their evaluations in Brandon’s experience lend support to our framework in the next section.

Hypothetical Learning Trajectory

Our trajectory is comprised of three layers – PSTs’ beliefs and knowledge about mathematical understanding, their values about students’ learning, and the features of questions they pose when asking a student about their mathematical work. We propose four main stages that PSTs progress through in the development of asking effective questions. In our descriptions of the stages below, we begin by talking about the features of questions PSTs in the given stage might prefer and then draw connections to the associated values and beliefs/knowledge.

We separated the proposed trajectory for PSTs’ beliefs from values and practice in order to emphasize the distinctions between the components of the trajectory that were based in our data (values and practice) and the components were not explicitly measured, but were emphasized in the methods course and may be connected to the value/practice constructs. The dashed arrows represent the tentative nature of these proposed connections. Although our trajectory depicts four distinct stages, we acknowledge the potential overlap between categories and that some PSTs may not develop understanding in the linear path implied by the figure. Nonetheless, the trajectory serves as a model for understanding a general progression of PSTs' understanding.

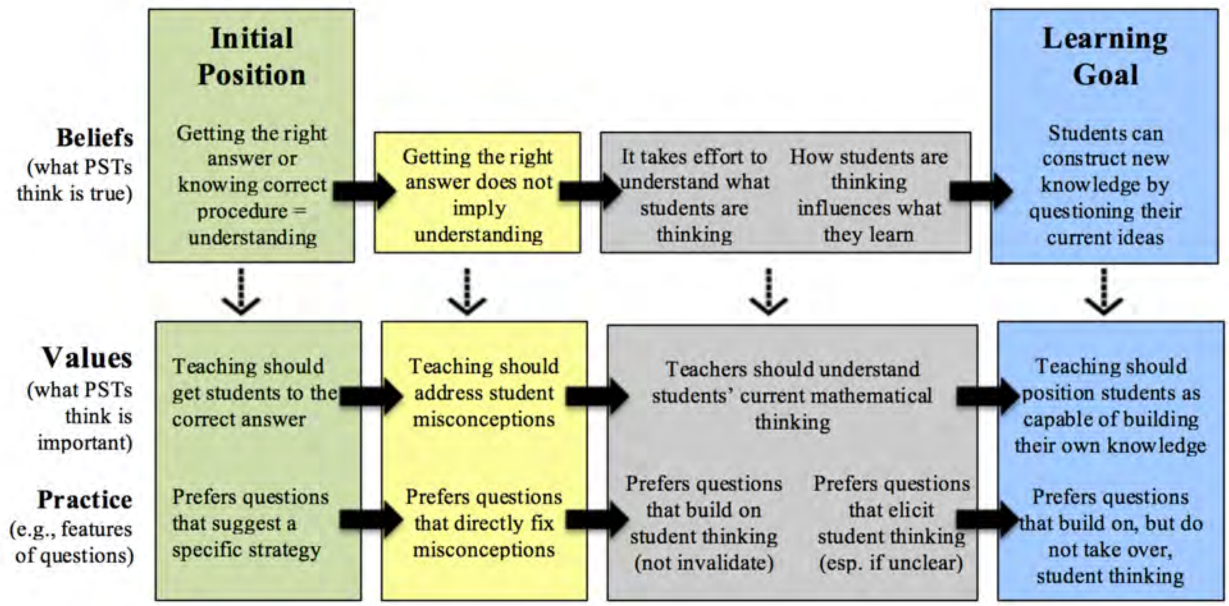

Figure 3. Hypothetical learning trajectory for asking effective questions.

Leading to correct answer (initial position). Based on literature and our prior experiences in methods classes, we began with the assumption that many PSTs enter into undergraduate programs with an unsophisticated view of teaching as telling, and default to using questions as a vehicle for directing students towards specific strategies. For example, one PST explained in the pretest why she thought the question, "why don't you try dividing each sub into 3 parts", was good by saying, "it might make more sense to the student if he divides each piece into thirds and can add them up more easily". Here, the PST projected her own strategy onto the student and assumed that her strategy might make it easier for the student to solve the problem than his current strategy. This reflection lends support to the idea that PSTs who ask questions designed to get students to the correct answer may equate answer-getting with understanding and may have a broad, vague idea of what they think is important for student learning.

Addressing misconceptions (yellow). At this stage, PSTs recognize the importance of asking questions that are specific to the student's work and begin preferring questions that directly confront the student's misconception. Funneling questions, such as "In the problem it says that there are three fourths and three sixths. Are fourths the same as sixths?" fit within this category as the question focuses the student's attention on their misconception without directly telling the student what to do. Of the 49 PSTs who initially selected this question, 34 preferred this question to the eliciting question they viewed subsequently. Nearly all (32/34) of the PSTs who preferred their initial funneling question gave justifications focused on whether they believed the question resolved Brandon's misconception. "My first question was better because he realized that fourths and sixths were not the same. The [eliciting question] just led him to point out where things are in his picture without realizing he was wrong." This response shows a PST who only considers whether the question helped Brandon "realize he was wrong" and failed to consider whether the question revealed more about Brandon's thinking or positioned Brandon as capable of discovering his own error.

Eliciting student thinking (gray). PSTs in the third stage value understanding students' current thinking in addition to helping them develop correct conceptual thinking. As a result, they tend to select questions that elicit the student's thinking about a specific aspect of their work. For example, the question in the Brandon experience, "Can you tell me more about where the fourths, the sixths, and the tenths are in your picture?" focuses the student's attention on how his answer of tenths relates to his drawing of fourths and sixths. This question also elicits his current understanding instead of directly pointing out his error. At the end of the Brandon experience, 19 of the 22 PSTs who preferred this eliciting question provided justifications that highlighted a desire to understand Brandon's thinking or allow him to come to his own understanding. For example, one PST liked the eliciting question because "we actually get the chance to observe Brandon's thinking and strategies. He is able to explain his thought process for us." As PSTs begin to value understanding students' current mathematical thinking, we hypothesize that they begin to realize the effort involved in understanding student thinking and recognize that the student's thinking influences what he/she learns.

Building on student thinking (learning goal). The final box represents the learning goal, where teachers pose questions that aim to build on, but not take over, the student's thinking. Such questions often *do* elicit student thinking, but the description implies that there are additional ways to use questions to help students move forward in their thinking without reducing the cognitive demand or taking over the mathematical work. This corresponds to a value for teaching that not only draws out student thinking, but positions students as capable of developing, questioning, and refining their own ideas. For example, in the posttest, the simulated student Toby determined that sharing two sandwiches with three people equally would result in each person getting 5/6 of a sandwich. The question, "Can you show me the 5/6 of a sub that each person will get?", asks Toby to pictorially represent his solution without indicating that his answer was incorrect. In doing so, Toby would have an opportunity to see that three shares of 5/6 of a sandwich would constitute more than two sandwiches—an unreasonable solution. Although 62 PSTs selected this question on the posttest, only 38 picked a similar question on the other posttest item. The PSTs who selected both of these questions did not exhibit clear patterns in the earlier experiences that suggested a consistent preference for questions that built on, but did not take over, student thinking. We interpret these findings to suggest that our sample did not include a sufficient number of PSTs who were at the final stage in the learning trajectory.

Discussion

Our data suggest that, across different instructional situations, PSTs show consistent patterns in the kinds of questions they select. PSTs who funneled in some situations tended to also funnel in others, and those who chose eliciting questions tended to be consistent in this choice as well. In addition, PSTs who selected both funneling and eliciting questions fell between the two groups in terms of preferences for questions that, on the one hand, take over student thinking, and, on the other, draw out and build on student thinking. These patterns suggest that PSTs were at different stages in their thinking about the questioning practice. We hypothesize that some PSTs (funnelers) prefer questions that lead students to correct answers and do not see value in questions that merely elicit student thinking. Indeed, several PSTs we placed at the beginning of the trajectory expressed dismay when questions seemingly left students still confused, even if those confusions were exactly the ones students needed to work through. At the next stage (funneler-eliciter), PSTs value questions that elicit students' thinking, but they also continue to value questions that lead students to the correct answer or resolve their confusion. Finally, PSTs farther along the trajectory (eliciters) value questions that draw out and build on students thinking, and in this study were also less likely to select questions that imposed a teacher's idea. PSTs at this stage were more likely to criticize questions for being too leading and to value questions that prompted a student to figure something out "on his own."

Establishing these stages is an important first step to designing experiences that support movement along the trajectory. What does it take, for example, for PSTs who value resolving student confusion, to begin noticing and appreciating how questions can help them understand students' current mathematical thinking? Once PSTs value building on student thinking, what kinds of experiences might support them in moving towards a preference for asking eliciting questions? Answering these questions involve consideration of the questioning practices themselves, the PSTs' skills in enacting them, and their values in teaching. In our future work, we hope to further refine this trajectory and continue to develop interventions to help PSTs get closer to enacting the questioning practices in the ambitious goals endorsed by NCTM (2014).

In this paper, we integrate a set of theoretical considerations that together serve as a model for investigating how high-leverage practices could be generative of teacher learning. We use the context of rehearsals to investigate how the use of a specified question sequence aimed at eliciting student mathematical thinking can afford opportunities for novices and instructors to consider goals of ambitious mathematics teaching. In our results, we provide thematic categories for the problems that arose as novices used the sequence of questions, and demonstrate how they afforded the teacher educator opportunities to connect novices' work to goals of ambitious mathematics teaching. In particular, we highlight how these opportunities arose in the midst of modifying to the question sequence and investigating the consequences of its enactment.

Keywords: Teacher Education-Preservice, Rehearsals, Classroom Discourse, Instructional Activities and Practices

Much of the work of teaching is non-routine, requiring a capacity to improvise in the midst of contingent interactions, marshalling knowledge and skill in the service of professional goals (Grossman, Compton, et al., 2009). Mathematics teachers, for example, must make judgments about how to respond to students individually and in groups, drawing on specialized knowledge of both mathematics and student thinking to further instructional objectives. All the while, they must treat all students as sensemakers and provide them with access to cognitively demanding tasks. For mathematics teacher educators, this problem of complexity is associated with another problem, one of enactment. Novice teachers must learn not only to analyze teaching but also to enact it. Some current approaches to teacher education employ "pedagogies of enactment" to engage novices directly in the interactive work of teaching (Grossman & McDonald, 2008). Within these pedagogies, teacher educators are organizing teacher learning around a set of core teaching practices derived from research on student learning and professional standards. These practices include, for example, eliciting and responding to student reasoning, representing student thinking, orienting students to each other's ideas, and attending to students' errors.

To help novice teachers learn to implement these practices, there is also increasing interest in developing enactment tools, such as talk moves or specific activity frameworks. Tools translate abstract conceptual tasks into more concrete steps and objectives (Wertsch, 1998), supporting the user in implementing particular practices toward a goal. There is concern, however, that a focus on enactment tools may reduce teaching to a set of techniques, without attention to important purposes and commitments that guide teachers' practice (Kennedy, 2015). In this study, we conceptualize the idea of "generative routines" as tools that support beginners to enact core teaching practices while simultaneously learning to use goals and professional commitments to guide decision-making. We ground the idea of generative routines in Hatano and Inagaki's (1986) notion of *adaptive expertise*, where they distinguish between routine and adaptive experts and argue that the latter are those for whom performance of procedural skills is enhanced by an understanding of their purposes. Adaptive performance, they argue, requires developing both efficiency in routines and the professional knowledge and judgment to be able to innovate and adapt to new situations. Research on the development of expertise suggests that this balance is achieved through deliberate practice (Ericsson, Krampe, & Tesch-Römer, 1993), which allows the developing practitioner to gradually refine specific aspects of performance through cycles of repetition with feedback.

Our study examines how generative routines can mediate novice teacher learning of ambitious mathematics teaching. We focus on a particular routine, a well-specified question sequence designed to support novices in the beginning work of eliciting and responding to multiple student strategies in mathematics: What did you see (or get)? → Did anyone see (or get) anything different? → How did you see it (or figure it out)? →Did anyone see it (or figure it out) in a different way? As initial prompts, these questions serve a technical purpose by providing the novice with a set of moves to elicit a range of ideas that represent student thinking and their different levels of understanding. As a result, the novice utilizing this tool is confronted with a suite of demands associated with responding to students' contributions that arise in the spaces in between consecutive questions.

Our overarching research question is *How can an enactment tool be generative for mathematics teacher learning?* More specifically, we address this question by investigating (1) the problems of practice that arise for novices in the context of using the question sequence, and (2) how these problems afford opportunities for novices and instructors to connect the sequence to goals of ambitious mathematics teaching. We focus on problems of practice because research suggests that they open spaces that are generative of teacher learning (Horn & Little, 2010).

Theoretical Framework

We conceptualize learning to teach as increased participation in a community of practice where people coordinate their efforts to accomplish culturally-valued activities using tools that mediate goal-directed actions and shared cultural understandings. This sociocultural perspective on learning posits that there is circularity between tool use and the learning it is meant to facilitate (Sfard & McClain, 2002). Cultural tools mediate a learner's participation in a practice while being themselves products of this process. A key aspect of this mediation process is the way tools direct participation toward various goals around which activities are organized. Wertsch (1998) theorizes two complementary ways in which tools mediate activity. First, a tool mediates action by translating what may stand as an abstract conceptual problem for a beginner into a series of concrete operations at which one can become proficient. Thus, learning to use a tool entails developing technical skills. Wertsch also argues that a tool can support enactment through the affordances (and constraints) it contributes to the development of goal-directed activity. In the case of practice routines, affordances arise when the use of a routine towards particular ends opens up "problem spaces," problem solving situations in which the user can work through her understandings of particular concepts (Salomon & Perkins, 1998).

Context and Methods

The context of this study is a mathematics methods course taught by two teacher educators, designed around a summer learning institute (SLI) that provides four weeks of daily remedial instruction in mathematics and language arts for approximately 140 rising third graders of variable mathematics skills. The institute serves as a field setting for twenty-five novice teachers. To prepare for, and subsequently learn from, their work with children, novice teachers participated in daily Cycles of Enactment and Investigation of instructional activities that are common to the elementary mathematics curriculum, designed for novices to work on principled instructional practices and mathematical knowledge in integrated ways (Lampert et al., 2013).

Each cycle begins with the novice teachers observing and analyzing an enactment of an instructional activity (IA) in a classroom context, either live or on video. Following the observation and analysis of the IA, novices next prepare to teach it to the SLI students, rehearsing it first publicly in front of their peers and the teacher educator who participate as students, exhibiting understanding of how children think about disciplinary ideas. The teacher educator acts as coach, enabling both the rehearsing novice and others in the group to study a range of actions a teacher might take in response to particular student performances. All novice teachers then enact the IA with students in elementary school classrooms, video-recording themselves and writing analytic essays on their own performance. Continuing the cycle, the teacher educator guides a collective analysis using records of the enactments.

A Question Sequence as a Generative Routine

In ambitious teaching, student ideas and contributions are the essence of mathematics discourse; thus, a teacher's work to elicit multiple student conjectures is particularly crucial. However, this practice is often at odds with many beginning teachers' instincts to seek correct answers. For this reason, we specified a sequence of four questions to be used routinely across different IAs to provide a beginning structure for some of the initial elicitation work novices must do to facilitate collective problem solving within instructional activities.

The first two questions, "What did you get?" and "Did anyone get a different answer?" (or variations of these questions), enable novice teachers to start gathering a set of possible solutions from multiple students while responding in a non-evaluative manner that positions different answers as conjectures for the group to evaluate. Once a representative set of conjectures has been elicited, the second pair of questions, "How did you figure that out?" and "Did anyone figure it out a different way?" provide novices with initial prompts to begin to elicit students' reasoning about these strategies. These initial prompts serve a technical purpose by providing the novice with a set of moves to elicit a representative range of student thinking. As a result, the novice utilizing this tool is confronted with a suite of demands associated with responding to students' contributions that arise in between the consecutive questions. Demands include pressing students to articulate their reasoning, establishing productive exchanges among students around key mathematical ideas, and representing different contributions clearly for collective consideration (Staples, 2007). These demands constitute a rich problem space associated with responding purposefully to student contributions that can be worked on collectively in rehearsals. In this way using the sequence as a tool creates affordances for novices to experiment with adapting to student performances.

Data Sources and Analytic Procedures

We analyzed 19 video-recorded rehearsals, representing the rehearsals facilitated by one of the teacher educators during the second and fourth weeks of the SLI. These two weeks of rehearsal videos were selected due to the prominence of the focal question sequence in the structure of the IAs being rehearsed.

To analyze the rehearsal videos, we used Studiocode©, a software package that connects analytic codes directly to segments of video. We identified all rehearsal segments in which the question sequence (QS) in its entirety was being rehearsed, hereafter referred to as QS segments, and then narrowed in on portions of these segments where there were pauses in the simulation for exchanges between the teacher educator (TE) and novice teachers (NTs). We refer to these sub-segments as TE/NT exchanges. There were 72 TE/NT exchanges within QS segments in our data set. Guided by our theoretical framework, we characterized the problems of practice that were discussed during these exchanges as a direct result of using the question sequence. To characterize this set of problems, we began with the two broad conceptual categories theorized by Wertsch (1998) and noted earlier: problems related to technical aspects of using the question sequence; and problems afforded through its use, i.e. problems arising as a consequence of asking questions in the sequence and eliciting student responses. Problems associated with aspects of practice unrelated to the question sequence were categorized as "other" and excluded from subsequent analyses. We then followed a process of thematic analysis (Boyatzis, 1998) to identify sub-categories, developing short descriptions of the problems worked on in each exchange and labeling them for themes. We then discussed our emergent thematic categories to refine a final set of inductive sub-categories for each of the two broad categories.

Inside both broad categories of problems, we then used open coding to characterize how participants drew on goals and professional commitments of ambitious teaching in addressing problems of practice. We developed analytic vignettes (Erickson, 1986) for a representative set of the TE/NT exchanges in order to characterize how a teacher educator can leverage work with an enactment tool, like the question sequence, to create opportunities to explicitly connect novice teachers' work on eliciting and responding to a set of professional commitments like treating all students as sensemakers and providing equitable access to content (see Ghousseini, Beasley, & Lord (2015) for more details).

Results

Our analysis demonstrates how the use of the question sequence as an enactment tool, both in its technical aspects and through the problem spaces afforded by its use, brought forward a number of problems of practice that the novice teachers and teacher educator then collaboratively addressed in the rehearsal context. In managing these problems, participants engaged in a form of inquiry during which the teacher educator guided novice teacher participation in considering questions and solutions related to the use of the tool and its consequences. In the process, the teacher educator had repeated opportunities to connect judgments about adapting the question sequence to commitments of ambitious teaching, like providing students equitable access to learning and treating them as sensemakers. The problems of practice related to the technical use of the QS emerged when novices considered both adaptations to the *wording* of specific questions within the sequence and to the *order* of these questions. The problems related to the affordances of using the QS emerged when the NTs had to manage unanticipated student responses. Such responses required the TE and NTs to determine how to respond to student solutions, support their collaboration, and represent their strategies. We share illustrative vignettes from each of these categories of emergent problems.

Problems Related to Technical Aspects of the QS

How to adapt the order of the questions in the QS. During one rehearsal, novice teachers practiced the IA of Quick Images, which focuses on helping students determine the total number of items in two ten-frames that are flashed quickly. Specifically, the novices used the QS to engage students in using the five- or ten-structure of the ten-frames to determine the total quantity. A novice teacher asks, "As we go down the list of questions, if the first student [who was] asked to explain their strategy is understanding the five- and ten- structure, can we just stop at that part, or do we need to [use the other questions in the QS] to ask for different strategies?" In other words, the problem of practice that the novice teacher is considering is "If the teacher hears the correct answer to the problem and the student communicates sound reasoning about it, is it necessary to solicit different answers and strategies?" In her question, the novice mentions the instructional goal of the ten-frame activity as a way of legitimizing the problem of practice that she is bringing forward for everyone's consideration. The TE, in response, provides several reasons why it still makes sense to continue with the next question in the sequence.

> TE: So you want to look for other strategies because you want to find out as much about what students are thinking as you can, because you are still kind of assessing. And it is not about "this is the only strategy that is legitimate." There are other strategies that are legitimate and valid strategies.

NT: But if we identify a student who is understanding the five and ten structure, could we not ask him to explain to the students too?
TE: That would be one move, or you could have other students revoice that strategy and see if they understand it.

This example illustrates the way practicing the question sequence afforded opportunities to attend to novices' personal understandings of the goals of teaching. In this example, the NT seems to be operating with the assumption that teaching is about getting quickly to an explanation of the correct answer. Ambitious teaching rests on a different set of assumptions— like the importance of investigating alternative explanations and incorrect answers— which the TE can negotiate in exchanges like this one. The TE's response stresses that the question sequence serves multiple goals beyond merely identifying the correct answer, and the correct strategy. It also emphasizes some aspects of the commitments of ambitious teaching: the importance of knowing the students as learners (finding out what they know and making instructional decisions accordingly) and treating students as sensemakers (legitimating different ways of reasoning about mathematics). Her response also underscores the importance of allowing students to collaboratively judge what is to be taken as shared. For instance, she suggests that even when a student proposes a correct strategy, the teacher should orient other students to his thinking and give them the space to make sense of it.

Problems Related to the Affordance Aspect of the QS

Representing students' ideas as a result of using the QS. In this example, the novice teacher is faced with a situation that, from an ambitious teaching perspective, demands that she respond to a student contribution in a way that makes their thinking visible to other students and connects it to the mathematical goals of the lesson. This situation occurred during the third rehearsal of a Quick Images activity. The rehearsing novice teacher (R-NT) has flashed a card that showed 12 dots (a full ten-frame on the left side of the card, and another ten-frame with only two dots on the right side). She asks a variation of the question "How did you figure that out?" to elicit a student's strategy for recognizing that a full ten-frame and two more dots was twelve in total: "How did you see 12?" As one student explains that she saw 12 as "the full ten-frame and two more," the R-NT attempts to represent the strategy on the card, roughly pointing with her fingers to the full ten-frame and then the two dots, while saying "10 and 2." The TE deems the R-NT's response appropriate by noting, "What you just did was a good idea, to use your finger [to represent the strategy on the card]." However, the TE points out that the manner in which the R-NT has represented the strategy on the card did not convey meaningful mathematical ideas to the students because she did not deliberately point to where "10" was on the card. One goal of this Quick Images activity is to help all students see that the ten-frame represents 10, which can be done by highlighting that the top and bottom rows each contain 5 dots when they are filled, and together the two rows add up to 10. The TE's comment indirectly underscores a key commitment of ambitious mathematics teaching—to provide equitable access to learning by visually representing student strategies for collective consideration, and to target particular mathematical concepts.

The TE then directs the R-NT to replay her response to the student strategy and practice using her finger more deliberately, tracing with her fingers where the 10 is while revoicing the student's strategy. Before she replays her response, however, the R-NT raises a concern about her own pattern of response in this kind of situation:

R-NT: Should I ask, umm, I feel when I [represent her idea in this way] that I validate her answer by saying it.
NT: Yeah, I was doing that yesterday in my class. I was repeating everybody's answer. I don't think that's what we're supposed to be doing.

R-NT: Like her answer will only be valid if the teacher says it again.
TE: So what would you do instead?

Two problems of practice are identified here by the NTs: one is concerned with how a teacher's revoicing move may be unintentionally interpreted by students to be a form of validation of particular answers; the other relates to the frequency of teacher revoicing of students' answers. Herbel-Eisenmann, Drake, and Cirillo (2009), in fact, documented similar concerns on the part of their in-service middle school teachers. They argued that teachers face dilemmas in using revoicing; they worry that an unintended function of revoicing could be to shift ownership of mathematical ideas from the students to the teacher. As a result, students may stop listening to their classmates and simply wait for the teacher to repeat different ideas. These unintended consequences of revoicing operate counter to a commitment of ambitious teaching: to treat students as sensemakers by giving them ownership of their intellectual work. By voicing their concerns in this example, the NTs seem to be acting on an implicit awareness of this commitment of ambitious teaching. With her question "What would you do instead?" the TE guides the NTs' participation in considering the use of revoicing as a form of representation of student thinking. The R-NT, in response, offers that as the student is explaining a strategy, she could just represent it on the card without doing a lot of talking. The TE directs her to try it; however, as the R-NT replays her response to test it out, she mainly represents the student strategy (of adding ten and two more) by roughly pointing to the ten frames on the card. Her replay of the response opens up an opportunity to investigate its consequences. The investigation starts when the TE intervenes again.

TE: So, the reason why you have to [restate the student strategy] is because what you're doing is you're taking her strategy and making it accessible to all the students by representing it on the card…. If you were just to use your finger, it's not- it's not connecting her strategy to what's on the card. So, you kind of have to say it in a way. Does that make sense?"

What the TE underscores in her intervention is that, in this case, the R-NT's response must support students' understanding of the meaning of "ten" by helping them connect verbal and pictorial representations of it. In this way, the TE connects the work of eliciting and responding to a guiding commitment of ambitious teaching: that giving equitable access to learning requires making explicit the different mathematical ideas that are shared during the lesson explicit.

In another example also taken from a Quick Images activity, a R-NT was standing in front of a white board, flashing different cards to a group of seven students who are sitting in a semi-circle. After flashing a card representing the problem 9 + 4, and asking the first two questions in the elicitation sequence (What did you get? Did anyone get anything different?), the R-NT gets two responses, 13 and 14. In responding to the two different answers, she turns the card face up for students to check their answers. However, as she does that, she orients her body and the card in the direction of one student who had incorrectly seen 14 dots. Given that this student was sitting at one end of the semi-circle, the TE intervenes, noting that by mainly angling the card toward that student, the R-NT was limiting the access of the students sitting at the other end of the semi-circle. She explains,

TE: Remember, this is about everybody processing. So be careful not to walk over and make it about you and this student. So if you could stay [in the center of the semi-circle] and show the face of the card so everyone can see. You can ask her to explain [while you are standing there].

R-NT: They really wanted to—and I made this mistake yesterday—they wanted to come up and show everybody how they did it. And I was letting them, but I think that I would not let them do this anymore.

TE: I would try to cut that out. You can just tell them “explain to me with your words,” and just help them articulate their strategy.

In this instance, the novice gets in a problem space after trying to respond to the two strategies that she elicited with the first two questions of the sequence. The problem of practice that is at play pertains to managing the position of the representation so that students can have access to the mathematical ideas that the group is attempting to address. Positioning the representation in a way that allows every student to see it communicates to them that they are all accountable for judging the reasonableness of answers. Twice in her intervention, the TE reminds the R-NT about this important commitment of ambitious teaching: “Remember, this is about *everybody processing*” and “show the face of the card so *everyone can see it*.” The R-NT’s justification for her move underlines a problematic situation that she was trying to remedy and suggests that she was trying to attend to the goal of students’ joint collaboration: “they wanted to come up and show everybody how they did it.”

Discussion

Our study illustrates the potential of deliberate practice with a generative routine for supporting the learning of adaptive performance. Generative routines, like the question sequence, can function as a stable procedure that can reduce some of the initial complexity of relational practice. At the same time, enacting the procedure opens up a rich problem space for novices, who must confront the contingencies of students’ improvisational responses. As such, generative routines can be more than scripts or processes that scaffold performance. When novices have opportunities to navigate these problem spaces in the company of more experienced others, generative routines can mediate learning about goals of professional practice, including the commitments that enable practitioners’ judgment in situations of uncertainty.

Our analysis reveals the important role played by the teacher educator in connecting the use of the tool to professional commitments of ambitious teaching. She participates in this role through various interpersonal engagements with the novice teachers, allowing them space for practicing the work of teaching while at the same time guiding their participation in it through various forms of interventions aimed at making explicit connections between particular courses of action and commitments of ambitious teaching. Our findings provide evidence of the teacher educator focusing the novices’ attention on the problematic situations that arise in practice and framing considerations for possible solutions around particular commitments of ambitious teaching. Without the teacher educator in this early stage of novice teachers’ experimentation with enactment tools like the question sequence, it may be difficult for them to recognize the problematic nature of situations and to translate their current understanding of the commitments of ambitious teaching into practice.

"WHEN WILL I USE THIS?" PRESERVICE TEACHERS' BELIEFS AND APPROACHES TO SOLVING MATHEMATICAL TASKS

Laura Willoughby
University of Delaware
LWilloug@udel.edu

The Common Core State Standards Mathematical Practice, Model with mathematics, specifies that students should be able to apply the math they learn in school to "everyday life, society, and the workplace." However, the way that mathematics is traditionally taught in school has led to an ingrained belief about what school math is and how it should be solved which may hinder PSTs from being effective at cultivating modeling practices in their students. This study reveals both roadblocks and openings that can be explored to improve teacher education in the future, specifically regarding transferring mathematical concepts between settings and contexts.

Keywords: Teacher Education-Preservice, Modeling, Instructional Activities and Practices

It is frequently assumed that school mathematics provides students with the preparation they will need for life, however there are multiple barriers in place that prevent this goal from being achieved. Lave (1992) suggests that trying to both provide students with a variety of tools and procedures and preparation for life are "not…compatible values – they are *contradictory.*" Stigler and Hiebert (1998) also reveal how the teaching of mathematics in schools is a cultural practice and that in the United States that practice leads to the belief that "school mathematics is a set of procedures." Simultaneously, the Common Core State Standards for Mathematics (CCSSM) Standards for Mathematical Practice 4, Model with mathematics, emphasizes the need for students to be proficient at applying the mathematics they know to "everyday life, society, and the workplace." Recognizing that Preservice teachers (PSTs) beliefs and understandings about mathematical tasks will influence what they convey to their students, it is important to develop instruction geared towards guiding them towards embracing the CCSSM guidelines which have influence many schools' curricula.

White and Mitchelmore (2010) describe traditional mathematics teaching as the "Abstract Before Concrete" method where procedures are taught with the expectation that students will be able to apply them to other contexts. This has not been shown to be effective and instead resulted in students viewing math as separate from life. A different approach has been met with more success in understanding and application.

The well-known Brazilian street-vendor study by Carraher, Carraher, and Schliemann (1985) revealed that children were able to correctly solve 98% of the given arithmetic problems when given in the context of their street vending responsibilities, 73.7% when given as a traditional word problem, but only 36.8% on a written formal assessment. Other studies have shown similar results comparing the quality of responses and reasoning on tasks that varied in their levels of authenticity (Palm, 2008; Walkington et al, 2013). These outcomes demonstrate the benefit of learning and solving math problems within a context that is relevant or authentic to the students' prior experiences. This is especially important given that the culture of schooling in the United States dictates that math is taught primarily in a classroom setting, and educators need to adapt best practices to the given setting.

Studies done by Cooper and Harries (2002) and Palm (2008) show that students in school settings struggle with problems that are intended to be realistic and relevant to the students' lives. Cooper and Harries suggest that the difficulties arise due to the students reacting to the "ground rules for school mathematics word problems," that allow them to only consider the numbers introduced and the expected operation to complete the problem. By comparing student responses on two sets of story problems, one considered "less authentic," the other considered "more authentic," Palm concluded that increasing the "authenticity" of the tasks will increase the students' ability to create realistic responses that incorporate their background experiences.

We can use information gathered by investigating PSTs' understandings of and approaches to mathematical problem solving to combat the perpetuation of the "mathematics as a set of procedures" mindset (Stigler & Hiebert, 1998). The following research questions were explored to elicit this information: 1. How do the approaches PSTs take to solve two similar sets of mathematical tasks, one presented in a real-world context, and the other presented without context, compare? And 2. Which tasks are preferred by the PSTs and why?

Method

Two sets of mathematical tasks were designed in different contexts. One included a hypothetical financial scenario that was deliberately designed around their intended profession as a teacher. The actual average salary for a fifth-year teacher in the same state as the university was selected for the salary base provided. Also included were common expenses faced by professionals including a cell phone bill, a car payment, rent for housing, and income tax. There was a description of a certificate of deposit (CD) account with compounding interest. The housing costs were based on actual prices of two bedroom apartments in the state while the other bills were taken from statistical averages for the country since more local data was not available. The PSTs were asked to solve tasks related to the scenario. When they asked for clarification, they were encouraged to make their own assumptions about what the question required.

The second set of tasks consisted of one percentage problem that was devoid of any context, and one compound interest problem. All of the necessary information regarding the interest account was provided including rate, initial deposit, length of time and compound frequency. The formula for compound interest was provided as a "hint" but they were not asked specifically to use the formula. This set is referred to as the "abstract" set.

Two first year PSTs, Elizabeth and Rachel, were recruited to complete a videotaped interview. Their teacher preparation program focuses on preparing teachers for grades k-8. They were not given any information regarding the tasks prior to being interviewed.

During the interview, the PSTs were asked to vocalize what they were thinking while solving the tasks. They were given the tasks in opposite orders to examine whether one style of tasks influenced the solution strategies used on the other. They were not allowed to look at the first set of tasks they completed while solving the second set of tasks. After each set of tasks, the PSTs were asked questions relevant to that particular set of tasks. After both sets of tasks had been completed, they were asked more questions about which set they preferred, whether they were now uncertain about other answers that had given in the first set of tasks, and what they found interesting about the two sets while they were solving the tasks. The PSTs had access to a scientific calculator throughout the interview.

The transcripts were coded using a combination of a priori coding along with open coding techniques. Some of the codes included were "numerical calculations": calculations devoid of unit labels, "contextual calculations": units, items, or labels were indicated while performing calculations, "relevance": whether the situation or the tasks currently relate to the PSTs own lives or may be relevant to a situation they find themselves in later, and "preference": indication of a preference of one style of tasks or one method of solving a task.

Results

Two primary findings emerged through the analysis. First, both PSTs expressed a preference for formulas when provided demonstrating a reliance on procedural computations. Second, both PSTs voiced appreciation for and favored the tasks that they considered relevant to their lives.

Both PSTs demonstrated a preference for the formula when solving the tasks related to compound interest even though neither task required use of a formula to determine a correct response. Elizabeth, who had been given the tasks related to the finance scenario first said emphatically, “oh, they give the formula, good!” when presented with the interest task with the formula provided. More importantly, even though she had correctly figured out the interest when first solving the interest task for the set of tasks based in context without the formula, when she was given the opportunity to solve with the formula at the end of the interview, she solved it incorrectly. When asked which method she thought was correct, she said the first way she did it was wrong, even though that was, in fact, the correct solution. “I feel like it should be the same, but they made a formula for it and this is what the formula says. [Elizabeth, 33 min. 10 sec.]” She had more faith in using formula than she did in her own logic and reasoning using the contextual clues given in the scenario.

Rachel, who had been given the abstract tasks first, had similar inclinations regarding her school math experience, “I…remember this formula from previous classes in high school [6 min 30 sec.]” but she would have liked to have been told the meaning of each of the letters in the formula, “saying like, P equals your initial deposit, or like n equals your, I’m not exactly sure, but like r equals rate [16 min 15 sec].” She clearly recognizes this as math she’s seen before in previous high school classes and rather than desiring to understand why the formula works in order to use it more effectively, she preferred to be told where to put the numbers in the given formula. She later says that “I feel like this would work with the formula from the previous task [26 min 15 sec]” when approaching the task in the contextual set of tasks that included compound interest. The formula was not provided on the task paper itself, but she wrote it on her own paper in order to use it. It is important to note that while she showed that she understood how formulas work in general, and what the compound interest formula was used for, she was not able to use it correctly in either context.

In fact, neither PST was able to compute the correct answer using the formula. They particularly struggled with what “n” represented,

> “Now I’m looking at the semi-annually part and seeing if I can do anything with that…Maybe it’s, okay well if I say like twice a year? Then maybe ‘n’ could be maybe I’m either thinking like two or point five [Rachel, 9min 20sec]”

> “…and then ‘n’ I would believe would be two cause it’s twice a year, ... and I have nowhere else to put that number, so I’m just going to go for it and see if this makes sense. [Elizabeth, 27min 45sec].”

If either PST understood the relationships between the variables involved in the formula, they may have had more confidence in determining the value and placement for “n.” Instead, both PSTs frequently mentioned the need to put the numbers in the formula, but neither elaborated on their understanding or interpretation of any of the other variables outside of how they knew which letter the numbers would replace in the formula. Neither attempted alternative methods of solving the problem without the formula while working on that set of tasks.

Both PSTs found the contextual set of tasks more relevant as well as more interesting. Elizabeth likened the bills to her future living arrangements where she will be responsible for paying for her part of a shared apartment. She also said that “it’ll be even more relevant to me in the future [18 min 20 sec].” Rachel admitted that she was not currently responsible for paying any of her own bills, but did acknowledge future relevance, “I should have a car and an apartment and … stuff like that so I should, in the next four years, have to be paying all these sorts of things [42 min 5 sec]." Their mutual preference for the contextual scenario tasks ties into their appreciation of the relevance of the scenario. Rachel articulates this connection well when she said, "You're given this problem where you're directly looking at something you're going to have to do in the future, then it's more interesting because … you will eventually have to take all these things into consideration. So it just makes more sense than just, like, stick this into this formula and find some answer [44 min 0 sec]."

Conclusion

The PSTs interviewed both showed a strong inclination towards the use of procedural methods and formulas over reasoning and alternate solutions. This indicates that both of them have internalized the belief that "math is a set of procedures (Stigler & Hiebert, 1998)" This has the potential to be problematic later as teachers when they try to teach their students proficiency in the use of mathematical skills for "everyday life, society, and the workplace. (NGAC, 2010)." Encouragingly, both PSTs recognized their own interest in solving interesting and relevant tasks which may help them understand the importance of providing similar tasks to their own students.

Many PSTs currently in teacher preparation programs likely did not encounter many modelling opportunities in their own classrooms. For this reason, further investigating their current understandings and beliefs on mathematically similar but contextually different tasks could inform the creation of more effective instruction on the importance of incorporating modelling in their own math classrooms. Smaller scale comparison activities can also be used within teacher preparation programs to demonstrate to PSTs their current biases and the importance to overcome them to potentially make math more inviting to their own students who will then no longer have to wonder, "when will I use this?"

"WELL, THEY UNDERSTAND THE CONCEPT OF AREA": PRE-SERVICE TEACHERS' RESPONSES TO STUDENT AREA MISCONCEPTIONS

Cristina Runnalls
University of Iowa
cristina-runnalls@uiowa.edu

Dae S. Hong
University of Iowa
dae-hong@uiowa.edu

The purpose of this study was to explore how elementary pre-service teachers responded to student misconceptions about area, within the context of their mathematics content knowledge. We carried out pre-assessments and interviews with 24 pre-service teachers enrolled in a geometry and measurement course. Findings indicated a misattribution of understanding to students, conceptual use of visual representations, and differences in response types depending on initial content knowledge. In many cases, pre-service teachers leveraged their understanding towards productive responses. Recommendations for supporting pre-service teachers in navigating the intersection between content and pedagogical knowledge are discussed.

Keywords: Measurement, Teacher Education-Preservice, Teacher Knowledge

The knowledge required for successful mathematics teaching is complex and made up of several components, including common and specialized subject matter knowledge, as well as knowledge of students and teaching (Ball, Thames, & Phelps, 2008). Specialized knowledge for teaching is significantly related to student achievement gains (Hill, Rowan, & Ball, 2005), highlighting the importance of developing this knowledge in pre-service teachers (PSTs).

Considering the importance of specialized subject matter knowledge, there exist concerns regarding the content knowledge of elementary PSTs. One content area that has drawn attention is area measurement. Past research has found that PSTs struggled with area concepts, exhibiting procedural understanding and misconceptions like those of students (Baturo & Nason, 1996; Livy, Muir, & Maher, 2012; Murphy, 2012). This apparent lack in content knowledge may lead to apprehension about the effectiveness of the PSTs' future area instruction. However, there is neither time to completely readdress the topic, nor would this be useful for all PSTs. Instead, it is fruitful to explore the ways in which PSTs put the area-specific knowledge they *do* possess to use, and the ways in which we can support their own personal transformations of knowledge.

The purpose of this study was to explore how elementary PSTs leveraged their knowledge to help address student misconceptions about area. We were interested in the connections between PSTs' content knowledge, responses to student work, and how PSTs negotiated the intersection between multiple types of knowledge. To this end, the research questions guiding the study were the following: (1) What types of pedagogical strategies do elementary PSTs engage in when responding to student area misconceptions? (2) How do elementary PSTs leverage their own understanding of area concepts into responses to student area misconceptions?

Related Literature

Geometric area has strong connections to experiences with the physical world, as well as other topics in mathematics (Sarama & Clements, 2009). Learning about area marks an early shift for students into two-dimensional mathematics, and has the potential to be used as a tool for estimation, manipulation, and visual representation. Unfortunately, several studies have found that students frequently do not understand these deep concepts, and instead take away from area instruction the formula *length* × *width* (Zacharos, 2006). PSTs have also exhibited the same area misunderstandings as students and may take these forward with them (Livy et al., 2012; Murphy, 2012). Despite some misconceptions, however, PSTs do have valuable knowledge about area measurement. PSTs in past studies have exhibited an understanding of area as two-dimensional space and a concrete measure which can be calculated (Baturo & Nason, 1996; Livy et al., 2012). While perhaps not ideal conceptual understandings of area, this knowledge represents a key starting point in mathematics content courses and for PSTs' future interactions with students.

One approach for understanding how PSTs knowledge may be used in teaching is to analyze their responses to hypothetical student work. This method allows PSTs a longer time for reflection and offers a low-risk setting for exploring pedagogical strategies. At the same time, responding to student work is a central component of mathematics teaching. Analyzing student work in the past has clarified how PSTs respond to errors and student-invented strategies (e.g. Busi & Jacobbe, 2014; Son, 2016). This method can provide insight into how we may support PSTs in developing their content knowledge into relevant and useful pedagogical knowledge.

The framework for this study is that of a mathematical knowledge for teaching composed of multiple components: common content knowledge, specialized content knowledge, knowledge of content and students, and knowledge of content and teaching (Ball et al., 2008). We were interested in exploring our PSTs' existing common and specialized content knowledge, and the transformation of this knowledge into mathematical knowledge for teaching.

Methodology

The study took place at a large Midwestern public university. The participants (n=24) were elementary PSTs enrolled in a 15-week geometry and measurement content course. The course is one of several available mathematics courses recommended in the first semester of enrollment. The participants were all female, and had diverse educational and mathematical backgrounds.

Data Collection

Data collected included an area pre-assessment, given prior to the course measurement unit. The assessment consisted of seven questions designed to assess both common and specialized content knowledge, as well as knowledge of students. Four questions addressed conceptual understanding of area (e.g. area as a covering of units). Three questions asked for responses to hypothetical student work. Assessment tasks and student transcripts were adopted from prior studies (e.g. Sarama & Clements, 2009; Zacharos, 2006). A sample task is given in Figure 1.

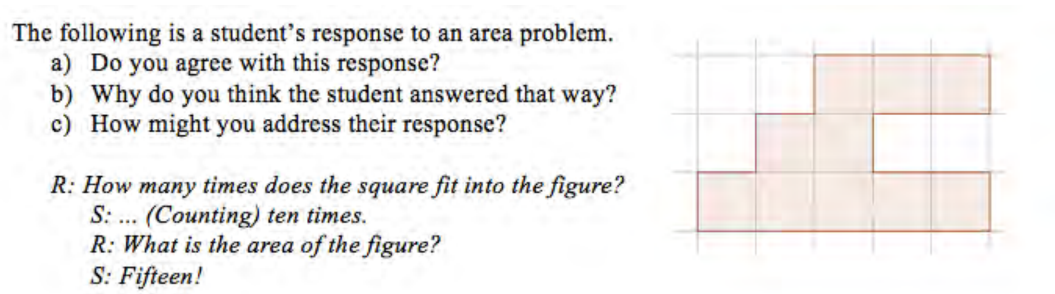

Figure 1: Written pre-assessment sample task.

Following the pre-assessment, interviews were conducted with all participants. Each semi-structured interview was conducted by the first author, and was approximately one-hour long. Participants revisited pre-assessment questions, providing further detail about their responses. Special care was taken to probe responses to student misconceptions, exploring in depth participants' knowledge of content and students as well as knowledge of content and teaching.

Data Analysis

Pre-assessments were examined first to determine participants' procedural and conceptual understanding. Responses were analyzed using a 3-level scale to determine approximate content knowledge, ranging from 0 points for an incorrect response (e.g. suggesting comparison of perimeter when asked for area), to 2 points for correct responses with accurate justification. Participants were divided into three levels according to natural divisions in the range of scores.

Once interviews were complete, these were qualitatively analyzed with pre-assessments and reflective memos. Our analytical framework for pedagogical strategies was borrowed from Son and Sinclair's (2010) framework for analyzing PSTs' responses, and consisted of categories such as conceptual versus procedural focus, show-tell versus give-ask, and pedagogical actions (re-explain, probe thinking, etc.). After an initial coding, the data were revisited to examine the ways in which specific levels of content knowledge interacted with pedagogical strategies. Responses to student misconceptions were viewed within the context of content knowledge, forming a bridge between specialized content knowledge and content-specific knowledge for teaching.

Findings

Analyses of the pre-assessments indicated that most participants possessed a procedural and formula-driven understanding of area. Participants applied the formula *length* × *width* whenever possible, and struggled in the absence of numerical computations. Four PSTs were categorized as high CK, twelve as medium CK, six as low CK, and two were excluded due to missing data.

Choices of pedagogical strategies differed among participants, varying according to content knowledge and personal preference. PSTs' pedagogical strategies were split somewhat evenly between procedural and conceptual responses, but were frequently teacher-focused and centered on *showing* or *telling* the student how to proceed. While most participants could identify key gaps in understanding exhibited by student work, they struggled to supplement those gaps. One frequent suggestion (11/24 participants) for Figure 1 task was for the student to carry out more practice problems, suggesting a high value on procedural fluency. Other recommendations included presenting alternate procedures (18/24 participants) or suggesting the student simply needed a re-explanation of the concept of area (14/24 participants).

Additionally, there was frequently a misattribution of understanding to students. Several participants claimed that the student from the Figure 1 task understood area, and only needed to review correct application of the formula. One participant stated that "They know you multiply base times height for simple shapes…they understand *that*, they just don't understand that you can divide this shape into those shapes that they know how to find the area of and then add them all together" (Participant #12). Through their responses, PSTs relegated errors in student work to procedural mistakes, rather than conceptual misconceptions. This belief then tended to limit the pedagogical strategies employed to a procedural focus.

Several interesting points arose from analyses of the connections between strategies and content knowledge. All four participants with high content knowledge preferred show-and-tell strategies, levering their content knowledge to provide multiple procedural approaches to the problem. These approaches tended to focus on arriving at the correct answer through multiple methods. Meanwhile, participants with low content knowledge were more likely to adopt give-and-ask strategies, offering questions and prompts for students even if they were not necessarily sure of the answers themselves. Participants with medium content knowledge tended to employ all varieties of pedagogical strategies, ranging from telling the student how to carry out a procedure to suggesting cognitive conflict and conceptual probes.

Another finding was the use of visual representations in conceptual responses. This type of response introduced cognitive conflict via visual representations of a "full" rectangle (compared to the partial shape as in Figure 1) and asked the student to note the discrepancy in areas. For some participants, a preference for visual diagrams seemed to stem from an inability to verbalize conceptual ideas, and they struggled in explaining the mathematics behind their diagrams. Despite this, they could still transform their understanding of visual diagrams into conceptual student help, drawing attention to key ideas even if they were unable to verbalize them.

Discussion

Despite exhibiting a lack of deep conceptual knowledge of area, many PSTs in this study were able to identify sources of error in student work and attempted to formulate appropriate responses. While pedagogical actions were frequently teacher-centered, there was a mix of both procedural and conceptual responses, and many participants succeeded in transforming their own understanding into productive advice for students. Most notable is that a high level of content knowledge was *not* required for this process, and many students at low and medium levels of content knowledge could provide conceptual feedback. While there were at times mathematical errors in this feedback, such approaches reflect a positive starting point for teacher educators to build upon. On the other hand, participants with high content knowledge preferred procedural responses, indicating that these PSTs may require an approach focusing on pedagogy rather than content. While a few participants reinforced errors in their responses, these were participants who had particularly weak content knowledge not reflective of the group.

These findings indicate that PSTs at all levels of content knowledge are able to identify and address common area misconceptions among students. While their pedagogical strategies may not be considered ideal, they form a key starting point from which teacher educators can begin to move forward. Encouraging students to not only identify misconceptions, but shift towards addressing them both conceptually and with mathematical accuracy is a key step towards supporting the transition to specialized content knowledge and knowledge about students and teaching. Most importantly, it remains critical to acknowledge the understanding that PSTs bring to the classroom, and to work from it towards common educational goals.

ADDRESSING MINDFULNESS, MINDSET, CONTENT KNOWLEDGE, AND ANXIETY IN MATHEMATICS FOR PRESERVICE TEACHERS

Natasha E. Gerstenschlager
Western Kentucky University
natasha.gerstenschlager@wku.edu

Janet L. Tassell
Western Kentucky University
janet.tassell@wku.edu

Research has demonstrated a connection between teachers' ability to teach and their content knowledge, attitudes, and beliefs (Ball, 1991; Ernest, 1989; Fennema & Franke, 1992; Wilkins, 2008). As such, Wilkins (2008) suggested that teacher education programs address these components alongside content knowledge. To address this, we developed and implemented seminars that incorporated strategies for improving mindfulness, reducing anxiety, improving self-efficacy, and shifting toward a growth mindset for our teacher candidate participants. Our project also included a personalized learning pathway component, designed to develop participants' self-efficacy and content knowledge in mathematics and their knowledge of how to use such pathways in their future classrooms. In this paper, we present preliminary qualitative results from this research.

Keywords: Affect, Emotion, Beliefs, and Attitudes, Teacher Beliefs, Teacher Education-Preservice

Perspectives

Research has consistently shown a link between mathematics teachers' content knowledge, attitudes, and beliefs and their ability to teach effectively (Ball, 1991; Ernest, 1989; Fennema & Franke, 1992; Wilkins, 2008). Similarly, links have been found between elementary teachers' mathematics anxiety and their students' anxiety (Beilock, Gunderson, Ramirez, & Levine, 2010). Likewise, Hadley and Dorward (2011) found that when elementary teachers had lower levels of anxiety about teaching mathematics, their students had increased mathematics achievement scores. This could be explained by the fact that as teachers' mathematics anxiety increases, their self-reported level of efficacy decreases (Swars, Daane, & Giesen, 2006). Unfortunately, even with years of research, students and teachers are still developing anxieties toward mathematics that is affecting students' ability to learn and teachers' efficacy.

Given this issue, Wilkins (2008) noted that teacher education programs must attend to these components in conjunction with content knowledge to improve the value of learning the content. Although these components are certainly necessary as a focus, new research on the ideas of mindfulness and mindsets in the classroom indicate that these might also need to be considered to help the mathematics education community overcome many barriers. In a recent study of fourth and fifth grade mathematics classrooms, students that engaged in mindfulness exercises did 15% better in mathematics than their peers (Schonert-Reichl et al., 2015). This study asserted that mindfulness is also connected to the teacher and subsequently to his or her classroom. Specifically, Schonert-Reichl and colleagues (2015) observed that teachers in the study who participated in mindfulness exercises indicated having less stress. In regard to mindset, Boaler (2016) recently noted the importance of mindset in learning mathematics. She stated, "the fixed mindsets that many people hold about mathematics often combines with other negative beliefs about mathematics, to devastating effect" (p. ix). Hence, the importance of the combined effect of mindset, mindfulness, anxiety, self-efficacy, and content knowledge needs to be explored.

In this project, we developed professional learning community seminars that incorporated strategies for addressing many boundaries within mathematics education including improving mindfulness, reducing anxiety, improving self-efficacy, and shifting toward a growth mindset for our participants, preservice elementary teachers (PSETs) currently enrolled in a mathematics methods course. Our project also addressed issues of access by including a personalized learning pathway component that was designed to develop PSETs' self-efficacy in mathematics, their content knowledge, and their knowledge of how to use and incorporate personalized learning pathways in their future classrooms. In this paper, we present preliminary results from our analysis that is currently underway.

Methods

Our research questions were: How does involvement in the project influence participants' mathematics mindfulness, anxiety, and mindset; and how does involvement in the project influence participants' mathematics self-efficacy? Given that both qualitative and quantitative data were needed to make inferences (Tashakkori & Creswell, 2007), we employed a mixed-methods research design. Specifically, we used a concurrent embedded design so that the quantitative and qualitative data could be triangulated to better understand how PSETs' participation in the project influenced the constructs of interest.

Quantitative data included a pre- and post-survey that assessed participants' mindfulness (Brown & Ryan, 2003), anxiety (Fennema & Sherman, 1978), mindset (Dweck, Chiu, & Hong, 1995), and self-efficacy (Enochs & Riggs, 1990; Enochs, Smith, & Huinker, 2000; Riggs & Enochs, 1990). To compare, the control group also took the surveys but did not engage in the seminars. All participants had taken the PRAXIS by the culmination of the project. This assessment provided an additional reference point that is an accessible reflection of their growth in content knowledge. Finally, we collected results from PSETs' engagement with the personalized learning pathway, Khan Academy. Khan Academy was chosen as the personalized learning platform due to it being free software and because it is frequently used in classrooms. This choice was intended to reveal both the potential usefulness and pitfalls of the platform.

Qualitative data collected from the intervention group included interviews, observation notes from seminars, and response to journal prompts. These sources were analyzed first using an open-coding scheme, and then, using these results to develop themes. All students in the project were enrolled in a mathematics methods course at a large university in the southeast United States. Participants could self-select into either the intervention or control group based upon their availability to participate in the seminars. Participants from the project's Fall 2016 semester included 13 PSETs in the intervention group and 16 in the control group. Participants in the intervention group were expected to participate in three professional learning seminars during the semester, each lasting approximately two hours, as well as engage in a personalized learning pathway during their personal time.

Results

In examining the correlations for both groups, the intervention group showed significant relationships between math anxiety (AMAS) and Personal Mathematics Teaching Efficacy (PMTE) ($r = -.753$), Mindset and teaching efficacy (PMTE) ($r = .451$), AMAS and Mindset ($r = -.496$), Mindset and GPA ($r = .435$), and PRAXIS score and GPA ($r = .462$). Significant relationships were also noted for the control group between PMTE and AMAS ($r = -.60$), Mindset and Mindfulness ($r = .523$), Mindset and GPA ($r = -.487$), PRAXIS scores and GPA ($r = .405$), and PRAXIS scores and the results on the proficiency exam ($r = .540$). Additionally, we used a paired sampled t-test to explore the relationship between variables assessed from pre- to post-test. Results revealed statistically significant changes from pre- to post-test for the intervention group for AMAS ($p = .000$), PMTE ($p = .000$), and Mindset ($p = .025$). Significant differences were not found for Mathematics Teaching Outcome Expectancy (MTOE) and Mindfulness. Statistically significant results were found for the control group for the variables AMAS ($p = .025$) and PMTE ($p = .006$).

Examining the Khan Academy data, we found a strong, positive correlation between the amount of time students practiced skills and the amount of concepts marked as mastered within the platform ($r = .940$). This is not surprising, but can be used to demonstrate to students the importance of practicing certain skills. As part of the participants' journals, they were asked to comment on their use of Khan Academy. These journals revealed that common topics students studied were fractions and topics they were expected to teach in their placement. Additionally, we also found that many enjoyed the personalized pace and focus, however, several did not regularly engage because of a lack of time or because they forgot.

The preliminary analysis of the qualitative journal entries revealed interesting results. In regard to mindfulness, analysis of participant journals indicated that, over the course of the project, several participants developed mindfulness in two areas of their life: their personal life and academic life (i.e., as a teacher candidate). As an example of the former, one participant described being more aware of their surroundings "rather than being on autopilot" (Journal 2, Participant 1). As an example of the latter, another participant claimed becoming more aware of their students so that they "can better teach them core math strategies" (Journal 2, Participant 2).

Similar results were found with respect to participants' math anxiety and mindset. For example, many participants indicated a general awareness of when their internal dialogue aligned with a fixed mindset and tried to change this internal dialogue. We see this in Participant 4's response on the third journal: "I have tried to intentionally speak growth mindset words to myself." Additionally, anxiety toward teaching mathematics seemed to decrease for participants. One participant stated that she "was less afraid [of] teaching [her two] math lessons this semester" (Journal 3, Participant 5). For math anxiety and self-efficacy, the preliminary qualitative results were sorted into three main themes. One theme was that many revealed an increase toward acknowledging their own ability to reduce their anxiety and/or increase their self-efficacy. Another theme was that some connected their anxiety/self-efficacy to events done to them (e.g., timed multiplication tests) or as something done by them (e.g., choosing to avoid "difficult" math classes). The last theme was that many acknowledged the tools that we introduced to them as a way to reduce anxiety and increase self-efficacy. In regard to mindset, awareness of participants' personal mindset and the importance of a growth mindset increased. Second, many saw a disconnect in certain areas where they were fixed in one area and growth in another. Last, many made a direct connection to teaching. After the seminars, they purposefully monitored their body language and speech inside their school placement so as not to indicate their fixed mindedness in a topic in hopes that their students will not have the same mindset that they do.

Conclusion

The "Improving Mindfulness, Anxiety, and Content Knowledge in Mathematics Pre-Service Teachers" project was designed to develop PSETs' self-efficacy in mathematics, their content knowledge, and their knowledge of how to use and incorporate personalized learning pathways in their future classrooms. The results from this study indicated that participants in the project developed a heightened awareness of their mathematics mindset and mindfulness. Participants also demonstrated lower anxiety related to teaching mathematics and increased self-efficacy in mathematics due to engagement with a personalized learning pathway (i.e. Khan Academy). If the analyses of the remaining data indicate similar results, implications for the teacher education community might include addressing how to incorporate similar activities and projects in teacher education programs.

DEVELOPING CRITERIA TO DESIGN AND ASSESS MATHEMATICAL MODELING PROBLEMS: FROM PROBLEMS TO SOCIAL JUSTICE

Despite the interest in modeling and the importance of social justice, there has not been much attention to connecting modeling with social justice. To fill this gap, we developed criteria for mathematical modeling problems that embrace the characteristics of problems and social justice through three phases: literature analysis, thematic categories, and piloting. The criteria will help teacher educators when selecting modeling problems to be used in teacher preparation programs and assessing the modeling problems posed by PSTs.

Keywords: Modeling, Equity and Diversity, Teacher Education-Preservice, Problem Solving

The purpose of this study is to develop criteria to design and assess mathematical modeling problems that embrace social justice contexts and to reflect on ways in which the criteria can be used to assess preservice teachers' (PSTs) ability to pose problems. Mathematical modeling has been emphasized since the Common Core State Standards for Mathematics (CCSSM) include model with mathematics as both content and process standards (National Governors Association Center for Best Practices & Council of Chief State School Officers [NGA & CCSSO], 2010). The CCSSM define modeling as "the process of choosing and using appropriate mathematics and statistics to analyze empirical situations, to understand them better, and to improve decisions" (p. 72). Although the emphasis on mathematical modeling grows in learning and teaching critical mathematics as described in the CCSSM, PSTs are not yet adequately prepared to design and implement effective modeling problems. The characteristics of modeling, especially linking mathematics to real-life situations and involving students into decision-making processes, are shared with social justice problems. However, there is little consideration of social justice in frameworks related to mathematical modeling. For example, frameworks for developing thought-revealing modeling activities (Lesh, Hoover, Hole, Kelly, & Post, 2000) or rubrics developed for evaluating students' processes and solutions to modeling problems (Anhalt & Cortez, 2015) address important real-life contexts in general, rather than focusing on social justice issues. Gutstein (2003), on the other hand, developed mathematics problems with real-life contexts that reveal the injustice world but did not provide criteria for developing such problems. In this paper, we describe how we initiated and piloted the criteria that help teachers pose modeling problems with social justice contexts and use it to assess modeling problems posed by PSTs.

Process of Developing Criteria for Modeling Problems with Social Justice Contexts

Phase 1: Analysis of Prior Research

Lesh and Lehrer (2003) define modeling as a "process" of developing mathematical descriptions for specific purposes in particular situations. In this sense, modeling is placed in a spectrum of problem solving because problem solving is a process that requires solvers to understand a puzzling situation and to find a solution of the situation (Baroody, 1992). Problem solving seems a broader range of mathematical processes than modeling because problem solving do not specify the puzzling situations while modeling is required to involve a real-world situation (Anhalt & Cortez, 2015). A similar relationship appears between problems and modeling problems. Although many teachers mistakenly use the term *problems* for any mathematical tasks, only the tasks satisfy certain criteria

Galindo, E., & Newton, J., (Eds.). (2017). *Proceedings of the 39th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* Indianapolis, IN: Hoosier Association of Mathematics Teacher Educators.

can be “problems.” Charles and Lester (1982) argued that problems must not show an obvious way to find a solution, and Van de Walle (2003) agreed problems must not have a predictable solution. When we compared the process of modeling with that of problem solving, more similarities revealed. Pólya (2004) proposed four phases of problem solving as understanding the problem, devising a plan, carrying out the plan, and looking back, which are similar to the mathematical modeling cycle.

The difference between problems and modeling problems is their contexts: the situations of modeling problems are articulated within a specific situation in the real world while problems do not necessarily include a real-world context. Some studies focus on a specific context of modeling problems without using the term, *modeling*. Among these, the problems involving social justice have a unique characteristic because these problems not only use the context of critical parts of the real-world but also encourage students to change their perspectives and take an action to solve the real problem. For social justice, it is critical to help students “understand, formulate, and address questions and develop analyses of their society” (Gutstein, 2003, p. 40).

Phase 2: Thematic Categories to Define Mathematical Modeling with Social Justice

We reconceptualized the relationships among problems, mathematical modeling problems, and social justice problems as shown in Figure 1. Because learners choose appropriate mathematics to analyze empirical situations when working on modeling problems, a specific solution pathway should not be given during this process. Therefore, modeling problems must satisfy the crucial condition of problems and need to be included in the set of problems (Figure 1). In addition, modeling problems are more inclusive than social justice problems.

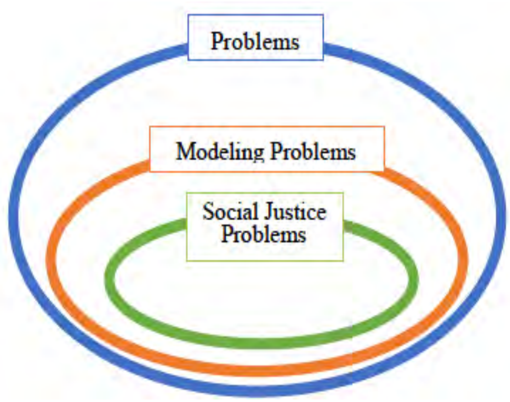

Figure 1. The relationships of problems, modeling problems, and social justice problems.

Although various types of contexts can be integrated into modeling problems, the goals of the problems of social justice is to support students not only to learn mathematics but also to actively develop their capability to read the world and become an agent of change. Thus, we placed the set of social justice problems within the set of modeling problems. The social justice problems are not defined as the tasks that just involve social justice contexts. If a task includes a social justice context only but provides a specific solution pathway, it is not a “social justice problem.” Within this operationalization, we developed a draft of criteria based on the related literature, which was refined through the piloting phase.

Phase 3: Piloting and Finalizing Criteria for Mathematical Modeling with Social Justice

The third phase was to use the criteria to analyze the modeling problems that PSTs developed. We collected data from 30 PSTs in two 4-year university-based teacher preparation programs in the Midwestern United States. Participants were sophomores to seniors enrolled in K-8 teacher preparation programs in each of their programs. The PSTs had some experience of solving modeling problems within their class before assigned the modeling problem development assignment. The criteria draft was not introduced to the PSTs although they learned the definition of modeling through reading relevant articles and discussions in class. The PSTs worked as a group of 3 people for approximately 2-3 weeks to develop their modeling problems. The first and second authors analyzed the collected 10 problems using the initial criteria and managed to reach a consensus through several discussions while finalizing the criteria.

Finalized Criteria for Social Justice Mathematical Modeling

Table 1 is the finalized criteria. The first three columns shown in Figure 1 indicate the subset relationship among problems, modeling problems, and social justice problems.

Table 1. Criteria for Modeling Problems that Address Social Justice Issues

			Criteria	Description
Social Justice Problems			Social Justice Context (Gutstein, 2003)	• The context involves unjust situations of the real world and encourages learners to be an agent of change by identifying mathematical conflicts and resolving the conflicts.
	Modeling Problems		Realistic Context, Problem, and Solution (Lesh et al., 2000; Schukajlow et al., 2012)	• The embedded context must be realistic and familiar to the target students. • The embedded problem(s) requires learners to identify variables and should likely happen in their lives. • The solution(s) must be realistic in the given real-world context.
			Multiple Representations (NGA & CCSSO, 2010)	• Multiple representations (e.g., tables, graphs, symbols, words) can be used to describe the problem situation.
			Generalizable/Transferable Knowledge (Lesh & Lehrer, 2003)	• The problem requires learners to apply their findings to other related problem solving situations. • The problem requires learners to develop mathematical knowledge that can be used in other similar situations.
			Shareable Approach (Lesh & Lehrer, 2003)	• Learners solve problems for a client outside classroom. • The problem-solving process and solutions can be shared with other people for their own use.
		Problems	Focus on Mathematics (Van de Walle et al., 2007)	• The problematic aspect should be due to the mathematics that learners are expected to learn as they solve the task. • Solving the task without using mathematics (e.g., common sense) should not be possible.
			Unpredictable Methods (Baroody, 1992)	• The task does not directly show how to solve it. • The task requires student's own method.

A social justice problem is most specific and must satisfy all seven criteria. The tasks that satisfy all criteria except for *social justice context* are categorized as modeling problems. The tasks satisfying only the last two criteria, *focus on mathematics* and *unpredictable methods*, are problems but neither modeling problems nor social justice problems. Our analysis revealed that most PSTs' modeling problems generally satisfied the criteria of problems but did not sufficiently meet other criteria. Among the criteria shown in Table 1, the most missed one was *social justice context*. None of the problems demonstrated any relevance to social justice. Additionally, the PSTs tended to ignore the characteristics of modeling problems, such as *generalizable/transferable knowledge* and *sharable approach*. Only one of the ten problems included some related features of generalizable or transferable approach.

Discussion and Implications

This study contributes to the extension of literature of mathematical modeling and social justice by demonstrating the process of designing criteria and using them with PSTs. The criteria can be used to develop and assess modeling problems. In our study, most PSTs did not address some of the other components in their problems, such as *social justice contexts*, *generalizable/transferable knowledge*, and *shareable approach*. We realized that these missing components require careful attention when introduced to PSTs. Furthermore, this study provides ideas for future research studies around modeling including social justice contexts. Hernandez, Morales, and Shroyer (2013) present a result that few PSTs identified the role of mathematics teachers as agents of change in society and assumed that one reason might be PSTs' lack of experiences or environments in which they lived and trained. Future studies can focus around changes in PSTs' awareness of social justice issues as they discuss the criteria developed in this study. The criteria have the potential for further investigations and validations in practice, which can initiate discussions among teachers, teacher educators, and researchers as they consider ways to achieve social justice through mathematical modeling.

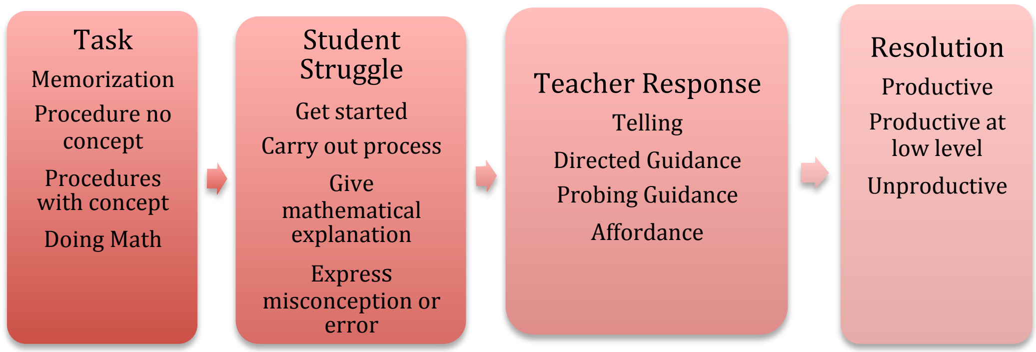
This study examines the development of preservice teachers' (PSTs) understanding of productive struggle in a semester-long mathematics content course. Our qualitative study includes 85 PSTs in four sections of a mathematics content course for prospective elementary and middle school teachers that focused on numbers and operations. Findings suggest that the PSTs develop the ability to attend to and interpret the mathematics underlying the student struggles. They also begin to identify strategies and practices that appear potentially useful for supporting productive struggle.

Keywords: Teacher Education-Preservice, Instructional Activities and Practices, Mathematics Knowledge for Teaching

Introduction

Principles to Actions (NCTM, 2014) calls for teaching practices that support *productive struggle* in learning mathematics. However, struggle is often seen in a negative light (Hiebert & Wearne, 2003) rather than as opportunities for learning. By *productive struggle*, we mean what occurs when, "students expend effort in order to make sense of mathematics, to figure out something that is not immediately apparent" (Hiebert & Grouws, 2007, p. 387). Studies suggest that providing students with opportunities to engage in struggle is an integral part of doing mathematics (Hiebert & Grouws, 2007; Warshauer, 2015). Research also suggests that teachers play an important part in productively supporting student struggles (Warshauer, 2015). Despite recent studies suggesting *productive struggle* as an important component of learning with understanding, teaching practices often attempt to remove the cause of student struggles and rarely to engage students in *productive struggle* with key mathematical ideas (Hiebert & Wearne, 2003; Hiebert & Stigler, 2004).

Our study attempts to address this issue by examining ways to prepare teachers to cultivate a *productive struggle* mindset in a mathematics content course for preservice teachers (PSTs). We introduced PSTs to student struggle episodes in video clip form where the PSTs observed the student and teacher interactions as the student struggled over a task. As a writing assignment, the PSTs were instructed to analyze the episodes aligned with a *productive struggle* framework (Warshauer, 2015) to identify student struggles, teacher responses, and the struggle resolutions. The PSTs were instructed to use the *teacher noticing* framework proposed by Jacobs, Lamb, & Philipp (2004) as a lens to guide them towards *attending* to, *interpreting*, and *responding* to the student struggles in each episode. In addition, they reported on what they noticed of the teacher responses in the struggle episodes that they observed as well as the resolution that was reached in the episodes. The Productive Struggle Framework that we refer to is given below.



This study aims to answer the following research questions:

1. What are the kinds of mathematical interpretations PSTs make about the student struggles they observe in video clips of student/teacher interaction about a task?
2. What teacher responses and actions do PSTs recognize as potentially useful to promote *productive struggle*?

This study seeks to provide insight into what are PSTs understanding of the mathematics that underlie student struggles and the kinds of teacher responses that appear to support the struggles productively. In particular, how are the PSTs coming to understand the role of *productive struggle* in the context of students' understanding of mathematics.

Methodology

Context

Setting and Participants. This study was conducted in 2016 over a 14-week period at a large university in the southern United States. The participants for the study consisted of 85 PSTs, each enrolled in one of four sections of the first of two mathematics content courses for elementary PSTs. Each author was the instructor for one of the four sections. The PSTs experienced three rounds of intervention throughout the semester to introduce them to *productive struggle* and its role in teaching and learning mathematics. The intervention consisted of analysis of video clips and transcripts of a student struggles aimed to expose PSTs to what a student struggle could look like in a classroom and how teachers respond to struggle in a productive manner that supports students learning of mathematics with understanding.

Data Collection. The PSTs completed open-ended pre/post surveys, which included questions about PSTs' familiarity with the concepts of *productive struggle*, accounts of their personal experiences with *productive struggle*, views of struggle as an opportunity for learning, and perceptions of how teachers support student struggles. The PSTs also completed three *productive struggle* writing assignments. The three approximately 3-page writing assignments spaced equally throughout the semester provided PSTs opportunities to witness real instances of struggle with mathematical content that they studied in their course work, examine teacher responses to the struggle, and consider how productive the struggle was for the student.

Data Analysis. The writing assignments and surveys were analyzed using qualitative content analysis. We coded inductively, with the goal of identifying themes and topics of discussion in the PSTs' responses as they aligned with the Productive Struggle Framework (Warshauer, 2015). In general, we examined the attending of student struggle, the interpretations of the mathematics behind the student struggle, description of teacher response, and the productive resolution of the struggle. Prior to coding, the researchers met with a sample of the writing assignments to discuss the coding scheme to promote high interrater reliability.

Findings

We report preliminary findings for our research questions:

Research Question 1: What are the kinds of mathematical interpretations PSTs make about the student struggles they observe in video clips of student/teacher interaction about a task?

In our preliminary analysis, we looked at the data from writing assignments 2 and 3 of the 85 PSTs. We found that the PSTs interpretation of the students' struggle ranged from minimal mathematical basis to those with a detailed mathematical explanation for what could be the source of the struggle. The PSTs identified a variety of mathematical sources to be the cause of the struggle which included: (1) procedural errors and misconceptions; (2) incorrect memorization of mathematical facts; and (3) underdeveloped conceptual understanding. Some PSTs related to the students' struggles in the videos and imposed their source of similar experience and struggle into their interpretation. In both writing assignments 2 and 3, PST generally attended to the students' struggles that they observed in the video clips, identifying the kinds of struggle as getting started, carrying out a procedure, error or misconception, or give a mathematical explanation. Their interpretation of the mathematics behind the student struggles, however, were more limited to errors of procedure or memorization. Interpreting the mathematical concepts often lacked depth and at times were misinterpretations of the mathematics behind the struggle. Table 1 provides some examples.

Table 1: Mathematical Sources of Student Struggles

Procedural Errors and Misconceptions	Incorrect Memorization	Underdeveloped Conceptual Understanding
Example: *"Doesn't understand that you would have to 'borrow' a number from the next column when subtracting with a zero, so that the zero would turn into a ten."*	Example: *"...she needs to remember that the number on the 'bottom' is always subtracted from the number on 'top'"*.	Example: *"She doesn't fully understand the concept of regrouping and base ten."*

Research Question 2: What teacher responses and actions do PSTs recognize as potentially useful to promote productive struggle?

The PSTs were asked to describe the teacher responses they noticed in the videos and identify the types of teacher responses according to the Productive Struggle Framework: (1) telling, (2) direct guidance, (3) probing guidance, and (4) affordance. Through analysis of writing assignments 2 and 3, we found that students considered probing guidance and affordance to promote productive struggle in the students.

Table 2: Teacher Responses

Probing guidance	Affordance
Example: *"She asked questions and used clarification to guide the student...asking him why and reiterating his explanations...allows the student to think for himself."*	Example: *"...teacher responds with patience and allows him the opportunity to once again focus on the problem in solitude and even steps away with the promise of returning on* call..."

It is interesting to note that PSTs changed their opinions of affordance with respect to promoting *productive struggle*. In writing assignment 2, PSTs thought affordance was not productive due to students being unable to answer the problem, but PSTs viewed affordance as a crucial part of writing assignment 3 because the student was given the opportunity to think on his own. In their final survey for the course, some of the PSTs noted teacher's affordances included giving students time and providing encouragement. In their words, let students, "... struggle for a while before returning to provide the students with time to think for themselves."

Conclusion

. As we examined the PSTs' identification of the types of student struggles observed in the videos and their mathematical interpretations, we found that most PSTs could identify when a student was struggling and describe the mathematical sources of student struggles, but many PSTs did not describe clear connections to the mathematical topics behind the struggle. Instead, some focused on describing the struggling student's actions, commenting on their body language and behaviors, and briefly mentioning the underlying content.

However, we found that the PSTs' descriptions of the teacher responses and their considerations of the productiveness of the struggle improved between writing assignments 2 and 3. In writing assignment 3, instead of just describing the teacher actions, the PSTs also included their perceived justifications for the teacher's actions. The PST's explanations of how productive the struggle was also moved away from being focused on whether the student got the right answer by the end of the clip to consideration of how the student could make sense of their mistakes and learn from them. The PSTs also placed emphasis on the teacher being patient and encouraging without giving the student the answer.

Overall, we found that the writing assignments helped the PSTs begin to make sense of recognizing not only when a student is struggling, but identifying what they are struggling with and how to interpret the mathematics behind that struggle. The writing assignments especially helped the PSTs make sense of how teachers respond to student struggles, and why teachers choose certain actions, particularly probing guidance and affordance, to help students through the struggle and build understanding. As PSTs reach the crossroad that connects their mathematical content knowledge to teaching practices, more research is needed into how to help them connect their mathematical content knowledge to interpreting the mathematics underlying student struggles and recognizing teaching practices that support student struggles productively.

DO THEY BECOME PARALLEL? PRESERVICE TEACHERS' USE OF DYNAMIC DIAGRAMS TO EXPLORE DIVISION BY ZERO

Justin Dimmel
University of Maine
justin.dimmel@maine.edu

Eric Pandiscio
University of Maine
ericp@maine.edu

We conducted an interview study to investigate how pre-service K-8 teachers explored a diagrammatic model of division. To create the diagram, we adapted the classic procedure for constructing the quotient of two segments to a dynamic geometry environment. The diagram had moveable points that allowed participants to set the directed (positive/negative) lengths of segments to be divided and the lengths of these segments determined the directed length of the quotient. Twenty pre-service K-8 teaches were interviewed in pairs. We report episodes of how they explored the diagrammatic representation of division by zero.

Keywords: Number Concepts and Operations, Teacher Education-Preservice

Introduction

Physical manipulatives (Green, Piel, & Flowers, 2008) and intuitive models (Jansen & Hohensee, 2015) can be effective aids that help preservice K-8 teachers hone their understanding of arithmetic. In this study, we adapted the classic procedures for constructing the quotient of two segments (Hilbert, 1902; Mcloughlin & Droujkova, 2013) to a dynamic geometry environment. The diagram had moveable points that allowed participants in the study to set the directed (positive/negative) lengths of segments to be divided and the lengths of these segments determined the directed length of the quotient. The purpose of the study was to investigate how pre-service K-8 teachers related their knowledge of division to a diagrammatic model.

Theoretical Framework

The division diagram is an example of a virtual manipulative (Reimer & Moyer, 2005; Steen, Brooks, & Lyon, 2006). It allowed users to explore ranges of quotients through dynamic dragging (Sinclair, Zazkis, Lilljedahl, 2004). Variations in color, line-thickness, and the gauges of the points in the display (Dimmel & Herbst, 2015) were used to group and emphasize different features of the diagrams: the segments that represented factors were blue and yellow, quotients were green, and the moveable segments of the diagrams were thicker than those that remained fixed (see Figure 1, below). The segments to be divided were perpendicular to each other and aligned with the x and y axes. The quotient of the blue (dividend) and yellow (divisor) segments is the intersection of the y-axis and the line drawn through (0,1) parallel to the segment (not shown) between the yellow and blue points. By dragging either the blue or yellow points, users can modify the diagram to show different quotients.

We focused on a diagrammatic model of division because it has mathematical advantages over physical manipulatives (e.g., base ten blocks, cuisenaire rods) that warranted study. In particular, the diagrammatic model of division provides a visual representation that shows division by 0 to be undefined. When the divisor is 0, the line that defines the quotient (i.e., the *quotient-line*) is parallel to the y-axis and there is no point of intersection. Research has shown that both practicing and preservice K-8 teachers have difficulty explaining why (or even knowing that) division by zero is undefined (Ball, 1990; Crespo & Nicol, 2006; Colleague, Author, & Colleague, date). Given these challenges, a model of division that naturalizes division by zero could be a valuable instructional resource. We asked: How do pre-service K-8 teachers relate their knowledge of division by 0 to a diagrammatic model?

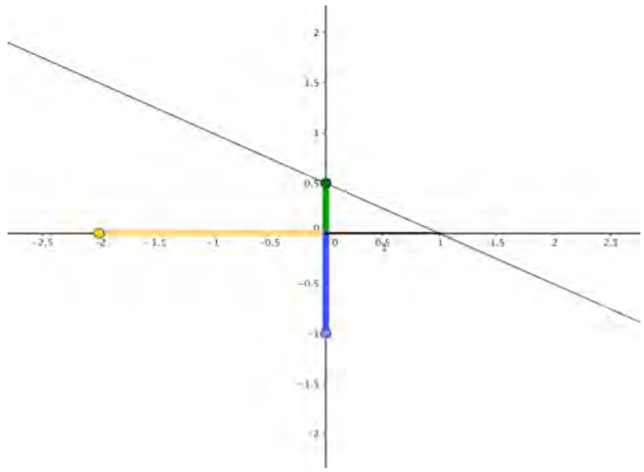

Figure 1. Diagram showing that (-1) / (-2) = (.5). In the diagram, the yellow point and blue point can be slid along the *x* and *y* axes. As they move, they determine the location of the green point.

Method and Participants

We conducted an interview study (Drever, 2003; Zazkis & Hazzan, 1998) of pre-service K-8 teachers. Participants were enrolled an elementary geometry content course at a mid-size university in New England. Twenty (20) students accepted the invitation. Participants were interviewed in pairs. Each of the ten (10) interviews we conducted were approximately 50 minutes in duration. Participants were compensated for their time with $20 Amazon gift cards.

Semi-Structured Interview Protocol

The interviews began with participants exploring the diagrammatic model. The prompts were initially open-ended, e.g.: “Please describe what you see”, and then progressed to more specific prompts used at the discretion of the researchers to guide student interactions with the diagram. The more specific prompts included cues for exploration, such as: “What parts of the diagram can you move ?”, and cues to engage participants’ conceptions of division, such as: “How could you describe the position of the green point in terms of the position of the yellow point and the position of the blue point?”

Data

The interviews were screen and audio recorded. The audio recordings of each interview were transcribed. We prepared multimodal transcripts (Jewitt, 2009) to capture participants’ actions on the diagram. We report below on segments of interviews where participants used dragging to explore division by 0.

Findings

Do They Become Parallel for a Second?

A feature of the diagrammatic model of division is that it visually shows that the quotient (i.e., the length of the green segment) increases without bound as the yellow point (the divisor) approaches 0. As the yellow point approaches 0, passes through 0, and moves away from 0, the quotient segment grows arbitrarily large, disappears for an instant (when the quotient-line is parallel to the *y*-axis), and then reappears the next instant. When it reappears, it is arbitrarily large and pointing in the opposite direction compared to when it disappeared.

Elli and Stella (interview 3, pseudonyms) investigated this switching behavior by moving the yellow point back and forth across the y-axis 11 times (over 3 minutes), at which point one participant asked: “Do they become parallel for a second?” where “they” referred to the quotient-line and the y-axis. The participants continued to explore the behavior of the diagram when the yellow point was at 0 or very near 0, and concluded: “They're not forming the triangle. And then that line that was making the hypotenuse is parallel to [it].” These participants convinced themselves that the quotient-line does become parallel to the y-axis when the yellow point moves to 0, but they did not explicitly relate this to the notion that division by 0 is undefined.

When It’s on 0, the Lines Become Parallel.

Rather than repeatedly dragging the yellow point back and forth across the origin, some participants immediately noticed the special behavior of the diagram when the yellow point passed through 0. Becca and Michelle (interview 9, pseudonyms) initially conjectured that the green line must be “under the blue line” when the divisor goes to zero. Michelle stated that: “Both the yellow and the green are at zero”, and then asked Becca (quietly): “Is that correct?” Becca can be heard saying “Ummmm…” while she considers the question. During this exchange, the divisor is at zero and the quotient-line is parallel to the y-axis. Michelle answers her own question: “I believe”, and as she does so, Becca says: “Ohhh….”. Once Michelle finishes describing the positions of the points, the interviewer asks Becca what she thinks:

Author 1: What do you think Becca?
Becca: Negative 4…you would do like the blue divided by the yellow…so negative 4 divided by 0 is undefined…that’s why the slope is undefined.
Author 1: And so is that the insight that you…it looked like you
Becca: Yeah, the light bulb.
Author 2: And what on the diagram represents undefined?
Becca: Like what line? The intersecting-line…if it’s like, vertical, the slope’s undefined.

Michelle and Becca continue this conversation and conclude that the green is just “not there” or else would be “infinite”. Jenny and Terry (interview 1, pseudonyms) expressed a similar idea. They brought in division by 0 explicitly to make sense of the parallel quotient-line when the yellow point was set to 0. Jenny and Terry interpreted the parallel line to mean that the quotient could be “anywhere or nowhere...because you could subtract 0 from 4 however many times you want, and you are never going to get 0.”

Conclusion and Scholarly Significance

We reported an interview study of pre-service teachers explorations of diagrammatic models of division. We found that participants in the study explored the diagrams systematically and were particularly drawn to the state of the diagram that represented division by 0. That all pairs of participants examined configurations of the division diagram where the yellow point was equal to 0 and that some pairs of participants related this to division by 0 being undefined provides evidence that preservice K-8 teachers could be receptive to the mathematical advantages of these virtual manipulatives.

Elementary mathematics educators are positioned at a crossroads: the basic mathematical ideas they are responsible for teaching rest on deep mathematical footings. How can we best prepare our K-8 mathematics teachers to recognize the intersections of advanced and elementary mathematical ideas they routinely encounter in their classrooms? Our study is significant because a theme in the literature is that elementary teachers have incomplete or incorrect conceptualizations of multiplication and division (Green, Piel, & Flowers, 2008). At the same time, researchers have called for the development of mathematical experiences that can help preservice teachers develop the capacity "for teaching mathematics with understanding" (Crespo & Nicol, 2006, p. 84). This study contributes to the work of creating such experiences by showing the viability of a virtual manipulative that could help preservice K-8 teachers deepen their mathematical knowledge and appreciate the connections between arithmetic and geometry.

The present communication is only focused on a few episodes registered in two interviews developed with Tania (an undergraduate teacher of primary education); this methodological tool contributed to Tania's case in the context of a broad research about fractions. The study object considered here was the exploration of multiplication and division of fractions (through problem solving) as well as her identification of the relation between both operations. It also recovered Tania's productions and problems designs for a potential approach to aforesaid operations in primary school classrooms.

Keywords: Teacher Education-Preservice

Introduction

It is necessary to investigate how the future teacher of primary school accomplishes semantic processes immersed in the construction of multiplication and division operations of fractions, considering that the effectiveness of her/his teaching practice in basic education will depend on the strength with which she/he develops these ideas and their corresponding didactic integration.

The previous statement is our research problem, from which we pose the following *questions* and analyze them in the present paper: Which are Tania's thoughts *when she multiplies and divides fractions* within the design and solving problems scope? *How this young future teacher relates both operations* in the semantic field of fractions?

In the next section we present some theoretical categorizations sustained by some authors, in the study of various general forms of thoughts, as well as with respect to the multiplicative thinking linked to fractions.

Theoretical Framework

In the study of thought, Piaget (1986) distinguished the *concept*, which is established as the inclusion of an object in a class as well as one class into the other. It is interesting to highlight that thus *the construction of the concept* is achieved by *multiple modes of abstraction.*

Vygotski (1993), regarding thought, conceived *concept* in terms of a *generalization* that appears in the subject consciousness as a complex act of thought, a process of words significance, instead of assimilation through memory. *Concepts are constructed around pre-concepts,* that is, none conscious content is eliminated only transformed into another of superior level, from a major generalization of the object.

Another point of view related to thought is the one provided by Lonergan (2008), who mentioned that *elaboration of concept* implies *the identification of interrelated aspects in an "object" as well as in the saying*. To say and to conceive are not isolated. *The elaboration of a concept requires a process of selection among data, empirical representation and image.* The concept is what can be expressed beyond empirical.

In contrast to the previous statements, Shön (1996) identified *reflection in action* as a production of a spontaneous and *intuitive thought related to everyday life experience*. He also mentioned that *the teacher can reflect in action* from the own experience and change a routine teaching practice using all her/his thought to act facing a new situation.

Valdemoros, Ramírez, and Lamadrid (2015) propose that in the discourse of a learner may appear *"signification and thinking cores"* full of sense for he/she, this is, *words and phrases that give consistency and clarity to the own praxis*, in an elementary way. Such *"signification and* *thinking cores"* offer cohesion to the cognitive products, despite the fact that the thinking of those who learn could be developed currently at the intuitive level, not having reached even the widespread expressions of the formation of concepts.

Related to the set of rational numbers, Kieren (1988) pointed *in his semantic network* that *multiplicative domains* are *linked to formal construct of equivalence and to multiplicative structure* related to functional and scale relations. Scale relation is assembled through *meanings of fraction* such as *ratio*, which indicate a numeric comparison between two magnitudes and an *operator* (the last construct refers to expand or to contract a whole with reference to another unit).

Fraction is based on two fundamental relations: part-whole relation and part-part relation (Piaget, Inhelder & Szeminska, 1966). The first of these relations is defined as the existing link between whole and a determined number of parts when the latter, continuous or discrete, is divided in equivalent parts. Part-part relation refers to the possibility that all parts can be divisible by themselves and considered as new wholes (Piaget et al., 1966). Such statements were ratified by Kieren (1988).

Conceptual field of multiplicative structures is composed of all *situations that mutually involve multiplication and division,* such as: simple and composed proportions, direct and inverse scales of ratio, fraction, ratio, rational number, among other ideas (Vergnaud, 1988). In particular, the *product of measures* as multiplicative relation shows the difference among diverse types of multiplication problems when, given basic measures, the measure-product is found; concerning division, given basic measures and measure-product, another basic measure should be found (Vergnaud, 1991).

Method

In this report, we show some relevant contents of Tania's multiplicative thought and detailed which are the main mathematical and didactical ideas manifested in her discourse during interviews, which emerged as some *signification and thought cores.*

We decided to interview Tania because she was the most outstanding student among her study group, during the fourth semester of the bachelor's degree in primary education. In this mentioned degree, future teachers are trained for teaching in all subjects that form part of the school curriculum in elementary education (that is the development of these studies in Mexico).

At the time Tania interviews took place, she had already coursed the subject of Arithmetic (third semester in this academic level). Though this research we could not have access -as observers- to Arithmetic and Teaching Practices courses, for this reason the relevance of Tania interviews was ratified for the recognition of some susceptible processes of thought within a possible development in the teacher in training.

We carried out two interviews of didactical cut with Tania because such a methodological proposal from Valdemoros (1997, 1998), and Valdemoros & Ruiz (2008), considered two moments of the development of the interview: a) an exploratory phase in which interviewer only deeply inquire for contents and mathematical processes of the interviewed; and b) a feedback phase, through which interviewer tries to promote a reflection that evidence the contrast between thinking contents and calculus procedures, and thus validate them based on their own production and refine its inconsistencies.

Qualitative validation of these results was obtained by mean of a methodological *triangulation at different moments, during interviews*.

Analysis of Results

Next are some relevant results from Tania's interviews, linked to multiplication and division of fractions, included in the scope of problem solving focused in the teaching of fractions. *Quoted* *expressions correspond to words and phrases* of Tania that we interpret as *signification and thought cores*, linked to the *reflection in action*.

Situation 1

Tania was asked to solve a division problem of fractions (centered on the recognition of the *inverse operation of a product of measures*). Such task was designed for 6th grade of primary school and Tania must communicate her didactic and mathematical reflections about it. The text of the problem requested *to calculate an unknown side of a rectangle board for a bookcase, given area* ($\frac{1}{2}$ *m^2) and a side* ($\frac{2}{3}$ *m)*; this task was complemented with the *graphical representation of the rectangle and the corresponding measures*. Tania thought for a while and then expressed: "you have to solve for the formula of the rectangle area [she holds up] and divide one-half into two-third". The phrase "solve for formula of the rectangle area" represented a heavy semantic load for Tania; it was a clear manifestation of a *signification and thought core.*

Situation 2

We asked Tania to write a problem referred to a division of fractions. She did not provide any oral evidence that she was capable of designing division problems of fractions for the teaching (inside or outside of a geometric field).

Situation 3

Tania continued striving to contrive a multiplicative problem referred to fractions. After proposing an ambiguous elaboration that remained incomplete, she opted to fold a sheet of paper while she was saying "*…this sheet represents a cake that I'm dividing in thirds and quarters, to recognize within it* $\frac{2}{3}$ *and* $\frac{3}{4}$ *fractions"*. Thus, Tania was intuitively leaned on *the relation part-part*, which emerged as a result of the "*paper folding"*. Finally, Tania colored the intersection among both fractions in the piece of paper (appointed the prior as "*the whole"* and "*the unit of reference"*). When we asked Tania which arithmetic operation has employed in both fractions, she could hardly express that she had obtained *"the product* $\frac{32}{3}$ *by* $\frac{3}{4}$*"*.

Overall, although Tania was eloquent during Situations 1 and 3, many of her mathematics and didactic difficulties were evident in the multiplicative field of fractions. Her mathematical thought did not show conceptualized multiplicative proposals, as of progressive *generalizations* and successive *abstractions* (according to those theoretic formulations from Vygotski and from Piaget).

Tania thought was manifested as outstandingly intuitive, partially fragmented, and linked to the own praxis (which promoted plenty of reflections in action, followed by pertinent adjustments to her proposals). For all this, ideas within identified signification and thought cores, provided a kind of strength and a link to such thought. In all this, we do not know in which extent the occasional influence that the Arithmetic course of the Bachelor's degree exerts on Tania.

Conclusions

The aforesaid *signification and thought cores* that Tania expresses in her present discourse, in terms of words and phrases either mathematical and didactical that regulate and define her design activity for the teaching, do not become concepts or pre-concepts yet, but it is possible that such elaborations in the future would constitute roots of thoughts more systematic, general and increasingly better integrated into the multiplicative processes of fractions.

During the interviews, *intuitive thought* immersed in Tania's explicit discourse was sometimes supported by reflections oriented towards teaching practice and a suitable *reflection in action* for those activities that she wants to promote in the classroom.

EXAMINING PRE-SERVICE TEACHERS' UNDERSTANDING OF THE COMMON CORE STATE STANDARDS FOR MATHEMATICAL PRACTICE

Jillian P. Mortimer
University of Michigan
jbpet@umich.edu

This study seeks to probe pre-service teachers' (PSTs') understanding of the Common Core State Standards for Mathematical Practice (SMPs) (NGAC & CCSSO, 2010) by having PSTs identify the potential for SMPs to be practiced and assessed through assessments, curriculum materials, and in practice. The ratings of the PSTs will be compared to those of curriculum authors, as well as to the other PSTs in the sample, in order to determine the amount of agreement based on specific characteristics such as mathematical knowledge for teaching and beliefs about mathematics. After patterns have been identified, PSTs will be strategically chosen for interviews to probe their thinking further. The results of this study will be useful to elementary mathematics teacher educators in thinking about ways to support PSTs in understanding the SMPs as well as helping PSTs to support students' development of the SMPs.

Keywords: Teacher Education-Preservice, Standards, Curriculum, Assessment and Evaluation

Introduction

The Standards for Mathematical Practice (SMPs), part of the Common Core State Standards (CCSSs) *(NGAC & CCSSO, 2010)*, stress the importance of processes and proficiencies that span all grade levels and mathematical content. The work in this study stems from two previous studies (Silver and Mortimer, 2015; Mortimer, 2016) in which the researchers asked what SMPs mathematics teacher educators' and mathematicians' saw potential to be assessed by assessment items. One of the most compelling findings from these studies suggests that, though the SMPs can be seen throughout an international mathematics assessment, experts are not always in agreement about what it looks like to assess the various SMPs. When probed about their differing assignments, experts reported that in many cases the SMPs were vaguely described. In other cases the assessment task could be solved using multiple strategies and thus it was challenging to know exactly what SMP someone would employ. As teachers are expected to be able to support students in learning and assess students' progress in the SMPs, more research is necessary on how to recognize and assess SMPs in assessments and classroom materials.

In this study I will examine the ways that PSTs make sense of the SMPs in the contexts of a lesson from a teacher's manual, a video of teaching and an assessment. Additionally, I will look at the PSTs' mathematics knowledge and beliefs in order to understand how these factors may influence their understanding and interpretation of the SMPs. This study lies at the crossroads between research and teacher education and the results of this study have the potential to provide insight for teacher educators on ways to support PSTs in developing their own understanding of the SMPs as well as support students in practicing and gaining skill in using the SMPs.

Theoretical Justification

Teachers' Mathematical Knowledge

Shulman (1986, 1987) began examining teachers' knowledge and how the ways of knowing content differ between teachers and other professionals. He explained teachers' knowledge as falling into three categories: content knowledge, pedagogical content knowledge, and curriculum knowledge. Building on this work, the research group involved in the Study of Instructional

Improvement (SII) endeavored to build a theory around what teachers need to know to teach mathematics, but began by examining practice and what teachers actually do in classrooms (Ball & Bass, 2003). This group went on to develop measures to assess teachers' mathematical knowledge for teaching (MKT). Studies implemented by this group have gone so far as to attempt to link teacher knowledge to student performance (e.g., Hill, Rowan, and Ball, 2005).

Teachers' Beliefs

In addition to teacher knowledge impacting instruction, McLeod and McLeod (2002) suggest that looking between the cognitive and affective processes, specifically at teacher beliefs, is important to understanding how teachers' approach instruction. Much of the research on teacher beliefs in relation to mathematics education has focused on teachers' beliefs about the nature of mathematics and mathematics teaching and how those beliefs impact their instructional practices (e.g., Thompson 1984).

Research Questions

1. Are PSTs able to identify places in the different domains of practice (e.g., the lesson, video of teaching, and assessment) that they will be expected to use as practicing teachers with the potential to assess or develop students' proficiency in the SMPs? To what degree do they agree with the curriculum authors? To what degree do they agree with each other?
2. How does PSTs' mathematical knowledge influence their ability to identify and make sense of SMPs in different representations of teaching? How does PSTs' mathematical knowledge impact their agreement with the authors of the curriculum materials? Does it differ by task?
3. How do PSTs' beliefs about mathematics influence their ability to identify and make sense of SMPs in different representations of teaching? How does PSTs' mathematical knowledge impact their agreement with the authors of the curriculum materials? Does it differ by task?

Methods

Participants

The twenty-four PSTs in this study are third and fourth year undergraduate students at a large, Midwestern public university earning a Bachelor's degree and teaching certificate, pending successful passing of the state teacher certification assessment. Similar to many pre-service and in-service teachers, these PSTs have had little to no explicit instruction on the SMPs. Though their mathematics methods course includes mathematics practices, as the doing of mathematics always does, the practices specified in the CCSS are not a focus of the course.

Instrumentation

Mathematical Knowledge for Teaching (MKT). Stemming from the work of the Study of Instructional Improvement (SII), The Learning Mathematics for Teaching (LMT) project created an assessment to measure school and classroom processes as well as teachers' facility in using mathematical knowledge in their classroom teaching (Learning Mathematics for Teaching Project, n.d.). The PSTs in this study are given the LMT assessment at two points during their program; the most recent implementation of the assessment will be used as the measure of their MKT.

Mathematics Beliefs Instrument (MBI). In order to measure PSTs' beliefs about mathematics the Mathematics Beliefs Instrument (MBI) will be used (Peterson, Fennema, Carpenter, & Loef, 1989, as modified by the Cognitively Guided Instruction Project). The instrument consists of three subscales: 1) Curriculum: the degree to which one believes that mathematics should be taught in relation to problem solving and understanding rather than focusing on facts and memorization; 2)

Learner: the degree to which one believes that students can construct their own mathematical knowledge; 3) Teacher: the degree to which teachers should organize instruction to facilitate children's construction of knowledge. The instrument is scored on a five-response Likert scale that, when added together, higher scores indicate that the teacher's beliefs are more aligned with cognitive beliefs.

The Tasks

Curriculum materials task. PSTs will be given a lesson from the Everyday Mathematics (EDM) curriculum materials as well as a copy of the SMPs. The curriculum materials will include pages from the Teachers' Manual. Though the authors already included places where they believe students have the opportunity to practice the SMPs, these designations will be removed so that there is no indication of which SMPs the authors intended to be addressed in the lesson. The PSTs, working independently, will examine the SMPs and the lesson. They will go through the lesson and indicate each instance in which they think an SMP is or has the potential to be practiced by students. PSTs will be asked to explain their judgments.

Lesson enactment task. PSTs will view a video of an elementary teacher teaching the mathematics lesson that they examined in the curriculum materials task. In the video the teacher will not explicitly name the SMP that she is intending to teach, but the SMP will be embedded in the work that the teacher and students are doing. Using the online video program Edthena, PSTs will be asked to identify which SMP or SMPs that they see being practiced in the video. They will do this by tagging specific places in the video and explaining their thinking in writing in the tag.

Assessment task. PSTs will look at a formative assessment, the journal pages that correspond to the lesson in the curriculum materials task, and indicate for each problem which of the SMPs have the potential to be assessed. PSTs will be asked to explain their judgments.

Analysis and Expected Results

PST and Expert Rater Comparisons

For each of the three tasks I will compare the ratings given by the authors of the curriculum materials and the ratings given by the PSTs. This comparison will result in descriptive statistics showing the frequency with which all PSTs agreed with the authors, if PSTs were more likely to agree with authors on particular tasks, or if specific characteristics of PSTs made them more likely to agree with the authors (e.g., PSTs with high MKT were more likely to agree with the curriculum authors than those with low MKT). Additionally, I will conduct a comparison among PSTs based on the PSTs' characteristics (i.e., PSTs' MKT and mathematical beliefs).

PST Interviews

I will choose PSTs to interview, selecting representatives of various groups based on the patterns that arise when comparing PSTs' ratings to the authors and other PSTs. These interviews will focus on probing PSTs' ratings in each of the three tasks to understand both why they chose the SMP that they chose in the tasks as well as the processes they used to determine their ratings.

Discussion

As the SMPs are a part of the CCSSs, they are part of the intended curriculum for all states that have adopted the CCSSs. As part of the intended curriculum, teachers are expected to have achieved expertise in the SMPs and feel confident supporting their students in developing the SMPs. Currently many schools of education do not address the SMPs in an intentional way. As discussed, the SMPs are challenging to identify, even for experts, so more support is needed for PSTs in this area. In order for the SMPs to be taught to PSTs in a meaningful way, more understanding of what PSTs already know and understand about the SMPs is needed.

The results from this study will provide the teacher education community with information about PSTs' understanding of the SMPs. The three different tasks may illuminate that PSTs are more skilled at identifying potential for SMPs to be practiced and assessed in different representations of teaching. Additionally we may learn that particular background knowledge and beliefs are important for PSTs in order to complete the tasks successfully. Ultimately the results of this study will support teacher educators in thinking about ways to provide instruction and practice to PSTs so that they enter the teaching field confidently able to support their students in developing their skills in the SMPs.

EXPLORING AN INTEGRATED NOTICING FRAMEWORK FOR SECONDARY MATHEMATICS TEACHER EDUCATION FIELD EXPERIENCE

Kathleen T. Nolan
University of Regina
kathy.nolan@uregina.ca

Traditional models for teacher education field experience often perpetuate a split between theory (university) and practice (school classrooms). One way for prospective secondary mathematics teachers to engage with theory at the classroom level is to involve them in a professional learning community during their field experience (internship). This paper shares research on the development of an alternative model for internship and for faculty supervision through the creation of a learning community and an integrated professional development process (incorporating lesson study, video analysis and the discipline of noticing). The research emphasizes the value of community and collaboration when reconceptualizing traditional models for internship, for the role of the faculty advisor, and for being/becoming a mathematics teacher.

Keywords: Teacher Education-Preservice

Research Purpose

Traditional models for teacher education field experience often perpetuate a split between theory (university) and practice (school classrooms). One way for prospective secondary mathematics teachers to engage with theory at the classroom level is to involve them in a professional learning community during their field experience (internship). This paper shares research on the development of a model for internship and for faculty supervision through the creation of a learning community and an integrated professional development process (incorporating lesson study, video analysis and the discipline of noticing). The overall research project has a tri-focal outcome of: (1) disrupting traditional discourses on theory-practice transitions in mathematics teacher education, (2) reconceptualizing the role of the university supervisor (faculty advisor) within the triad of prospective teacher, cooperating teacher and supervisor, and (3) positioning university-school partnerships and collaboration at the centre of professional development approaches in teacher education programs.

Research Context and Modes of Inquiry

My research in the area of secondary mathematics teacher education focuses on the structures and roles of that specific component of teacher education programs referred to as the school practicum or field experience (Nolan, 2012). Specifically, I conduct self-study research into my role as a university supervisor (faculty advisor) during teacher education field experience. In my university's four-year undergraduate teacher education program (located in a Canadian province), the culminating field experience is a four-month internship in schools. Each prospective teacher (intern) is paired with a cooperating (mentor) teacher in the school and assigned a faculty advisor, who is expected to visit, observe, and conference with each intern only 3-5 times during this internship. Over the years, as a faculty advisor for prospective secondary mathematics teachers, my role in this internship model felt superfluous, even token (Nolan, 2015).

To move my role beyond tokenism in the field, I initiated a research project to design and facilitate an alternative internship model for secondary mathematics teacher education field experience. I refer to this model as the Teacher-Intern-Faculty Advisor (TIFA) Internship Learning Community model. During each of four distinct internship semesters (2013-2016), the TIFA learning community consisted of three interns, their cooperating teachers, and me as faculty advisor (and researcher). In the model, TIFA participants engage in a unique professional development process in which I integrate three components: a modified approach to lesson study (Gorman, Mark, & Nikula, 2010), the video recording and editing of classroom teaching episodes, and a video analysis process based in the discipline of noticing (Mason, 2002). I refer to this professional development process as an *Integrated Noticing Framework*.

Theoretical Perspective: Introducing the Integrated Noticing Framework

The *Integrated Noticing Framework* (herein referred to as INF) is based on a belief that "it is critical for teachers to first notice what is significant in a classroom interaction, then interpret that event, and then use those interpretations to inform their pedagogical decisions" (van Es & Sherin, 2008, p. 247). In addition, teachers (both novice and experienced) need to feel safe within a non-judgmental environment in order to further their growth and development as teachers, especially in this age of inquiry (reform-based) mathematics pedagogy. The INF professional development process developed for my internship community model values the experiences and interpretations of teachers, providing an environment for working collaboratively and for sharing experience, expertise, and multiple perspectives on teaching and learning in secondary mathematics classrooms.

The three individual components of the INF involved in my TIFA learning community (lesson study, video analysis, and noticing) are not entirely dissimilar from those described in other research on mathematics teacher education noticing (see, for example, Coles, 2013; Sherin, Jacobs, & Philipp, 2011). What is unique about this research project and professional development initiative lies not so much in WHAT is done but in HOW the process serves to disrupt normalized practices in the education of new mathematics teachers. The INF is conceptualized and enacted in two parts.

Integrated Noticing Framework Part I

In the first part, the TIFA learning community meets together at my university for one full day each month (over the duration of the four-month field experience, or internship) to participate in a *modified lesson study* process. The outcome of this part of the process is the creation of a 'research lesson,' which is then taught by each of the interns in her/his own school classroom setting. The teaching of the lesson is video recorded, then edited by the intern to create a 12-minute video clip, and finally brought back to the next TIFA professional development day at the university. The lesson study process used in part one of the INF is referred to as 'modified' since, as a community, we adopt the position that it makes the most sense for each cooperating teacher and intern pair to further develop the main outcomes and activities of the lesson (as initially planned by the TIFA community) based on their own specific school and classroom contexts, rather than fully developing a uniform and context-free script for all to follow.

Integrated Noticing Framework Part II

During the TIFA learning community meeting, the team engages in video viewing and analysis based in the *discipline of noticing*. As Mason (2011) explains, the *discipline of noticing* is a collection of techniques for preparing to notice in the moment; for reflecting on past events to understand what one wants to, or is sensitized to, notice; and for learning to notice in the moment so as to act freshly rather than habitually (p. 48). As a group, the TIFA community views all three intern teaching videos, using a noticing framework to stimulate discussion and reflection on the videos. My INF noticing process (adapted primarily by drawing on Coles (2013)) consists of four phases: (1) View each video, taking individual 'noticing notes' while viewing; (2) remain in silence for 2 minutes, organizing one's noticing notes to highlight what will be shared with the TIFA community; (3) give an *account of* what was observed in the video (sharing *what was observed directly*, in detail, avoiding all interpretation at this stage); and (4) *account for* what was observed (this is the interpretive stage where possible meanings or explanations for what was observed in the video are presented and discussed). The four phases are enacted, in turn, for each of the three intern videos, being especially careful to separate phases (3) and (4) so as to allow the observations to be voiced and heard, prior to any interpretations, questions, or discussion being introduced into the process.

Data and Discussion of Results

As Coles (2013) notes: "If I am not careful I will only see... that which I already think and believe" (p. 11); this is especially true for mathematics teacher education field experience practice and supervision. In my university's teacher education program, the prospective teachers and school mathematics cooperating teachers already feel that they 'know' what internship is all about and the role of the faculty advisor within. Research indicates that prospective teachers view the practice-based experiences of teacher education as the most important part of their program and the most significant influence on be(com)ing a teacher and shaping a professional identity (Britzman, 2003). There is little surprise, then, that introducing disruptions into the usual, normalized internship experience can be met with skepticism, even frustration. However, my research data indicate that those participating in this community's integrated noticing framework embraced change (the 'disruptions') because of the benefits they saw and experienced firsthand.

Benefits of the TIFA community approach have been noticed on a number of levels, including those beyond what was anticipated in my original goal of disrupting my token role as a supervisor. For instance, there have been noticeable influences on interns' desires and abilities to be reflective on their process of becoming a teacher; they articulate the many benefits of having "more eyes on what you're doing and how you're working with students" (intern, TIFA 2014) through this collaborative community approach to video analysis. Similarly, cooperating teachers have expressed surprise by the ways in which the learning community and INF have had such a major impact on them – not only in their roles as cooperating teachers but as classroom mathematics teachers who, like the interns, are also trying to grow and develop as inquiry-based teachers. Each year of running the TIFA community and collecting research data, cooperating teachers were asked about challenges and rewards of being involved in this enhanced internship project and if the community played any the role in their own professional development as mathematics teachers. One cooperating teacher responded:

> As far as rewards… just seeing what other cooperating teachers noticed, and then getting the opportunity to give feedback on other intern's lessons, and even getting to know other interns and other cooperating teachers… that collaboration piece is nice. (Cooperating teacher, TIFA 2014)

As alluded to in the above quote, the community approach has also had a significant impact on the intern and cooperating teacher's relationship with each other, as well as their relationship with the other intern and cooperating teacher pairs in the learning community. Participants commented on how beneficial it was to plan a lesson together, to video record aspects of that lesson and then engage in the noticing process as a collaborative and supportive group. Additionally, the overall impact of the internship learning community on connecting and building relationships between university teacher education programs and schools cannot be overlooked. School principals and teachers throughout the province have requested involvement in this internship model, recognizing it as a way to enhance the processes of both becoming *and being* a mathematics teacher.

Finally, related to the originally articulated goals of the enhanced internship and INF, my role as a faculty advisor, as explored through self-study approaches, has unquestionably moved my role beyond tokenism in the field. For example, when I asked my interns about my role as a faculty advisor in comparison to what they know about other interns' experiences, one intern responded:

> Just based off of the experiences of my friends who aren't in the TIFA community, the faculty advisor came out once or twice; they didn't really have a relationship established with them. This

> [TIFA community] is good 'cause we were able to establish a relationship and then actually get effective feedback on what we could improve. [Intern, TIFA, 2015]

Scholarly Significance

The complexity of mathematics teacher education field experience means that there is little overall agreement on many issues: the role of the cooperating teacher, the role of supervision, and even the role of practicum in general. Bullough, et al. (2002) suggest that "[t]here is a growing need for experimentation with configurations of field experience and for the generation and study of new models to determine their effectiveness" (p. 69). My professional learning community model, operationalized through the use of the INF, responds to this suggestion, reflecting my efforts as a mathematics teacher educator and supervisor to experiment with and generate new models. In this research, my role as a faculty advisor creates spaces for a collaborative community of teachers to witness the power of transforming theory-practice transitions into engaging and reflective pedagogical practice in mathematics classrooms.

Despite the importance of teachers' conception of mathematical modeling, limited attention is given to this area in the current literature. In this study we examined 78 preservice teachers' (PSTs) views of mathematical modeling and how their conceptions are reflected in their performance of mathematical modeling problems. Analyses of survey responses revealed that our PSTs seem to develop narrow views of mathematical modeling. In addition, although a large portion of PSTs mistook mathematical modeling with mathematical models or with traditional word problems, we found a positive association between PSTs' conceptions of mathematical modeling and their mathematical modeling abilities.

Keywords: Modeling, Teacher Education-Preservice

Introduction

Mathematics education community at large has recognized the importance of mathematical modeling at school level, which concerns how well students are prepared to solve real-world problems that they encounter beyond school, to solve problems in their future professions, as citizens and in further learning (Galbraith & Stillman, 2006). The Common Core State Standards for Mathematics (National Governors Association Center for Best Practices [NGA] & Council of Chief State School Officers [CCSSO], 2010) also highlights mathematical modeling as one of the eight Standards for Mathematical Practice for all grades but also as conceptual category in high school. Thus, preparing effective teachers of mathematics who promote students' conceptual understanding and mathematical modeling abilities is one of the most urgent problems facing teacher educators. The purpose of this study is to explore PSTs' conceptions of mathematical modeling and effective modeling instruction and to investigate any relationship that might exist among PSTs' conceptions of effective modeling instruction, mathematical modeling, and their mathematical modeling performance. In exploring the relationship between PSTs' conception of effective mathematical modeling instruction and their mathematical modeling abilities, we specifically focus on two popular modeling problems – (a) Deciding a departing time for airport and (b) finding the best estimate of the total number of people in concert. The research questions that guided this study are: (a) What are the characteristics of PSTs' thinking about effective mathematical modeling instruction and mathematical modeling? and (b) Is there any relationship among PSTs' conceptions of effective mathematical modeling instruction, mathematical modeling, and their mathematical modeling performance?

Theoretical Perspectives

Mathematical modeling is a powerful vehicle for students' mathematical learning. However, the term "mathematical modeling" is easily confused. Research reported several confusions teachers and students have. For example, the term of mathematical modeling is often considered as mathematical models or traditional word problems. Although there exist distinct differences between "modeling as content" and "modeling as vehicle" (Galbraith & Stillman, 2006), teachers tend to "treat [mathematical modeling] more as a venue for learning other mathematics" (Zbiek & Conner, 2006, p. 89). Mathematical modeling involves a cyclical process as shown in Figure 1 in which real-life problems are understood and translated into mathematical language (*formulate*), solved within a symbolic system (*compute*), and the solutions tested back within the real-life system (*interpret, validate, and report*).

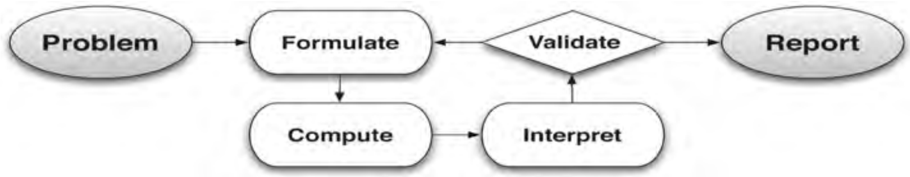

Figure 1. The basic modeling cycle introduced in the CCSSM (NGA & CCSSI, p. 72).

In this study, using the three meanings of mathematical modeling by Stanic and Kilpatrick (1989) and the three teaching approaches to mathematical modeling by Schroeder and Lester (1989), we explored PSTs' conceptions of mathematical modeling and effective mathematical modeling instruction. Building on Schroeder and Lester's framework, the following three perspectives of mathematical modeling instruction can be identified in mathematics classrooms: (1) teaching *for* mathematical modeling, (2) teaching *about* mathematical modeling, and (3) teaching *through* mathematical modeling. In addition, drawn from Stanic and Kilpatrick, we believe that *mathematical modeling as art* should be a goal of effective mathematical modeling instruction. According to them, three different meanings were attributed to the notion of mathematical modeling in mathematics education-- *mathematical modeling as means to a focused end (content), mathematical modeling as a skill,* and *mathematical modeling as art.* In the first perspective, mathematical modeling can be viewed just as *content* to practice skills. Similarly, the second perspective considers mathematical modeling as one skill taught in school mathematics. In contrast, in the third perspective, mathematical modeling should be viewed as an act of discovery through creative use of mathematical thinking.

Methods

78 PSTs from two different university sites were invited for this study. Participants had some experience of solving modeling problems within their class work. In the beginning of the semester, all participants completed the tasks shown in Figure 2. They showed misconceptions on mathematical modeling and did not provide a realistic answer to the problems. Two 3-hour sessions were devoted to help them understand mathematical modeling. By the end of the semester, a written task (see Fig. 2), was used for the study as part of final assessment.

Part 1: Please answer the following questions in as much detail as possible.

1. When people say mathematical modeling, what does the word "mathematical modeling" mean to you?
2. What do you believe constitutes effective mathematical modeling instruction?

Part 2: Solve the following problems.

1. Your best friend is coming to visit. She told you that her bus arrives at 4:00 pm. You live 10 miles away from the bus station. The speed limit is 40 miles per hour. When should you leave your house? Explain your reasoning.
2. A popular band recently came to a music festival. A field of size 100 m by 200 m was reserved for the audience. The concert was completely sold out and the field was packed with all the fans standing. Which one of the following is likely to be the best estimate of the total number of people that attended the concert? 10,000, 20,000, 100,000, 200,000, or 400,000? Explain your reasoning.

Figure 2. Main task of this study.

For the analysis of PSTs' written response to mathematical modeling and effective mathematical modeling instruction, we used an inductive content analysis approach. PSTs' responses to the notions of mathematical modeling and effective mathematical modeling instruction were categorized based on themes emerging as researchers read multiple cases. Then we explored the subcategories under each analytical aspect according to the framework (see Table 1 later). For the modeling task, we first created a rubric based on correctness of PSTs' responses to each item and then assigned a score for each item. To examine relationship among PSTs' conceptions of mathematical modeling, effective mathematical modeling instruction, and their mathematical modeling performance, we run SPSS statistical program (e.g., ANOVAs).

Summary of Selected Findings

Psts' Conceptions of Effective Mathematical Modeling Instruction

To investigate PSTs' conception of effective mathematical modeling (MM) instruction, we reviewed their responses and classified the responses into four aspects based on common themes (see Table 1). Out of the four aspects, the most popular category is *teaching* aspect (i.e., what instructional strategies or teaching practice need for effective MM instruction?), followed by mathematical modeling *steps* aspect (i.e., what step is required for MM lesson?), *problem features* aspect (i.e., what is considered as a good problem for MM instruction?), and *purpose* aspect (i.e., what is a good MM lesson aimed at?).

Table 1: Four Aspects of PSTs' Conception of a Good Mathematical Modeling Lesson and Frequencies

Category	Sub-category	# of PSTs	Relation to 3 MM approaches
1. Purpose aspect (29)	a. To find a realistic solution	10	For
	b. To develop critical/ logical /reflective thinking	14	Through
	c. To develop a good understanding of math	5	Through
2. Problem aspect (39)	a. Real-life problems	14	Through
	b. Problems that requires student prior knowledge	5	Through
	c. Practice problems that use the same technique	4	For
	d. Problems that require multiple solutions	11	Through
	e. Problems that require explanations	5	Through
3. Mathematical modeling steps aspects (42)	a. Structuring a lesson for all five modeling steps	14	About
	b. Identifying problem	12	About
	c. Devising a strategy	3	About
	d. Carrying out	2	About
	e. Interpreting	11	About
	f. Validating	5	About
4. Teaching aspect (78)	a. Emphasizing different ways of solving problems	20	Through
	b. Giving examples about how to solve	10	For
	c. Giving definitions on mathematical modeling	9	For
	d. Giving enough time to work on problems	6	For/Through
	e. Providing a direct, clear direction and structure	25	For/About
	g. Lessons that are interesting to students	8	Through

Note. Majority of PSTs addressed multiple categories. These responses were coded in multiple categories as long as the categories were present in their written responses.

After identifying the four aspects, we collectively considered them to categorize PSTs' conceptions of effective MM instruction into the three groups by referring to Schroeder and Lester's (1989) identification. Out of 78 participants, 42 participants considered effective MM instruction as teaching *about* mathematical modeling, 13 participants as teaching *through* mathematical modeling, and 20 participants as teaching *for* mathematical modeling. This finding indicates that despite the consistent emphasis on teaching *through* mathematical modeling in current mathematics education, a large portion of our PSTs still did not have a clear view of teaching *through* mathematical modeling. In a similar way, we categorized PSTs' conception of MM into three groups by referring to Stanic and Kilpatrick's (1989) identification. Out of 78 PSTs, 42 PSTs considered MM as *content*, 22 PSTs as a *skill*, and 14 PSTs as *art* of discovery.

Relationship between PSTs' Conceptions and Their Modeling Performance

For the first problem that asks students to decide when to leave their house, about 42 % PSTs responded that they would leave their house at times before 3:45 pm to go pick up their friend (correct realistic answer); 58% responded that they would leave their house at 3:45 pm. For the second modeling problem that requires students to determine the best estimate of the total number of people that can attend the concert in the size 100 m by 200 m, 42 % PSTs responded that there were 100,000 fans (correct realistic answer) whereas 38% provided a mathematically correct answer, 20,000. After coding PSTs' written responses and grading mathematics tasks, we quantified the data analysis result to examine relationship among PSTs' conception of mathematical modeling, a good mathematical modeling lesson, and their mathematical modeling performance. A chi-squared test showed that there is a positive relationship between PSTs' conception of mathematical modeling and their conception of effective mathematical modeling instruction, $\chi^2 = 16.888$, $df = 2$, $p = 0.002$**.** In addition, there was a significant difference of mean scores concerning mathematical modeling competence among groups of PSTs who perceived different views on mathematical modeling, $F(2, 73) = 3.292$, $p = .024$. PSTs who perceived mathematical modeling as *art* showed highest mean scores in the mathematical modeling tasks, followed by PSTs who with mathematical modeling as *means* to a focused end.

Discussion and Implications

This study contributes to the current literature on mathematical modeling and the knowledge base of teacher education. The findings of this study suggest that teacher educators need to find a better way to help PSTs perceive mathematical modeling as *art* and effective mathematical modeling instruction as teaching mathematics *through* mathematical modeling (Son, 2016). One approach would be: Have PSTs experience three different perspectives of teaching mathematical modeling and compare affordances and limitations of each approach. Then teacher educators need to give PSTs more opportunities to experience teaching *through* mathematical modeling in their mathematics methods courses where PSTs engage in mathematical modes of thought by analyzing and interpreting the problems. Furthermore, intervention studies that experiment with these suggestions are needed to find a better way to support PSTs' conceptions regarding mathematical modeling, modeling lessons and their mathematical modeling abilities.

HOW PRESERVICE TEACHERS' CONCEPTIONS OF PROBLEM-POSING RELATE TO THEIR PROBLEM-POSING COMPETENCY WITH FRACTION OPERATIONS

Ji-Won Son
University at Buffalo-SUNY
jiwonson@buffalo.edu

Mi Yeon Lee
Arizona State University
mlee155@asu.edu

Despite the importance of teachers' conception of problem-posing and their problem-posing competency, limited attention is given to this area in the current literature. In this study, we examined preservice teachers' conception of problem-posing and their problem-posing performance. We asked preservice teachers to define problem-posing. We then investigated how their conceptions of problem-posing were reflected in their mathematical problem-posing performances in the context of fraction operations. Analyses of 67 preservice teachers' written responses revealed that a large portion of the preservice teachers defined problem-posing as general actions for teaching. However, preservice teachers who viewed problem-posing as a means of improving problem-solving tended to provide correct word problems that include multiple solution paths in a realistic context.

Keywords: Teacher Education-Preservice

Introduction

The purpose of this study is to examine elementary preservice teachers (PSTs)' conception of problem-posing. We also investigate how their conceptions of problem-posing are reflected in mathematical problem-posing performance. With increased interest in curricular and pedagogical innovation in mathematics education, mathematics educators have paid attention to problem posing. According to *Principles and Standards for School Mathematics* (NCTM, 2000), the use of problem-posing activities in the mathematics classroom should be encouraged to improve students' mathematical understanding and creativity. In a similar vein, Kilpatrick (1987) highlighted that "problem posing should be viewed not only as a goal of instruction but also as means of instruction" (p. 123). However, problem posing has been used with multiple meanings that range from "the generation of new problems" or "the re-formulation of the given problem" to "a means to improve students' problem-solving" or "a window into students' mathematical understanding" (Silver, 1994). While the first two meanings of problem posing are related to doing mathematics (Brown & Walter, 2005), the rest two meanings are associated with the features of inquiry-oriented instruction. Thus, what is meant by problem posing is often subject to interpretation in a particular context, which suggests the need for exploring how mathematical problem posing is conceptualized by teachers and whether there exists any relationship between their conceptions of problem posing and their problem-posing abilities. The research questions that guided this study are: (1) how do PSTs view problem posing?; (2) how do PSTs pose word problems related to fraction multiplication and division?; and (3) how is their notion of problem posing reflected in their ability to pose word problems related to fraction operations?

Theoretical Perspectives

Problem posing has long been recognized as a critically important component of the mathematics curriculum, and is considered to be an essential part of doing mathematics (NCTM, 2000). Kilpatrick (1987) conceptualized problem-posing as reformulating an existing problem in order to make it your own. Different from Kilpatrick (1987), Stoyanova and Ellerton (1996) defined problem-posing as "the process by which, on the basis of mathematical experience, students construct personal interpretations of concrete situations and formulate them as meaningful mathematical problems" (p. 518). The subjective nature of this definition—one should decide in which aspect the problem is meaningful and for whom—is apparent. Silver (1994) identified six different perspectives on mathematical problem-posing, which include: (1) problem-posing as a feature of creativity or exceptional mathematical ability; (2) problem-posing as a feature of inquiry-oriented instruction; (3) problem-posing as an important component in the creation of mathematics by professional mathematicians; (4) problem-posing as a means to improve students' problem-solving; (5) problem-posing as a window into students' mathematical understanding; and (6) problem-posing as a means of improving students' disposition toward mathematics. Then, what would be a good conception of problem-posing for teachers? Among Silver's six categories, some are related to doing mathematics whereas other conceptions are considered to be strategies for developing students' mathematical problem-posing abilities. There is no clear distinction in Silver's six categories of problem-posing. Thus, the notion of "problem-posing" is used with a variety of not-always-compatible meanings and is applied to a variety of not-always-compatible teaching/learning situations. In this study, by reconceptualising Silver's six categories, we intended to explore PSTs' conception of problem-posing and its relation to their problem-posing abilities.

Methods

Data for this study came from 67 PSTs at two different university sites. Each PST was enrolled in either an elementary mathematics content course or an elementary mathematics methods course jointly designed and taught by the two authors. A written task was used for the study, which consists of two parts (see Fig. 1). We purposefully selected three fraction multiplication and division problems because these types of problems require deeper understanding of fractions, fraction multiplication and division.

Part 1: Please answer the following questions in as much detail as possible.

1. When people say problem posing, what does the word "problem posing" mean to you?
2. Create a metaphor that describes your conception of problem posing:
3. Why do you think that metaphor is relevant in describing your conception of problem posing?

Part 2: Suppose you are posing a word problem to help students develop a good understanding of fraction multiplication and division. What word problem would you pose teach each fraction operation below? Describe your problem in a way that you pose it to your students.

1. $1/4 \times 2/3 =$
2. $4/3 \times 48 =$
3. $3 \div 1/5 =$

Figure 1. Main task of this study.

In order to answer the first research question, PSTs' responses to the notion of problem-posing were categorized first based on Silver's (1994) six perspectives on problem-posing. As we identified emerging themes from multiple cases, we modified Silver's perspectives on problem-posing into seven categories and then coded the data. For the second research question related to problem-posing task, correctness of PSTs' responses was determined and then various contexts and common misconceptions/errors in the creation of word problems were explored. In answering the third research question that examines the relationship between PSTs' problem-posing performances and their notions of problem-posing, correctness of PSTs' three word problems relating to fraction operations was determined first. After that, we explored patterns that existed between their problem-posing performances and their notions of problem-posing by looking at the number of PSTs with correct word problems, the existence of multiple path ways and problem contexts in the word problems with respect to the different notions of problem-posing.

Summary of Selected Findings

PSTs' Conceptions of Problem-Posing

In order to categorize PSTs' conceptions of problem-posing, we first re-conceptualized Silver (1994)'s six perspectives on mathematical problem-posing based on the following four questions in order: (1) do PSTs define problem-posing from the mathematics perspective of doing mathematics or from the teaching perspective?; (2) if they define from the teaching perspective, do they consider problem-posing as a general action for teaching or an action for creating reform-oriented instruction?; (3) if it is for creating reform-oriented instruction, who is the one posing problems?; and (4) if the main problem poser is the teacher, what is the purpose of the action of problem-posing? We thus sorted PSTs' conception of mathematical problem-posing (PP) into the seven categories:

1. PP as a feature of exceptional mathematical ability or creativity,
2. PP as a necessary component in good problem-solving,
3. PP as essential student actions for inquiry-oriented instruction,
4. PP as essential teacher actions to improve students' problem-solving,
5. PP as a means of *formative assessment* for students' mathematical understanding
6. PP as a means to increase student *interest, disposition, motivation* on doing math
7. PP as general teacher actions of teaching,

Table 1 shows the number of PSTs categorized into each of the seven perspectives of problem-posing. While the first two perspectives (PP1 and PP2) define PP from mathematical action, the remaining perspectives consider PP as a means for instruction. However, depending on the pedagogical purposes for and emphasis on PP, PSTs' conceptions of PP can be further divided into the subcategories ranging PP3 to PP7. About 20% PSTs defined PP only focusing on mathematical action and around 80% considered the purpose and subjects of problem-posing in in defining PP.

Table 1: PSTs' Conception of Problem Posing and Their Frequencies

<table>
<tr><td rowspan="4">Criteria</td><td colspan="2" rowspan="2">Math-focused</td><td colspan="5">Instruction-focused</td></tr>

</table>

PSTs' Problem-Posing Competencies in Fraction Multiplication and Division

In order to explore how their conceptions of problem-posing were reflected in their problem-posing actions, we asked PSTs to create a word problem to three fraction number sentences: (1) 4/3 x 48, (2) ¼ x 2/3, and (3) 3÷ ⅕. Among the three problems, we considered the first problem the most challenging (4/3 x 48), followed by the third problem (3÷ ⅕) and the second problem (¼ x 2/3). In the analysis of PSTs' word problems, we considered the following three aspects: (1) whether to focus on mathematics correctly; (2) whether to be realistic; (3) whether to provide multiple solution pathways. We first determined PSTs' word problems based on correctness. As we expected, the first problem, finding 4/3 of 48 was the most challenging to our PSTs; only seven PSTs provided a correct word problem. We further analyzed each PST's word problem with respect to the context and whether multiple solutions/representations are required (Table 2).

Table 2: Frequency of Realistic/Multiple Solutions Among Correct/Partially Correct Responses

Problems	Correct		Partially Correct	
	Realistic	**Single path**	**Realistic**	**Single path**
4/3 x 48 =	7 out of 7	7 out of 7	4 out of 6	6 out of 6
¼ x 2/3	33 out of 33	33 out of 33	5 out of 5	5 out of 5
3 ÷ ⅕ =	20 out of 20	20 out of 20	2 out of 2	2 out of 2

Table 2 presents although our PSTs tended to create realistic contexts, if they were not asked to do, they seem to not consider the tasks that can be solved in different ways by using multiple representations or strategies.

Relationship between the Notion of PP and PP Competency

In order to further understand the relationship between PSTs' conception of problem-posing and their problem-posing competency, we categorized each student based on the correctness of three word problems, which resulted in the following six groups of PSTs: (1) Group 1: students with correct answers to all three problems; (2) Group 2: students with correct answers to #2 and #3; (3) Group 3: students with correct answers to #3 and #1; (4) Group 4: students with correct answers to #1 and #2; (5) Group 5: students with correct answer to #3; (6) Group 6: students with correct answer to #2; (7) Group 7: students with correct answer to # 1; (8) Group 8: students with incorrect answers to all three problems. We found that when PSTs had limited PP competency (Groups 5-8), they tended to view PP as general teacher actions of teaching that focus only on creating the problem or delivering the problem to the students. In contrast, PSTs in Group 2 tended to possess different conceptions of PP, which are related to the features of inquiry-oriented instruction. These findings suggest that we need to consider not only how to develop skills related to PP but also how to change their conceptions of PP.

Discussion and Implications

This study has implications for teacher educators working to design mathematics education courses for PSTs, as well as for researchers interested in better understanding of teacher knowledge, beliefs and strategies. That is, the findings of this study suggest elementary mathematics teacher education programs need to include more problem-posing activities so that PSTs can experience the benefit of problem-posing from a variety of perspectives. This study also suggests the importance for future research to continue to investigate preservice and in-service teachers' conceptions of problem-posing.

IDENTIFYING CRITICAL TOPICS FOR TEACHING MATHEMATICS FOR SOCIAL JUSTICE IN K-5 SETTINGS: CONNECTIONS AND TENSIONS

Marrielle Myers
Kennesaw State University
mmyers22@kennesaw.edu

This study examines PSTs selections of critical topics for a social justice project in a K-5 methods course. This study builds on previous work focused on using students' funds of knowledge in instruction. Using the Flint water crisis as an authentic context, I looked for evidence that PSTs selected topics that would allow elementary students to read the world with mathematics. Findings indicated that although PSTs chose topics that "raised awareness," lessons did not fully address issues of power, privilege, and resource inequities. Implications for PST preparation, suggestions for scaffolding, and future research are discussed.

Keywords: Equity and Diversity, Teacher Education-Preservice

Introduction

As a mathematics educator focused on equity and social justice, preparing pre-service teachers (PSTs) to disrupt stereotypes and engage *all* students in meaningful mathematics is a focal point of my practice. After using a funds of knowledge (FOK) approach in a K-5 mathematics methods course for three semesters, findings from my research indicated that what PSTs learned via the FOK project was compartmentalized to that assignment. I also found that PSTs did not use this knowledge when planning additional lessons and small group activities throughout the duration of the course. Additionally, the lessons that PSTs planned were very shallow in their treatment of culture and only included topics such as students' names, foods, favorite toys, and other general interests. In short, their understanding of real world knowledge was shallow and their work lacked substantive evidence of community-based funds of knowledge (Gonzalez, Moll & Amanti, 2005).

Background

For decades, scholars have articulated the need for teachers to teach using culturally relevant practices and build connections between students lived experiences and classroom instruction (Ladson-Billings, 1995; Moll et al, 1992; Gonzalez, Moll & Amanti, 2005). To meet this need, a funds of knowledge framework has been previously implemented in mathematics methods courses (Aguirre et al, 2012). Moll & Greenburg (1990) argued that students' homes and communities are "valuable educational resources for teachers." Moreover, Jiménez and Semingson (2011) argued that funds of knowledge is an additive approach to schooling in which teachers learn to "build on students and families strengths" as opposed to a subtractive model or deficit model (p. 5).

Many students' community experiences and knowledge can be critical depending upon the student's background and current sociopolitical contexts (Gutstein, 2007). Because there can be overlap between community mathematics and critical mathematics, it is necessary to think about the ways in which the constructs work together as well as PSTs beliefs about teaching using such an approach. In a study of 92 PreK-8 PST, Simic-Muller and colleagues found that although PSTs initially had a "narrow" definition of real-world situations, they could articulate more controversial topics when pressed to do so (Simic-Muller, Fernandes, & Felton-Koestler, 2015). They go on to suggest that PSTs could benefit by starting this trajectory with topics that are more widely accessible.

Methods

Context

The study involved 17 PSTs enrolled in my K-5 mathematics methods course in the spring 2016 semester. These PSTs were in a cohort and were simultaneously enrolled in a literacy methods, social studies methods, science methods, and health/PE course. Additionally, PSTs had a 200-hour field component that accompanied their methods block. This course occurred during the first semester of their senior year and preceded their full-time student teaching practicum.

In an effort to move PSTs from focusing on students' interests, I modified the course to include assignments that focused on current events with the ultimate goal of creating "critical tasks." I defined critical mathematics tasks to be tasks that are based on a current societal ill, inequity, or injustice. To introduce this concept to my PSTs we did an in-depth study of the Flint water crisis, what led to this crisis, and how it was being addressed. I chose to study Flint so that I could model an authentic context (Leonard & Evans, 2012) and so that the PSTs could first engage in this pedagogy as a learner before being expected to take it up in their own instruction (Felton-Koestler, 2017).

Before starting this activity, I provided PSTs with a list of articles to read and hash tags to follow on social media for one week prior to starting our discussion. As we unpacked the Flint water crisis, I drew from Gutstein's work in which he defined critical knowledge as, "knowledge about the sociopolitical conditions of one's immediate and broader existence. It includes knowledge about why things are the ways that they are and about the historical, economical, political, and cultural roots of various social phenomena" (2007, p. 110). We then talked about how we could use mathematics to better understand multiple facets of this crisis. PSTs worked in grade-level groups to create lesson plans that were directly connected to the Flint water crisis. After this group project, PSTs were asked to select their own critical context and develop an accompanying mathematics lesson.

Findings

These findings are based on analysis of PSTs group lesson plans, individual lesson plans, and post-project reflection survey. A number of themes emerged among the critical topics selected including: raising awareness, current events (local and national news), student connections, as well as influences from other courses. In the following paragraphs, I share examples from a few of the themes that emerged from PSTs topic selection and justification. I also share tensions that PSTs faced while identifying these topics. A more detailed report of all themes can be found in a forthcoming paper.

Raising Awareness

Some PSTs selected critical topics intended to raise awareness for the students they served. These tasks included world poverty, school poverty, world hunger, and the rice shortage in the Philippines. PSTs explained these selections with the following comments:

> I chose this topic [poverty] because most of the students come from very affluent families. These students pretty much have everything they need to survive. I wanted them to have an opportunity to see that not everyone lives like they do…There are children my students [sic] age that go hungry everyday. Many of these children die of starvation. By showing them with fractions what portion of the world has what they have and what does not, I think the students will come away with a better understanding and be grateful for the things they do have.

Although these examples have the potential to address power, class, and resource inequities, PSTs failed to fully capitalize on that potential in developing their mathematics tasks. For example, the PST indicates that fractions can be used to make comparisons between what some children have compared to others. This lesson could have been enriched by simultaneously discussing issues of privilege with issues of poverty. A subtext to these PSTs explanations is that they wanted to make their students grateful by comparing their current situations to those less fortunate than themselves.

Current Events (Local and National News)

Other PSTs selected topics based on current events. Among these tasks were job creation, flooding in the Midwest, the 2016 election, and school lunch. These task selections were particularly pertinent as one PST suggested that this project caused her to, "pay more attention to the mathematics in current events." Other PSTs indicated that although they did not initially stay abreast of current events, they chose to follow various news sources on their social media outlets. Although each of these examples came from local and national news sources, it is important to note that PSTs justifications for why they were critical varied.

As stated, the 2016 election and the structure of government was selected as a topic. The PST stated that:

> The students in my … classroom are currently studying the three branches of government and how they work together to pass laws and run the country. Also, since the presidential election is coming up, I felt like this was a good task to use to integrate social studies and math using a topic students are interested in and already have background knowledge on. This is a critical topic because it is an issue that people are divided on and that Americans are interested in and playing a role in right now…Students hear about the election and government from their friends, home, and school, and encounter many different opinions that might not be based in fact. If I use this topic in a math task, I am able to give them more information in an unbiased setting that lets them form their own opinion of the critical topic.

A second PST reported on The Frankfurt Company breaking ground in the community surrounding her school. This company was set to invest over $20 million into a local project and create 100 permanent jobs for the area. She commented that The Frankfurt Company, "will employee many families in and around the Bunby County area beginning in 2017 and the years to follow. This is an event that will make an impact on the community, one in which I felt they should be aware of." This topic could have been extended to acknowledge issue of power and class. For example, how can we assume equitable access of job opportunities at the Frankfurt Company? And will there be equal pay for equal work for the given positions?

Tensions

A few tensions arose while analysing this data. First, some PSTs selected topics that they were interested in while others chose topics that they thought their students would be interested in. This shows that PSTs were struggling to balance their interests with students' interests. Some of this tension was because PSTs indicated that they needed to do their own research on a topic prior to developing a task for their classrooms. Another tension that resulted from this analysis was age and grade level tensions. Some PSTs thought that certain critical topics were not appropriate for young students and went on to say that critical topics would have to be adapted to make them "grade appropriate." This tension mirrors findings from other scholars in the field (Simic-Muller, Fernandes, & Felton-Koestler, 2015).

Implications

There are a number of findings that have emerged from this work that demonstrate promise for using this type of pedagogy in a methods course. First, some PSTs were able to use their understanding of the Flint water crisis project to identify other topics and use those topics to develop critical tasks appropriate for their field placement grade levels. Others had difficulty identifying a critical topic. It also clear that PSTs need more information on the historical, political, and social implications of societal issues to help them better frame their understanding of what makes an issue problematic, therefore leading to the development of a critical task. These findings support Bartell's (2013) piece in which she found that in-service teachers had varying definitions of what it meant to teach mathematics for social justice ranging from awareness, to cultural exposure, to student empowerment.

This study highlighted the layers involved in this process, particularly that PSTs may need assistance teasing apart the elements or their critical topic such that any resulting lesson plans fully address issues of social justice. A final implication of this work is that the selection of a critical topic and the development of a task should be an iterative process. PSTs could have benefited from additional conversations that pushed or challenged their thinking even more.

Responding to student contributions during whole-class discussions is a complex instructional practice. Coached rehearsals are a way to support teacher candidate (TC) learning. This study investigates TCs' practice of responding to student contributions during rehearsals of leading whole-class discussions. Two key findings emerged through video analysis. The rehearsing TC had general patterns of responding, with some nuanced variation when responding to a contribution that was mathematically problematic. Second, analyzing teacher responses as sets of interactions contingent on student contributions and key mathematical ideas provided greater insight into the practice of responding. These findings have important implications for research on this complex practice.

Keywords: Instructional Activities and Practices, Teacher Education-Preservice; Classroom Discourse

Rehearsals are a valuable pedagogical tool to support teacher candidates (TCs) in learning complex instructional practices, such as leading whole-class discussions (e.g., Boerst, Sleep, Ball, & Bass, 2011). One challenge in leading whole-class discussions is responding to student contributions in ways that position them as resources to advance the class's learning of key mathematical ideas. In this paper, we describe emerging understandings about the practice of responding to student contributions, as well as strategies for analyzing TC practice during rehearsals of leading whole-class discussions.

How teachers respond to students' ideas is consequential for students in shaping their beliefs and mathematical understandings (e.g., Borasi, 1994). There are many different ways that teachers respond to students during whole-class discussions, such as re-voicing what the student said or using other talk moves (Chapin, O'Connor, & Anderson, 2013), steering the discussion toward the mathematical point (Sleep, 2012), building on student thinking (Leatham, Peterson, Stockero, & Van Zoest, 2015), allowing other students to respond, recording the student contribution on the board, and more. Skillfully responding to student contributions rests on noticing and interpreting student's mathematical ideas (e.g., Jacobs, Lamb, & Philipp, 2010) and can be particularly difficult when the contributions have mathematical ambiguities or errors.

Theoretical Framing

We take the view that whole-class discussions are a complex set of interactions among teacher and students. The teacher engages in interrelated moves to elicit student participation, encourage students to respond to one another, and further student understanding of the mathematical concepts being discussed (Boerst et al., 2011). These teacher moves are necessarily situated in the context of the classroom and the type and purpose of the discussion. Developing skill in the practice of leading discussions is challenging for TCs, though they can develop such skill through purposeful opportunities to approximate and reflect on practice (e.g., Grossman et al., 2009), such as rehearsing leading a discussion in a methods class (Lampert et al., 2013). Rehearsals afford opportunities for teacher educators (TEs) to deliberately construct moments for TCs to respond to student thinking; rehearsals also afford opportunities for the TE to provide in-the-moment feedback or engage TCs in collectively reasoning about how to respond (Lampert et al., 2013; Singer-Gabella, Stengel, Shahan, & Kim, 2016). We examine ways rehearsals can support TCs in learning to respond to students' contributions during whole-class discussions. We investigate this through the use of a discussion structure deliberately designed to surface multiple types of student contributions and provide TCs opportunities to respond.

Methods

Our analysis of TC practice takes place in the context of secondary mathematics methods courses at two large, public universities. TCs rehearsed leading sorting discussions (Baldinger, Selling, & Virmani, 2016), where "students" (other TCs) sorted cards with examples and non-examples of linear functions in order to develop and refine their definition of linear function. In each rehearsal, an error was introduced as a way to construct an opportunity for the rehearsing TC to navigate responding to a mathematically problematic student contribution, in addition to correct student contributions. Each rehearsal was video recorded.

The video analysis occurred in two phases. The first phase involved defining the unit of analysis and chunking the videos into segments. The structure of a sorting discussion involved the teacher asking students to share cards that were easy or hard to sort. Based on this structure, one frequent student contribution during the rehearsals was naming a specific example or non-example. For example, in one rehearsal, the rehearsing TC said, "Can you share an example of what you think a linear function is?" The "student" replied, "$y = 3x + 5$." The TC followed up, saying, "Good, $y = 3x + 5$…why did you come up with that?" The student responded, "…because it's in $y = mx + b$ form." In other cases, a student contributed the card and reasoning in a single talk turn. Student contributions also occurred as a card was discussed. These contributions tended to expand on or disagree with what another student said. The teacher's response occurred in the teacher talk immediately following student talk, but also in subsequent interactions. To capture the complex and interactive nature of teacher responses to students, we used the introduction of a new card and all the discussion related to that card as our unit of analysis. We then had to determine what counted as a *student contribution* and what counted as the *response* to that contribution. The initial student contribution was considered to be the card and associated reasoning, and the teacher response was considered to be the set of interactions—including teacher talk, student talk, and recording—that related to that card. This chunking method enabled us to identify patterns that occurred in response to different types of initial contributions. This follows work of others who argue that building on student thinking is more than a single teacher move (Van Zoest, Leatham, Peterson, & Stockero, 2016).

The second phase of analysis involved coding the initial student contributions as having errors (i.e., being mathematically problematic in some way) or not, and identifying the patterns of moves made by the teacher over the course of their response to the initial student contribution. All four researchers independently watched and annotated rehearsal videos to document patterns of responding. The annotations were discussed and synthesized to reach consensus about how to describe the teacher response around each card brought up in the rehearsal. In this paper we present data from one of the six rehearsals.

Preliminary Findings

Our initial analysis of one of the rehearsals revealed two primary findings. First, we documented patterns of practice in how the TC responded to student contributions, and noticed nuanced differences in the nature of the responses based on whether or not the student contribution contained an error. Second, we found that analyzing teacher responses as sets of interactions contingent on student contributions and key mathematical ideas provided greater insight into the practice of responding to students during whole-class discussions.

Patterns of Practice in Responding to Student Contributions

Our analysis revealed patterns of responses across cards. For example, the TC was fairly consistent in her use of a set of talk moves to respond to student contributions. Typically, this TC would elicit student reasoning if it was not initially offered, she would re-voice and often record the student reasoning, and she would orient the other students to the initial contribution by asking other students to elaborate. In some cases, this TC would purposefully steer the conversation toward the definition of linear function, or probe student reasoning. The sequence and frequency with which the TC utilized these moves varied across the six cards discussed during her rehearsal; however, this set of moves was common for every card.

Despite a clear pattern of responding, our analysis also revealed subtle differences in responses when the student contribution was mathematically problematic. For example, the TC often asked questions like, “Can someone else add in why they think that is also an example?” as a way to encourage students to build on the mathematically correct reasoning already shared during the discussion. The TC used a very similar move when a student shared that the card $y = 17 - 5x$ was an example of linear function, but incorrectly reasoned that it was linear because it had a slope of 17 and a y-intercept of 5. In this case, the TC said, “Does anyone want to elaborate on that, or give another opinion, agree or disagree?” In response to initial contributions that are correct or contain errors, this TC used an orienting move. However, in response to the error, the TC explicitly asked about the possibility of disagreement, which was not part of her questioning when there was not an error. Despite using the same general sequence of moves, the TC’s response to the error revealed differences in how those moves were used as compared to responses to contributions without errors. This also raises the question of how different moves interact with one another in the context of different types of student contributions.

Analyzing Teacher Responses as Sets of Interactions

Our approach of analyzing sets of moves that included teacher talk, student talk, and recording had many affordances for capturing the complex practice of leading a mathematical discussion. For example, the orienting moves used by the TC are very similar, but they played out differently. When discussing mathematically correct reasoning, the orienting move resulted in another student adding more reasoning, and the TC incorporated that contribution into the discussion and moved on to the next card. When discussing the incorrect reasoning, right after the orienting move, the TC made an additional re-voicing move, reiterating the part of the student reasoning that was incorrect. The TC used numerous additional re-voicing, probing, and recording moves, and allowed students to respond directly to one another before she brought the discussion of this card to a close. This contrasting use of common teacher moves highlights the importance of considering sets of teacher moves in concert with the student contributions themselves – for instance, whether there is an error or not, or whether the mathematics of the idea is of central importance in that moment. Different moves are more or less effective at different times in the discussion as they are contingent on and interact with student contributions.

Discussion

Rehearsals of sorting discussions provided valuable insight into how TCs respond to student contributions. Through analysis of sets of interactions, we were able to identify common patterns of responding that utilized productive talk moves. At the same time, by considering the complexity of leading whole-class discussions, we identified subtle differences in how these talk moves were used based on the nature of the student contribution. The work of responding to student thinking is contingent on the mathematics being discussed and interactions among the teacher and students (Lampert et al., 2013; Leatham et al., 2015). The particular structure of the sorting discussion allowed for an intentional opportunity to insert incorrect mathematical thinking, and to provide opportunities to respond to different types of student contributions. Using the card under discussion as the unit of analysis potentially makes it easier to see patterns and regularities, and also highlights nuances in teacher practice around responding to student contributions, because the boundaries for different segments of the discussion are clearly marked. This promising analytic technique could also provide a tool for comparing TCs' practice when leading sorting discussions across settings, such as rehearsals and enactments in field placements. On-going work to explore patterns in how TCs respond to student contributions is important for developing more systematic uses of pedagogies of practice for teacher learning.

We traced the impact of a designed unit of instruction on mathematical modeling on Prospective secondary teachers' knowledge about and efficacy towards teaching modeling. Analysis indicate that although teachers maintained modeling to be an important skill to be developed, absence of extensive experiences with mathematical modeling in the course of their own mathematical preparation hindered their ability to access pedagogical actions to be used in teaching.

Keywords: Modeling, Secondary Teacher Preparation, Mathematical Knowledge for Teaching

The demand that mathematics teachers will infuse mathematical modeling in curriculum is now paramount in the educational reform efforts in the US as pioneered by the Common Core State Standards of Mathematics (CCSSM, 2010). There is some evidence that due to absence of information regarding the nature of mathematical modeling misconceptions exist among teachers regarding modeling and its associated pedagogies (Gould, 2013). The international community of researchers on teaching and learning of mathematical modeling have stressed the need to explore models and programs that might assist teachers to meet implementation challenges and to document potential impact of these efforts on teachers (Cai et al. 2014). The current paper addresses these two areas. One question guided our inquiry:

8. What is the impact of a unit of instruction on teaching mathematical modeling on teacher candidates' perceptions of teaching mathematical modeling in schools?

Background

The methods course that served as the site for the current study is the second of a sequence of two courses on methods of teaching high school mathematics. The focus of the first course is on teaching of Algebra, Calculus and number theory concepts. Using Principles of Inquiry based Learning and Teaching (Artigue and Blomhøj, 2013) the course draws attention to connections among student thinking, instruction and assessment. The second course addresses teaching and learning of Geometry, Measurement, Probability, Statistics and Discrete Mathematics. Mathematical modeling strand was to be addressed explicitly during three weeks of instruction.

Methodology

First, a survey of knowledge of mathematical modeling for teaching was designed and administered to collect base line data on the candidates' perceptions about teaching mathematical modeling in schools. Second, in light of survey results and areas that seemingly needed developing, a unit of instruction on mathematical modeling for teaching was conceptualized and implemented during three course sessions (approximately 8 hours). A post implementation survey was then administered on the last session of the academic semester to trace impact of the experiences provided for participants as expressed by them.

Participants

The participants consisted of 11 prospective secondary mathematics teachers. The participants had completed all coursework towards a major in mathematics and were enrolled in the second course of a sequence of two methods courses on teaching in secondary schools.

Survey

The survey consisted of 20 items and addressed four areas. The first part of the survey collected biographical information from the participants, the range of mathematics courses they had completed, and their assessment of courses in which they believed they had gained mathematical modeling experiences as learners.

Four items addressed the participants' claimed comfort level with mathematical modeling, teaching it, and their perception of the importance of modeling for school learners. Additionally, they were asked to identify how frequently they had observed mathematical modeling be implemented in classrooms.

The third part of the survey consisted of open response items that collected data on the participants' description of mathematical modeling, similarities and differences they observed between modeling tasks and other kinds of activities used in classrooms, and processes they associated with mathematical modeling. The participants were asked to provide illustrative examples in each part.

The last portion of the survey aimed to obtain specific data on the participants' ability to identify suitable examples of modeling tasks to be used with middle and high school students as well as how they envisioned gauging learners' progress when engaged in such tasks. We had anticipated that the participants' responses to the last set of questions would allow us to more carefully detail their knowledge related to modeling based curriculum and instruction.

The same survey was administered again during the last session of the academic semester and upon conclusion of the experimental unit of instruction.

Findings

Phase I: What Teachers Felt They Knew

All 11 participants reported having had exposure to mathematical modeling and having gained knowledge of mathematical modeling in their Discrete Mathematics course. A half of the participants reported that they felt they had adequate exposure to modeling experiences in their calculus, differential equations, and probability and statistics courses.

In describing mathematical modeling and its process, 7 (64%) participants characterized it as using mathematics to represent and analyze real world situations. The participants' responses however varied according to the amount of detail they chose to include in outlining their thinking. 3 (27%) participants perceived mathematical modeling as using manipulative, simulations or world problem to demonstrate a mathematical concept.

In explaining specific actions associated with modeling two common themes emerged. One group equated mathematical modeling process with problem solving. The second type of description concerned data modeling with a focus on statistical context. None of the participants referenced defining variables, setting parameters, building a mathematical representation of the situation, and refining the model (Blum and Leiβ, 2007) as part of the modeling process.

On the follow up question that asked the participants to report how they would assess school learners' mathematical modeling progress, all but one participant offered general descriptions that ignored the unique features of mathematical modeling. In order to illustrate differences between modeling tasks and other types of mathematical activities, participants relied on phrases such as "open ended", "multiple approaches", "multiple solutions" to describe their thinking.

Phase II: Course Design

In light of the survey results, we set four goals for our work with the participants so to help them: (1) develop a deeper understanding of the mathematical modeling process and its intricacies, (2) discriminate between mathematical modeling as a process and solving routine application problems,

(3) learn about suitable resources that could be used for simulating modeling tasks, and (4) understand how student learning could be gauged using the modeling cycle as a platform for assessment. The participants were introduced to the modeling cycle on the first day of implementing the modeling unit and revisited it during each session.

Each course session was divided into two parts. During the first part of the session, the participants worked on one or two modeling tasks, compared and constructed their answers, and engaged in refining their solutions. These discussions also granted us the space to introduce how different mathematical tools the participants may not have considered either independently or collectively, could be used to construct more robust models (Approximately 3 hours).

The second part of the session was devoted to deliberations on how the same tasks could be implemented in schools. The participants were introduced to specific resources they could use in designing modeling experiences and available simulations they could utilize in instruction to ground learners' activities. Participants were encouraged to identify the type skills they could address as school learners worked on the specific tasks they examined (approximately 3 hours).

Phase III: Course Outcomes

Descriptions of mathematical modeling and its process. On both surveys the participants were asked to describe mathematical modeling and what they perceived as specific processes involved in this sort of mathematical work. In the post implementation survey, 9 (82 %) participants described mathematical modeling as using mathematics to represent, analyze and solve real-world problems. Comparing these responses to those on pre-implementation survey, their remarks were more reflective of modeling as a process (Blum and Leiß, 2006).

In the post implementation survey, when asked to outline actions that may be involved in mathematical modeling process, 8 (72 %) participants noted specific cognitive actions (making sense of the situation, identifying/defining variables, making assumptions, using mathematics to build a model, interpreting the model, and revisiting the initial model). Compared to their responses to the same question on the pre-implementation survey, these descriptions more closely match stages depicted in the modeling cycle. Two of the participants associated modeling with using manipulative or simulation to demonstrate concepts.

Example generating. In the post implementation survey, when asked to illustrate the differences between modeling activities and other types of mathematical activities, phrases such as "open ended", "multiple representations", "real world connection", "multiple approaches", "a variety of directions" and "multiple entry and exit points" "minimal constraints", "opportunity to define relevant variables", and "revisiting solutions" were referenced by all 11 participants. 10 (91 %) of the participants referenced "minimal constraints", "revisiting solutions", and "define relevant variables" to describe modeling tasks, which were not present in their responses in the pre-implementation survey.

Assessing modeling progress. Compared to pre-implementation survey on which none of the participants appeared to have had a platform for gauging learners' modeling progress on the post implementation survey 7 (64 %) of them offered specific plans relying on the language of modeling cycle for identifying specific behaviors they would seek out.

Discussion

A majority of the participants in our study did perceive mathematical modeling as the process of using mathematics to solve real world based tasks and their understanding of the complexities associated with teaching it increased. The participants also believed modeling cognition to be difficult to nurture. Because of this, compared to teaching other content areas, they felt less efficacious in helping children develop proficiency in the area. Two particular challenges they articulated included how to effectively build on the learners' extra mathematical knowledge when engaging them in model building process as well as managing diverse student backgrounds. These issues have not been adequately addressed in the literature.

Analysis of the post implementation survey data revealed that although course experiences did not have any significant impact on the participants' sense of efficacy towards teaching mathematical modeling, their description of the modeling process, knowledge of task design, available resources, along with ways they could monitor student progress towards establishing more sophisticated mathematical models increased. Participants felt vulnerable towards gauging their own instructional interventions in the course of learners' modeling process. This is not surprising since developing strategic intervention skills (Blum, 2011) has been identified as a particularly complex one to acquire and one that demands time and practice to mature.

Data also indicated that the participants possessed greater control when generating modeling activities suitable for the middle grades learners. Examples of tasks they provided contained detail and tended to precision in describing specific mathematical skills that could be taught or reinforced with them. Lastly, it appeared that the course managed to provide the participants with a language through which they could articulate ideas about mathematical modeling, its form and content. Because of this we argue that while inclusion of experiences we designed appeared to have had been useful in familiarizing the participants with some key issues and methodologies, they were not by any means sufficient to have helped them reach proficiency level. Significant need exists for additional reports by scholars around different models used for assisting prospective teachers develop pedagogical capacities towards implementing modeling based curriculum and instruction.

METHODS OF ANALYZING PRESERVICE TEACHERS' FACILITATION OF MATHEMATICS DISCUSSIONS

Allyson Hallman-Thrasher
Ohio University
hallman@ohio.edu

This study examined how preservice elementary teachers' (PSTs') ability to facilitate productive mathematics discussions on problem-solving tasks developed during a 6-week field experience. Data were collected in 6 weekly cycles of planning (written plans), enactment (video of co-teaching sessions with pairs of children), and reflection (collaborative reflections based on video). Data were analyzed using cognitive demand of a task implementation (Stein, Smith, Henningsen, & Silver, 2000) and math-talk (Hufferd-Ackles, Fuson, & Sherin, 2004). Problematic aspects of data analysis led to the revision of the math-talk framework. I share the process used to modify an existing framework to fit the context of this study and the data analysis used to determine changes in the PSTs' ability to facilitate mathematical discussion.

Keywords: Classroom Discourse, Teacher Education-Preservice, Research Methods

Facilitating a mathematics discussion is a high leverage practice, one that novices need to be able to carry out (Ball & Bass, 2000) and that has a big payoff for student learning (Ball, Sleep, Boerst, & Bass, 2009). Yet, enacting mathematics teaching practice focused on discussion poses several challenges, especially for novices: balancing productive struggle (NCTM, 2014) with student frustration and progress on a task; knowing when and how to intervene (Ball, 1993); and requiring students explain and justify, not memorize and apply, algorithms. Nathan and Knuth (2003) found that teachers "seemed to have in their minds what they expected of their students in terms of dialogue and a solution" (p. 121) and when teacher expectations were unmet, a one-way dialogue resulted. This study focused on preservice elementary teachers' (PSTs) abilities to facilitate mathematics discussions with pairs of children during a field experience. I describe the study design and problematic issues of analysis that led to revising an existing framework.

Existing Frameworks

Several frameworks for studying discourse-based classrooms have been described, but their usefulness for investigating novices who are learning to facilitate mathematical discussions is limited. Knuth and Peressini (2001) categorize discourse as univocal (speaker delivers message with intended meaning to audience) or dialogic (multiple speakers generate meaning of a message), which borders on "stereotyping mathematics class discussions as either good or bad" (Crespo, Oslund, & Parks, 2011, p. 130). Truxaw (2004) adds to dialogic-univocal discourse with categories of inert and generative verbal assessment, but these broad characterizations still only provide snapshots of practice, not development over time. Yackel and Cobb's (1996) sociomathematical norms provide a more detailed picture of mathematics discourse. However, the specific elements of discourse they attended to (what counts as mathematically different and sophisticated solutions and what constitutes an adequate explanation) represent complex issues of practice whose negotiation may not be accessible to novices.

Hufferd-Ackles, Fuson, and Sherin (2004) developed a framework for studying math-talk that addresses some of these problematic issues. Organized hierarchically as a 4x4 matrix, it includes four levels (0-3) and four components: *questioning*, *explaining* mathematical thinking, source of mathematical *ideas*, and *responsibility* for learning. The four components allowed me to zoom in on specific teacher moves and compare them to other features of class discussion. The multi-leveled feature of the framework ranging from a strictly teacher-directed classroom to a description of dialogic discourse allows for a study of changes over time. In this study I used math-talk to examine how teacher moves to facilitate mathematical discussion influenced cognitive demand of a task implementation (Stein et al., 2000).

Methods

This study was conducted via a 6-week field experience integrated within my mathematics teaching methods course. For the field experience PSTs and methods instructors made weekly visits to an elementary school where PSTs worked with children on problem-solving tasks. PSTs were to facilitate mathematics discussions that elicited and explored children's thinking without advancing PSTs' ideas. Classroom teachers and methods instructors had purposefully structured the experience to focus on problem-solving tasks not related to the children's classroom work to relieve PSTs of the need to "cover" material and to give them the freedom to focus on practices coherent with university course work. In methods class, PSTs solved the tasks and hypothesized how students might solve them while I modeled practices for facilitating discussion.

I selected 4 groups of 3 PSTs each from my methods course based on class assignments and observations. Classroom teachers chose 5th graders who they considered to be academically average. In the first 3 weeks, PST groups enacted two high-demand tasks with a different pair of elementary children each week. They repeated this process for the second 3 weeks with two new tasks. Repeating each task three times with new children helped familiarize PSTs with children's approaches to tasks and provided opportunities to refine their responses to children's strategies. Each week was based on a cycle of planning, enactment, and reflection (Kazemi et al., 2010). At the start of each 3-week block PSTs constructed a hypothetical student-teacher dialogue to follow each of several typical (correct and incorrect) solutions for each task (modified from Crespo et al., 2011). Then, using my feedback on the dialogues, PSTs wrote a plan that listed hints and questions they would provide in several scenarios: a child who could not start the task, a child with a specific misconception, a child who was on the right track but had not solved the task, and a child who had solved the task but not connected it to any mathematics concept. I provided feedback again before task implementation. The enactment of the weekly cycle was captured on video by one PST while the other two group members co-facilitated, with recorder role rotating weekly. After each weekly session, each PST group reviewed video to compose a collective written analysis of their and their children's work and to revise their plans based on what they learned from working with children.

To analyze the reflection data I noted excerpts of thoughtful analysis and issues that recurred over several sessions. To analyze planning and video data, I intended to assign a level (memorization-0, procedures without connections-1, procedures with connections-2, and doing mathematics-3) for cognitive demand, and a level (0-3) for each of questioning, explaining, ideas, and responsibility. I hypothesized that a teaching episode could be assigned different levels for each component of math-talk (e.g., Level 2 in questioning, Level 1 in explaining, etc.) which differs from Hufferd-Ackles et al.'s (2004) idea that the four components developed together (e.g., all components should be assigned the same level). However, I encountered several difficulties with the video analysis that led to revisions I discuss in the following section.

Results: Revised Framework

The first problem encountered during data analysis was an inability to cleanly apply levels of cognitive demand and levels of components of math-talk to a single task enactment. The guideline for applying a level was to look at what more than half of the students were doing more than half the time (Stein et al., 2000),but this guideline proved too coarse a grain-size and did not capture interesting conversational turns. What might start as a *doing mathematics* implementation would decline to *memorization* when a PST used leading questions, and later the PST would pull out of a downward trend of low-level questioning when a child began to generate his or her own ideas. Even if I had been able to assign one level from each category to a task implementation as a whole the different contributions to the task enactment made by each participant in the group meant I was not able to attribute the pedagogical decisions and moves to a single individual. Therefore, I decided to parse each task enactment into segments that allowed me to cleanly apply one level for each of the five categories to the pedagogical moves of one PST. To be consistent with plans, which required PSTs to respond to no solution, a correct solution, an incorrect solution, and a partially correct solution, these events also defined the start of segments in the video data where PSTs responded to children's work. When watching the first group's full video data PSTs responded to more than just children's solutions. I identified additional segment markers: responding to an idea (a question or observation about the task) and responding to a strategy (either described by the child or as they executed but had not complete it). A segment started when a PST responded to a child's idea, strategy, solution, or lack of solution and ended when the child offered a new idea, strategy, solution, or when the PST intervened to help a child who stalled out.

The second issue was that the math-talk framework, originally developed from studying one experienced teacher's whole class discourse, did not translate smoothly to the context of two novices working with a pair of children. Within the first group's transcripts I found exemplars for each level of each category and added more specific detail to the descriptions of category levels to help me more easily identify them in my data. I revised the Level 2 descriptions to have the common thread of the teacher prompting student-to-student interactions. Because many of the Level 3 descriptions included activities the teacher "expected" and my participants' intentions and expectations were not discernible from the video data I rewrote Level 3 descriptions to focus on observable data. I then composed a general description of each level so that a feature common to all components within a level distinguished it from previous and subsequent levels. Level 0 is solely teacher directed, in Level 1 the teacher makes attempts to elicit student thinking but is unable to use that thinking to move work on the task forward, in Level 2 the teacher prompted students to talk to one another, and in Level 3 students exercise mathematical authority.

Third, periodically a segment had features of two consecutive levels or fell into a "gap" between the levels. PSTs also made pedagogical changes that improved the discussions, but that did not warrant increasing them to the next level of a math-talk category. Therefore, I concluded mid-levels were needed and searched for examples of them in the data and composed corresponding descriptions. The addition of these levels to the framework occurred in cycles, similar to the process used to develop the original framework (Hufferd-Ackles et al., 2004). When I identified several similar segments that did not fit into the 0 to 3 levels of a component in the framework I coded those segments with the appropriate mid-level, composed a description for that cell of the matrix based on the newly coded segments, and composed a general description of the mid-level. I then recoded any earlier video segments to ensure the assignment of levels for that component was consistent across the data. As I found more examples of mid-levels for a math-talk component I refined the descriptions for that cell. This process continued until I coded all segments of the first group to fit in exactly one level for each component. Using the 7-level revised framework I coded all the other groups' data.

Several types of charts were useful to determine how the PST's pedagogical moves in facilitating mathematics discussions influenced cognitive demand. Plotting in chronological order each PST's segments of all implementations of all tasks along the x-axis and the levels for cognitive demand along the y-axis, I was able to see trends in each PSTs' implementations over the course of the study. To understand how the four components of the math-talk framework were associated with the cognitive demand I plotted in chronological order each PST's segments of all three implementations of each task along the *x*-axis and the levels for each category along the *y*-axis. Plotting segments of particular types of solutions, strategies, or ideas, (none, incorrect, partially correct, correct) on the *x*-axis against the levels for each category along the *y*-axis allowed me to examine how the questioning, explaining, ideas, and responsibility for different types of segments were associated with cognitive demand.

Conclusion

These revisions were necessary to fit the context of this study, and analyzing the video data using two frameworks in the manner described was essential for allowing me to systematically examine the relationship between cognitive demand and quality of the mathematical discussion. This analysis revealed examples of how a teacher might use instances being overly directive to catapult the students' work to a higher cognitive demand and examples of how a teacher's response to student thinking could dramatically shift the cognitive demand and quality of the mathematical discussion. My revisions to the use of the frameworks supported a fine-grained analysis of discussions that highlighted pedagogical moves, key conversational turns within one discussion, and an image of how novices developed and facilitated children's work over a session of problem solving and over multiple sessions.

NATURE OF MATHEMATICAL MODELING TASKS FOR SECONDARY MATHEMATICS PRESERVICE TEACHERS

Jia He	Eryn M. Stehr	Hyunyi Jung
Utah Valley University	Georgia Southern University	Marquette University
Jia.He@uvu.edu	estehr@georgiasouthern.edu	hyunyi.jung@marquette.edu

This study investigated the nature of written modeling tasks reported by instructors of required courses in five secondary mathematics teacher education programs. These tasks were analyzed based on a framework addressing potential cognitive orientation (simple procedures, complex procedures, and rich tasks) and purpose (epistemological, educational, contextual, and socio-critical modeling) of the tasks. Our analysis suggests that most tasks included questions of more than one cognitive orientation and more than half of the tasks were coded as contextual modeling. We also found that tasks that were coded as contextual modeling offered opportunities for future teachers to engage with questions at all levels of cognitive orientation. The nature of several modeling tasks, along with the ideas for refining the current frameworks, are presented for future implications of analyzing and developing modeling tasks.

Keywords: Modeling, Teacher Education-Preservice, Algebra and Algebraic Thinking

Connecting educational theory to practice is critical in supporting future secondary mathematics teachers to develop the skills and understanding necessary to enact effective mathematical modeling tasks. The *Common Core State Standards for Mathematics* included modeling as a mathematical practice and content standard; modeling is described as a full iterative process used to solve rich mathematical tasks (NGO & CCSSO, 2010). However, the meaning and purpose of mathematical modeling has been found to vary widely in both theory and practice (e.g., Anhalt & Cortez, 2015; Kaiser & Sriraman, 2006). To connect current theories to practice, we applied two frameworks with distinct perspectives to analyze the nature of modeling tasks. We collected tasks as part of a larger research project Preparing to Teach Algebra (PTA), which investigated opportunities secondary teacher education programs provide for future secondary teachers to learn about mathematical modeling. As we focus on the nature of these tasks, we answer the question, "*What is the nature (i.e., potential modeling purpose and cognitive orientation) of modeling tasks reported by secondary teacher preparation programs?"*

Theoretical Framework

In this secondary analysis of the larger *PTA* study, we use two frameworks proposed to characterize intended modeling purposes (Kaiser & Sriraman, 2006) and cognitive orientations (White & Mesa, 2014) of mathematical tasks. Kaiser and Sriraman (2006) conducted a historical analysis of research papers focused on mathematical modeling and, based on their findings, proposed five categories of purposes of mathematical modeling. Of their five categories, we focus on four we found relevant to our analysis: *epistemological, educational*, *contextual*, and *socio-critical* modeling. Kaiser and Sriraman described *epistemological modeling* as mathematical modeling with the purpose of developing mathematical theory. *Educational modeling* occurs when "real-world examples and their interrelations with mathematics become a central element for the structuring of teaching and learning mathematics" (p. 306). In this type, modeling is used explicitly as a tool for teaching and learning other mathematical content. *Contextual modeling* occurs when the purpose of modeling is to develop further understanding of modeling itself by engaging in the modeling process to solve a task embedded in a real-world context. *Socio-critical modeling* supports "critical thinking about the role

Galindo, E., & Newton, J., (Eds.). (2017). *Proceedings of the 39th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* Indianapolis, IN: Hoosier Association of Mathematics Teacher Educators.

of mathematics in society" (p. 306); with this purpose, mathematical modeling is used as a tool to critically investigate and potentially change real-world situations that are relevant to students.

White and Mesa (2014) proposed a framework for differentiating potential cognitive orientations of mathematical tasks. The framework includes three main categories: *simple procedures, complex procedures,* and *rich tasks*. *Simple procedures* are defined as those tasks requiring students to draw on factual or procedural knowledge; they must "remember factual information" or "recall and apply procedures" (p. 14). Students are told which fact or procedures to use, and they must remember them and apply them in the task. *Complex procedures* include tasks requiring students to draw on procedural and conceptual knowledge: to "recognize and apply procedures" (p. 14). In these tasks, students are not told explicitly which procedures to use, but instead are expected to draw on their understanding to choose an appropriate procedure and apply it in the task. Finally, *rich tasks* include any tasks that prompt students to write explanations of procedures, to interpret, compare, or make inferences, or to analyze, evaluate, or create situations or structures. Rich tasks involve high-level mathematical thinking and offer students more opportunities to make their own decisions when solving tasks.

Method

As a part of the larger *PTA* study, we focused on the potential cognitive orientations and purposes of modeling for nine written tasks involving mathematical modeling in instructional materials collected from five universities. Because almost all tasks included multiple subquestions in which each of them varied in terms of richness, we defined our coding unit as a subquestion rather than a task. We coded subquestions in terms of potential cognitive orientation (i.e., simple, complex, rich) and purpose of modeling (i.e., epistemological, educational, contextual, socio-critical). Two researchers each coded the questions independently, and resolved all discrepancies. When we coded a question, we also considered questions prior to the one we were coding. For instance, a question was coded as rich the first time it appeared because it prompted students to analyze. But if similar questions follow in later sections, those later questions might not present new challenges to students. Answering similar questions lowers the cognitive orientation by becoming a routine procedure, thus, we coded such a question as either simple or complex rather than rich.

Results

Cognitive Orientation of Mathematical Tasks

Table 1 presents an analysis of task purposes (first column) and cognitive orientations (remaining columns). If a task is designated in one of the seven categories (e.g., R, SC) in Table 1, it means that its subquestions were coded by the cognitive orientation(s) in that category. For example, the Traffic Flow task is under the category of "Simple & Rich (SR)". This means that all questions in this task were coded as either simple or rich, with at least one in each category.

Overall, three out of nine tasks included subquestions that fell into only one cognitive orientation. For example, all questions from the task Bezier's Curve were coded as simple. One question asks to find $x(0)$ in terms of the constants a_0, a_1 and a_2 if $x(t) = a_0 + a_1t + a_2t^2$. Even though the overall task presented an interesting mathematical problem, each smaller question required using simple procedures (e.g., substituting 0 for t). Only one task (i.e., Traffic Flow) included questions that fell into exactly two cognitive orientations. Most tasks included a variety of questions, with at least one in each of the three cognitive orientations. For instance, the Wooody's Film Frame task focused on using computer animators to tell stories about changes in Wooody's position using linear transformations. One question that was coded as *simple* asked to compute the product of two matrices. Another question stated, "Wooody discovered a pensieve at (1, -2). What is the linear transformation here?" Though this question required students to analyze, students were asked similar questions immediately before, but because the question does not specify a particular procedure, we coded it as complex. At the end of the task, a question asked students to write an ending to the story of Wooody's moving and to describe how to illustrate it. This question involved creating and analyzing a new situation and was coded as rich. We found that most tasks included questions from more than one cognitive orientation and thus provided students with multiple cognitive orientations in modeling tasks.

Socio-critical Modeling							
(none)							

Modeling Purpose of Mathematical Tasks

Overall, we coded three tasks as educational modeling, five as contextual modeling, and one as epistemological modeling. We saw no socio-critical modeling tasks. Although we were open to coding individual questions within a task with multiple purposes (similar to our cognitive orientation analysis), we did not find any with multiple purposes. Subquestions presented in the Traffic Flow task, which we coded as educational modeling, provided detailed guideline for preservice teachers (PSTs) to solve the problem that embedded specific concepts in linear algebra (e.g., write the augmented matrix). The instructor's main purpose seemed to be for PSTs to practice linear algebra skills rather than building their own models. The Google Page Rank Algorithm task, on the other hand, involved a realistic context and provided PSTs an opportunity to explore different structures of web networks; thus we coded it as contextual modeling. Specifically, this task provided opportunities for PSTs to investigate how Google uses a stochastic matrix along with a Markov chain and its steady-state vector to determine the PageRank of each page on the website. The Quadratic and Its Secondary Difference task was coded as epistemological modeling because of the potential for PSTs to generate relationships between quadratics and second differences through modeling. We found that more than half of the tasks addressed realistic problems and sometimes instructors used modeling mainly to practice the newly learned concepts. Another intriguing point was that tasks coded as Contextual Modeling included subquestions of all types of cognitive orientations.

Discussion and Conclusion

In this study, we described the use of two theoretical frameworks addressing purposes and cognitive orientations of tasks to support the analysis and potential construction of effective modeling tasks. We noticed that tasks' subquestions coded as "rich" can entail varying degrees of richness. We saw three ways to structure a potential rich task in our data. One way was to give an open question (e.g., in the Egg Launch task, one question asks students which of the three teams will win the contest and to explain why) without providing subquestions for scaffolding. The second way is to give a series of questions with each question building on the previous ones. The open question appeared at the end of the task. We argue that even though both tasks included open questions, the first type was richer than the second because the first type required PSTs to create their own process to reach the final goal. The third way is a combination of the first two cases: starting with an open question, providing a series of questions, and restating the same open question at the end of the task. The benefit of the last type is to provide students with differentiated instruction because the instructor can provide the opportunity for students to either explore the task or follow the scaffolding questions depending on students' academic needs.

White and Mesa (2014) argued that the "rich task" category included the subcategories: Understanding, Applying Understanding, Analyzing, Evaluating, and Creating. They mapped these five categories across four types of knowledge: factual, procedural, conceptual, and meta-cognitive. In our analysis, we found that tasks in which students were asked to *create* a mathematical object or process were much richer than tasks where students were asked to simply *explain* a result or process. As we see different levels of cognitive demand within the "rich task" category, we suggest that instructors pay attention to these differences and present various opportunities for students to experience different types of rich tasks.

In terms of our analysis on purposes of modeling, we found no tasks to be socio-critical in nature and would recommend that PSTs are given opportunities to design and modify such tasks. PSTs need to encounter thinking processes, such as those described by Cirillo, Bartell, and Wager (2016) when they converted a modeling task "Dairy Queen" into a task involving social justice. PSTs can also be benefited by posing modeling problems as they lean about characteristics of modeling problems that address social justice issues (I, Jung, & Son, 2017). Opportunities for PSTs to learn about modeling can be enhanced when instructors consider different modeling purposes and cognitive orientation of tasks described in our study.

This paper describes the implementation of a traditional (face-to-face) and an online module aimed at developing preservice elementary teachers' (PSETs') professional noticing skills and the extent to which participation in these modules affected their attitudes toward mathematics. Using the Attitudes Toward Mathematics Inventory (ATMI, Tapia & Marsh, 2004), statistical analyses revealed significant increases in each of the instrument's four factors (value, enjoyment, motivation, and self-confidence) for those enrolled in a traditional experience, while the online participants experienced significant change in only two factors (enjoyment and self-confidence). Overall, both groups experienced significant improvements in attitudes toward mathematics with no significant differences in the changes between the two groups.

Keywords: Teacher Education-Preservice; Technology; Affect, Emotion, Beliefs, and Attitudes

Introduction

Research exploring mathematics teacher noticing has experienced exponential growth following the work of Sherin, Jacobs, and Philipp (2011). Professional noticing is an ability to recognize and act on key indicators significant to one's profession. In the area of mathematics education, such noticing typically involves the enactment of key skills aimed at facilitating an instructional environment that is responsive to students' mathematical needs and development (Jacobs, Lamb, & Philipp, 2010). Professional noticing has been examined with respect to classroom teaching practices (Sherin & van Es, 2009), preparation and planning (Santagata, 2011), and teacher knowledge (Thomas, Jong, Fisher, & Schack, in press) to identify just a few examples of the breadth of research in this area. Germane to the inquiry described in this paper is the manner in which professional noticing relates to attitudes and if the relationship varies depending upon the delivery mode of the professional noticing instruction. It has long been argued that teachers' attitudes and beliefs are an important part of the way teachers understand mathematics (Jong & Hodges, 2015; McLeod, 1994; Schoenfeld, 2011). As changes to postsecondary systems advance towards experiences that are increasingly mediated by technology, examinations of the relationships between professional noticing experiences and attitudes toward mathematics across varying instructional contexts is warranted. Towards that end, this study addresses the following research questions: (1) To what extent does participation in a professional noticing module influence preservice elementary teachers' (PSETs') attitudes toward mathematics? (2) To what extent do PSETs' attitudes toward mathematics vary in response to participation in a professional noticing module in varied learning environments (face-to-face or online)?

Methodology and Data Sources

Measure Description

PSET attitudes and beliefs toward mathematics were measured using a modified version of the Attitudes Toward Mathematics Inventory (ATMI, Tapia & Marsh, 2004, Schackow, 2005). The

ATMI was selected based on its high level of reliability (α=.97) and ease of administration. This 40-item Likert-scale inventory consists of the following four factors: value, enjoyment, self-confidence, and motivation. It was administered online for both the online and face-to-face participants.

Sites and Participants

The PSETs in this study participated in an instructional module focused on the development of professional noticing and knowledge of an early numeracy trajectory, the Stages of Early Arithmetic Learning (SEAL, Steffe, 1992). All PSETs were enrolled in an elementary mathematics methods or a content and methods blended course at one of five participating public universities in a south central state. The module was a component of the methods or blended course at each institution. PSETs either completed the online module (n = 152) as a component of a face-to-face course or a course delivered via interactive video, or they completed an in-class instructional module (n = 285) as part of their traditional instruction.

Professional Noticing Module Descriptions

Face-to-Face Module

The face-to-face module, four class sessions embedding authentic video vignettes of children engaging in mathematics, used whole-class discussions, small group discussions, homework practice, and a culminating experience in which PSETs completed a video-based diagnostic interview with an elementary student. The ATMI was administered near the beginning and end of the semester in which the module was implemented.

Online Module

The asynchronous online module consisted of four lessons that closely resembled the four days of the face-to-face module. It was embedded in a Learning Management System through which PSETs watched the same video vignettes as the face-to-face participants and attended to their observations through online survey tools. PSETs in the online setting engaged in similar activities as the face-to-face setting, however discussion was asynchronous and a variety of tools were incorporated for small group activities. The pre- and post-tests were completed prior to starting the module and at the conclusion of the modules, typically a two-week period. Students participating in the online module were not required to complete the final assignment of a video-based diagnostic interview that was part of the face-to-face course.

Results

Attitudes and Beliefs in a Face-to-Face Environment

The four factors of the ATMI (value, enjoyment, motivation, and self-confidence) as well as the total scores (sum of each) were analyzed using a repeated measures ANOVA of the pre- and post-assessments. Results from the face-to-face environment (n = 285) revealed a statistically significant increase in all four factors of the ATMI as well as the total score as shown in Table 1.

Table 1: Descriptive Statistics and Repeated Measures ANOVA from Face-To-Face Environment

Variable	Pre Mean	Post Mean	Pre SD	Post SD	F	Sig
Value	44.50	45.07	4.259	4.472	6.978	.009*
Enjoyment	34.51	35.63	9.330	8.986	16.906	<.001*
Self-Confidence	50.92	53.61	14.069	13.742	49.364	<.001*
Motivation	15.27	15.97	4.045	4.121	23.618	<.001*
Total	145.20	150.28	28.354	27.800	49.038	<.001*

*Significant at p = .05

Attitudes and Beliefs in an Online Environment

Initial analyses of the descriptive statistics of the four factors and total scores among the online participants revealed that all four factors of the ATMI, as well as the total, increased between the pre and post-assessments. Repeated measures ANOVA were also conducted (n = 152) to determine if those increases were statistically significant. The enjoyment and self-confidence factors, as well as the total score, were found to have statistically significant increases, while the changes in the value and motivation factors were not significant. The results, along with their descriptive statistics, are shown in Table 2.

Table 2: Descriptive Statistics and Repeated Measures ANOVA from Online Environment

Variable	Pre Mean	Post Mean	Pre SD	Post SD	F	Sig
Value	44.89	45.06	4.30	4.43	.312	.577
Enjoyment	35.40	36.14	8.78	9.43	4.267	.041*
Self-Confidence	50.93	52.41	14.67	14.25	7.674	.006*
Motivation	15.95	16.18	4.04	4.39	.973	.326
Total	147.18	149.8	28.09	28.84	6.949	.009*

*Significant at p = .05

Face-To-Face or Online: Does it Matter?

A one-way ANOVA was conducted to determine if the two participant groups' pre- and post-assessment total scores were significantly different. The results revealed that there was not a statistically significant difference in the pre-test total scores and the post-test total scores between the face-to-face and the online groups ($F_{pre} = .487$, $p = .486$; $F_{post} = .029$, $p = .866$). Significant differences between the online and face-to-face groups could have called into question baseline assumptions between the delivery format of the two groups. The changes (post-pre) in each factor of the ATMI as well as the change in the total scores were analyzed to determine if there were statistically significant differences between the growth of the two groups. The total ATMI score of the face-to-face group was statistically significantly higher than the total ATMI score of the online group, but none of the four factors of the ATMI score were found to be statistically different as shown in Table 3.

Table 3: One-Way ANOVA Results Comparing Mean Change Scores in Face-To-Face and Online Groups

Change Variable	Change Online	Change F2F	F	Sig
Value	.16	.57	1.227	.269
Enjoyment	.74	1.12	.679	.410
Self-Confidence	1.49	2.69	3.397	.066
Motivation	.23	.70	3.262	.072
Total	2.63	5.08	3.986	.047*

*Significant at p = .05

Conclusions

We hypothesized that participation in the professional noticing module, embedding a video-intensive design aimed to capitalize on PSETs' nurturing perspective toward children (Ambrose, 2004), would result in significant changes in PSETs' attitudes toward mathematics. All PSETs, whether participating face-to-face or online, experienced statistically significant changes in total score and two of the four factors, enjoyment and self-confidence. The lack of significance in the motivation and value factors in the online group could be a function of the limited number of items in the ATMI attributable to these factors coupled with the smaller sample size for that group. While both delivery methods revealed statistically significant increases in some factors, indicating that both delivery methods can result in positive attitudinal changes, the significant difference between the change scores of the online and face-to-face groups warrants future research in this area. The results imply that the growth of attitudinal changes in a face-to-face format is significantly higher than those changes in the online format. This can be attributed to the amount of time and intervening events between the pre and post assessments since the face-to-face participants had a longer time period between the two. Or, it could be attributed to the potential lack of depth of online conversations similar to the findings by Wallace (2003). Further study in this area would do much to support or dispel prevailing expectations regarding the design of not only professional noticing instructional materials but also the delivery mode of a mathematics methods course.

PRE-SERVICE SECONDARY TEACHERS' MEANINGS FOR RADIANS AND DEGREES

We report the results of a teaching experiment that examined two pre-service secondary mathematics teachers' meanings for angle measure in degrees and radians. Our results suggest that an instructional focus on degrees prior to radians might obstruct pre-service teachers' development of a quantitative way of understanding angle measure.

Keywords: Measurement, Cognition, Teacher Education-Preservice

Introduction

Moore and colleagues (Moore, 2013, Moore et al., 2016) have demonstrated the affordances of leveraging students' *quantitative reasoning* (Thompson, 1990, 2011) to support their understanding of several foundational trigonometry concepts, including angle measure. Quantitative reasoning is a characterization of the mental actions involved in conceptualizing situations in terms of *quantities* and *quantitative relationships*. A *quantity* is an attribute, or quality, of an object that admits a measurement process (Thompson, 1990). One has conceptualized a quantity when she has identified a particular quality of an object and has in mind a process by which she might assign a numerical value to it in an appropriate unit. *Quantification* refers to the mental actions involved in conceptualizing an appropriate unit of measure as well as a measurement process, and results in an understanding of "what it means to measure a quantity, what one measures to do so, and what a measure means after getting one" (Thompson, 2011, p. 38).

A Quantitative Understanding of Angle Measure

Achieving a quantitative understanding of angle measure involves identifying an attribute of a geometric object to measure and conceptualizing a process by which to measure it. One might conceptualize quantifying the "openness" of an angle as measuring the length of the arc of a circle centered at the angle's vertex that the angle subtends. For the measure of the angle to be independent of the size of this circle, the subtended arc length must be measured in units that covary with the length of the subtended arc so that the ratio of *subtended arc length* to *unit length* is invariant for an angle with a fixed amount of openness. In other words, the unit of measure must be proportional to the subtended arc length and, by extension, the circumference of the circle that contains it. Because the size of the circle centered at the angle's vertex is immaterial to the angle's measure when the subtended arc length is measured in units proportional to the circle's circumference, measuring the length of any single subtended arc amounts to measuring them all. Conceptualizing angle measure in units of *radians* entails understanding that the angle's measure is an equivalence class of arc lengths, each measured in units of the length of the radius of the arc the angle subtends (Thompson, 2008; Moore et al., 2016). Analogously, conceptualizing angle measure in units of degrees involves understanding that the measure of an angle is an equivalence class of arc lengths, each measured in units that are $1/360^{\text{th}}$ of the circumference of the circle, centered at the vertex of the angle, containing the subtended arc.

In summary, achieving a quantitative understanding of angle measure involves: (1) identifying subtended arc length as the attribute being quantified when measuring an angle; (2) recognizing that any unit of angle measure must correspond to a magnitude proportional to the circumference of the circle containing the subtended arc; (3) realizing that radians and degrees satisfy the criterion specified in (2); and (4) understanding the measure of an angle as a measure of a class of subtended arcs.

The process by which students construct a quantitative understanding of angle measure is indeed complex. Identifying a concrete attribute (i.e., a quantity) to measure and conceptualizing units of measure whose magnitudes vary presents unique challenges that make the process of measuring angles considerably more elaborate than other measurement processes. Although researchers (e.g., Moore (2013)) have shed light on the trajectory by which students construct a quantitative understanding of angle measure, much remains to be understood about the conceptual operations involved in developing particular meanings that comprise components of a robust and coherent angle measure scheme. The present study seeks to build upon the work of Moore (2013), Moore et al. (2016), and Thompson (2008) by clarifying the implications of any of the four understandings listed above on students' development of subsequent meanings that are necessary for conceptualizing angle measure quantitatively.

Methodology

We investigated the development of two pre-service secondary mathematics teachers' meanings for angle measure in radians and degrees as they participated in a teaching experiment (Steffe & Thompson, 2000) designed to support their construction of a quantitative understanding of angle measure. In a teaching experiment, the schemes that students construct through spontaneous development are brought forth through exploratory teaching and the interest of the researcher is to discern how students reorganize their cognitive schemes as they experience specific teaching actions.

During the teaching experiment the two participants, Melissa and Kyle, were enrolled in a mathematics content course for pre-service secondary teachers at a large university in the Midwestern United States. Melissa and Kyle participated in four teaching episodes, the first and fourth individually and the second and third together. Each teaching episode lasted between 60 and 75 minutes and all episodes occurred within a span of two weeks. All teaching episodes were video recorded and selectively transcribed. Members of the research team met between teaching episodes to discuss provisional hypotheses about the development and current state of Melissa and Kyle's meanings for angle measure and to modify tasks for subsequent teaching episodes.

We employed grounded theory procedures (Corbin & Strauss, 2008) to analyze the video data. Specifically, we began by performing an iteration of open coding to identify instances in which Melissa or Kyle revealed characteristics of their meanings for angle measure. We then conducted an iteration of axial coding to construct and refine categories of episodes identified with particular codes from the initial open coding. For each category, we articulated the conceptual operations that appeared to inform Melissa and Kyle's language and actions. Finally, we identified shifts in the meanings Melissa and Kyle demonstrated and described the instructional actions that appeared to initiate these shifts.

Results

We limit our discussion of the data to the second and third teaching episodes, and primarily to Melissa's understandings of angle measure.

We began the second teaching episode by supporting Melissa and Kyle's identification of subtended arc length as the quantity one measures when assigning numerical values to the openness of an angle. We accomplished this by presenting Melissa and Kyle with a dynamic animation that showed an angle in standard position with its terminal ray rotating counter-clockwise and asking, "What are some things you notice?" After a few minutes of discussion both Melissa and Kyle abstracted the property that a particular point on the terminal ray traces out a circle centered at the vertex of the angle. They noticed that the openness of the angle covaries with the portion of the circle's circumference traced out by the point on the varying ray of the angle, which allowed them to recognize that the angle's openness is in direct correspondence with the portion of the circle's circumference that the angle subtends. This recognition prompted Melissa and Kyle to conclude that measuring the length of the subtended arc is one way of quantifying the openness of the angle.

After Melissa and Kyle had identified subtended arc length as an attribute one might measure to quantify an angle's openness, the interviewer used the dynamic animation to place the angle's terminal ray in a particular position and asked, "If we wanted to somehow assign a numerical value to the size of the angle, what are some suggestions you have for doing that?" Melissa suggested partitioning the circumference of the circle centered at the angle's vertex into eight equal pieces and then counting the number of these pieces contained in the subtended arc. She drew an image of the angle in standard position on a sheet of paper, sketched a circle centered at the angle's vertex whose circumference was split into eight equal pieces, and approximated that the terminal ray extended between the first and second tick marks on her circle. Melissa then concluded that the angle has a measure of "1.5 out of 8." The interviewer then asked, "What in this picture has a measure of 1.5?" Had Melissa conceptualized angle measure quantitatively, she would have identified a *quantity* (i.e., a measurable attribute) that has a measure of 1.5 and she would have specified a unit of measure. Specifically, she would have explained that the length of the arc the angle subtends has a measure of 1.5 in units of $1/8^{\text{th}}$ of the circle's circumference. Melissa's response, "Just the angle. … Just back to the openness; the openness that appears between the two rays" suggests she was not conceptualizing the value of 1.5 as the measure of a quantity. With prompting she subsequently elaborated: "The angle has a measure of 1.5 and everything else has a measure of a ratio of 1.5 out of 8 … the arc, the area, the angle could all be made as a ratio of 1.5 out of 8." Although Melissa acknowledged that the angle has a measure of 1.5, she did not recognize that this implied that the length of the subtended arc must also have a measure of 1.5 in units of a fractional portion of the circle's circumference. Instead, she claimed that the subtended arc (and the area of the subtended sector) have "a measure of a ratio of 1.5 out of 8."

Melissa reasoned similarly with degrees. She conceptualized an angle's measure in degrees as conveying the fraction of the circle's circumference subtended by the angle. While a useful understanding—and indeed necessary for abstracting the property that any unit of angle measure must satisfy—for her it appeared fundamentally non-quantitative since she did not describe an angle's measure in degrees as resulting from a multiplicative comparison of a measurable attribute and a unit of measure.

The interviewer introduced the idea of radians at the end of the second teaching episode. He showed Melissa and Kyle an image of an angle and stated that its measure is 2.5 radians. The interviewer then asked, "What in this picture has a measure of 2.5?" After a long pause Melissa replied, "The arc length. … That length is 2.5 times the radius." She subsequently explained that to measure an angle in radians, one must divide the length of the subtended arc by the length of the radius of the circle centered at the angle's vertex. Melissa described the value resulting from this division as "the number of radius-lengths in the arc." She also correctly drew an angle with a measure of 3.4 radians and in response to the interviewer's question, "What does it mean to say that an angle has a measure of 3.4 radians?" explained, "The arc length is 3.4 times the length of the radius." These occasions, and others, suggest that Melissa conceptualized angle measure in radians quantitatively—as a measure of subtended arc length in units of the arc's radius.

Melissa continued to demonstrate her quantitative understanding of angle measure in radians at the beginning of the third teaching episode. She accurately approximated the measure of an arbitrary angle in radians and described an angle's measure in radians as resulting from a multiplicative comparison of the subtended arc length and the length of the arc's radius. However, when the interviewer reintroduced degrees a few minutes later by prompting Melissa to describe what it means to say an angle has a measure of 51.7 degrees, she claimed that the angle subtends $51.7/360^{\text{ths}}$ of the circumference of the circle centered at the angle's vertex. After being prompted to identify the length of the arc that an angle with a measure of 51.7 degrees subtends, Melissa attempted to convert the angle's measure to radians so that she would know "how many radius-lengths are in the subtended arc." By failing to recognize that the angle subtends an arc that has a length of 51.7 measured in units of $1/360^{\text{th}}$ of the circumference of the circle centered at the angle's vertex, Melissa again demonstrated a non-quantitative way of understanding angle measure when reasoning about degrees.

Discussion

The findings of this study suggest a different learning trajectory for angle measure than that proposed by Moore (2013). Moore argues for the importance of students recognizing that an angle subtends the same fraction of all circles centered at its vertex. We observed Melissa demonstrating a non-quantitative way of understanding angle measure in degrees that differed from her quantitative understanding of angle measure in radians. We conjecture that her difficulties stemmed from a focus on a multiplicative relationship between a subtended arc length and the circumference of the circle containing it. Our results suggest that introducing radians prior to degrees might support students' construction of quantitative scheme for measuring angles in both radians and degrees.

PRE-SERVICE TEACHER TASK DESIGN: COLLABORATIONS WITH MASTER TEACHERS

Michael S Meagher	Michael Todd Edwards	Asli Ozgun-Koca
Brooklyn College – CUNY	Miami University of Ohio	Wayne State University
mmeagher@brooklyn.cuny.edu	edwardm2@muohio.edu	aokoca@wayne.edu

Pre-service mathematics teachers collaborated with Master Teachers to experience rich problem solving, design of rich tasks, and authentic implementation of rich tasks in high school classrooms. The pre-service teachers made small strides in their own ability to design tasks. There were indications that the pre-service teachers became more open to open-ended tasks and student struggle but their were limitations in their ability to enact these ideas in task design.

Keywords: Teacher Education-Preservice, Teacher Knowledge, High School Education

Introduction

As teacher candidates make the journey to being teachers one of the greatest challenges is designing quality tasks that will engage students in inquiry-based mathematics and be accessible to all students. Adding to the inherent challenge of this task is the fact that typically lesson plans and tasks designed in pre-service contexts, prior to student teaching, are never taught in classrooms making it difficult for teacher candidates to develop and refine their task design. In order to address this challenge we designed the CRAFTeD cycle (Meagher, Edwards & Ozgun-Koca, 2011b), inspired, in part, by Lesson Study research, to give teacher candidates the opportunity to see tasks that they designed implemented in classrooms and, therefore, promote growth in their individual task design.

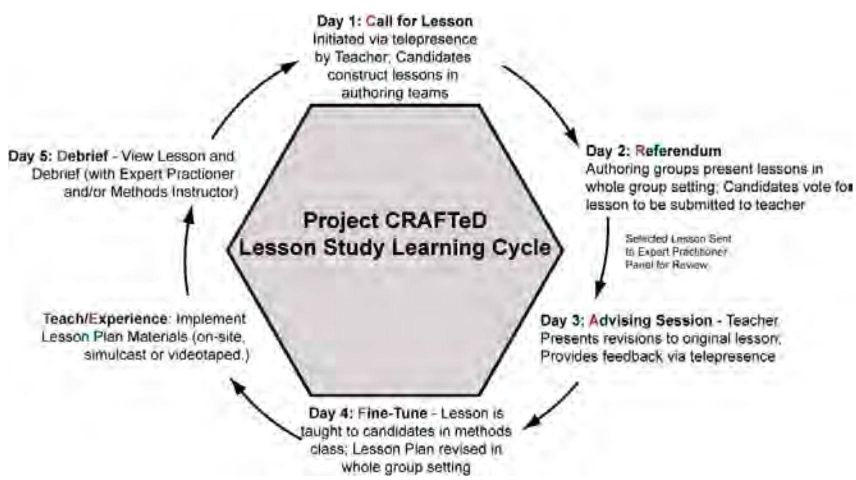

Figure 1. CRAFTeD cycle.

The cycle emerged from our previous work (Meagher, Ozgun Koca, Edwards, 2011a) where the decisive influence of the field placement in terms of exemplars became apparent.

(i) A class of preservice high school teachers will write Lesson Plans on a given topic and then work together to develop improved lessons/short units designed often for technology-rich environments; (ii) experienced inservice teachers will review the lessons/short units and present an initial redesign; (iii) the inservice teachers will teach the lessons, observed by the preservice teachers;

(iv) the preservice teachers and inservice teachers will meet together to reflect on and redesign the lesson based on their experiences in the classroom.

This paper reports the early results of a pilot project designed to measure growth in teacher candidates' ability to design tasks for mathematics classrooms that require "higher level demands" (Stein & Smith, 1998) with the intervention of CRAFTeD cycles.

Literature Review and Relationship to Research

Pre-service teachers early in their program develop lesson plans - typically in isolation - that are never taught in a classroom, creating a disconnect between planning, implementation, and assessment of student learning (Allsopp et al. 2006; Meagher, Edwards & Ozgun-Koca, 2011a). While university methods instructors laud the merits of student-led inquiry, exploration, and discovery-based teaching methods, secondary mathematics teachers in too many schools "set aside" such teaching in favor of instruction directly focused on student preparation for high-stakes, multiple choice state tests (Seeley, 2006). Developing communities of practice (Wenger, 1999) and lesson study groups (Fernandez, 2002) can help candidates and practicing teachers adopt a more research-based focus in their lesson planning and develop a shared repertoire of resources which transcend individual contributions. Providing candidates with opportunities to experience their lessons taught by Master Teachers in authentic classroom settings increases motivation for lesson writing. Preservice teachers demonstrate a trajectory of learning about lesson plans in a cycle of designing a lesson to be taught by a Master Teacher and reflecting critically on the implementation of that lesson (Meagher, Ozgun-Koca & Edwards, 2011b)

Methods and Methodologies

Participants in the study were students in the second semester of a two-semester sequence of methods classes both involving field experience and both prior to student teaching.

At the very beginning of the semester the teacher candidates, working in pairs, revised tasks that were part of the final project of the previous semester (Version 1). The teacher candidates then participated in three CRAFTeD cycles wherein they experimented with different degrees of scaffolding of the tasks. Finally, the teacher candidates, working in their original pairings, revised their tasks from the beginning of the semester (Version 2). Both versions of the tasks were independently scored by two of the research team using a rubric based on Stein & Smith (1999) as measure of growth among the teacher candidates in their ability to design tasks with the potential for higher order mathematics.

We collected (i) Versions 1 and 2 of the Teacher Candidate's lesson plans; (ii) Candidate commentaries on their lesson plans; (iii) Candidate reflections on the semester.

To analyse the data Version 1 and Version 2 tasks were graded independently by two members of the research team. The qualitative data was analysed using the constant comparative method (Glaser & Strauss, 1967) to establish trends in the data.

Results

Quantitative data

Each version of the tasks designed by the students was scored independently but two members of the research team using a rubric based on Stein and Smith (1998) with the scores averaged. Each section of the task was given a score as follows: Memorization: 1 point, Procedures without Connections (2 points), Procedures with Connections (3 points), Doing Mathematics (4 points). The scores were then averaged for the entire task to get an overall score for each task as written by the teacher candidates. The scores for each pair of teacher candidates for each Version of the task are presented in Table 1 below:

Table 1: Scores from Version 1 and Version 2 of the Tasks

	1	2	3	4	5	6	7	8	9	10	11	12	13
Version 1	1.75	1.33	2.57	2.71	1.75	1.80	2.33	2.40	2.50	1.80	1.40	1.67	1.50
Version 2	2.2	1.57	3.33	2.71	1.83	2.00	2.33	2.40	2.50	1.80	1.50	1.67	1.80

As can be seen in the table there was some improvement over the course of the semester (the class average increased from 1.96 to 2.13) with a movement toward "higher order demands" (Stein and Smith, 1998). Furthermore, the number of sections within the tasks scoring 3 or 4 improved slightly from 19 to 22. The improvements were not very large and some possible reasons are explored in the qualitative data analysis.

Qualitative Data

When teacher candidates submitted Version 2 of their tasks they also submitted a commentary on the task in general and responded specifically to a prompt on what they changed from Version 1 to Version 2 and what motivated those changes.

The following significant trends emerged in the data:

(i) A recognition of the need for student struggle with abstract and open-ended tasks. Through experiencing iterations of the CRAFTeD cycle the teacher candidates recognized the need for more open-ended tasks although that recognition did not always result in the design of quality open-ended tasks. The teacher candidates reflected on this with comments such as:

> "In my second revision of the materials, I felt it was important to put more abstract thinking in the problems rather than simple procedures . . . Getting an answer is one thing, but having an understanding of what is actually going on is entirely different, so I added understanding questions to my procedural tasks." (Teacher Candidate 1)
>
> and
>
> [In the revision] the teacher . . . will skip a lecture on the triangle inequality and instead allow the students to discover it on their own." (Teacher Candidate 3)

Other revisions to tasks included moving an open-ended portion to the beginning of the lesson and using a brief open-ended element as a launch in place of the, now widespread, "mini-lesson" of, for example the Santa Cruz New Teacher Project.

While there was a recognition of the need for more open-ended questions the successful design of such questions was not always in place with many of the questions being far too open-ended and therefore unproductive e.g. "With the students around you, see if you can come up with some real-world examples of derivatives and slopes" (Teacher Candidate 1).

(ii) An unsophisticated view of "higher level demands" and a view that differentiation means "easy" and "hard" tasks. There was evidence throughout the teacher candidates' revisions that their notion of "higher level demands" was often tied to more complicated procedural work rather than an engagement with "conceptual ideas that underlie the procedures to complete the task successfully and that develop understanding." Teacher candidate 7 noted that he "ordered the problems on this worksheet in such a way that the least difficult and closed questions are in the beginning" (Teacher Candidate 7). Teacher candidate 9 revised an "angle chase" to involve the students chasing 10 or 12 angles instead of 2 or 3 but without adding any new concepts to the work required to identify the measures of the angles.

(iii) A recognition of the need to give students an opportunity to discuss mathematics. The successive iterations of the CRAFTeD allowed teacher candidates to see their task design in action on classrooms and, in particular, to see students engage with the materials. With this came a recognition that structuring opportunities for students to discuss mathematics is an important element of task design. Teacher candidate 13 noted "math learning is a social activity. When the team communicates using math language, student's memory of the terms learned in this lesson will be deepened. Also, students will be more engaged when they learn together." Another candidate noted that "In this final revision of my lesson plan I chose to add a section where students were asked to discuss what the algebraic properties in the chart really meant. This is something that I had previously ignored but . . . now find important" (Teacher Candidate 12).

(iv) A recognition of the potential of technology to help students engage in mathematics. The instructor of the class and the Master Teachers that were participants in the project emphasized the affordances of technology in designing higher order tasks as well as engaging students. The exemplars experienced by the teacher candidates in the CRAFTeD cycles resulted in changes in the revisions of the tasks. Teacher candidate 14 noted that "Technology seemed to hold students' attention more easily in our field experiences and engage them in an interactive way." Teacher candidate 2 revised her task to allow students to explore limits with technology "When this lesson was originally given, the class had a hard time visualizing the nature of these limits that approach infinity. With the sketch [created in Geogebra], they can explore the infinite limits with more ease" (Teacher candidate 2).

In a similar fashion to the poorly designed open-ended questions discussed in the previous section there was evidence in the teacher candidate's revised tasks that, while they were eager to deploy advanced digital technologies, the tools they provided to students were often unannotated sketches with no instructions as to how they can be used to explore the mathematical content of the task. The potential for students to aimlessly engage with the sketch and discover very little was often quite high.

Conclusion

The pilot study described above was designed to provide pre-service mathematics teachers with experiences in rich problem solving, experiences in designing rich tasks for implementation, and experiences in how those tasks can be authentically implemented in high school classrooms. The pre-service teachers make small strides in their task design but, arguably larger strides in their openness to the importance of open-ended tasks, student struggle and student collaboration in mathematical work. However, there were notable limitations in their ability to enact these ideas in task design.

PRESERVICE ELEMENTARY TEACHERS' PERCEIVED PREPAREDNESS OF HIGH-LEVERAGE PRACTICES IN MATHEMATICS TEACHING

Ji-Eun Lee
Oakland University
lee2345@oakland.edu

This study examined elementary pre-service teachers' (PSTs') perceived preparedness of high-leverage practices (HLPs) in mathematics. Eighty-one elementary PSTs who enrolled in four sections of an elementary mathematics methods course participated in a survey that involved identifying their self-reported confidence and competence levels on HLPs. This study specifically investigated the comparison between PSTs' perceptions of HLPs and the mathematics teacher educators' expectations. Findings showed some glaring differences between the PSTs' perceptions and experts' perceptions in regards to the complexity of some HLPs. This study suggests that initial teacher training programs should include more specific investment in PSTs' insights into details of each teaching practice in mathematics by deliberate decompositions.

Keywords: Instructional Activities and Practices, Teacher Education-Preservice, Teacher Beliefs

Purpose of the Study

The recent recognition of the significant work teachers actually do in classrooms suggests teacher preparation programs offer pre-service teachers (PSTs) more explicit opportunities to be engaged in key teaching practices (Ball & Forzani, 2009; Grossman et al., 2009; NCTM, 2014). An example of these efforts is the establishment of a set of "high-leverage practices" (HLPs), which are considered to be the basic fundamentals of teaching practice (Ball, Sleep, Boerst & Bass, 2009; Davis & Boerst, 2014). This is a critical shift in teacher preparation programs, so it is essential to assess PSTs' current understanding of HLPs as well as to develop activities which promote PSTs' use of HLPs. To do so, teacher educators should first understand how PSTs perceive HLPs in mathematics teaching and learning; however, research regarding PSTs perceptions of HLPs is limited. In response to the need for investigating PSTs' own perceptions, this study intended to accomplish two specific objectives: (a) Identifying PSTs' perceived preparedness for specific HLPs in mathematics and (b) Comparing between PSTs' perceived preparedness and the experts' (mathematics teacher educators') expected learning progressions. Ultimately, this study aimed to gather information on PSTs' conceptualizations of HLPs and provide insight into how to best support the development of practice-based teacher preparation programs.

Theoretical Framework

High-leverage Teaching Practices

There have been continuous efforts towards developing a common set of indicators for the disposition, knowledge, and skill that are required for beginning teachers; however, it is still challenging to define what should be taught in teacher preparation programs across many institutions (Levine, 2006). One of the recent movements in teacher education is focusing on a set of HLPs that support high-quality student learning. By seeing the work of teaching as an 'unnatural' act that should be taught, this view highlights the importance of doing and practicing teaching, rather than simply 'teaching about teaching' (Ball et al., 2009; Grossman & McDonald, 2008). This involves decomposing complex teaching practices into small, teachable HLPs in order for novice teachers to access various components of the work of teaching (Ball & Forzani, 2009; Grossman et al, 2009). This should be done by attending to developing teachers' adaptive expertise to be sure that it does not serve to de-professionalize teaching (Ball & Forzani, 2009; Hamerness, Darling-Hammond, & Bransford, 2005).

Research on Pre-service Teachers' Perceptions of Teaching Practices

Research on PSTs' perceptions of good teaching practices shows mixed results for various aspects of teaching. Some researchers address PSTs who enter teacher education programs with a positive, but generally simplistic view of teaching (e.g., Whitebeck, 2000). Many of them also enter the program with high confidence in terms of their ability to perform well, which may be a display of "unrealistic optimism" (Weinstein, 1988). Some PSTs believe that teaching is easy and that it is about transmitting information (Feiman-Nemser, McDiarmid, Melnick, & Parker, 1989). In contrast, other studies report that PSTs consider a 'teaching personality' more important than content or pedagogical knowledge. This view is in line with the popular myth that some people are 'born teachers.' Whitebeck (2000) suggests that some PSTs enter teacher preparation programs to learn the 'tricks of the trade' and others believe that they are 'born teachers.'

Overall, previous research on PSTs' views of good teaching was very focused on the entry-level PSTs and examined the beliefs, expectations, and perceptions that they bring to the teacher preparation program. It is expected that this study will extend previous research in this area by exploring the perceived self-efficacy of PSTs on specific HLPs and offering suggestions for mathematics teacher educators on how this baseline data can be incorporated when designing PSTs' experiences in mathematics teacher education programs.

Methods

Eighty-one elementary PSTs who enrolled in four sections of a mathematics methods course at a Midwestern university in the United States participated in the study. For most participants, this was one or two semesters prior to the culminating, semester-long, full-time student teaching experience in an actual classroom. At the beginning of the semester, PSTs had a chance to review the descriptions of each HLP (from teachingworks.org). They were asked to select five HLPs they felt they could perform confidently and competently at the time of responding. PSTs completed this listing activity individually followed by a subsequent group debriefing session. For the purpose of this report, we are focusing on reporting the quantitative analysis of PSTs' perceived preparedness as reflected in their lists of HLPs. A pair of mathematics teacher educators (experts) provided their expected learning progressions in teacher preparation programs in order to compare expert judgment to the information coming from the PSTs in this study.

Results

This section reports on three distinct clusters of HLPs from the results of the larger study by highlighting aspects that contrast PSTs' perceived level of preparedness and the researchers' expected learning progressions.

Complexity of Interactive Structure

This study clustered four HLPs together to view PSTs' perceived level of preparedness in facilitating varied interactions with students as well as creating a classroom climate that promotes such interactions: Leading a Group Discussion (LGD), Setting up and Managing Small Group Work (SGW), and Eliciting and Interpreting Individual Students' Thinking (EIIS). Experts' expected learning progression was having PSTs gradually exposed to increasingly complex and challenging situations, starting from working with individual students and small groups to the whole group discussion. However, unlike the experts' expected progressions, PSTs responded that they felt more prepared in LGD and SGW than EIIS (see Table 1).

Table 1: Perceived Preparedness on Complexity of Interactive Structure (N=81)

	Listed as 5 most confident HLPs	Listed as 5 least confident HLPs
LGD	44 (54%)	12 (15%)
SGW	47 (58%)	7 (9%)
EIIS	12 (15%)	27 (33%)

Subject-Matter Knowledge

Another cluster consisted of two HLPs that rely on teachers' subject-matter knowledge and their ability to identify common patterns of student thinking in subject knowledge. This cluster includes Explaining and Modeling Content, Practices, and Strategies (EM) and Diagnosing Particular Common Patterns of Student Thinking and Development in a Subject-matter Domain (DST). Although experts believe these two HLPs should go hand-in-hand, diagnosing students' patterns of thinking in mathematics can provide an effective way of explaining and modeling. PSTs' responses showed different perceptions (see Table 2).

Table 2: Perceived Preparedness on Identifying and Using Subject-Matter Knowledge (N=81)

	Listed as 5 most confident HLPs	Listed as 5 least confident HLPs
EM	18 (22%)	18 (22%)
DST	6 (7%)	44 (54%)

Knowledge of and Relationship with Students

Experts examined several HLPs that rely on teachers' knowledge of and relationship with students: Building Respectful Relationships with Students (BRR), Talking about a Student with Parents or Other Caregivers (TSP), and Learning about Students' Cultural, Religious, Family, Intellectual, and Personal Experiences and Resources for Use in Instruction (LS). Experts expected that LS would provide a good basis for accomplishing BRR and TSP. Table 3 shows PSTs' predominant perceived confidence in BRR. It was the most frequently selected HLP as a confident practice among 19 HLPs.

Table 3: Perceived Preparedness on Knowledge of and Relationship with Students (N=81)

	Listed as 5 most confident HLPs	Listed as 5 least confident HLPs
BRR	66 (81%)	2 (2%)
TSP	23 (28%)	36 (44%)
LS	22 (27%)	19 (23%)

Discussion

These results are based on PSTs' perceived preparedness on HLPs, which do not necessarily represent their actual competencies on HLPs. Regardless of this limitation; however, the data provided valuable information on discrepancies between mathematics teacher educators' and PSTs' perceptions on HLPs. The data also indicated the need for ways to best to support PSTs' learning in teacher preparation programs.

Teaching is complex, and the 19 HLPs provide a new perspective on teacher preparation by decomposing the complex work of teaching (Ball & Forzani, 2009; Grossman, Compton, et al., 2009). However, this study indicates that ambiguity of understanding still exists among PSTs on the meaning and constructs associated with each HLP. For example, the work of leading a group discussion requires multiple practices such as eliciting student thinking, probing, orchestrating, and making contributions (Selling et al., 2015). This contrasts PSTs' high level of confidence in leading a group discussion and low level of confidence in eliciting and interpreting individual students' thinking. This result leaves a question about PSTs' conceptions of "leading discussion," which may rely significantly on their unexamined assumptions. This suggests that there is a need for more deliberate and detailed decomposition of each teaching practice. The practices with a low level of preparedness perceived by PSTs (e.g., Implementing norms and routines for classroom discourse and work, Selecting and designing formal assessments of student learning) also have important implications for PST training. Further research is required to determine the decomposed parts of each HLP and ways to sequence them to establish contextually relevant and responsive teacher preparation programs.

PRESERVICE TEACHERS' DEVELOPMENT OF KNOWLEDGE OF AUTHENTIC ASSESSMENT MATHEMATICS TASKS

Olive Chapman
University of Calgary
chapman@uclagary.ca

Kim Koh
University of Calgary
kkoh@ucalgary.ca

Mathematics teachers are expected to adopt new approaches to assessment that better address reform goals in school mathematics curriculum. This study is investigating an approach consist-ing of Authentic Assessment Learning Activities [AALA], based on an "authentic intellectual quality framework," to help preservice mathematics teachers to develop expertise in the selection, adaptation, and design of authentic assessment tasks. The approach was piloted with three preservice teachers specializing in mathematics education. Data sources included inter-views, journals, and tasks created by participants. Findings provided initial evidence to support the use of the AALA in teacher education as a potentially effective way of helping preservice teachers to not only develop useful knowledge of authentic assessment, but also mathematics knowledge for teaching associated with the design of authentic assessment tasks in mathematics.

Keywords: Assessment and Evaluation, Teacher Education-Preservice

Mathematics curriculum reforms aimed at mathematical literacy and 21st century competencies (Darling-Hammond & Adamson, 2010; Koh, 2014; Wyatt-Smith & Cumming, 2009), such as critical thinking, reasoning, problem solving, communication, and collaboration, require corresponding reforms in how students' learning and performances are assessed in the mathematics classroom (e.g., National Council of Teachers of Mathematics [NCTM], 2000; Romberg, 1995). This means that teachers implementing such reforms must make changes to their assessment practices to include authentic assessments that enable richer demonstration and more holistic representation of what students know and can perform in mathematical and real-world contexts. However, research indicates that teachers are not well equipped to deal with reform-oriented assessment practices. For example, studies found that a large majority of pre-service teachers in Canada and the United States had low levels of assessment literacy (DeLuca & Klinger, 2010; Mertler, 2009; Volante & Fazio, 2007). Thus, there is a need to support mathematics teachers' development of their assessment literacy in designing and implementing classroom assessments that are well aligned with the objectives of reform-oriented mathematics curriculum. This study is investigating the use of the Authentic Assessment Learning Activities (AALA) to develop preservice mathematics teachers' expertise in the selection, adaptation, and design of authentic assessment mathematics tasks. Authentic tasks replicate real-world problems that require students to demonstrate their mathematical understanding through the application of essential mathematical knowledge and skills in problem solving (Koh, 2014).

Theoretical Framework

The AALA used in this study aim at the development of teachers' understanding of sound principles of classroom assessment and expertise in the selection, adaptation, and design of authentic assessment tasks in mathematics. The AALA include *criteria for authentic intellectual quality* (Koh, 2011a; 2011b), design principles of authentic assessment and associated rubrics, the Structure of Observed Learning Outcome (SOLO) taxonomy (Biggs, & Collis, 1982), and curriculum alignment. The *criteria of authentic intellectual quality,* developed by Koh, consist of the following five criteria and their respective elements: (1) depth of knowledge (factual knowledge; procedural knowledge; advanced concepts), (2) knowledge criticism (presentation of knowledge as a given; comparing and contrasting information; critiquing information), (3) knowledge manipulation (reproduction; organization, interpretation, analysis, evaluation, synthesis of information; application/problem solving; generation/ construction of new knowledge), (4) extended communication, and (5) making connections to the real world beyond the classroom. The mathematics indicators for each of the elements are detailed in Koh (2011b).

The criteria of authentic intellectual quality were adapted from Newmann and Associates' (1996) framework of authentic intellectual work, the revised Bloom's taxonomy of knowledge (Anderson & Krathwohl, 2001), and the different dimensions of learning by Marzano (1992). Newmann et al.'s (1996) "authentic intellectual work" consists of three broad criteria: construction of knowledge, disciplined inquiry, and value beyond the school. Specific standards are embedded within each of the criteria, which "provide a benchmark for teachers to judge whether particular forms of instruction and assessment are likely to help students produce authentic work" (Scheurman & Newmann, 1998, p. 3). The revised Bloom's taxonomy was used to further unpack and define the construction of knowledge and disciplined inquiry criteria.

Method

The AALA are being investigated in a larger funded project with preservice teachers (PSTs). They were successfully used with practicing elementary school teachers in Singapore (Koh, 2011a, 2014) and are now being adapted for use with PSTs. This paper reports on the pilot study with three PSTs specializing in mathematics education; one at the elementary and two at the secondary school levels. The secondary PSTs were in the fourth term of their two-year Bachelor of Education program and had completed an assessment course, while the elementary PST was in the second term of the same program and had not completed the assessment course. All three participated in the AALA during four two-hour sessions led by the researchers at the university during the summer and for homework. They engaged in readings, discussions, and applications of the AALA. Based on the AALA, they individually analyzed actual assessment tasks used in a *unit of work* for a mathematics topic and Grade of their choice and then designed the assessment tasks for a different topic and Grade using the criteria of authentic intellectual quality.

Data sources for the pilot consisted of group interviews with the three participants at the beginning and end of their engagement with the AALA; participants' journals of their thinking and analysis of authentic assessment tasks; researchers' notes and audio-recordings of selected participants' discussions during the sessions with the AALA; and the assessment tasks analyzed and designed by the participants. The interviews explored the PSTs' thinking regarding: their conceptions of the nature and purpose of authentic assessment in mathematics and of the expertise needed in authentic assessment, their learning experiences with the AALA, the authentic assessment task design, their use of the criteria for authentic intellectual quality, the impact of the AALA on their mathematics knowledge for teaching, the use of authentic assessment to promote students' learning and thinking of mathematics, and their plans for using the authentic mathematics tasks they designed in their future teaching. The interviews were audio recorded. All audio-recordings were transcribed. Data analysis included a focus on identifying their conceptions of authentic assessment, what they valued and what was challenging in working with the AALA, and their level of understanding of designing authentic assessment tasks. The data were coded to identify themes in their thinking and experiences with the AALA. For example, coding of interviews to identify their conceptions of authentic assessment was both open-ended and based on the authentic assessment framework. Change/growth in conceptions of authentic assessment was determined by comparison of the pre-and post-AALA engagement coded data. The assessment tasks they developed were scored using the criteria for authentic intellectual quality with 4-point rating scales (ranging from 1 = no requirement/no demonstration to 4 = high requirement/high level) to determine their level of understanding.

Results

Findings of this pilot study indicated that PSTs' engagement in the AALA was effective in helping them to enhance their understanding of authentic assessment tasks in teaching mathematics. Before engaging in the AALA, there was little difference between the two participants who had completed the assessment course in their teacher education program and the one who had not regarding their conceptions of authentic assessment tasks. While the course enabled them to develop initial understanding of forms of assessment *of* and *for* learning, it did not allow them to conceptualize authentic assessment, in general, and authentic assessment tasks in mathematics, in particular, in ways that were meaningful to assess what students know and can perform in mathematical and real-world contexts. They indicated that the AALA were useful in providing them with a systematic way of making sense of selecting, unpacking, adapting, and designing authentic tasks for assessment and helped them to understand what it means to be authentic regarding tasks and process to assess learning in mathematics.

The criteria of authentic intellectual quality, which the PSTs used to guide their analysis of the assessment tasks for the *unit of work* they chose (e.g., slope of a linear function, perimeters of polygons, rates of change), challenged their thinking in evaluating the level to which the tasks required deep understanding and promoted knowledge criticism, higher-order thinking, reasoning skills, and connections to the real world beyond the classroom. But this was central in helping them to understand the strengths and limitations of the tasks they selected from their practicum experiences and to make meaningful suggestions to modify them. The AALA also contributed to their development of mathematics knowledge for teaching as they engaged in identifying the instructional objectives and conceptualizing the authentic tasks. The criteria of authentic intellectual quality challenged their understanding of mathematics concepts involved in the assessment tasks and made them think about them in alternative ways as well as think about alternative ways of engaging students in learning mathematics. As one of the PSTs explained: "I think it's really interesting that our perception of how well we understand a concept is certainly pushed and tested when you're trying to develop a task." Another noted:

> I found it challenging to narrow down the task and imagine what expectations I had for the final project. … As students begin their work on the task, I would like to have exemplars of work for students to gain a better understanding of the expectations.

The final assessment tasks the participants created for *units of work* of their choice (e.g., algebraic expressions (grade 7) and linear relations and functions (grade 10)) indicated a developing practical level of understanding of authentic assessment tasks. Based on the SOLO taxonomy, the tasks covered the assessment of different instructional objectives ranging from a basic understanding of concepts to complex problem-solving. The Grade 10 tasks, for example, consisted of a project designed for students to apply their mathematical concepts and thinking to solve a real-world problem. These tasks included the following expectations:

1. Students will pair up and flashcards with different figures will be distributed (i.e., labeled graphs, images of everyday objects (e.g., basket of fruit, ski hill, thermometer, etc.), table of values, bank statements, and equations. Students will discuss in their groups: *What relationships exist within the photo(s)? How could you represent these relationships?*
2. Data Collection & Explanation. Students will devise a way to relate and graph their collected data. They should be able to interpret and explain the relationships among their data, graphs,

and situations in small collaborative groups. They also should be able to state a reasonable domain and range, and explain any restrictions they set.

3. Data Interpretation & Manipulation. In small groups, students will analyze their graphs and collected data and identify if their relation is linear. They should be able to further explain how they know, orally and through a written piece, which they will keep for their final submission. … At this stage, students should be able to confirm if their relation is a function, through both peer and self-assessment.

The main concern about the AALA was the need for more time and practice with analyzing and creating tasks to allow for deeper engagement with the AALA and group discussions.

Conclusion

The study suggests that the AALA have the potential to help PSTs to develop useful know-ledge of authentic assessment mathematics task design. They also have the potential to support PSTs' development of mathematical content and pedagogical knowledge for teaching associated with the critique, redesign, and design of the tasks. Continued investigation of the AALA in the larger project will involve a larger number of PSTs and aim at deeper understanding of how these activities could support their learning of both authentic assessment mathematics tasks and mathematics knowledge for teaching. They will also be tracked into their teaching as beginning teachers to investigate whether or how they can implement their knowledge in their teaching.

PRESERVICE TEACHERS' PERSPECTIVES ON AND PREPARATION FOR TEACHING MATHEMATICS EQUITABLY

Michael D. Dornoo
The Ohio State University at Newark
dornoo.1@osu.edu

Lynda R. Wiest
University of Nevada, Reno
wiest@unr.edu

This study investigated preservice teachers' perspectives on and preparation for teaching mathematics equitably. Overall, participants indicated that student demographics should influence the way they teach, but this varied by teacher and student group.

Keywords: Teacher Education-Preservice, Elementary School Education, Middle School Education, Equity and Diversity

Purpose of the Study

This study investigated preservice teachers' perspectives on and preparation for teaching mathematics equitably. The research questions were: 1) What attitudes and beliefs do preservice teachers report in relation to teaching mathematics equitably to all students? 2) What preparation do preservice teachers report in relation to teaching mathematics equitably to all students? What preservice teacher preparation do they recommend? 3) What key instructional approaches do preservice teachers suggest for teaching mathematics equitably to all students?

Perspectives

The science, technology, engineering, and mathematics (STEM) disciplines play a key role in societal progress and economic prosperity and possess high status and career promise (Shapiro, Grossman, Carter, Martin, Deyton, & Hammer, 2015). However, some groups are underrepresented in STEM. For example, females tend to show less favorable dispositions toward STEM, which can influence their achievement and participation (Shapiro et al., 2015). Students from underrepresented racial/ethnic groups attain lower achievement test scores on standardized mathematics tests (Snyder & Dillow, 2015), and a sizeable performance gap exists between students who are English language learners (ELLs) and those whose first language is English (Institute of Education Sciences, 2016). Students from lower-income families show weaker self-efficacy, lower school performance, and higher school drop-out rates than students from higher-income families, and the achievement gap between students from lower- and higher-income families has widened in recent decades (e.g., OECD, 2013).

Teachers need to understand the relationship of these types of student background variables to mathematics teaching and learning in order to support all students' needs (Civil, 2014). Teacher education can play an important role in facilitating more favorable teacher dispositions and practices in relation to serving diverse students (Hwang & Evans, 2011).

Methods

Participants

Participants were 203 upper-division undergraduates. Of these, 77.8% were ages 18-25, and 22.2% were ages 25 and older. These prospective teachers were enrolled in elementary education (44.0%), dual elementary/special education or special education (40.5 %), and secondary mathematics education (15.5 %).

Instrumentation and Data Collection

Participants completed an author-constructed survey titled Preservice Teachers' Perspectives on and Preparation for Mathematics Instruction for Diverse Learners, which has nine closed-format items rated on a Likert scale with space to explain ratings and two open-ended questions.

Data Analysis

Quantitative data were analyzed as a whole and disaggregated by age and program of study. The Kruskal-Wallis or Mann-Whitney *U* test was used to test for significant differences between participant subgroups. Written comments were categorized into conceptual categories, or themes.

Results

Beliefs About Planning and Delivering Mathematics Instruction to Diverse Students

Participants tended to agree that student demographics should influence how they teach mathematics. They most strongly agreed that students for whom English is a second language should influence their mathematics instruction and tended to agree that student socioeconomic status should also be considered. Participant responses were fairly equally divided in regard to the role of student race/ethnicity, and participants tended to disagree that gender should be a factor in planning and carrying out mathematics instruction. Participants tended to agree that it is challenging to design and implement fair mathematics instruction according to student race/ethnicity and language and least challenging according to gender. The older age group was more likely to agree that student socioeconomic status should be considered and is challenging in planning and carrying out mathematics instruction. Five dominant themes appeared across participants' written comments, each of which follows with a sample comment:

Students' learning differences. "Students that come from different backgrounds have different ways of learning. Teachers should incorporate these differences into their lesson plans."

Varied teaching methods: "I think that capable teachers are flexible and able to use various methodologies to meet the needs of the array of students they encounter."

Real-world connections: "The way I intend to teach mathematics is to link with the real-world that will benefit all students regardless of demographics."

Students' prior knowledge: "The ideas that students bring into the classroom should help you understand them and teach them better. Gender and race/ethnicity, in some ways, do influence a student's background knowledge."

Resources and supplies: "This is very important in assigning projects or assignments. Teachers have to know what resources are going to be available for all the students."

Preparation for Teaching Mathematics Equitably

Participants tended to agree that they are prepared to support the mathematics learning needs of all students, mainly in relation to gender and socioeconomic status, but they expressed somewhat weak preparation in relation to race/ethnicity and home language. They tended to agree that their strongest preparation for teaching mathematics equitably came from their college coursework. Dual elementary/special education majors were significantly more likely than elementary and secondary majors to report that they can support the mathematics learning needs of all students, especially non-native English speakers.

Written comments show the following themes:

Mathematics as a "weakness." Some participants indicated that they are not well prepared to teach mathematics to diverse students because they consider the subject area their "weakness."

Teaching diverse learners. Some participants reported having a good grasp of mathematics content but not knowing how to teach diverse students. In this regard, one said, "Teaching mathematics is harder than [teaching] other subjects." Some expressed unpreparedness, but others showed confidence that they could find the tools and resources they need.

Teaching non-native English speakers. Participants deem themselves ill prepared to support non-native English speakers in mathematics instruction, explaining, "I believe that non-native English speakers is the only factor that requires different and well prepared instruction."

College coursework, practicum, and personal experiences. Most students said their strongest preparation for teaching mathematics equitably came from college coursework, although some named field experiences and a still lesser number personal work experiences.

Cultural awareness and learning styles. Most participants had limited experience interacting with members of other cultures. They suggested that they be guided in ways to examine the curriculum for cultural inclusiveness and exposed to ways to learn students' background and prior experiences in order to adapt their instructional approaches.

Experience in diverse classrooms. Several participants noted that the program did not provide opportunities to teach mathematics to diverse learners during field experiences.

Hands-on assignments and projects. Participants asserted that they might be prepared to teach mathematics fairly to diverse students if they were taught instructional strategies to draw on real-life situations and use manipulatives and other hands-on materials.

Resources and resourcefulness. Participants identified other people (e.g., special education teachers, aides, counselors, and other teachers) as the most important resource available to them. They also requested assistance locating instructional materials and resources for diverse students.

Perspectives on Appropriate Instructional Skills and Needed Preparation

Participants suggested six main approaches for teaching mathematics equitably to all students:

Group work. Participants stated that when students work collaboratively they are able to tackle and persevere on more conceptually difficult problems.

Mathematical connections. Participants commented that connections between mathematics and other subject areas, one's personal interests, and so forth should be emphasized.

Influential mathematicians and role models. A few participants emphasized the importance of introducing role models from underrepresented groups (e.g., females).

Different teaching strategies. Participants reported that using a variety of modes of instruction can benefit diverse students.

Language support. For example, "We must teach mathematics concepts and vocabulary."

Varied challenges for different groups. Participants voiced most concern about designing mathematics instruction for non-native English speakers and least about gender, such as: "Gender and socioeconomic status shouldn't matter when you teach math, but it might be hard to teach kids that don't speak English and that are from different cultures."

Discussion and Conclusions

This study shows that preservice teachers tend to consider themselves prepared to teach mathematics to diverse students and find this goal important. However, they were least concerned about gender and most concerned about students whose first language is not English. The lack of concern about gender is problematic, given continued issues for females in STEM (Wiest, 2011). Participants' concern about teaching ELLs is worrisome with respect to the need for competence and a sense of self-efficacy in relation to this dimension of teaching. However, it is encouraging that preservice teachers appear to be sensitized to its importance.

The participants in this study consider teacher preparation coursework and field experiences to be important in their preparation to teach mathematics to diverse students. However, they want more field experience and more resources for taking on and continuing this preparation. Some participants reported their own mathematics content weaknesses to be a concern, which is important for teacher education to address (Hourigan & O'Donoghue, 2015).

Older teachers were significantly more likely to consider students' socioeconomic status to be important to consider and to be a challenge in planning and implementing equitable instruction. Perhaps this is due to their extended real-world experience, which might lead to greater recognition of the role of this factor in people's lives. Secondary preservice teachers were also more likely to say they should consider student SES in their instructional efforts. Perhaps SES differences are more obvious in older youth, but more attention to the importance of SES in education appears to be needed. Dual elementary/special education majors were significantly more likely than elementary and secondary majors to consider themselves prepared to support the mathematics learning needs of diverse students, especially non-native English speakers. Participation in a program that includes attention to a student population with specific education needs might raise their sense of self-efficacy for teaching diverse students in general.

Findings such as those reported in this paper can help teacher educators determine how to enhance programs that prepare preservice teachers to teach mathematics effectively to diverse students.

PROSPECTIVE ELEMENTARY TEACHERS' KNOWLEDGE OF MULTIPLICATIVE STRUCTURE THROUGH CLINICAL INTERVIEWS

Ziv Feldman
Boston University
zfeld@bu.edu

Little is currently known about how students and teachers make sense of multiplicative structure in the context of elementary number theory. This study uses APOS theory to investigate six prospective elementary teachers' developing understanding of multiplicative structure through clinical interviews prior to and following a three-week unit of instruction on number theory. Results reveal the ways in which participants developed more coordinated understandings of multiplicative structure, and suggest benefits for attending to prime factorization in content courses for prospective elementary teachers.

Keywords: Teacher Education-Preservice, Number Concepts and Operations

Background Information

Multiplicative structure is defined by Zazkis and Campbell (1996a) as "conceptual attributes and relations pertaining to and implied by the decomposition of natural numbers as unique products of prime factors" (p. 541). Research has shown that a richer understanding of multiplicative structure can facilitate students' transition from arithmetic to algebra, deepen their understanding of divisibility, and support their work with fractions, decimals, and rational numbers (Campbell, 2006; Brown, Thomas, & Tolias, 2002).

In order for K-8 students to make sense of multiplicative structure, PTs must first develop a deeper understanding of its meaning and applications. However, PTs' knowledge of multiplicative structure reveals an overreliance on computation-heavy procedures (Zazkis & Campbell, 1996a). For example, when asked to determine whether $M = 3^3 \times 5^2 \times 7$ is divisible by 7, many PTs ignored the structure of M, and instead multiplied the prime factors together and carried out long division.

This paper describes the results of clinical interviews were administered as part of a larger study (Author, 2012) examining PTs' understanding of multiplicative structure in the context of five number theory topics: factors, prime factorization, divisibility, greatest common factors (GCF), and least common multiples (LCM). Overall, 59 PTs enrolled in three sections of a mathematics content course at a private university in the northeastern U.S. completed five number theory lessons over a three-week period. Written assessments were administered to all participants prior to and immediately following the three-week instructional unit.

Theoretical Framework

Dubinsky's (1991) Action-Process-Object-Schema (APOS) theory served as the foundation for the 2012 study described above. APOS theory is a constructivist theory of learning that stipulates that individuals construct their own understanding by interacting with their environment. Developing a deeper understanding of a mathematical concept involves constructing and organizing more abstract and connected mental representations. As the individual makes these constructions, he reaches increasingly sophisticated levels of understanding. APOS theory identifies these levels as *actions*, *processes*, *objects*, and *schema*.

Actions are repeatable, algorithmic procedures. An individual who possesses an action-level understanding of a mathematical concept requires step-by-step instructions on how to perform the action. When an individual repeats an action enough times that he can construct an internal representation for that action, the individual can often execute the action mentally without actually performing the individual steps. The action is said to have been interiorized into a *process* (Dubinsky & McDonald, 2001). An individual encapsulates a process into an *object* when he begins to see the process as a single entity consisting of a static structure; the underlying concept exists independent of its associated process. A *schema*, or structured mental network, is formed when processes and objects become connected. Through analysis of the data (as described below), it became necessary to subdivide the *process* code into two sub-codes: *process without coordination* and *process with coordination*. The former reflects an inability to combine, explicitly or implicitly, two or more concepts to make sense of a problem situation; the latter reflects one's ability to make such combinations.

Individual Clinical Interviews

This paper presents the results of six individual clinical interviews administered prior to and immediately following the three-week number theory unit. Six female participants were selected from the larger sample to participate in one hour-long individual clinical pre- and post-interviews. They were selected by random sampling, stratified by prior mathematical achievement levels based on their pre-test scores and recommendations from their math content course instructors.

The purpose of each interview was to identify participants' in-the-moment thinking around multiplicative structure. Using a think-aloud protocol (Patton, 2002), the interviewer asked participants to describe their reasoning out loud as they solved each problem. Both pre- and post-interviews consisted of thirteen math questions assessing participants' understanding of the five number theory topics. Questions were identical across pre- and post-interviews except that the numerical values were changed.

In order to describe participants' understanding of multiplicative structure, interview transcripts were coded using APOS theory's levels of understanding (action=1; process without coordination=2; process with coordination=3; object=4; schema=5). Three phases of coding were undertaken. During phase one, pre-interview data were analyzed by participant and by question. Phase two repeated phase one for all post-interview transcripts. During phase three, participants' pre-interview and post-interview transcripts were compared in order to identify differences in their exhibited levels of understanding.

Findings

Analysis of the six interview participants revealed that all displayed improved understandings, to varying degrees, of topics related to multiplicative structure following number theory instruction. Due to space limitations, only portions of the results of each participant's interviews will be discussed.

Participant #1: Ellen

Compared to her peers in the sample, Ellen was considered a high achieving mathematics student based on her course instructor's recommendation and her performance on the pre-test (57% vs. sample mean of 30%). Her pre-test score was the highest score in the study's sample. During her pre-interview, Ellen showed a tendency to work with procedures (*action* and *process* levels) because she struggled to coordinate prime factors. For example, when asked to determine if $N=2^3 \times 3^2 \times 5^2 \times 17^3 \times 31^5$ was divisible by 51, Ellen could not coordinate divisibility by 3 and 17 to recognize divisibility by 51.

During her post-interview, however, Ellen revealed a greater ability to make connections across topics (*schema* level) and view concepts flexibly (*object* level):

> If the number can be broken down again into prime factors, I would do that first and then look to see if all of the prime factors needed for the number it's asking for were listed in the number N,

because if the prime factors of – all of the prime factors of the number they're looking for are inside N, then it must be divisible by that number.

Participant #2: Margaret

Based on her course instructor's recommendation and on her initial pre-test score (42%), Margaret was considered a high achieving mathematics student relative to her peers in the sample. During the pre-interview, she worked exclusively at the action and process without coordination levels.

During the post-interview, her understanding fluctuated between action and object levels. While she displayed a deep understanding of the relationship between factors and prime factors on some problems, when a problem had no obvious solution strategy, Margaret reverted back to lower levels of understanding. For example, when asked to identify the factors of $N = 3 \times 4 \times 5$ and $R = 13 \times 17 \times 19$ during the post-interview, Margaret could not identify any composite factors that were not already visible in the factorizations.

Participant #3: Amanda

For the purposes of this study, Amanda was considered an average achieving mathematics student based on her course instructor's recommendation and pre-test score (26%). Prior to instruction, Amanda showed evidence of a limited and inconsistent understanding of multiplicative structure. She was able to coordinate prime factors at the process with coordination level, but in certain circumstances required executing action level computations in order to identify divisibility.

Her post-interview work, however, revealed a consistent view of number theory as a connected body of concepts (schema level). Her explanations began to reflect a greater awareness of the close relationships between divisibility, prime factorization, GCF, and LCM concepts. Additionally, Amanda was now able to generalize the relationships between prime factors and divisibility: "I know that any of the numbers, if I can find their prime factorizations within N then N would be divisible by the numbers."

Participant #4: Zoe

Zoe was considered an average achieving mathematics student based on her course instructor's recommendation and her pre-test score (24%). Prior to instruction, Zoe exhibited a limited understanding of how prime factorization can be used to determine divisibility and a procedural understanding of GCM and LCM concepts. Her pre-interview work was most often coded at the process without coordination level for divisibility, prime factorization, and LCM concepts, and at the action level for GCF. For example, she was able to correctly identify that 5 is a factor and 7 is not a factor of $N = 23 \times 3^2 \times 5^2 \times 17^3 \times 31^5$, without doing any division computation, but she had difficulty identifying composite factors and non-factors.

Following instruction, however, Zoe's mental representations of certain procedures strengthened. Her understanding of divisibility and prime factorization improved primarily to the process with coordination level, as she was now generally able to coordinate distinct prime factors in order to identify divisibility. For example, Zoe was able to find almost all composite factors of $N = 3 \times 4 \times 5$ and $R = 13 \times 17 \times 19$.

Participant #5: Jane

Based on her poor performance on the pre-test (22%) and her course instructor's recommendation, Jane was considered a low-achieving mathematics student for the purposes of this study. Prior to instruction, Jane's understanding was primarily at the *action* and *process without coordination* levels. Her internalized image for factor was that a factor is a number that is *visible* in the prime factorization of another number.

Jane's understanding of multiplicative structure improved following the three-week unit. Jane's post-interview work was coded almost exclusively at the *object* level, characterized by complete coordination of distinct prime factors and the ability to articulate clear explanations of GCF and LCM concepts. Jane's notion of factor changed from numbers that are *visible* in the prime factorization of a number to coordinated products of distinct prime factors.

Participant #6: Christina

Based on her course instructor's recommendation and her performance on the pre-test (16%), Christina was considered a low-achieving mathematics student. Prior to instruction, Christina's understanding of multiplicative structure was the most procedurally-oriented of all of the interview participants in the study. Her pre-interview work was coded primarily at the *action* and *process without coordination* levels for divisibility topics and exclusively at the *action* level for GCF and LCM topics.

Following instruction, Christina's displayed richer understandings of all of these concepts (process with coordination). Her mental representation of factor became more coordinated and generalizable, so she paid more attention to prime factorization. For example, Christina's revised understanding of factors as combinations of distinct primes allowed her to solve difficult problems, like finding the factors of N = 3 x 4 x 5 and R = 13 x 17 x 19.

Conclusion

The analysis described in this paper provided descriptions of the ways in which six prospective teachers' understanding of multiplicative structure in the context of various number theory topics evolved following instruction. The data reveal that all participants developed more coordinated images for multiplicative structure, though they did not always make even progress across topics. Some made more progress on problems dealing with divisibility but less on those dealing with greatest common factors. Some displayed rich understanding on one question, only to regress back to less efficient strategies on other questions. This study provides evidence that attending to multiplicative structure can support prospective teachers' use of prime factorization and understanding of divisibility.

PROSPECTIVE TEACHERS' STRATEGIES AND JUSTIFICATION IN THE GENERALIZATION OF FIGURAL PATTERNS

Cara Haines
University of Missouri
clhbd3@mail.missouri.edu

Wenmin Zhao
University of Missouri
wz2mb@mail.missouri.edu

Samuel Otten
University of Missouri
ottensa@missouri.edu

This study investigated the ways in which prospective teachers (PSTs) solved figural pattern tasks. Specifically, we focused on PSTs' approaches to generalization, the nature of their solutions, and types of justifications. The findings revealed that PSTs employed three approaches to generalization: recursive, recursive-explicit, and explicit. PSTs' explicit generalizations were mostly constructive in nature, as only one PST developed a deconstructive generalization. Additionally, PSTs' justifications fell into two categories: example-based or figure-based. Together, these results suggested that the type of justification PSTs provided related to the type of generalization approach they employed.

Keywords: Algebra and Algebraic Thinking, Teacher Knowledge

Introduction

Substantial research on mathematics thinking and learning has focused on the strategies that students employ as they attempt to generalize mathematical patterns. One vein of this research investigated students' generalization strategies and the types of reasoning and thinking associated with those strategies (e.g., Amit & Neria, 2008). According to Lannin, Barker, and Townsend (2006), "generalizing numeric patterns is viewed as a potential vehicle for transitioning students from numeric to algebraic thinking" (p. 3). However, as school algebra instruction is often criticized for "rushing from words to single letter symbols" (Mason, 1996, p. 75), the importance of deriving explicit generalizations from patterns is often overemphasized. Such an overemphasis can influence students to generalize patterns by manipulating numbers and symbols without meaning, and thus, interferes with the development of their algebraic thinking. For example, Rivera and Becker (2008) found that students who generalize patterns numerically without considering contextual features (e.g., geometric figures) were most likely to attempt to fit an explicit formula onto the numbers they extracted from the figural pattern. This approach, however, excludes an important factor in the development of algebraic thinking and sense-making—connecting the visual images of the pattern and the symbolic generalization.

In their study of prospective teachers' (PSTs') generalization of numeric patterns, Zazkis and Liljedahl (2002) found that PSTs typically associated the legitimacy of generalizations with algebraic symbolism. Given that this association might have implications on PSTs' instruction (e.g., how they support their future students in developing algebraic thinking), we were interested in further investigating how PSTs generalize patterns. Additionally, we wondered whether PSTs' association of algebraic symbolism with legitimate generalization in Zazkis and Liljedahl's study was due in part to the fact that the PSTs were asked to generalize numeric patterns. Therefore, in our study we sought to investigate the types of strategies PSTs used to generalize figural patterns. Furthermore, because justifications are related to generalizations (Ellis, 2007), we were also interested in the types of generalizations PSTs derived and the ways in which they provided justification. Thus, in our research, we addressed the following questions: (1) What strategies do PSTs use to generalize linear and quadratic figural patterns?; (2) What types of generalizations do they provide?; and (3) What is the nature of the justifications they provide for their generalizations?

Methods

Eight PSTs (seven females and one male) were selected as participants from a Midwest university in the United States. Of the eight participants, seven were in their early 20s, while one female PST was 37 years old. All participants were in the third year of a traditional four-year teacher education program. The PSTs' foci were evenly split between secondary and elementary mathematics education. Potential differences between these groups of PSTs, however, were not a focus of our study.

The data include audio- and video-recordings of one-on-one clinical interviews with the PSTs and also their written work on four figural pattern tasks (see Table 1). These tasks were designed to afford opportunities for both generalization and justification. They were classified (unbeknownst to the participants) by the type of functions embedded in the pattern (i.e., linear or quadratic). The inclusion of both linear and quadratic tasks was intended to allow for variation in PSTs' approaches. The PSTs were asked to provide a generalization for each pattern and were given a series of prompts depending on their progress. For example, if PSTs employed only a recursive approach, we posed what Stacey (1989) referred to as a "far generalization" task. That is, we asked them to extrapolate the 100th figure to investigate whether they were able to establish an explicit rule for the pattern.

Table 1: Figural Pattern Tasks

Linear figural patterns	Task 1 	Task 2 Quadratic figural patterns	Task 3 	Task 4 
After transcribing the interviews and reviewing the written work, we engaged in an open coding process to identify PSTs' strategies, generalizations, and justifications. These three aspects were coded independently (e.g., the approach to generalizing was separated from the type of generalization that resulted), and we generated initial codes individually before meeting as a team to finalize codes. This process yielded the framework in Table 2.

Findings and Discussion

Table 2 includes the number of instances in which each generalization approach, nature of generalization, and type of justification was observed. We found that most PSTs approached generalization by first identifying changes between figures (i.e., a recursive approach). Generalizations derived from this process were most often constructive in nature. This finding is not surprising, as Rivera and Becker (2008) showed that individuals tended to identify additive relations between pattern figures and thus most often developed constructive generalizations. Regarding the types of justifications PSTs provided, the results of our analysis showed that the frequencies of example- and figure-based justifications were roughly similar.

Table 2: Framework for Figural Pattern Generalization and Justification

Component	Description	Example	Number of Instances
Approach to generalization			
Recursive	Participant utilizes patterns that exist between successive cases to determine the next case in a sequence.		3/32 (9.4%)
Explicit	Participant directly relates two (or more) co-varying quantities together, often by a rule or formula.		10/32 (31.3%)
Recursive-explicit	Participant initially identifies the recursive pattern but later attempts to generate an explicit rule.		19/32 (59.4%)
Nature of generalization			
Constructive	Participant recognizes that figures consist of non-overlapping parts.		29/32 (90.6%)
Deconstructive	Participant recognizes overlapping sub-configurations in the pattern structure OR that imaginary parts (that are eventually removed) could be added to the existing figures to create squares or rectangles.		3/32 (9.4%)
Type of justification			
Example-based	Participant substitutes a value in their generalization expression and uses the truth of the statement to determine the validity of the conjectured rule.		15/32 (46.9%)
Figure-based	Participant draws connections between the explicit generalization and the figural pattern.		17/32 (53.1%)

In addition to the results provided in Table 2, we also noticed patterns that spanned across categories. More specifically, there were differences in the ways PSTs employed recursive-explicit approaches and, consequently, in the nature of their justifications. PSTs who used recursive-explicit approaches either extracted the numeric pattern from the figural pattern or focused on both extracted numbers and geometric figures. These "sub-strategies" of the recursive-explicit approach were related to particular types of justification.

PSTs who extracted numeric patterns often abandoned the figures in their reasoning and attempted to fit an explicit formula onto the numeric pattern. Some failed to develop an explicit formula through trial-and-error and accepted their initial recursive generalization as a solution. Other PSTs, however, were successful in fitting an explicit formula to the numeric pattern through trial-and-error. In either case, though, the participant was unable to justify how the explicit generalization related to the figural pattern. Therefore, PSTs who focused on between-figure changes often justified their solutions by providing examples to verify correctness.

On the other hand, PSTs who focused on both the structure of figures and any numbers they extracted from the pattern consistently noticed and utilized the functional relationship between the figure number (i.e., the figure's position in the pattern) and the figural structure in their generalizations. Furthermore, they were always successful in providing both explicit generalizations and figure-based justifications. These results suggest that PSTs who derived generalizations in such a manner were fluent in their transitions between figures and symbols and, therefore, were able to provide valid justifications for their generalizations.

These results have implications for both PST education and future research. As generalization is a central component of algebra, PSTs should be prepared to support their future students in approaching generalization in ways that support the development of algebraic thinking. Provided that algebraic thinking includes the understanding of functional relationships, while generalizing, PSTs should be able identify such relationships within figural patterns. Furthermore, although deriving the symbolic representation of an explicit rule is warranted as a learning goal of generalization in algebra, it should not be overemphasized as it can distract individuals from recognizing important functional relationships (e.g., relationships between algebraic symbols and geometric figures) and developing more sound justifications for their generalizations. Additionally, given that PSTs' prior experiences in generalization and justification likely influence the ways they approach such problems, future research might consider investigating the learning opportunities that might be beneficial for the expansion of PSTs' current conceptions of generalization.

QUANTITATIVE REASONING AND INVERSE FUNCTION: A MISMATCH

Teo Paoletti
Montclair State University
paolettit@montclair.edu

I extend the body of research investigating students' quantitative reasoning by examining the interplay between a student's meanings developed through her school experiences and her quantitative reasoning in the context of inverse functions. I present one student's activities in a teaching experiment designed to support her in reasoning about a relation and its inverse function as representing an invariant relationship. Although the student engaged in such reasoning, her school mathematics experiences constrained her in relating this reasoning to her inverse function meanings. I conclude with implications and areas for future research.

Keywords: Cognition, Teacher Education-Preservice, Design Experiments

Many researchers (Brown & Reynolds, 2007; Kimani & Masingila, 2006; Vidakovic, 1996) examining students' inverse function meanings have maintained an emphasis on composition of functions as critical to students developing productive inverse function meanings. However, collectively researchers have found students hold compartmentalized inverse function meanings, typically related to executing specific actions in analytic or graphing situations (Brown & Reynolds, 2007; Kimani & Masingila, 2006; Paoletti, Stevens, Hobson, LaForest, & Moore, 2015) and the extent to which students relate these actions to function composition is an open question. For instance, many students rely on a technique of "switching-and-solving" when determining the inverse function of a given function represented analytically (i.e., given $y = x + 1$ they switch x and y then solve for y to obtain $y = x - 1$). Together, these researchers' findings indicate that curricular approaches to inverse function have been ineffective in supporting students in developing productive inverse function meanings. This report, along with Paoletti (2015), which I elaborate on below, begins to address the apparent need to re-conceptualize the teaching and learning of inverse relations and functions.

Theoretical Framing

I examined the possibility of supporting students developing inverse function meanings via their quantitative reasoning (Thompson, 1994, 2011). I conjectured a student could construct a (non-causal) relationship between quantities (e.g., quantities A and B). Once constructed, she could choose to consider one quantity as the input of a relation (e.g. A input, B output) while anticipating the other quantity would be the input of the inverse relation (e.g., B input, A output). With respect to graphing, a student maintaining such understandings can interpret a single graph as simultaneously representing a relation and its inverse relation. Such a student anticipates that the quantity on either axis can serve as the input to a relation; although this reasoning may seem trivial, Moore, Silverman, Paoletti, & LaForest (2014) illustrated that students are often restricted to reasoning about the input quantity exclusively represented on the horizontal axis.

In Paoletti (2015), I presented an undergraduate student's (Arya's) activity as she reorganized her inverse function meanings compatible with this theoretical framing. At the outset of the study, Arya relied on switching-and-solving and understood a function and its inverse function represented different relationships. Arya experienced several prolonged perturbations during the teaching experiment; resolving these perturbations supported her in reorganizing many of her meanings. By the end of the study Arya understood that a relation and its inverse relation represented an invariant relationship and Arya made sense of switching-and-solving by changing the quantitative referent of each variable when switching variables. Arya's inverse function meanings highlight the viability of the ways of thinking I describe above.

Methods and Task Design

I conducted a semester-long teaching experiment (Steffe & Thompson, 2000) with two undergraduate students, Katlyn and Arya (pseudonyms), enrolled in a secondary mathematics teacher education program. I collected data from three interviews and 15 paired teaching episodes. I used the interviews and episodes to investigate Katlyn's mathematical activity, to build models of her mathematics, and to explore the mathematical progress Katlyn made over the semester (Steffe & Thompson, 2000). Data analysis consisted of open (generative) and axial (convergent) approaches (Strauss & Corbin, 1998). Through an iterative process of generating, refining, and adapting hypotheses of Katlyn's mathematics, I was able to characterize her thinking at a specific time and to explain transitions in Katlyn's meanings.

Results

For brevity's sake I do not detail Katlyn's activities throughout much of the teaching experience as they are compatible with Arya's activities reported elsewhere (Paoletti, 2015). Katlyn entered the teaching experiment with her predominate meaning for inverse function involving switching coordinate values graphically and switching-and-solving. She experienced several sustained perturbations that supported her in reorganizing her meaning for graphs (i.e., interpreting the vertical axis as representing a function's input) and her in-the-moment meanings for inverse function (i.e., interpreting a function defining the relationship between volume and side length of a cube and its inverse function as representing the same relationship; she switched the quantitative referents of each variable to make sense of switching-and-solving). Based on my observation of these in-the-moment meanings, I conjectured Katlyn had possibly reorganized her meanings such that she understood a relation and its inverse represented an invariant relationship with the distinction being which quantity she considered the input. I tested this conjecture in a interview two months after the last episode explicitly addressing inverse relationships.

I provided Katlyn with a video of a cylinder with constant radius and a varying height and asked her to determine the relationship between the cylinder's height and surface area. Katlyn determined the analytic rule $SA = 2\pi r^2 + 2\pi rh$ by imagining the net of the cylinder composed of two circles with constant area and a rectangle with varying area (i.e. h varies and r is constant). She drew a linear graph representing the relationship between height and surface area. She stated, "As like the height is increasing, surface area is also increasing." Conjecturing Katlyn might consider surface area as the input, I asked, "Is there another way to read [the graph]?" Katlyn responded, "As surface area increases, height increases.... whatever happens to one is like happening to the other one." Although Katlyn chose to coordinate height first, she understood this was not the only option; from the researcher's perspective Katlyn reasoned about a relation and its inverse relation as she anticipated considering either quantity varying first.

I asked Katlyn to determine the analytic rule of the inverse function conjecturing she would maintain the relationship she had just described. However, Katlyn reverted to switching-and-solving, obtaining $SA = (h - 2\pi r^2)/(2\pi r)$. I asked Katlyn to "talk me through what you did there".

Katlyn: It's funny that you say that 'cause I'm tutoring two girls and we were doing inverses yesterday. And I don't, and I still can't explain why we do this. I was trying to think of a way to explain it to them, and I didn't know the answer. Um [*pause*]. Because that's what I've been told to do for six years…

TP: Okay. So you said you were just tutoring someone on this?

Katlyn: Yeah, and… they were just like, 'well how do I do it?' And so I told them, like you have to make sure the… function is one-to-one so like for every… input there's only one output and for every output there is only one input. All that nonsense that doesn't, I don't really know why we do that. But that's what has to happen before you can switch your input and output and then solve. So, why do we do this? I don't know. But I know this is what the answer is and I. Yeah, I don't know.

TP: Okay and so this is the answer [*pointing to* $SA = (h - 2\pi r^2)/(2\pi r)$]?

Katlyn: Yes. Yeah, yeah… I just don't know what it means, like I don't, why do I care about this [*pointing to* $SA = (h - 2\pi r^2)/(2\pi r)$]?

TP: So say a little bit more what do you mean you don't know what this [*pointing to* $SA = (h - 2\pi r^2)/(2\pi r)$] means?

Katlyn: I don't know what it means. I know [$SA = (h - 2\pi r^2)/(2\pi r)$] is the inverse, for surface area of a cylinder. That is all I know. Why is it the surface area? What does it, what does the inverse for surface area mean? I guess I'm thinking like. [*pause*] Okay, it reminds me of that time that we were doing like volume of a cube being like side-squared and then we switched the two and then I was like, okay so now, *s* means volume and *V* means side[length]. So now does here, [*pause*] surface area mean height and height mean surface area? Or did we just not finish the problem in class to conclude about what, I don't, I don't remember. I have no idea why we do this.

TP: So, you're starting to say here [*pointing to* $SA = (h - 2\pi r^2)/(2\pi r)$]. If, if *SA*… represented height, and *h* represented surface area?

Katlyn: Well, it wouldn't make any sense. Because then it would just be the same. Like if you multiplied [$SA = (h - 2\pi r^2)/(2\pi r)$] all back out you would get [$SA = 2\pi r^2 + 2\pi rh$], I guess. And so like I'm attributing [$SA = (h - 2\pi r^2)/(2\pi r)$] to be the same thing where this is now height [*pointing to SA in* $SA = (h - 2\pi r^2)/(2\pi r)$] and this is now surface area [*pointing to h in* $SA = (h - 2\pi r^2)/(2\pi r)$]. That doesn't make any sense. We might as well have kept it that way [*indicating* $SA = 2\pi r^2 + 2\pi rh$]. [*pause*] That's probably not right then cause it has to mean, it has to mean something different.

From the researcher's perspective, Katlyn described the relation and its inverse relation in the moments prior to the term "inverse" being raised. However, when asked to determine the analytic rule representing the inverse function, Katlyn reverted to the activity of switching-and-solving. She used this technique, which she learned as a student and was reinforced as a tutor, despite her being aware that she understood neither *why* she engaged in this activity (e.g., "So, why do we do this? I don't know") or *how to interpret* the results of this activity (e.g., "I just don't know what it means… why do I care about this"). Katlyn recalled the volume-side length situation months earlier and considered switching the quantitative referent of each variable but eventually rejected this concluding a function and its inverse represent different relationships.

Discussion and Concluding Remarks

Katlyn's activity highlights difficulties students can encounter when their quantitative reasoning does not align with their other, possibly non-quantitative, mathematical meanings. Compatible with Arya (Paoletti, 2015), Katlyn reorganized several of her meanings during the teaching experiment (e.g., conceiving that either axis could represent the input quantity). However, Katlyn did not consistently relate these reorganized meanings to her inverse function meanings. One possible explanation for this is that Katlyn was engaging in activity in-the-moment, both in the study and in her tutoring, to alleviate a perturbation without reflecting on how this activity was related to other situations or contexts (e.g., considering that decontextualized and contextualized situations have their own set of rules). Future research examining ways in which to support students in relating their quantitative reasoning with their other, possibly non-quantitative, mathematical meanings for inverse relations as well as other mathematics concepts would benefit the field.

Katlyn's activity highlights how the commonly taught switching-and-solving technique can impede students success making sense of relationships between quantities, interpreting relations and functions in context, and developing connected inverse function meanings. The ways of thinking described in the theoretical framing, as exhibited by Arya (Paoletti, 2015), can provide a way for students to overcome the barriers created when students are taught techniques without understanding why they are engaging in or how to interpret the results of the techniques. Future researchers should continue to explore how a quantitative approach to inverse relations can support undergraduate students, as well as younger students who have not had instruction in function and inverse function, in developing productive relation, function, and inverse function meanings. More broadly, future researchers should continue to reconsider how and why we teach concepts in K-14 school mathematics, like inverse function, in which procedures are emphasized over reasoning about relationships between quantities (Thompson, 2008).

RESPONDING TO STUDENTS DURING WHOLE-CLASS DISCUSSIONS: USING WRITTEN PERFORMANCE TASKS TO ASSESS TEACHER CANDIDATE PRACTICE

Matthew P. Campbell

Responding to student reasoning in whole-class discussions and making those contributions central to the mathematical work of the class is especially challenging when students contribute ideas that are incomplete, imprecise, or not yet correct—what we call "errors." We highlight our work supporting and assessing teacher candidates' (TCs') development of skill with the work of responding to student errors. We discuss our use of written performance tasks that call for TCs to play out discussions in response to a classroom scenario. We consider what these written responses reveal about TCs' practice and present findings and examples that have emerged.

Keywords: Teacher Education-Preservice, Instructional Activities and Practices

Whole-class mathematics discussions support participation in authentic mathematics communities and the development of a broader set of mathematical proficiencies and practices (Kilpatrick, Swafford, & Findell, 2001). Effectively leading discussion entails responding to student reasoning and making student contributions central to the mathematical work of the class (Boerst, Sleep, Ball, & Bass, 2011). It is especially challenging to treat student contributions that are incomplete, imprecise, or not yet correct – what we will call "errors" – as instances of sense-making (Brodie, 2014). The work of responding to errors rests on noticing and interpreting student reasoning (Jacobs, Lamb, & Philipp, 2010) and involves the in-the-moment task of building understanding from errors, in part by positioning others to make sense of the reasoning (Bray, 2011). We are interested in supporting teacher candidates (TCs) in developing skill with leading discussion and the practice of responding to errors. Furthermore, we are interested in ways to assess these developing skills for our work as researchers and as teacher educators.

Theoretical Framework

We take the perspective that TCs can develop skilled practice through purposeful opportunities to approximate and reflect on practice (Grossman et al., 2009). While this serves as a foundation for our use of pedagogies of teacher education such as coached rehearsal (Lampert et al., 2013) and our use of video to better understand TC practice and development, as teacher educators and as researchers we strive to find other ways to approximate teaching practice and to monitor TCs' practice. We have taken up the design and use of written performance tasks (e.g., Bray, 2011) as an additional way to put TCs in the position to make sense of and respond to student reasoning. Through these tasks, TCs demonstrate how they might play out instructional scenarios where they must respond to student errors in the context of whole-class discussions. We highlight our research efforts around the following question: What do TCs' written responses to classroom scenarios reveal about their practice of responding to student contributions?

Designing Performance Assessments

We drew inspiration from the work of Zazkis (2017) and Crespo, Oslund, and Parks (2011) around scripting classroom interactions. In our tasks TCs are presented with a realistic classroom scenario involving a whole-class math discussion and student contributions, including student errors. Respondents are asked to continue the discussion using multiple lines of transcript. TCs are also asked to provide a rationale for why they continued the discussion the way they did, to analyze student reasoning, and articulate how they would want the student's thinking evolve. Performance tasks have the potential to provide more standardized measures of teacher practice across time and contexts. These tasks can also capture TCs' instructional practice, pedagogical reasoning, dispositions about students and teaching, and content knowledge.

We designed two performance tasks for our study. The tasks have parallel structures and differ along two dimensions: (1) mathematical content; and (2) classroom task situation. These differences were built in to diffuse the impact of TCs' specific mathematical knowledge and knowledge of particular tasks and classroom activity structures. For one task, TCs were presented with a scenario centered on the use of a card sorting activity (Baldinger, Selling, & Virmani, 2016) designed to elicit and refine a definition of a polygon. The other task involved a scenario with a task asking students to interpret a position-time graph by writing a story.

Prior to implementing these tasks with TCs, we engaged in two phases of piloting. First, we conducted three cognitive think-aloud interviews with experts in mathematics education or teacher education. This gave us insight into what drew the attention of a reader, what seemed extraneous or distracting, and what seemed unclear. After making revisions, we piloted the tasks with eight first-year teachers or student teachers who had already taken mathematics methods coursework. This process helped us develop a sense of the types of responses we might elicit and led to another round of revisions, specifically around the prompts presented after each scenario.

Methods

We collected responses from 25 secondary mathematics TCs in methods courses at two large, public research institutions. Seventeen participants came from one institution at which they were engaged in a yearlong post-baccalaureate licensure program. The other eight participants from the second institution were enrolled in a shared methods course across multiple licensure programs. Each program's mathematics methods coursework had as a central component a series of practice-focused teacher education pedagogies, such as coached rehearsal.

The performance tasks were administered using Qualtrics in October 2016. TCs completed the tasks individually during the methods class. Response times to complete both tasks together ranged from 11:24 (minutes and seconds) to 42:37, with a median duration of 25:34.

We focus our analysis on the transcripts TCs wrote to continue the discussion in the card sorting scenario. We used a priori and emergent codes to describe TCs' error-handling practices evident in the transcripts. With a more established coding protocol, each transcript was coded individually by two authors. Inter-coder reliability was assessed and any disagreements were resolved through discussion, which allowed for further code refinement. We then engaged in a process of analytic memoing and theme building (Miles, Huberman, & Saldaña, 2014) to capture prevalent, distinct, or novel features of TCs' practice of responding to student errors in whole-class discussions, as represented through their written responses.

Preliminary Findings

From these initial analyses, three themes have emerged that we discuss below, with examples and commentary. These themes also serve as part of our continued analyses. In the card sorting scenario presented to TCs, the classroom discussion began after students were working in small groups with the teacher asking for students to name cards that they knew for sure were polygons. One student, Rosalia, offers Shape Q (see Figure 1) and, after a back-and-forth with the teacher, shares that it is a polygon because "it is a square" and that "all the sides are straight lines." After the teacher asked for another card, Jessie offers Shape J (see Figure 1), stating that it was like Shape Q, emphasizing that it is a square.

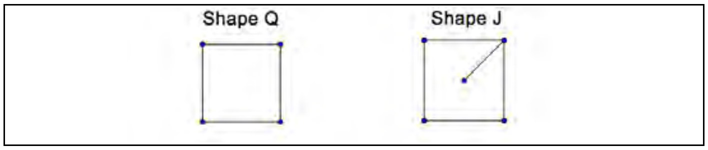

Figure 1. Two cards presented in scenario as examples of polygons.

Bringing Error to Resolution

One feature of TCs' responses was the way in which, within a relatively short dialogue, the error made by the student was resolved or corrected. This occurred in nine of 25 transcripts, and in many cases, the original student corrected their own error, as in the example below:

Teacher: It does look like a square but what is different about Shape J and Shape Q?
Student: There is a line from one corner of the square to the center.
T: Correct, what do you think we can conclude by noticing the line from the corner?
S: We can conclude that this is not a polygon, because they are not all connected.

We found other variations of error resolution, including where another student or the teacher corrects the error. There were five additional transcripts that we considered to be boundary cases of this phenomenon, such as where the last turn of talk has the teacher posing a question that was potentially leading toward resolving or correcting the error in a subsequent student response. In contrast, only one TC used a "tabling" move – explicitly pausing the conversation on a particular idea—with a few other responses including the teacher move of asking for a third card. These findings illustrate that student errors appear to be something that many TCs think could or should be resolved quickly, and often in a one-on-one exchange between teacher and student.

Focus on the Differences Between Cards

As the correction of student errors is a common (though not necessarily productive) response, we went into our analysis of the transcripts with attention to the way errors were resolved (and whether or not they were resolved in the short transcript provided by TCs). From our initial phases of analysis, other codes emerged. One such feature was the way in which transcripts included a teacher move that drew attention to the difference between Shapes J and Q, which occurred in 23 of the 25 transcripts. Furthermore, 17 of the transcripts had such a move as the first teacher move. The prevalence of such a move is notable, though we are not yet sure what this ultimately says about responding to errors. For example, is it a productive move, or is it a move that is explicitly detrimental? While, through further analysis, we have found that the move is often associated with funneling or leading questioning in the response, it is also mixed as to whether or not error resolution is part of the response. We also are continuing to consider what this teacher responding move is, as the move is potentially particular to the circumstances of the scenario—two students, each providing a different example and providing certain reasoning.

Introducing Multiple Students

A final notable finding from our analyses was the way in which some TCs added additional students to the discussion. Nine of the TCs introduced a new student, in some cases creating a new name. Three other TCs reintroduced the other student referenced in the scenario (Rosalia). Other TCs described discussions that included prompts posed to the whole class and, while some of these had unclear direction and purpose, others were more pointed, such as the prompting of students to "turn and talk" with a peer. Overall, we are struck by the way in which some TCs responded to student errors in ways that fostered more discussion and oriented the hypothetical students to one another's ideas. This stands in contrast to the constructed discussions that involved a back-and-forth, teacher-to-student pattern that was present in many other responses.

Discussion and Conclusion

In this report, we have outlined our creation, use, and initial analyses of written performance tasks used to assess TC practice, specifically around the work of responding to student contributions in the context of whole-class mathematics discussions. As part of our full project, the data we highlight in this paper were collected as a pre-assessment. We will be administering these written performance tasks again as a post-assessment, which will allow for further consideration of these tasks and one opportunity to determine changes in TC practice.

We see this work having conceptual, methodological, and pedagogical contributions to the field. Conceptually, this work contributes to the field of literature unpacking the practice of responding to students' contributions. Methodologically, we contribute to the area of research focused on teacher practice through the development of additional tools. Pedagogically, we see the use of performance tasks as not only a data collection and evaluation tool, but also as a formative approximation of practice for TCs.

STUDYING PRESERVICE TEACHER BELIEFS ABOUT TEACHING MATHEMATICS FOR SOCIAL JUSTICE OVER TIME

Cindy Jong
University of Kentucky
cindy.jong@uky.edu

Thomas E. Hodges
University of South Carolina
hodgeste@sc.edu

This paper reports on the Teaching Mathematics for Social Justice-Beliefs scale (TMfSJ-B) within the Mathematics Experiences and Conceptions Surveys (MECS). Elementary preservice teacher data were collected across three institutions (n=146) over three time points (i.e. pre-methods, post-methods, and post-student teaching) to examine whether entering beliefs about teaching mathematics for social justice changed over time. Baseline data indicated that homogeneity did not exist between the groups; thus, disaggregate data were used for analyses. One of the two institutions showed positive increase in TMfSJ-B across the three time points. The other two institutions had an increase in TMfSJ-B from the first to the second time point; however, both had a decline from the second to third time point. We explored what factors within the mathematics methods course and student teaching experiences influenced potential changes.

Keywords: Equity and Diversity, Teacher Beliefs, Teacher Education-Preservice

Theory and Objectives

Teaching mathematics for social justice (TMfSJ) is informed by critical theory and critical pedagogy within both teacher education and mathematics education research (Cochran-Smith, 2010; Wager & Stinson, 2012). While TMfSJ is described in a variety of ways to include access and equity to a higher quality mathematics to using social issues to teach mathematics to disrupting school norms (Gates & Jorgenson, 2009; Gutstein, 2006), there is clearly a growing interest in the field of mathematics education to study issues of equity and social justice among preservice teachers. For the purposes of our study, the definition we use is based on the notion that TMfSJ provides opportunities for all students "to learn rigorous mathematics in culturally specific, meaningful ways that seek to improve the economic and social conditions of marginalized individuals and groups, and that work toward[s] reduc[ing] deficit-oriented beliefs about who is or is not 'good' at mathematics" (Leonard & Evans, 2012, p. 100).

While there have been some efforts to integrate TMfSJ theory and pedagogy into teacher education programs (Koestler, 2012; Leonard & Evans, 2012), little is known about how such approaches have influence beliefs and whether beliefs oriented toward TMfSJ are sustained over time. Our study aims to address a gap in the literature by examining elementary preservice teacher (PST) beliefs about TMfSJ from pre- to post-mathematics methods coursework to post student teaching. The research questions explored in this study were:

1. What, if any, changes occur in beliefs about teaching mathematics for social justice over the duration of the mathematics methods course and into student teaching?
2. What factors within the mathematics methods course and student teaching experiences accounted for changes in beliefs, if any?

This focus contributes to the knowledge base on mathematics teacher development by observing both a cognitive aspect of TMfSJ and experiences within a teacher education program. As Philipp (2007, p. 259) explains, beliefs are "psychologically held understandings, premises, or propositions about the world that are thought to be true. Beliefs are more cognitive, are felt less intensely, and are harder to change than attitudes."

Methods

The Mathematics Experiences and Conceptions Surveys (MECS; Jong & Hodges, 2015) was administered at three time points: (a) at the beginning of mathematics methods coursework; (b) at the end of mathematics methods coursework; and (c) at the conclusion of the student teaching semester. Participants were undergraduate preservice elementary teachers at three institutions across the United States (n=146). Each version of the MECS included the same TMfSJ-B scale to capture baseline data and changes over time. The MECS also included different experience scales across various iterations (e.g. math methods course experience, field experience, student teaching) to account for factors that might influence beliefs.

Context

Three land grant, research extensive universities in the Southeastern United States participated in the study. A general description of the elementary education program progression and integration of TMfSJ concepts are delineated as follows: University A's elementary teacher education program requires candidates to take a course in social justice and culturally relevant pedagogy upon admission into the professional program (junior year). Candidates take a mathematics methods course that is offered on site at an elementary school, taking part in demonstration lessons by a classroom teacher and working directly with elementary students by making careful observations of children's thinking. The course integrates issues of TMfSJ during these site-based sessions. University B's elementary teacher education program does not require a separate foundational course on diversity, because the goal is to integrate issues of equity throughout methods coursework. The one required mathematics methods course integrates readings and reflections on TMfSJ topics. It is also the case that PSTs are placed in a diverse classroom for at least one field placement. University C, an elementary education program with an explicit focus on STEM content preparation, includes two mathematics methods courses. During the first of the two methods courses, candidates take a co-requisite course in diversity and social justice. Candidates are intentionally placed in diverse school settings during internship.

Data Analysis

To examine changes in TMfSJ beliefs and answer our first research question, we used a Repeated Measures ANOVA (Huck, 2012). To address the second research question, we used multiple regression models to identify factors to explain the TMfSJ beliefs. Prior to conducting our analyses, raw data were converted to logit values using Winsteps (Linacre, 2016). In addition, the TMfSJ-B scales in MECS-2 and MECS-3 were anchored to the MECS-1 scale to be able to make direct comparisons. In Winsteps, the Teaching Mathematics for Social Justice- Beliefs scale had an item reliability of 0.99 and a person reliability ranging from 0.72-0.76 across the three versions of the MECS, indicating that the items had a wide difficulty range and variance but the ability variance of the participants were not as wide in range.

Results

Levine's test of homogeneity indicated that there were statistically significant differences among the baseline TMfSJ beliefs across the institutions; thus, analyses were conducted using the disaggregate data. Mean values for each university across the three iterations of the MECS are presented in Table 1 and Figure 1. Results of the RM-ANOVA analysis indicated only one significant change across all eighteen pairwise comparisons: University B had a significant gain ($p = .002$) for TMfSJ-B from pre- to post-methods.

Multiple regression models were created to examine which factors could help explain TMfSJ beliefs at each time point. At the pre-methods level, we examined whether the PK-12 mathematics experience was influential, but it was not a significant factor across any of the institutions. At the post-methods level, we examined whether the mathematics methods course or field experiences explained the variance in TMfSJ-B, but they were not significant factors. At the post-student teaching level, mathematics methods course and student teaching experiences were entered into the model. The two factors were not significant predictors for Universities A or B. For University C, it was found that the following two factors accounted for 12.6% of the variance in TMfSJ-B post-student teaching ($R^2 = 126$, $F(2, 51) = 3.675$, $p = .032$): the mathematics methods experience and the student teaching scales. In addition, the student teaching pedagogy scale accounted for 12.6% of the variance in TMfSJ-B post-student teaching ($R^2 = 126$, $F(1, 52) = 7.49$, $p = .008$).

Table 1: Mean TMfSJ Scores by Institution

Institution	Pre-methods	Post-methods	Post-Student Teaching
University A (n=38)	1.560	1.813	1.902
University B (n=54)	.877	1.252	1.092
University C (n=54)	.974	1.126	1.038

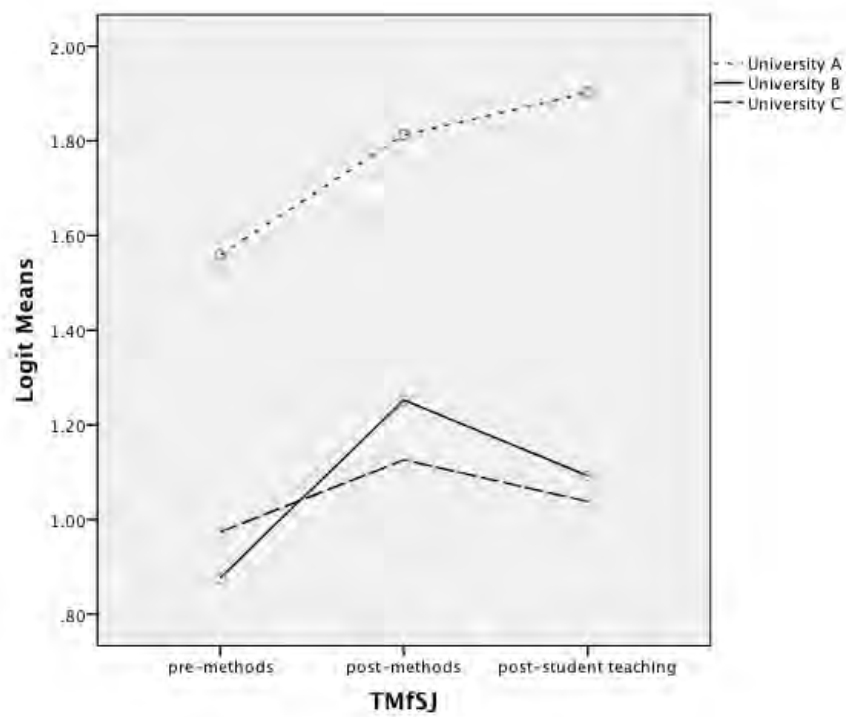

Figure 1. Disaggregate logit means of TMfSJ beliefs over time.

Discussion

Entering TMfSJ-B were somewhat similar for University B and C, while significantly higher for University A. Both University B and C followed similar trajectories – growth in beliefs from pre to post mathematics methods, then a decline in beliefs measured at the end of the student teaching semester. On the other hand, University A saw gains at both the post methods and end of student teaching time points. We were somewhat surprised that a significant change was not found (p=.079) for University A from pre- methods to post-student teaching since positive gained were made at both time points. However, the sample sizes may have been too small at the institutional level. It is also possible that there is a ceiling effect to the beliefs measured at University A, since the baseline beliefs were high.

In exploring the growth trajectories at each university, it might well be that higher entering beliefs among candidates at University A were more sustainable across student teaching in relation to the more tenuous TMfSJ-B found at University B and C. That is, more strongly held beliefs were more entrenched and less susceptible to regression than the beliefs held by candidates at University B and C. As such, foregrounding issues of equity and social justice early in candidates' programs, with the stated goal of developing more productive beliefs, may well lead to sustained teaching that promotes the educational advancement of historically marginalized people.

While our experiences scales did little to explain the variance in TMfSJ-B, there are important contextual differences they may not have been captured in MECS instrumentation. University A candidates have a course with explicit focus on social justice and culturally relevant pedagogy prior to mathematics methods coursework. As such, candidates may be positioned to more thoughtfully consider issues of social justice in mathematics upon entrance to the methods semester. Further University A also includes site-based mathematics methods delivery, where candidates have opportunities to theorize from practice in a diverse school setting (cf. Hodges & Jong, 2015). Given the uneven nature of student teaching experiences, the data presented here suggest engaging in systematic and strategic efforts to increase candidates' capacity to take on productive beliefs about social justice in mathematics early in teacher preparation programs may well lead to beliefs that support more equitable instruction in mathematics classrooms.

USING NARRATIVES TO ARTICULATE MATHEMATICAL PROBLEM SOLVING AND POSING IN A TECHNOLOGICAL ENVIRONMENT

Dana C. Cox
Miami University
dana.cox@MiamiOH.edu

Suzanne R. Harper
Miami University
harpersr@MiamiOH.edu

In this study, we set out to create an environment for preservice secondary mathematics teachers where we could test the capability of technology to capture episodes of technology-enabled problem solving and answer the question, how do these captured episodes support the articulation of mathematical processes such as problem solving or problem posing? In a collaborative context, screencasting and Interactive Geometry Software were used to create a rich narrative captured in verbalized thinking as well as on-screen activity. The data provided an auditable trail of authentic practice that preservice teachers did not articulate on their own.

Keywords: Teacher Education-Preservice, Problem Solving, Technology

Background and Theoretical Framework

Preservice Secondary Mathematics Teachers' (PSMT) beliefs about technology use in the classroom seem to be drawn from previous vivid episodes or events in their lives (Pajares, 1992), events that likely occurred in the mathematics classroom during their years spent as K-12 students. In order to influence PSMTs' beliefs about the role technology plays in the classroom, we should give them opportunities to experience vivid episodes of mathematical problem solving with technology, and find a way to make these episodes explicit (Cox & Harper, 2016). Equipping PSMTs with accurate records of problem solving practice is necessary for reflection; articulating thinking and reasoning after-the-fact is challenging. Lesh and Zawojewski (2007) call for research into how to document and assess understandings and abilities related to problem solving that relies on data consisting of *auditable trails* of the non-linear activity of problem solvers. We need a way to capture an authentic, accurate and articulated episode to facilitate further reflection on the affordances of technology for doing and learning mathematics. In this study, we set out to create an environment where we could test the capability of technology to capture episodes and *how do these captured episodes support the articulation of mathematical processes such as problem solving or problem posing?*

We choose to use the term narrative as a storytelling term. The narratives that we construct from collected data/auditable trails of documentation (Lesh & Zawojewski, 2007) are mathematical stories about what PSMTs think, say, do, construct, and see while working on a mathematical task. We focused here on the creating and interpreting an auditable trail of problem solving behavior that is specific to a technology-rich context.

Data Collection and Analysis

We assigned 15 PSMTs the task to create a dynamic geometric sketch that embodied a "Kaleidoscope". At the time of this study, the PSMTs were in the seventh week of a course on mathematical problem solving with technology, and were reasonably fluent with Interactive Geometry Software (IGS). We instructed them to engage with the task for approximately 15 minutes in partnerships (and one triad) using a single computer equipped with IGS. The intent was to give PSMTs a task, tools and environment that pushed for and supported verbal communication, negotiation, and collaborative mathematical problem solving.

During the construction phase and class presentations, four sources of data were collected. First, PSMTs submitted the completed IGS sketches of kaleidoscopes. Second, we collected *construction* *screencasts* documenting and linking on-screen activity and verbal communication during the construction phase. We define screencast as a digital recording of computer screen output, also known as a video screen capture, often containing audio narration. Third, we video recorded presentations and discussions of IGS sketches amongst the whole group of 15 PSMTs. Fourth, individual PSMTs recorded *reflection screencasts* where they addressed the problem solving process as well as their intentions behind the completed kaleidoscope.

From each captured episode, we created a rich narrative of problem solving and problem posing activity. In this paper, we focus our attention on the narrative of one partnership: Abby and Olivia. Abby and Olivia are second-year PSMTs who had previous experience working together. This narrative was selected over six others because it demonstrates the potential of technology to both facilitate and articulate mathematical processes, but also for the variety of moments that it provides for analysis. In this sense, this narrative is remarkable in its clarity.

A detailed methodology behind creating the narrative using *thick analysis* can be found elsewhere (Harper & Cox, 2017) thus we will provide only a brief description here in the interest of space. To develop the narrative, we used the creation screencast as the foundation of the analysis while data from the IGS sketch, the recorded class discussion, and the reflection screencasts were used to interpret the creation screencast. Because the IGS sketch was data with which we could interact, it enabled us to form and test our own conjectures about how the sketch worked, giving us insight into the problems Olivia perceived in the behavior of the kaleidoscope model. This is particularly important to the following episode. The data collected during whole class discussion and reflection screencasts gave us descriptions from the PSMTs about the intentions and emotion behind their mathematical work. It was also useful as we compared the way problems were posed by the partnerships during the creation screencast with the way individual PSMTs articulated those problems after-the-fact.

Results

Our narrative of Abby and Olivia's work includes four episodes where problem solving and problem posing can be articulated (Cox, Harper & Edwards, Under Review). For this brief report, we choose to focus on the potential of just the final episode, *A Return to Symmetry.*

Once Abby and Olivia created a first draft of their kaleidoscope sketch, they analyzed their model with a critical eye. With animation features of the sketch engaged, both PSMTs were drawn to the motion of two sets of points: those placed directly on the radii of the circle (*radius points*), and those placed on the circumference (*circumference points*). This visual effect provoked Olivia to pose a question about the model (Figure 1) that articulates a new problem. Olivia's question goes ignored and unanswered as the PSMTs focus on another idea.

After watching the creation screencast we became curious about the problem Olivia was trying to articulate. This curiosity was captured in our researcher notes (Figure 1). Our subsequent discussion produced two questions: 1) what problem was Olivia "seeing" in the motion of the kaleidoscope that caused her to question whether or not the model was valid? Specifically, what points or regions prompted her to ask if "they are allowed to move between the segments;" and, 2) could we use their original IGS sketch to determine how the points were moving and test the mathematical validity of their kaleidoscope model? In essence, we wondered if we could both articulate and solve Olivia's problem.

<table>
<tr>
<td>

Construction Screencast Transcript

(04:10) O: I'm also wondering if they are allowed to move between the segments. If they are allowed to move beyond just…let's stop where it looks like.

[O stops the animation at a strategic, intentional point and gestures to the yellow-circled circumference point as she asks a question. A screenshot of this moment is shown to the right]

(04:23) O: I'm wondering if they are allowed to move beyond, go around the circle past the sector. It's really a mirror so they have to stay within it.

</td>
<td></td>
</tr>
<tr>
<td colspan="2">

Researcher Notes

The part where Olivia questions "moving beyond" is really interesting. It seems as if the PSMTs are watching the animated points and imagining that they move from one sector into another. In reality, it's an optical illusion and the animated points, if labeled, would clearly just move within the sector ...Wait? Do the points on the outside of the circle limit themselves to one sector, or do they move out?

</td>
</tr>
</table>

Figure 1. Associated data including transcript, illustration, and research notes.

Since we had access to Abby and Olivia's original IGS file, we were able to conduct a "thought experiment" to find out whether the circumference points were really "moving beyond" the 60-degree arc. This helped us to better understand what Olivia was seeing and describing in the creation screencast. We also wanted to know how the motion of the model was limited in ways by the IGS that would either be removed (solving the problem) or that would prevent it from matching our physical expectations of a kaleidoscope.

To support our investigation, Olivia made herself available for a brief interview after her participation in the study had concluded and during our data analysis phase. In this interview she provided additional insights into the construction of their kaleidoscope. She proudly mentioned that she had recreated a new kaleidoscope on her own, one where the "shapes do not go outside the pie." Considering this comment carefully, we are now confident that Olivia was concentrating on the polygons (and not the circumference points) that spanned multiple sectors of the circle when she asked "if they are allowed to move beyond, go around the circle past the sector." We went back to Abby and Olivia's original creation screencast and captured an image of the initial polygons spanning multiple sectors and since there were no constraints for the circumference points, these points could move "beyond" a 60-degree arc of the circle, yielding polygonal images in the dynamic model that are never seen in a real kaleidoscope.

Discussion and Implications

We have collected an *auditable trail* of problem solving with technology that records the process of problem solving and moments of problem posing. This record of practice is fluid and allows researchers and students to drop into action at any point and explore through thought experimentation "what might have happened if". Specific to this case, it was only because of the auditable record of practice that we were able to see that Olivia had identified a problem in the creation screencast, but had not articulated it clearly to Abby (and perhaps to herself at the time). Interpretation required further articulation and was supported by the IGS data.

Both PSMTs utilized the IGS sketch they created as a source of evidence and illustration in their reflection screencasts, however neither Abby nor Olivia mentioned the symmetry problem. Olivia's interrogation of the polygons in the creation screencast was ignored in both of the reflections produced by the PSMTs. More broadly, Abby ignored the prompt to discuss "insights you had along the way and the impact of those insights on your model" entirely. Olivia went so far as to deny that insight occurred, which stands in contradiction to the data presented here and elsewhere in the narrative. When urged to reconsider her question in the closing interview, Olivia was amazed to hear the insight she had achieved (problem she had posed) and was able to better articulate her concerns as well as a way to improve the original sketch (solve the problem).

Thus, the reflection screencasts provided a limited view of the episode and failed to capture accurate and articulated mathematical practices, in spite of it being an authentic first-hand account. From an analytical standpoint, the PSMTs controlled in their reflections what they presented and in that way limited our view of and understanding of their process to those parts of the story of which they were aware. A comparison to the generated narrative exposed blind spots in their self-analysis. What power we give to our PSMTs when we give them access to an auditable trail with which to narrate a more accurate and articulated account of their insights.

While there is a well-established professional conversation around the role of problem solving and problem posing in mathematics education, more needs to be done to define what experiences PSMTs need with respect to each and conduct research into making these experiences and the supporting mathematical practices more explicit (Cox & Harper, 2016). More can be done to create auditable trails (and from them narratives) to use to prompt deeper reflection about the role technology can play in problem solving. By creating a real-time record of practice, we remove the barrier of having to store within our short-term memory not only the outcomes of our mathematical struggles, but the messiness associated with that work. Mathematical thinking is freed from a chronological and linear path, and we can document the interconnectedness of it as well as the signposts of paths not taken.

A FRAMEWORK FOR INVESTIGATING NOVICE TEACHERS' PCK

Allyson Hallman-Thrasher
Ohio University
hallman@ohio.edu

Derek Sturgill
Ohio University
ds278604@ohio.edu

Jeff Connor
Ohio University
connorj@ohio.edu

Keywords: Teacher Education-Preservice, Teacher Knowledge

Our university has developed a one-year master's program with initial teaching licensure for STEM career-changers and individuals with STEM degrees. The assumption underlying such programs is that this population needs only coursework in pedagogy and a teaching practicum (Selke & Fero, 2005). Yet, a focus on only pedagogy without attending to content ignores research indicating the impact of pedagogical content knowledge (PCK) on teacher effectiveness (Ball, Thames, & Phelps, 2008; Goos, 2013). Boundaries between PCK and content knowledge are unclear and no single framework addresses PCK for both mathematics and science teachers. In studying how STEM content backgrounds influence PCK, we developed a framework to help articulate and investigate novice mathematics and science teachers' knowledge.

Participants were 5 mathematics and 8 science teacher candidates in our program. We interviewed them three times throughout their program and first year of teaching. We asked them to describe the impact of and connections between their STEM backgrounds and their teaching practice. Open coding of interview data and existing research on PCK informed our framework.

Our framework focuses on overlapping areas of mathematical knowledge for teaching (Ball et al., 2008) and models for science PCK (Lee & Luft, 2008; Magnusson, Krajcik, & Borko 1999): knowledge of discipline, purposes of teaching, curriculum, students' understanding, and teaching/instructional strategies. *Discipline knowledge* includes content knowledge from all STEM fields. *Knowledge of purposes of teaching* addresses the reasons why certain content is taught. *Knowledge of curriculum* refers to understanding how topics develop and connect over the K–12 curriculum. *Knowledge of student understanding* involves knowing typical student approaches to particular tasks and topics more generally. *Knowledge of teaching/instructional strategies* concerns knowing different ways to teach a particular content.

Our framework has served as a useful guide for distinguishing and analyzing data. We found that participants' *discipline knowledge* did not translate to *knowledge of student understanding*. Participants were challenged by making content accessible to students and "ways to explain what seems elementary to me" (Jennie, 2). However, *discipline knowledge* did support *knowledge of teaching/instructional strategies* by saving them time needed to relearn content and contributing to developing innovative classroom activities that incorporated real-world applications of STEM.

GENERATING ALGEBRAIC EQUATIONS FOR PROPORTIONAL RELATIONSHIPS

İbrahim Burak Ölmez
University of Georgia
i.burakolmez@hotmail.com

Keywords: Teacher Knowledge, Teacher Education-Preservice, Algebra and Algebraic Thinking, Number Concepts and Operations

The purpose of this study was to investigate reasoning of 6 future middle grades mathematics teachers on a quantitative definition of multiplication when generating equations for proportional relationships. Past research has consistently reported that proportions involving whole-number multiples is easier to solve than proportions involving fraction multiples (e.g., Kaput & West, 1994; Karplus, Pulos, & Stage, 1983). However, no studies have examined how a definition for multiplication can support and constrain generating equations for proportional relationships.

The theoretical framework of this study is based on a quantitative definition of multiplication articulated by Beckmann and Izsák (2015), as follows: In the equation $M \bullet N = P$, M is the number of equal-size groups, N is the number of units in 1 or each group, and P is the number of units in M groups. This definition of multiplication leads to two solutions using the variable parts perspective, a largely overlooked perspective on proportional relationships (Beckmann & Izsák, 2015). This study was part of a larger, ongoing project on future middle grades (grades 4-8) mathematics teachers' ecology of multiplicative reasoning. One project team member taught a cohort of future teachers for two semesters in 2014-2015. In the first semester, the future teachers received instruction on developing the quantitative definition of multiplication. In the second semester, they reasoned with the variable parts perspective on proportional relationships and developed algebraic equations by reasoning about relationships among quantities. Six future teachers were recruited based on their performance on a fractions survey that focused on multiplication and division with fractions. Data for the present study came from individual cognitive interviews conducted with each future teacher at the end of the second semester.

The main finding we report is that the quantitative definition of multiplication facilitated future teachers' generation and explanation of equations for proportional relationships. Future teachers who did not have this definition of multiplication experienced difficulties in developing appropriate equations. As a future direction, middle grades programs should focus on providing future teachers opportunities to develop capacities for reasoning with the definition of multiplication across problem situations.

Keywords: Teacher Education-Preservice

Mathematics education researchers have begun to leverage practices from complex instruction to address inequities that occur during mathematics instruction (Boaler & Staples, 2008; Featherstone et al., 2011). Featherstone et al. (2011) define assigning competence as "the practice of drawing public attention to a given student's intellectual contribution to a group's problem-solving efforts" (p. 88). While research has provided illustrations of what assigning competence looks like in classrooms, less is known about how to teach the practice to pre-service teachers. This study examines an attempt to teach assigning competence as a practice to pre-service teachers and analyzes how pre-service teachers appeared to take up the practice.

Data Sources and Methodological Approach

Data sources used in this study include lessons plans, notes, and student artifacts (e.g. assignments, assessments, and notes). Given the variety of data sources, we based our analyses on Miles and Huberman (2013) and used triangulation to identify patterns in our data.

Findings

Four themes emerged from our analysis: (1) identifying the practice; (2) connecting the practice to its core aims; (3) developing specific teaching strategies; and (4) conceiving teachers' power and responsibility. First, pre-service teachers grappled with identifying and understanding the meaning of assigning competence, confounding it with praise and making individual students "feel good." Second, we found evidence that pre-service teachers grappled with recognizing the importance and value of assigning competence in mathematics instruction. Third, pre-service teachers had concerns about implementing strategies for assigning competence. Finally, pre-service teachers had concerns about the power and responsibility they could deploy as teachers to disrupt classroom inequities.

Discussion

The work of assigning competence offers a way to bring together core strands of the work of teaching that are high-leverage for beginning teachers: eliciting and interpreting students' strengths, knowing and seeing mathematics in teaching, perceiving status hierarchies and inequities among students, developing specific teaching moves to interrupt those inequities by positioning particular students as competent. However, preservice teachers in our study had difficulty learning to do all of the parts together. In this session, participants will learn about an instructional design for teaching assigning competence to pre-service teachers, details about the design and methodological approach of the study, and consider next steps in developing this important practice with pre-service teachers.

Keywords: Teacher Beliefs; Teacher Education-Preservice; Affect, Emotion, Beliefs, and Attitudes

It is well documented in literature that teacher beliefs influence teaching practices (Stipek, Givvin, Salmon, & MacGyvers, 2001; Wilkins, 2008). However, little research has been done involving preservice elementary teachers' mathematical epistemology. Understanding such beliefs will support improvement in teacher education programs. In this poster, we present our preliminary work to address: What are PSTs' epistemic beliefs regarding mathematics?

We developed a survey on PSTs' epistemic beliefs by combining an open-ended question about learning mathematics together with closed form items measured on a five point Likert scale. The closed form items draw from Wheeler's Epistemological Beliefs Survey for Mathematics (EBSM) and measures beliefs in seven dimensions of epistemology, including: source of knowledge, certainty of knowledge, structure of knowledge, speed of knowledge, personal innate ability, general innate ability, and real-world application (Wheeler, 2007). Each dimension describes a continuum that ranges from non-availing beliefs (having no or negative influence on learning outcomes) to availing beliefs (associated with better learning outcomes). The survey was administered to all PSTs enrolled in a mathematics content sequence for teachers at a large, urban university in the Pacific Northwest. Previous research with the EBSM has not focused on preservice elementary teachers, thus our extension of the tool will provide a new perspective of preservice elementary teachers' mathematical epistemology.

Initial results for the PSTs who responded to our survey (n=53) suggest that certainty of knowledge and speed of knowledge are PSTs most availing dimensions. That is, PSTs perceive mathematical knowledge as evolving rather than absolute and that learning is gradual rather than quick. Conversely, source of knowledge and general ability were found to be the least availing dimensions, suggesting that PSTs view knowledge as external to the learner rather than constructed by the learner and perceive learners to have a general learning skill set that is fixed rather than developed. Additionally, PSTs were fairly homogenous in the belief that learning math depends most on having a good teacher.

Further qualitative analyses of survey responses and follow-up interviews are forthcoming and will serve to identify themes in PSTs' mathematical epistemologies. These findings will help inform preservice elementary teacher education as well as professional development for elementary teachers already in the field.

With the goal of enriching experiences in mathematics education of elementary and secondary teachers, faculty from School of Education (SOE) and Mathematics Department at University of Indianapolis organized collaborative initiatives. Driving collaboration was the desire to strengthen our education programs by bridging gaps between pre-service teachers' pedagogical knowledge, math content knowledge, and instructional practice. The research questions that drove our efforts were: (1) How do we structure meaningful collaboration? and (2) What specific areas do we focus on to create synergy between departments?

The structuring of our collaboration was grounded in Wenger & Wenger's (2015) community of practice. Such communities are "groups of people who share a concern or a passion for something they do and learn how to do it better as they interact regularly" (p. 1). We have created a professional learning community (PLC) of mathematics educators at the University. Our PLC consists of two math educators from the SOE along with two math educators and a mathematician from the Mathematics Department. The committee meets regularly to coordinate collaboration on various aspects of mathematics teacher preparation. Through this framework, we problem solve, request information, seek other's experiences, coordinate our efforts, discuss developments, map our knowledge, and identify gaps.

After structuring a PLC, areas of focus were identified. We chose to focus collaborative efforts on: (1) Recruitment and retention: Developing new initiatives to recruit and retain secondary mathematics education majors. (2) Assessment: Although coordinated by the SOE, math department faculty supervise secondary mathematics education student teachers and assist in assessing candidates' mathematics content knowledge. Likewise, mathematics educators from the SOE assist in reviewing candidates' content portfolios required by the math department. (3) Instruction: Mathematics educators collaborate on curriculum and instruction of existing courses in both departments. We further collaborate on programmatic changes for both the elementary and secondary education majors. This promotes greater synergy between different components of the existing curriculum and infuses new teaching methods and content foci while benefitting from the expertise of the faculty. (4) Outreach: Faculty from both departments engage in outreach activities in area schools. These include attendance at PLCs in area schools and possibilities of professional development and the mentoring of practicing teachers.

The structure and focus of our math education PLC has the potential to open doors to explore the collaboration initiative's impact on the University and our students. Our work has just begun.

MATHEMATICS CONTENT COURSES FOR ELEMENTARY TEACHERS: CURRENT STATE OF PROGRAMS

Brooke Max
Purdue University
bmax@purdue.edu

Keywords: Teacher Education-Preservice

The intersection of higher-education practices and elementary education is challenging to navigate. Mathematics teacher educators must consider the trajectory of a preservice elementary teacher throughout her teacher education program and beyond. One way to bring coherence to elementary teacher education programs is to consider and implement the recommendations of organizations with a goal of improving the mathematics instruction and learning for all students.

The Common Core State Standards of Mathematics (National Governors Association Center for Best Practices and the Council of Chief State School Officers, 2010) released Standards for Mathematical Practice (SMPs), which span grades K-12 and focus on mathematical practices and processes. After the release of the SMPs, *The Mathematical Education of Teachers II* (MET II) (Conference Board of Mathematical Sciences [CBMS], 2012) responded with updated recommendations for elementary education programs. Included were 12 semester-hours studying mathematics from a teacher's perspective with half in the area of number and operations and the remaining in measurement and data and geometry. There is also a recommendation for some attention to methods of instruction.

A recent trend of addressing the SMPs in mathematics content for elementary teachers textbooks (e.g., Sowder, Sowder, & Nickerson, 2017) attempts to bridge the gap between K-12 schooling and higher education in terms of processes of mathematics. However, we need to know more about what is currently happening in the mathematical content courses to see if these recommendations are being incorporated and to think about where to move forward in these courses to support the mathematical practices of preservice elementary teachers.

This study adds to the work of Masingila, Olanoff, and Kwaka (2012) to gain more information on the current state of mathematics for elementary education courses in the United States (e.g., who teaches them, how many credit hours are required) through a survey of instructors. Forty-four respondents, with an average of nearly 11 years experience instructing mathematics content for elementary teachers courses, described 82 such unique courses. Analysis will include the resources used (e.g., textbook, technology, manipulatives) in these courses as well as the inclusion of and attention paid to the MET II topic recommendations (CBMS, 2012) and SMPs.

This study gives a broader picture of the current state of mathematics content for elementary teachers courses in the United States, taking into consideration multiple recommendations.

BELLRINGERS: A MEANS OF INTEGRATING MATHEMATICAL CONTENT, PEDAGOGY AND REFLECTION ON PRACTICE IN METHODS COURSES

Mary A. Ochieng
Western Michigan University
maryachieng.ochieng@wmich.edu

Keywords: Teacher Education-Preservice, Teacher Knowledge, Instructional Activities and Practices.

The practice of teaching is complex – involving the coordination of multiple activities and drawing on different types of knowledge related to the learning context (Ball & Forzani, 2009). However there is not time in methods courses to address every aspect of teaching that preservice teachers (PSTs) need to learn. In this study we explore the use of bellringers – brief mathematical tasks implemented as students arrive for class – as a means of addressing multiple instructional goals with preservice teachers.

Seven PSTs enrolled in a middle school mathematics methods course at a large Mid-western university were involved in preparation and enactment of bellringers during the first five to seven minutes of class. To prepare for this we identified characteristics of effective bellringers and used these characteristics to develop a rubric that was used to guide the PSTs in designing high-quality bellringers and to support them to critique each other's bellringer implementations. In preparing and implementing the bellringer, PSTs were expected to apply what they were learning in the course: topics such as task analysis, effective questioning, and the five practices for orchestrating productive mathematics discussions (Smith & Stein, 2011). Implementation was also expected to model instruction based on student thinking – a recurring theme throughout the course. This was followed by a whole-class debriefing session, where they received feedback from their peers and the instructor. The debriefing was used as an opportunity to review important mathematics and as a context to discuss important concepts from the methods course related to pedagogy. All bellringer enactments and debriefing sessions were video taped. After all the PSTs had implemented a bellringer, the PSTs wrote a reflection paper on bellringers.

Analysis of the reflection papers and debriefing conversations showed that PSTs were able to apply what they were learning in the course and deepened their mathematical and pedagogical understandings. The debriefing sessions and writing of the bell ringer reflection further supported the preservice teachers in reflecting on and refining their instructional practice (NCTM, 2000).

The results of this study indicate that the process of bellringer preparation, implementation, debriefing, and subsequent written reflection may be useful as an instructional tool in methods courses to address multiple goals.

The Challenge of Developing Preservice Teachers' Relational Teaching of Mathematics

One of the goals of mathematics teacher educators (MTEs) is to develop activities for mathematics methods courses that support preservice teachers' (PT's) practice for developing relational understanding of mathematics in students. Following Skemp (2006), we define relational understanding as knowing "what to do and why" in contrast to instrumental understanding which only focuses on rules and procedures without reasons (Skemp, 2006, p. 89). Because many PTs come to a mathematics methods course with an instrumental understanding of mathematics, it is common for MTEs to focus on developing PTs' relational understanding of mathematics resulting in less focus on teaching PTs relational teaching methods. This study explores how PTs' practices and views of mathematics learning and teaching evolve and transform from instrumental to relational after the implementation of a relational teaching practice presented in their mathematics methods course.

Response to the Challenge

This impirical study is grounded in the whole-group teaching experiment approach (Heinz, Kinzel, Simon, & Tzur, 2000) and focuses on the PTs' development of teaching practices intended to develop students' relational understanding of a mathematics concept. Prior analysis of a pilot study conducted by the authors produced a three-part framework for use by MTEs to plan and implement practices for developing PTs' understanding of teaching for relational understanding. This poster presents data gathered and analyzed from this more in depth action research study. PTs' self-reflection journals and lesson plan artifacts from three methods courses are analyzed using multiple cycles of In-Vivo and Process coding for emerging categories and themes. Preliminary analyses show that PTs' views of mathematics learning and teaching have begun to evolve from predominantly instrumental to include relational components and thus their teaching practices are evolving to reflect teaching for conceptual understanding. As experience with relational teaching methods deepens, understanding of how students learn mathematics matures.

Implications

This study holds promising positive implications for MTEs' instructional practices. The approach used by these three MTEs presents a clear opportunity to shift the teaching of mathematics from fostering instrumental to relational understanding. Future longitudinal studies will be used to determine if this shift continues into the PTs' full-time mathematics instruction.

Keywords: Equity and Diversity, Teacher Education-Preservice, Elementary School Education

In an analysis of the final course taken in high school across ethnic/racial groups, Battey (2013) shared disproportionate outcomes among the identified groups, which reveals the road traveled in mathematics education and foreshadows the road ahead…maybe. Gutiérrez (2007) offers another route, a vision for an equitable future, through a definition of equity as "(b)eing unable to predict students' achievement and participation based solely upon characteristics such as race, class, ethnicity, gender, beliefs, and proficiency in the dominant language" (p.41). It is in this intersection of the current destination, implied by Battey, and a potential destination, as implied by Gutiérrez, that we position a social justice mathematics methods learning module for elementary pre-service teachers (PSTs).

The module was iteratively designed over two years to engage PSTs with data from Battey's article through a task that used relevant mathematical content (i.e. proportional reasoning and argumentation) and progressive learning structures (i.e. complex instruction (Cohen, 1994)).

PSTs were asked to represent a future set of data given Gutiérrez's definition of equity. Next, teachers were positioned as critical in determining mathematics outcomes for students through an exploration of literature and examination of PSTs' experiences. Finally, PSTs were exposed to tools, resources, and ways of being that can be used to work toward a more equitable future.

Given 80% of teachers in the U.S. are white (Goldring, et al, 2013), and schools are becoming increasingly diverse, mathematics teacher educators must understand how to develop PST awareness of the inherent power toward academic and economic opportunities that exist within the position of mathematics teacher. The module described above was enacted with PSTs at two large public universities, one within a rural setting in the south with predominantly white students and the other in an urban setting in the northeast with diverse students. One focus of the project is to understand how each context uniquely challenged and supported PSTs. This poster will advance the work in this project and present findings related to the following questions:

1. What was learned from teaching a social justice mathematics module designed explicitly to raise awareness and agency around issues of equity in the mathematics methods courses?
2. How is the nature of what is learned similar and/or different between two distinctive populations of PSTs who engaged with the module?

PRE-SERVICE MATH TEACHERS' CONCEPTIONS OF CLASSROOM CULTURE

Amanda Opperman
Michigan State University
griff345@msu.edu

Keywords: Teacher Education-Preservice

As pre-service teachers stand at the crossroads between their preparation and their career as practicing teachers, it is imperative that they are prepared to engage in "fundamental element[s] of teaching practice" (Lampert, 2001, p. 53) such as building a classroom culture. This research explores the question: How do pre-service math teachers conceptualize classroom culture?

What Is Classroom Culture?

Classroom culture consists of all activities and expectations that facilitate students' interaction with subject matter content (e.g., Collins & Green, 1990; Lampert, 2001). Teachers' pedagogical practices influence the classroom culture that they co-create with students. More specifically, Bowers, Cobb, and McClain (1999), building on prior work (e.g., Yackel & Cobb, 1996; Yackel, Cobb and Wood, 1991), delineated three aspects of mathematics-related classroom culture: *social norms*, the ways in which students are expected to interact with one another about math; *socio-mathematical norms*, agreed-upon standards for judging mathematical contributions; and *classroom mathematical practices*, knowledge that is taken as shared within a classroom.

Study Design

Five undergraduate seniors at a large Midwestern university participated in the study. These participants were enrolled in their final math methods course before entering their student teaching field placements. Semi-structured interviews, audio-recorded and later transcribed, were the primary means of data collection. Data was coded using the three aspects of mathematics- related classroom culture as a framework, and two additional coding categories were created based on the data. Quotes from each participant's interview responses were identified and coded into mutually exclusive categories. Then, patterns were identified out of this initial coding.

Findings

Social norms were much more a part of participants' responses than socio-mathematical norms; classroom mathematical practices were not addressed at all. Additionally, the participants generally seemed to have a rather broad definition of classroom culture for math classes that went beyond the three aspects laid out by Bowers, Cobb, and McClain (1999). Participants included beliefs about mathematics that they wished to instill in their students as part of their descriptions of classroom culture, as well as specific actions or decisions on the part of the teacher that serve to facilitate classroom culture.

ENGAGING TEACHER CANDIDATES IN PURPOSEFUL ANALYSIS AND REFLECTION USING VIDEO AND THE LESSONSKETCH PLATFORM

Diana Bowen
University of Maryland
dbowen85@umd.edu

Monica Dunsworth
University of Maryland
mrd@umd.edu

Keywords: Teacher Education-Preservice, Technology

Preparing teacher candidates (TCs) for the complex and contingent practice of teaching requires TCs to learn to notice (see Sherin & van Es, 2005), analyze, respond, and (later) reflect on what is significant in teaching situations and connect these experiences to broader principles of teaching and learning. By analyzing and reflecting on their own practice, TCs have an opportunity to develop strategies for interpreting what is happening in the classroom (Sherin & van Es, 2005).

This research examined 6 TCs' responses across three video analysis experiences. These experiences are integrated into two secondary mathematics methods courses and consist of group discussions as well as individual analyses. With the second and third iteration there was also a formal write up for the analysis and reflection. Initially, TCs analyzed videos from a public dataset, and in later iterations TCs analyzed videos from their own clinical practice. Performing analysis of video using the LessonSketch platform affords TCs the opportunity to tag, discuss, and reflect on practice in a central location virtually and/or in person. The design of the video analysis experiences includes specific and purposeful structures for analysis and reflection to foster TCs' abilities to improve their practice through noticing.

Preliminary findings show increases in both the level of sophistication and preponderance of evidence employed by TCs to justify claims. For example, in the initial video analysis, TCs' often provided a superficial description of what students and teachers were doing. In contrast, for the third iteration TCs reflected on what students were feeling and thinking, in addition to how and why TCs responded to students. In the third cycle, TCs often tied their analyses to broader teaching principles and practices such as questioning, revoicing, and wait time. Analysis of and reflection on videos of their own teaching provide TCs with a forum to self-report their use of teaching practices and provide justifications. This research confirms video analysis experiences as an intentional tool for developing TCs' abilities to notice while also suggesting potential structures for facilitating this work with TCs. Additionally, this research demonstrates the usefulness of LessonSketch as a workspace for enhanced video analysis experiences.

PRE-SERVICE TEACHERS' UNDERSTANDING AREA MEASUREMENT: SPATIAL THINKING

Cetin Kursat Bilir
Purdue University
cbilir@purdue.edu

Keywords: Teacher Education-Preservice, Geometry and Geometrical and Spatial Thinking

The purpose of this research is unpacking PTs' conceptual understanding of the measurement of area of rectangular and non-rectangular shapes. Area measurement is a significant topic in geometry (CCSSM, 2010; NCTM, 2000) and provides a link between the abstract world of numbers and the concrete world of objects (Hilbert, 1981). In addition, the concept of area can be a model for teaching multiplication of fractions and composite numbers (Hirstein et. al., 1978). Despite the importance of understanding area concept and its measurement and the difficulties pre-service teachers have understanding area concept and its measurement, a few studies has been conducted in this topic.

To address this need, I have chosen to focus on problem solving strategy of PTs in different figures context for determining PTs' understanding of area measurement of rectangular and non-rectangular shapes. My research question will be "how do pre-service elementary mathematics teachers understand the measurement of area of rectangular and non-rectangular figures?"

To explore this understanding, I used theories about understanding and Battista's level of sophistication. My data will be collected using clinical interview methodology (Clements, 2000; Goldin, 2000), which was pioneered by Piaget (1975). I will choose four participants who are PTs enrolled in sections of a course entitled "Mathematics in The Elementary School" at a large public Midwestern university in the U.S. PTs will be interviewed in one-on-one sessions for initial and four explanatory interviews.

Findings determined that PTs' level of understanding area measurement change according to type of figures and numbers. PTs treated the partial units in different ways. In addition, PTs approaches to decimals are dominated by their whole number reasoning. Identifying PTs' understanding provide opportunities to mathematics educators to design more useful and helpful courses for PTs.

EXPLORING WAYS PROSPECTIVE TEACHERS MAKE COMMENTS AND ASK QUESTIONS IN SMALL GROUPS

Byungeun Pak
Michigan State University
pakbyun1@msu.edu

Keywords: Teacher Education-Preservice, Classroom Discourse, Equity and Diversity

Many mathematics teacher educators agree that teachers learning to implement small groups is important for student learning academically and socially (e.g., Featherstone, Crespo, Jilk, Oslund, Parks, & Wood, 2011). The field of mathematics teacher education, however, knows little of how teacher candidates (TCs) intervene, or make comments and ask questions, in small groups and why TCs intervene in small groups. The lack of understanding how TCs intervene might act as a barrier to helping teacher educators promote the TCs to succeed in implementing small groups in their classrooms. Given that practicing teachers use a range of comments and questions with small groups for different purposes (e.g., Dekker & Elshout-Mohr, 2004; Gillies & Boyle, 2006), examining the types of interventions teachers can make in small groups, and the purposes of those interventions can help teacher educators support TCs to better implement small groups.

This project explores ways TCs intervene in small groups and for what purposes. The research question is, therefore, How do TCs intend to use comments and questions when intervening in small groups in mathematics teaching and why?

This project took place in a mathematics methods course for elementary TCs in their student teaching internship year. Data sources include the responses of 26 TCs to an online survey. The participating TCs were asked to make open-ended responses to survey questions about their perceptions of teachers' roles and their purposes in intervening in small groups. TCs were also asked on the survey to respond to four scenarios describing different small group situations.

Data analysis followed a basic qualitative method. The focus of this analysis was on the range of comments and questions TCs made in response to the scenarios and their intervention purposes. The findings are: (1) TCs tend to make comments and questions that in function extend student's mathematical thinking, elicit students' work, encourage students to work together, and provide content-help; (2) TCs tend to use comments and questions to achieve multiple purposes such as mediating students' thinking and making group-interaction go smooth; and (3) TCs tend to have the same comments and questions but with different purposes.

As a whole, this project will provide more detailed understanding of ways TCs make comments and ask questions to small groups. The understanding will contribute to designing a strategy for teacher educators in an elementary mathematics methods course to support TCs with regard to intervention in small groups.

PRESERVICE TEACHERS' ANALYSIS OF LEARNING GOALS: THE ROLE OF MATHEMATICS KNOWLEDGE FOR TEACHING

Sandy Spitzer
Towson University
sspitzer@towson.edu

Christine Phelps-Gregory
Central Michigan University
phelp1cm@cmich.edu

Keywords: Mathematical Knowledge for Teaching

One ongoing challenge in mathematics teacher education is the difficulty of providing preservice teachers (PTs) with the knowledge, skills, and dispositions required for expert teaching during relatively short preparation programs. Researchers and teacher educators (e.g. Hiebert, Morris, Berk, & Jansen, 2007) have suggested that one fruitful way to navigate this challenge would be to educate PTs to learn from their own teaching over time. Researchers are working to define and operationalize the precise skills needed for teachers to systematically learn from teaching (e.g., Spitzer & Phelps-Gregory, 2017). One identified such skill is the ability to analyze mathematical learning goals. Analyzing learning goals in terms of their conceptually important ideas, or "key concepts," is necessary for teachers to plan instruction around those ideas, collect evidence which illuminates student understanding, and build lasting knowledge (Jansen, Bartell, & Berk, 2009). Previous research indicates that prospective teachers have some skill in analyzing learning goals, but generally only use this skill in supportive contexts and when directly prompted (Morris, Hiebert, & Spitzer, 2010).

Theoretical consideration and emerging empirical evidence indicates that there is a link between teachers' mathematics knowledge for teaching, or MKT (see Ball, Thames, & Phelps, 2008, for details on MKT) and their ability to analyze learning goals. However, much remains to be known about the exact ways in which these two skills support each other. To investigate these links, we asked PTs (n = 53) to decompose a learning goal into its key concepts, using two prompts based on previous research (Morris et al., 2010). We also administered a short assessment of PTs' MKT around the same learning goal (concepts of comparing decimals). Results indicate that there was an association between PTs' scores on the MKT assessment and their ability to identify key concepts of the learning goal. When constructing an ideal student response, PTs with higher MKT scores identified a mean of 0.93 (SD = .95) key concepts of the learning goal, whereas PTs with lower MKT scores identified a mean of only 0.42 (SD = .65) key concepts ($p < .05$). Our poster will expand on this and other findings to illuminate the connection between PTs' MKT and their ability to analyze learning goals.

Implications of this research will inform teacher educators working to prepare teachers who can successfully examine their own instruction, enhancing their teaching at the crossroads of theory and practice.

FOOD SECURITY: A CONTEXT FOR CONTROVERSIAL TOPICS IN MATHEMATICS EDUCATION

Jennifer Y. Kinser-Traut
University of Arizona
jkinser@email.arizona.edu

Keywords: Equity and Diversity, Instructional Activities and Practices, Teacher Education-Preservice

Simic-Muller, Fernandes, and Felton-Koestler (2015) argued the importance of mathematics educators incorporating controversial mathematics tasks into their classrooms. Additionally, mathematics education research suggests that teachers, including prospective teachers, should learn about their students' community funds of knowledge (CFoK) and connect mathematics to that knowledge (Moll, Amanti, Neff, & Gonzalez, 1992). This poster presents the benefit of using food systems and food security as a context that is accessible to real-world mathematics applications and connects to students' CFoK, but can also move into topics that are more controversial. Food offers a progression moving from real-world contexts of food (e.g., how have recipes and portions changed across generations) to controversial topics of food security (e.g., how much more money does healthy food cost?). Food security is defined as "enough food [being] available" from a global to household perspective (Pinstrup-Andersen, 2009, p. 5) or knowing where your next meal is coming from. In regards to mathematical connections, food security is a rich context as it offers tasks for early elementary to high school grades.

In this poster, I will offer specific mathematics tasks for a variety of grade levels that move from real-world contexts to the controversial. For example, in understanding how vast food markets are, second and third graders can calculate the average distance a tomato travels (approximately 2000 miles) as it goes from field to table or geometry students can determine the density of grocery stores as a factor of household income to learn about food deserts--areas with very limited access to fresh food. The context of food security would offer prospective teachers an opportunity to discuss a common everyday concern (eating) while also thinking about how to mathematize the issue. Additionally, the context of food security offers a wide range of ways to connect to CFoK, concerns allowing for real-world situations, controversial issues, and issues of injustice. In summary, food security offers a context to move from real world to topics that are more controversial, pushing prospective teachers to help "mathematics serves as a mirror and a window into people's lives" (Simic-Muller, et al., 2015, pg. 75).

PROSPECTIVE ELEMENTARY TEACHERS' KNOWLEDGE OF THE ARBITRARY NATURE OF THE FRACTIONAL UNIT

José N. Contreras
Ball State University
jncontrerasf@bsu.edu

Keywords: Teacher Knowledge, Rational Numbers

One of the most fundamental ideas in developing fractional thinking is the concept of the unit or whole. Even though there have been research studies conducted to examine PET's knowledge of fractional concepts (e.g., Tobias, 2013), few have focused on teachers' knowledge of the arbitrary nature of the unit. This study analyzes 54 prospective elementary teachers' explicit knowledge of the arbitrary nature of the unit within fractional contexts involving drawn diagrams. The participants were enrolled in two sections of a content course for PETs.

The research subjects completed two questionnaires. The first questionnaire consisted of an open-ended task that asked them to identify and justify what fraction or fractions the shaded diagram depicted in figure 1 could represent. The second questionnaire consisted of six tasks that asked participants to identify and justify whether the same diagram could represent the following fractions: $\frac{3}{4}$, $\frac{3}{5}$, $\frac{3}{10}$, $1\frac{1}{2}$, $\frac{1}{2}$, and 1. After all students completed questionnaire 1, they were given questionnaire 2. By providing a diagram with a shaded portion and asking PETs the fraction or fractions that the shaded part of the figure could represent or whether the shaded diagram could represent certain fractions, there was a demand for an explicit awareness of the arbitrary nature of a unit.

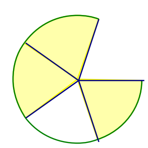

Figure 1. Diagram from first questionnaire.

A content analysis for each student' response was performed. A majority of the students (about 60%) thought that the shaded portion of the diagram could represent (only) 3/4. While other students (about 15%) thought that the diagram could represent 3/5, all students justified their responses based on the idea that the unit or whole needs to be physically present, that is, the circle needs to be completed. It is interesting to report that none of the students was able to think of a situation for which the shaded diagram could represent 3/10. For the picture to represent 3/10, the students needed to physically see 3 parts out of 10. Furthermore, none of the students were able to reconceptualize the three shaded equal parts of the diagram as 1/2 because they did not have physically present the other 2 parts. Other findings and implications of the study will be displayed in the poster during the presentation.

MATHEMATICS TEACHER EDUCATORS' KNOWLEDGE OF DIVISION OF FRACTIONS AND ITS RELATIONSHIP TO THEIR INSTRUCTIONAL PRACTICE

José N. Contreras
Ball State University
jncontrerasf@bsu.edu

Keywords: Teacher Knowledge, Mathematical Knowledge for Teaching

Even though some research has been conducted to examine teachers' knowledge of mathematical concepts and procedures, few research studies have examined mathematics teacher educators' knowledge of mathematical concepts and procedures and its impact on their instructional practices. To begin closing this gap, I examined Mr. Frank knowledge of division of fractions and how he used this knowledge when teaching a unit on division of fractions to a group of prospective elementary teachers. Prior to instruction, I asked Mr. Frank to complete several tasks to gain an understanding of his knowledge of division of fractions. The tasks included (a) creating both quotative and partitive word problems whose solutions can be represented by division expressions with and without reminders (e.g., $3\frac{9}{10} \div \frac{3}{5}$ and $4\frac{1}{2} \div \frac{3}{4}$); (b) solving each word problems using diagrams; (c) explaining why each created problem is a division problem; (d) explaining why each problem can be solved using a multiplication expression (i.e., multiplying by the reciprocal of the divisor); and (e) developing and justifying other ways of representing and solving the problems. Considering that Mr. Frank has an undergraduate degree in mathematics and a Masters' degree in mathematics education with over 15 years of teaching experience, it was not surprising that his written responses revealed that he had a profound understanding of division of fractions. He was not only able to create a diversity of word problems and use diagrams to solve them, he was also able to create alternative explanations of why division of fractions can be performed by a multiplication operation.

To examine the impact of Mr. Frank's knowledge of division of fractions on his instructional practices, classroom observations were conducted when he taught the unit on fraction division. It is worth noticing that he developed tasks in which he asked students to solve both quotative and partitive division problem using diagrams and to justify the division of fractions algorithm and interpret the contextual meaning of the reciprocal of the divisor. However, it is also worth mentioning that he did not use other components of his knowledge to provide alternative justifications of why division of fractions can be performed by multiplying by the reciprocal of the divisor because "too many explanations can be overwhelming to students with a weak conceptual understanding of division of fractions."

Evidence of Mr. Frank's knowledge of division of fractions and its impact on his teaching will be displayed during the poster presentation. However, as argued by Castro Superfine and Li (2014), further research is needed to understand the knowledge that mathematics educators need for helping preservice teachers develop their mathematical knowledge.

THE INTERSECTION OF BELIEFS AND MATHEMATICS ANXIETY IN ELEMENTARY PRESERVICE TEACHERS LEARNING TO TEACH MATHEMATICS

Kathleen Jablon Stoehr
Santa Clara University
kstoehr@scu.edu

Amy M. Olson
Duquesne University
olsona@duq.edu

Keywords: Teacher Beliefs, Teacher Education-Preservice

Theoretical Framework

Mathematics anxiety describes the discomfort or fear that occurs when mathematical tasks are perceived as potential threats to self-esteem (Trujillo & Hadfield, 1999). Negative physiological effects (Luo, Wang, & Luo, 2009), may lead to the disruption of the ability to process information and thus, disrupt learning and performance (Gresham, 2007). Furthermore, mathematics anxiety may shape pre-service teachers' (PSTs) beliefs about doing and teaching mathematics (Stoehr, 2017).

Methods and Results

PSTs were recruited from two larger studies in a large teacher education program (n = 4 narrative participants, n = 53 survey participants). An iterative analysis (Bogdan & Biklen, 2006) was used to demarcate the narratives that pertained specifically to mathematics anxiety and beliefs about teaching mathematics. Narrative themes included: 1) *understanding the mathematics content*, 2) *knowing how to teach a mathematics lesson* and 3) *feeling responsible for student learning*.

An exploratory factor analysis of survey items resulted in four factors being retained based on Eigenvalues > 1.0 and visual analysis of the scree plot. Three factors thematically converged with the qualitative data are described above. Five items (α = .900) explained 32.1% of the variance and converged with the first theme. Four items (α = .886) explained 21.4% of the variance and converged with the second theme. Four items explained 7.7% of the variance (α = .689) and converged with the third theme. The remaining factor assessed *mathematics test anxiety* and explained 9.6% of the variance.

Conclusions

The converging findings in these two studies support that PSTs experience significant anxieties related to learning mathematics content and instructional strategies. PSTs experience additional anxiety when they feel responsible for student achievement. This places PSTs' experience of mathematics anxiety at the crossroads of their own and their students' learning, and suggests future research to explore whether these anxieties are a direct extension of one another.

NUMBER TALKS WITH PRESERVICE TEACHERS TO DEVELOP THREE LEVELS OF UNIT FOR FRACTIONS

Natasha E. Gerstenschlager
Western Kentucky University
Natasha.gerstenschlager@wku.edu

Angela T. Barlow
Middle Tennessee State University
Angela.barlow@mtsu.edu

Keywords: Teacher Education-Preservice; Teacher Knowledge

Teachers' understanding of multiplication of rational numbers including fractions and decimals is often a procedural understanding that lacks conceptual depth (An, Kulm, & Wu, 2004; Armstrong & Bezuk, 1995; Ball, Lubienski, & Mewborn, 2001; Izsák, 2008; Sowder et al., 1998). Furthermore, Izsák (2008) stated that teachers' ability to understand three different levels of unit in rational numbers is a "necessary but not sufficient" (p. 139) condition for them to be able to respond and interpret students' conceptions of multiplication of fractions. In response, we developed a series of number talks for use with pre-service teachers as a way to develop their understanding of three levels of unit within fractions with the anticipated outcome of teachers' having a better understanding of fraction multiplication.

Number talks, or short conversations around mathematical problems that students solve mentally, have been described as useful in K-12 mathematics classrooms because they offer opportunities for students to "reason about quantitative information; utilize number sense; discern whether procedures make sense; identify which procedures are applicable to specific situations; check for reasonableness of solutions and answers; and communicate mathematically to others" (Parrish & Dominick, 2016, pp. 14-15). As such, they can be considered a high-impact practice that has the potential to help students develop a deeper understanding of mathematical ideas. In this study, we utilized number talks in a mathematics content course on rational numbers for pre-service elementary teachers. The participants engaged in carefully designed number talks on the topic of rational numbers at the beginning of each of their class meetings. The number talks were designed to expose participants to three levels of unit within whole numbers and fractions prior to instruction on multiplication of fractions. During this poster session, we will present results from this mixed-methods study including the design of the study, participants' scores on pre- and post-tests for multiplication of fractions, and participants' responses and rationales for number talks. Implications for the teacher education community will be shared.

Keywords: Teacher Education-Inservice, Teacher Knowledge

The math education has mainly focused on the problems that arise in teaching and learning mathematics. Thus, it is a priority to highlight the need for an approach between teachers and research in math education. The Seminar Rethink Mathematics (SRM) was born in 2004 looking for this link. The objective of this research is to describe the type of knowledge of the research in Mathematics Didactics that is offered to the teacher through the scientific production of the SRM.

The SRM is an online seminar that is organized into cycles that group sessions. Each session presents the opportunity to interact with the researcher around one of his published results, so each session revolves around a research product (article, report, thesis, book chapter or book). A live dialogue is carried out commonly between two teachers and the researcher, where the reference material is discussed with a view to applying it in one of the dimensions of professional teaching. (Suárez and Ruiz, 2013)

The framework of this study is the Pedagogical Content Knowledge in an Educational Context, PCK-EC model (Pena-Morales, 2016), which characterizes the dimensions of teacher's knowledge in five categories: teachers' attitudes, knowledge of technology, knowledge of learners' cognition, knowledge of the subject matter and knowledge of pedagogy. The database contains the abstracts obtained from the reference document of each session. Here is an example of the result obtained for Session 60: The session "Mathematical visualization, representations and use of technology" is located in the *Knowledge of technology* category, as it analyzes "the problem of using the graphical calculator for the construction of concepts in the mathematics classroom" from the "Constructing Mathematical Concepts" approach. The session looks for "the reflective use of technology in the math classroom" (Hitt, 2003). Based on the results, we can conclude that the approach between teachers and educational mathematics, in terms of scientific production, focuses on two categories that characterize the dimensions of teacher knowledge: almost half (43.6%) of the sessions so far carried out could be classified in the category *Knowledge of pedagogy.* The next highest frequency category (34.5%) is *Knowledge of student cognition*. There are approximately 60% of the sessions classified in one category, 24% in two categories and 16% in three categories.

Acknowledgments

This paper has been made possible thanks the support received from the projects 20131847 and 20170638 approved for The Research and Graduate Studies Secretariat of the National Polytechnic Institute in Mexico.

PRE-SERVICE SECONDARY MATHEMATICS TEACHERS AS LEARNERS: IMPLICATIONS FOR THEIR TEACHING OF CONCEPTUAL UNDERSTANDING

Michelle Frederick
Tiffin University
meadowsml@tiffin.edu

Joanne Caniglia
Kent State University
jcanigl1@kent.edu

Keywords: Teacher Education-Preservice, Teacher Knowledge

The purpose of this study was to describe pre-service secondary teachers' (PST) thinking as they attempted to solve high cognitive demand tasks (Stein & Smith, 2007) by applying the SOLO taxonomy. In addition, we examined the relationship between PST's conceptual knowledge and their problem posing based on videos of their student teaching practice. The following research questions framed this study: (a) What levels of thinking are PSTs' at in the SOLO taxonomy when confronted with problems with high cognitive demand? (b) How might PSTs' level of thinking (in SOLO taxonomy) relate to their problem posing in their student teaching classrooms?

Theoretical Framework

Addressing the multiple components of the research questions posed in this study required a framework with the capacity to examine and crosscut students', teachers', and tasks' "depth of knowledge." The study employed: (1) Skemp's theory of instrumental and relational understanding, (2) the SOLO taxonomy by Biggs and Collis (1982), and (3) the concept of problem posing as it relates to a teacher's capacity to develop rich problems according to Crespo (2003). This latter section described specific teacher roles for problem-posing, the impact it has on students, strategies, and the need for problem posing in teacher education.

Methodology

To answer the research questions, we classified and investigated PSTs' responses to rich mathematical tasks using the SOLO Taxonomy. In addition, we compared their taxonomy levels with the level of problem posing criteria developed by Crespo (2003). The use of video analysis and PSTs reflection statements were analyzed through pattern matching (Yin, 1989) where statements from pre-service teachers were compared with assessments of three mathematics educators and external criteria.

Results and Discussion

Of the 15 students' solutions, eight were classified as multi-structural on the SOLO Taxonomy, meaning that they were able to see many aspects of the problem, yet not comprehend how each piece of information was able to fit together. The remaining students were classified as pre-structural (n=4) or uni-structural (n=3) meaning that they were not able to either grasp the problem or not see the intricacies. The problems posed by PSTs in their videos were transcribed and showed that more than a significant majority emphasized procedural fluency over conceptual understanding. The findings of this study called us to examine the intersection of the qualitative relationship between PST's ability to solve conceptual problems and their problem posing in the classroom. This intersection of problem solving theory and the study of PST's problem posing is an important crossroad in teacher education.

Current reforms have called for a stronger emphasis on teaching and learning mathematics that elicits and uses evidence of students' thinking builds on procedural fluency from conceptual understanding (National Council of Teachers of Mathematics, 2014). Despite the wealth of existing literature on pre-service secondary mathematics teachers' abilities to notice, attend to, and respond to students' mathematical reasoning, we still know little about how these skills related to identifying evidence of students' learning are taught in methods courses. In this poster, we share how three mathematics educators at three different universities are collaborating to study challenges and progress with developing pre-service secondary mathematics teachers' skills with enacting lessons from a worthwhile high school curriculum called Interactive Mathematics Program (IMP). More specifically, this study examines the challenges that the mathematics educators and pre-service secondary mathematics teachers (PSMTs) encountered during the preparation, enactment, and analysis of rehearsals.

This study had 16 PSMTs from the second author's methods course, and each PSMT taught a lesson from the same unit in the IMP curriculum (Fendel, Resek, Alper, & Fraser, 2011) called *Small World, Isn't It?* To prepare PSMTs to learn from their teaching, they were engaged in the pre-rehearsals that included solving tasks, studying enactment of the same tasks, and analyzing the relationship between the instruction and students' learning opportunities. The rehearsals included planning and enacting a task from the IMP, and providing peers with feedback on videotaped lessons. Our data sources included PSMTs' lesson plans with solutions to their tasks, their video recorded lessons, their peers' in-class work, and their teaching reflection papers. To analyze what counts as PSMTs' learning from teaching, we followed the techniques of grounded theory (Strauss & Corbin, 1990) to identify themes to support our understanding about what we believe each PSMT was learning. The results of this study show that the PSMTs' understanding of mathematical concepts within their assigned lessons affected the way they enacted the tasks. For example, if a PSMT solved the task procedurally and anticipated that their classmates will do the same, then they were less likely to have purposeful questions prepared to advance their peers' mathematical reasoning and making sense of mathematical concepts during enactment. These results highlight the need in mathematics teacher education programs to better prepare and support PSMTs to teach mathematics both procedurally and conceptually in their future classrooms.

Keywords: Equity and Diversity, Instructional Activities and Practices, Teacher Education-Preservice

Preparing secondary teachers to teach in the 21st century during the Common Core-era of mathematics education requires a changing of perspective from how the preservice teachers (PSTs) learned mathematics themselves (Garmon, 2004). A difference in the PSTs' cultural background and the demographics reflected in urban and inner-city schools could cause disequilibrium and a lack of understanding between the teacher and the students (Gutstein & Peterson, 2005; Sleeter, 2001). Although it can be complicated or hard for some teachers; teaching in this situation requires an alternative view on the preconceived ideas that teachers hold about their students and mathematics (Padron, Waxman, & Rivera, 2002). Teaching from a social justice perspective is a way to effectively cater to an urban population of students (and non-urban as well).

This study addresses issues raised at a large, southern, public predominantly white institution where PSTs have no formal course in preparing them to teach diverse populations in a classroom. PSTs were asked to respond openly and candidly through multiple surveys to express their knowledge and understanding of what it means to teach social justice within a mathematics classroom. Through culturally relevant practices, two instructors led their classes of PSTs in an activity adapted from Gutstein and Peterson (2005) that utilized a social justice lens. The goal was to engage PSTs in an opportunity to experience learning social justice within a mathematics task and to broaden their view of teaching mathematics to include a social justice perspective. We recognize that this is just an introduction to social justice, but we are attempting to integrate this perspective of teaching in a mathematics classroom. The purpose of this research was to primarily use qualitative data to answer the following questions: (a) What are PSTs' initial conceptions of teaching for social justice? (b) How do PSTs view the concept of social justice and its role in mathematics education? (c) After the intervention (activity), what are changes in the initial conceptions of PSTs on teaching for social justice in mathematics?

Using the PSTs' responses, the researchers compared initial conceptions of teaching for social justice to understandings after the activity. This poster will illuminate the responses of the participants in this study and show how students' views shifted.

WHO TEACHES MATHEMATICS CONTENT COURSES FOR PROSPECTIVE ELEMENTARY TEACHERS? RESULTS OF A SECOND NATIONAL SURVEY

Joanna O. Masingila
Syracuse University
jomasing@syr.edu

Dana Olanoff
Widener University
dolanoff@widener.edu

Keywords: Teacher Education-Preservice

The mathematical experiences that prospective elementary teachers have during their teacher preparation are vitally important. Recommendations from *The Mathematical Education of Teachers II* (Conference Board of the Mathematical Sciences, 2012) call for (a) "mathematics courses that develop a solid understanding of the mathematics they will teach", (b) "coursework that allows time to engage in reasoning, explaining, and making sense of the mathematics they will teach", with "at least 12 semester-hours on fundamental ideas", and (c) "teachers should develop the habits of mind of a mathematical thinker and problem-solver" (pp. 17-19). Additionally, instructors of mathematics content courses for prospective elementary teachers play an important role in helping prospective teachers acquire the knowledge they need for teaching.

In 2010, we conducted a national survey of higher education institutions in the United States to answer the question, "Who teaches mathematics content courses for prospective elementary teachers, and what are these instructors' academic and teaching backgrounds" (Masingila et al., 2012). In 2016, we conducted a second national survey to examine the situation six years later. We made some changes to the survey from 2010 by (a) asking about number of credits instead of number of courses, (b) adding some mathematical content areas when asking what content is included in the courses, (c) asking if a textbook is used and, if so, which one, and (d) changing the questions about academic and teaching background of instructors and supervisors to be more concise. We surveyed 1,740 institutions and a faculty member from each of 413 institutions (23.7%) participated in the survey.

The survey results demonstrate that the majority of institutions are not meeting the recommendations of at least 12 semester-hours of mathematics content. Additionally, most instructors for these courses do not have elementary teaching experience and have likely not had opportunities to think deeply about the important ideas in elementary mathematics, and most institutions do not provide training and/or support for these instructors. If nothing changes with the preparation and professional development of these instructors, the cycle of unprepared prospective teachers whose college experience has little effect on their mathematical understanding (CBMS, 2012) will continue.

We will present all of the findings from this national survey, including (a) the number of credits of mathematics content courses that are offered and required, (b) the content included in these courses, (c) whether a textbook is used, and if so, which one, (d) the academic and teaching background of the course instructors, and (e) whether there is training and/or support for course instructors, and if so, what is the training and/or support.

PROSPECTIVE TEACHERS' UNDERSTANDINGS OF MATH PRACTICE: MAKE SENSE AND PERSEVERE

Lindsay Keazer
Central Connecticut State University
keazer@ccsu.edu

Hyunyi Jung
Marquette University
hyunyi.jung@marquette.edu

Keywords: Teacher Education-Preservice, Problem Solving, Standards, Elementary School Education

The Common Core State Standards for Mathematical Practice (SMP) build upon efforts to engage students in reasoning and sense making and reduce reliance on memorization of procedures. The first mathematical practice (SMP1) underlies other SMPs with its focus on developing students' thinking strategies and perseverance for problem solving.

Prospective elementary teachers are grappling with learning to teach mathematics in ways that incorporate SMPs. A study by Gerberry & Keazer (2015) found that one third of prospective teachers surveyed recognized that SMP1 was about developing students' thinking processes, while others interpreted the practice as students relying on a procedure or scaffolding techniques to solve a problem. SMP1 may be challenging for prospective teachers to understand because it highlights a shift away from traditional emphases of following procedures, and towards a focus on developing thought processes for solving complex, non-routine problems.

In this study, prospective teachers (n=71) enrolled in four mathematics courses for elementary teachers at two institutions were surveyed about their understanding of SMP1. Specifically, we aimed to answer the research question: *How do prospective elementary teachers conceptualize SMP1, in terms of the tasks they would use to foster SMP1 and how they would assess student engagement?* The survey asked prospective teachers to think about their future classroom where they would be responsible for helping students engage in SMP1. One question was, "Describe a math activity or a math problem that you would pick for your students to give them an opportunity to demonstrate their ability to engage in SMP1. After you describe the math problem or activity, explain how it allows students to demonstrate that they have engaged in the practice." Guided by grounded theory (Glaser & Strauss, 1967), survey responses were reviewed repeatedly, coded, and compared for the nature of the math tasks selected to foster SMP1 and the methods suggested for assessing student engagement.

The most common themes found in prospective teachers' responses were that SMP1 tasks should be context-based problems with multiple ways for students to solve them. In addition, almost half of the respondents indicated that students should generate the solution strategies. A minority of respondents, however, indicated that solution strategies should be provided by the teacher, which contradicts the intention of SMP1. Our findings build on the conference theme *Synergy at the Crossroads* of research and practice because prospective teachers' conceptualizations of SMP1 have significance for informing the design of coursework activities to improve the preparation of prospective teachers.

THE EVOLUTION OF REPRESENTATIONS AND TALK IN A MIDDLE SCHOOL CONTENT COURSE

Eric Siy
University of Georgia
ericsiy@uga.edu

Keywords: Teacher Education-Preservice, Number Concepts and Operations, Classroom Discourse

Departing from the perspective of doing mathematics as an individual's activity, research on doing mathematics within classroom microcultures have been an active research agenda. However, as a field, we know little about the microcultures of mathematics courses for prospective teachers (i.e., content courses). In this poster, I examine two crucial component of the classroom microculture – representations and talk. I take the view of representations as a product (National Council of Teachers of Mathematics, 2000). With this view, representations are encoded objects that result from thinking, maybe for purposes of communicating (Greeno & Hall, 1997; Pimm, 1987). More specifically, I ask how do representations evolve over time? Moreover, I also look at the parallel development of classroom talk with the representations.

To investigate the different ways the talk and representations evolve, I take a cultural-cognition approach (Saxe, 2015). Saxe (2015) posited humans participate in joint problem solving by using collective practices i.e., representing and talking. Moreover, as certain goals of a community shift, the representational forms and functions also shift. For example, as addition problems evolve from adding sets of objects to include fractional amounts, representations and talk evolve. In this poster, I present the evolution of two representations used in a content course for prospective middle school teachers – strip diagrams and double number lines.

Using classroom video data from a semester-long content course, I examine whole-class discussions of student strategies when solving problems involving multiplicative concepts e.g., division, ratio. From the video data, I distill the relevant features of the representations as indicated in student talk. I segment the semester by mathematical topic and examine the features of the representations and talk unique to each segment. The analysis is currently in nascent phases thus, the poster would include a complete set of results I am not ready to report in this proposal. The results section would show examplars indicative of the representations and talk within each segment, the differences between segments. By showing the exemplars, I intend to indicate how the talk and representations evolve over time.

EL RAZONAMIENTO DE PROFESORAS EN FORMACIÓN ACERCA DE LA VARIACIÓN EN SITUACIONES DE RIESGO
PRESERVICE TEACHERS' REASONING ABOUT VARIATION IN RISK SITUATIONS

José Antonio Orta Amaro	Ernesto A. Sánchez Sánchez	María Eugenia Ramírez-Esperón
ENMJN	DME-Cinvestav	UAA
jaortaa@gmail.com	esanchez0155@gmail.com	meramiremx@cinvestav.mx

En esta investigación exploramos el razonamiento de profesoras en formación acerca de la dispersión de datos (variabilidad o variación) cuando es analizada en problemas donde se comparan conjuntos de datos que involucran situaciones de riesgo como lo son las apuestas en juegos y la duración de vida en tratamientos médicos. En esta comunicación se presentan las respuestas que dieron 97 futuras profesoras de nivel preescolar a dichos problemas. Los problemas fueron resueltos antes de que las estudiantes normalistas iniciaran un curso de procesamiento de información estadística y los resultados mostraron la dificultad que ellas tienen para interpretar la dispersión en este tipo de contextos. Por los resultados obtenidos consideramos importante reflexionar acerca de la instrucción de las estudiantes sobre los significados de medidas de centro y dispersión con la finalidad de contribuir en su formación.

Keywords: Análisis de Datos y Estadística, Conocimiento del Profesor.

Introducción

La variación es la causa subyacente de la existencia de la estadística que está presente en todos lados y por lo tanto en conjuntos de datos (Watson, 2006). Además Moore (1990) enfatiza la importancia de medirla y modelarla, y encontramos que investigadores como Wild y Pfannkuch (1999) incluyen la percepción de la variación como parte de los tipos fundamentales del razonamiento estadístico. Asimismo, Garfield y Ben-Zvi (2008) observan que "la comprensión de las ideas de dispersión y variabilidad en los datos es una componente clave en la comprensión del concepto de distribución y es esencial para hacer inferencias estadísticas" (p. 203). Por su parte, Burrill y Biehler (2011) proponen una lista de siete ideas estadísticas fundamentales en las cuales la variación se ubica en el segundo lugar. Respecto del aspecto escolar, Franklin, Bargagliotti, Case, Kader, Sheaffer y Spangler (2015) mencionan que los profesores deben reconocer las características de la estadística y comunicarlas de manera clara y, particularmente, poner énfasis en la variabilidad y el papel del contexto, y en la descripción de la variabilidad considerar que los datos están constituidos de una estructura (la media o la mediana) alrededor de la cual varían. En relación con ello, Canada y Makar (2006) encontraron que al resolver problemas sobre distribuciones los profesores en formación presentan una percepción intuitiva de la variación, la cual describen con lenguaje informal y que la media es poco utilizada. Otros estudiosos como Mooney, Duni, VanMeenen y Langrall (2014) mencionan que al investigar acerca de la percepción de la variabilidad, en situaciones de azar, los profesores en formación reconocen que debe presentarse cierta cantidad de variabilidad, pero no tienen certeza sobre cuánta. De las investigaciones precedentes se desprende que es necesario proveer a los futuros profesores con experiencias tanto en el análisis de datos como en situaciones de azar donde se desarrollen conceptos como *centro*, *variación*, *distribución*, *valores esperados* y las relaciones entre ellos. Para explorar la comprensión y razonamiento de los alumnos acerca de la percepción, descripción y medición de la variación en los datos se han utilizado diferentes contextos y problemas por ejemplo, variabilidad en el muestreo (Watson & Moritz, 2000), azar (Watson & Kelly, 2004), mediciones repetidas, variación en el crecimiento de plantas (Lehrer & Schauble, 2007; Petrosino, Lehrer & Schauble, 2003), y clima (Reading, 2004). De acuerdo con estos investigadores, las situaciones de riesgo proveen otro escenario para indagar el razonamiento que tienen los estudiantes acerca de la variabilidad (Sánchez & Orta, 2013). Por ello, esta comunicación tiene como objetivo explorar la manera en que futuras profesoras del nivel preescolar interpretan la dispersión de datos en situaciones de riesgo, con la finalidad de que sepan conceptos estadísticos fundamentales con miras a su mejoramiento profesional. Por este motivo es importante incluir en su formación el conocimiento de conceptos estadísticos, que le permitan favorecer la recolección, representación e interpretación de información en el nivel preescolar (SEP, 2011). Además de considerar que estos serán enseñados posteriormente a sus alumnos en otros niveles educativos (Ball, Thames & Phelps, 2008).

Marco de Referencia

Esta exploración se ubica en el área de razonamiento estadístico cuya propuesta es comprender como razonan las personas con ideas estadísticas (Garfield & Ben-Zvi, 2008) y así proponer características para crear escenarios de aprendizaje, puesto que cuando los participantes de una investigación tratan de justificar sus respuestas, muestran los elementos a los que le dan importancia, en particular los datos que eligen, las operaciones que realizan, sus creencias y sus conocimientos. Aunque en ocasiones las respuestas de las personas no son tan explícitas para revelar claramente su razonamiento, de cualquier manera muestran indicios para identificar algunos de sus rasgos. En este estudio identificamos algunas características del razonamiento de profesoras en formación ante situaciones de riesgo. Una parte importante en una investigación en didáctica de las matemáticas son los problemas. Al resolverlos éstos deben promover en las personas la capacidad de pensar y razonar y así proveer al investigador de resultados relevantes que aporten información al área de estudio. Los problemas deben también llamar la atención de quienes los resuelven para que puedan comprometerse con su solución y aumentar las probabilidades de la comprensión del concepto que se quiere estudiar. En la estadística el razonamiento debe articular ideas como media o dispersión, expresadas con números, con situaciones reales basadas en datos, es decir, el razonamiento estadístico está íntimamente relacionado con el contexto, y los números en contexto implican información (Moore, 1990). Los problemas sobre toma de decisiones bajo incertidumbre son comunes en estadística, este tipo de problemas han sido utilizados para promover y analizar características importantes del razonamiento estadístico de las personas. Además, las situaciones que requieren de la comparación de conjuntos de datos son utilizadas frecuentemente para involucrar a los alumnos en el razonamiento con datos (Garfield & Ben-Zvi, 2008). En esta exploración se presentan dos situaciones de toma de decisiones y comparación de conjuntos de datos en los cuales la dispersión es importante, y ésta puede ser asociada con la noción de riesgo, la cual está asociada con la incertidumbre presente en un suceso que implica una amenaza. Estas situaciones aparecen cuando hay resultados no deseados que, como consecuencia, provocan pérdidas o daños. Un problema paradigmático en un escenario de riesgo consiste en elegir entre dos juegos de apuestas de los cuales se muestran pérdidas y ganancias (Kahneman & Tversky, 2000). Considere el siguiente problema:

> Las ganancias observadas de *n* repeticiones de un juego A (x_n) y *m* del juego B (y_m) son:
> Juego A: $x_1, x_2 \dots ; x_n$
> Juego B: $y_1, y_2 \dots ; y_m$
> ¿En cuál de los dos juegos participarías?

Una solución puede ser la siguiente: 1) comparar las medias aritméticas de ambos juegos ($\bar{x}$ y $\bar{y}$); 2) si $\bar{x} \neq \bar{y}$, elegir el juego cuya media es mayor; 3) si $\bar{x} = \bar{y}$, se tienen dos opciones: 3a) elegir cualquier juego; 3b) analizar la dispersión de los datos en cada juego y elegir uno de acuerdo con las preferencias hacia el riesgo. Estas preferencias pueden ser definidas como generalizaciones de las actitudes hacia el riesgo:

En general, la preferencia por un resultado seguro y el rechazo de un juego cuyo resultado tiene un valor esperado igual o mayor a dicha ganancia es llamada aversión al riesgo. Y el rechazo de una ganancia segura y la aceptación de un juego cuyo resultado tiene un valor esperado menor o igual a esa ganancia es llamada propensión al riesgo (Kahneman & Tversky, 2000, p. 2).

En un juego la dispersión de las ganancias (incluidas las pérdidas) puede ser considerada una medida de riesgo: entre mayor dispersión más riesgo. Una persona adversa al riesgo preferirá un conjunto de datos menos disperso en lugar de otro cuyos datos tengan mayor dispersión, mientras que una persona es propensa al riesgo cuando prefiere la opción cuyos datos son más dispersos.

Método

En este estudio participaron 97 profesoras en formación de una escuela normal pública de la Ciudad de México que cursan la Licenciatura en Educación Preescolar (atención a niños de 3-6 años). Para explorar las ideas de las futuras profesoras se utilizó un cuestionario con dos problemas sobre comparaciones de conjuntos de datos (ver Figura 1).

Problema 1. En una feria, se invita a los asistentes a participar en uno de dos juegos. Juan puede participar en un juego, pero no en ambos. Para saber por cuál decidirse observa, anota y ordena los resultados de dos muestras de 10 personas que han participado en cada juego. Las pérdidas (-) o premios (+) en efectivo que han obtenido las 20 personas se muestran en las siguientes listas:

Juego 1:

15 -21 -4 50 -2 11 13 -25 16 -4

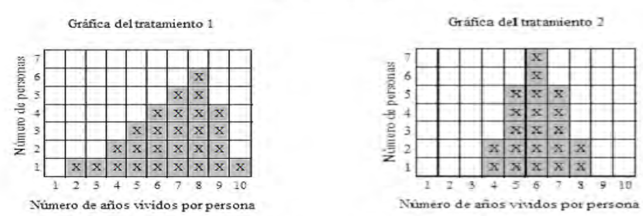
Juego 2:

120 -120 60 -24 -21 133 -81 96 -132 18

a) Si tienes la posibilidad de participar en un solo juego, ¿Cuál juego elegirías? ¿Por qué?

Problema 2. Considera que debes aconsejar a una persona que padece una enfermedad grave, incurable y mortal, pero que es tratable con medicamentos que pueden extender la vida por varios años. Es posible elegir entre dos tratamientos. Las personas tienen diferentes reacciones a las medicinas, para algunas tienen el resultado previsto, mientras que para otras pueden ser más o menos benéficas. A continuación se muestran los años que han vivido varios pacientes tratados con cada una de las opciones mencionadas; cada dato de los que se muestran corresponde al tiempo que ha sobrevivido un paciente con el respectivo tratamiento. Después se muestran las gráficas correspondientes a los tratamientos.

Tratamientos



a) ¿Qué tipo de tratamiento preferirías (1 o 2)? ¿Por qué?

Figura 1. Problemas resueltos por las profesoras.

El cuestionario fue resuelto por las profesoras en formación previo a iniciar el curso de procesamiento de información estadística. Los problemas tenían un inciso donde se plantea una situación de toma de decisiones. En el problema 1 se dan las ganancias y pérdidas de dos juegos y se pide elegir el juego en el que más convendría jugar y en el problema 2, los tiempos de años vividos en forma gráfica de dos grupos de pacientes después de someterse respectivamente a uno de dos tratamientos, y se solicita decidir cuál es el mejor tratamiento. En el primer problema las *medias aritméticas* de los conjuntos de datos son iguales mientras que en el segundo son diferentes. En ambos casos es importante la interpretación de la dispersión asociada con el riesgo para justificar la elección. A continuación se comentan los resultados obtenidos en cada uno de los problemas resueltos por las profesoras, se inicia este apartado presentando las respuestas al problema 1 y después se muestran las correspondientes del problema 2. Para analizar las respuestas en primer lugar

Galindo, E., & Newton, J., (Eds.). (2017). *Proceedings of the 39th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* Indianapolis, IN: Hoosier Association of Mathematics Teacher Educators.

se observó la decisión que tomaron, es decir, el conjunto de datos que eligieron y en segundo lugar, se categorizaron las respuestas con base en las estrategias de comparación que describieron en sus justificaciones siguiendo las sugerencias de Birks y Mills (2011).

Resultados

Problema 1

La solución normativa del problema 1 consistiría en comparar las *medias* y posteriormente considerar la dispersión (que a través del rango sería suficiente). En el caso de que se perciba el riesgo en ambos juegos, la opción elegida dependerá de las actitudes del riesgo de quien resuelve el problema: Elegirían el juego 1 aquellos que son adversos al riesgo, mientras que optarían por el juego 2 los propensos al riesgo. Las frecuencias con las que se eligió alguna de las opciones fueron las siguientes: 58 (de 97) futuras profesoras eligieron el juego 1, mientras que 31 de ellas seleccionaron el juego 2, y 5 participantes respondieron que elegirían cualquiera y las 3 restantes no respondieron. Ninguna de las argumentaciones para dichas elecciones siguió el esquema de razonamiento que se describió en el párrafo precedente; aunque algunas se aproximaron. Un procedimiento común en todas las estrategias consistió en sumar las ganancias de cada juego (los valores positivos) y agregar sus pérdidas (valores negativos pero sin considerar el signo), obteniéndose cuatro valores G_1, G_2, P_1, P_2. La forma en que combinaron estos valores produjo las siguientes comparaciones:

Comparación de la diferencia entre ganancias y pérdidas. En 30 casos, la estrategia consistió en encontrar la ganancia global cada uno de los juegos. Esto mediante la comparación de las diferencias entre ganancias y pérdidas: $G_2 - P_2 = G_1 - P_1 = 49$. Este procedimiento prefigura el uso de la *media*. 16 alumnas participantes eligieron el juego 1, 8 normalistas el juego 2 y 6 futuras profesoras mencionaron que cualquiera. Por ejemplo, una estudiante argumenta: “al hacer las operaciones la diferencia de ambos juegos entre perder y ganar es de 49”. Aquí advertimos que no se tiene en cuenta la dispersión de los datos ni consideraciones de riesgo.

Comparación de la suma de pérdidas o ganancias. 19 respuestas se basaron, ya sea en la comparación de la suma de las ganancias (eligieron el juego 2, porque $G_2 > G_1$) o en la comparación de la suma de las pérdidas (eligieron el juego 1 porque $P_1 < P_2$, pues $-P_1 > -P_2$). En algunas de estas respuestas se percibió el riesgo. 9 participantes eligieron el juego 1 y 10 participantes el 2. Por ejemplo una participante eligió el juego 1 y la justificación de su elección fue la siguiente: “Existe la posibilidad de poder obtener una ganancia ya que de acuerdo con los resultados de las muestras del juego 1 las ganancias fueron de 105 y pérdidas de 56, pero en el segundo juego las ganancias fueron de 427 y las pérdidas de 378. En conclusión en el primer juego se perderá menos que en el segundo aunque los premios sean mejores en el segundo”. Mediante esta argumentación consideramos que la justificación de la elección fue con base en la comparación de la suma de las pérdidas, observando que son menores en el juego 1, y descubrimos aversión al riesgo ya que en la justificación se comenta “se perderá menos”.

Comparación de relaciones proporcionales entre ganancias y pérdidas. En 6 casos se compararon relaciones proporcionales entre pérdidas y ganancias, notando que es mayor la del juego 1: $\frac{G_1}{P_1} > \frac{G_2}{P_2}$, por tanto, optaron por este juego. Dado que las *medias* son iguales, la anterior desigualdad se reduce a $P_1 > P_2$, en el fondo esta estrategia consiste en elegir el juego 1 porque se pierde menos. Un ejemplo de este tipo de respuestas fue mencionada por una estudiante, quien mencionó: “porque por los datos se refleja que en este juego hay más probabilidades de salir ganador ya que el número de ganadores casi duplica el de perdedores y aunque fue menos cantidad lo ganado que en el juego 2, en el 1 es más seguro ganar aunque sea poco, y yo no elegiría el juego 2 porque aunque se ganan cantidades más grandes de igual forma se pierde mucho”. En este ejemplo se observa, por un lado el uso de la razón entre las ganancias y las pérdidas y, por otro la aversión al riesgo ya que en parte del argumento se comenta que "es más seguro ganar aunque sea poco".

Comparación de las medias aritméticas. Sólo hubo 2 respuestas en las que el juego elegido fue el 1, donde mostraron el uso de la media aritmética para hacer la comparación entre los juegos, en una de ellas además de presentar la media aritmética (4.9) con la justificación siguiente: "Las cantidades son más bajas, están más cercas de la media". En el ejemplo se advierte, además de la mención de la media, la noción de la dispersión al elegir el juego 1 con valores cercanos al centro del conjunto de datos.

Problema 2

La solución normativa del segundo problema puede reducirse al cálculo de las *medias* de los tiempos de vida de cada tratamiento, notando que los datos del tratamiento 1 tienen mayor *media* (6.7) que los del tratamiento 2 (6). Con lo anterior, también puede elegirse el tratamiento 2, considerando la dispersión mediante el rango e interpretándolo como riesgo. Se creería que el riesgo con el tratamiento 1 (rango = 8) es mayor que el riesgo con el tratamiento 2 (rango = 4) y que la disminución en el riesgo podría compensar la diferencia entre las medias. En este último caso la elección estaría motivada por una aversión al riesgo. En este problema 60/97 profesoras en formación eligieron el tratamiento 1 y 37/97 el tratamiento 2. En los argumentos que justifican las elecciones de las participantes se pueden identificar las siguientes estrategias de comparación:

Comparación de centros. En 31 respuestas se compararon los valores modales observados en cada gráfica. En 19 de ellas se eligió el tratamiento 1, posiblemente comparando las modas de los conjuntos de datos (8 > 6), por ejemplo, una justificación fue: "hay más probabilidades de vivir más años (8 aprox.)". En 12 casos eligieron el tratamiento 2 probablemente con base en la proporción de personas que vivieron seis años, por ejemplo: "aquí me garantizan 7 personas que van a vivir 6 años seguros, sin embargo en el "1" 6 personas viven 8 años, es seguro pero yo voy más por el número de personas que tomaron el tratamiento". En esta estrategia aunque se tienen en cuenta los centros de los conjuntos de datos, se ignora la variación de los datos.

Comparación de valores extremos. 19 participantes eligieron con base en uno de los valores extremos. Cuando el tratamiento elegido fue el 1, en 8 respuestas se argumentó que con ese tratamiento se podrían vivir hasta 10 años; 2 estudiantes justificaron dicha elección indicando que vivirían por lo menos 1 año. En 9 casos se eligió el tratamiento 2, justificando que se vivirían por lo menos 4 años. Un ejemplo de este tipo de respuestas donde se eligió el tratamiento 1 fue: "El tiempo vivido en años por persona es mayor; se puede llegar a vivir 9 o incluso 10 años, lo que en el otro tratamiento no". En las respuestas donde el tratamiento elegido es el 1, es probable que la elección sea motivada por una propensión al riesgo, ya que se menciona que se puede vivir hasta 10 años; mientras que las respuestas donde el tratamiento elegido fue el 2, es probable que sean motivadas por una aversión al riesgo, pues comentan que al menos pueden vivir 4 años.

Comparación de cardinalidad. Doce estudiantes que eligieron el tratamiento 1 basaron su elección en la cardinalidad del conjunto de datos (27 > 21) y entre sus argumentos comentaban que más personas habían vivido con esa opción. Por ejemplo: "porque hay más probabilidad de que funcione ese tratamiento ya que fueron 27 las personas beneficiadas"

Comparación con el rango. En 6 respuestas se hizo alusión al rango. En estas respuestas se ponderó el riesgo, aunque de manera confusa, por ejemplo: "prefiero probar el tratamiento donde hay una mayor probabilidad de obtener un resultado más próximo o al menos que si te asegure o muestre que vivirás mínimo dos años más o máximo 10 años". En 4 respuestas el tratamiento elegido fue el 1, mientras que 2 eligieron el 2 con el argumento del hecho de asegurar un periodo de vida de 4 a 8 años.

Comparación de centro y extremo. En 4 respuestas se eligió el tratamiento 1, en uno de estos casos se expresa que se podían vivir hasta 10 años y en promedio 8 (en realidad es la moda), y en 2 restantes se eligió el tratamiento 2, probablemente, considerando que por lo menos vivirían 4 años y en promedio 6 con la justificación: “porque en el tratamiento 1 la mayoría de personas lograron vivir 8 años y en el tratamiento 2 la mayoría sólo logró vivir 6 años y no hay ni una persona que haya vivido 10 años, al contrario del primer tratamiento que una persona ha logrado vivir 10 años. Por lo tanto si ya una persona logró los 10 años la persona que necesita el consejo puede también vivir 10 años”. En la respuesta es claro que la estudiante observó centros (valor *modal*) y extremos para tomar una decisión, quizás también la preferencia por el riesgo sea la propensión, porque con ese tratamiento “1 persona ha logrado vivir 10 años”.

Comparación del centro y la dispersión. En una respuesta se combinaron centro y dispersión para justificar la elección. El tratamiento elegido fue el 2 y la justificación: “El tratamiento fue más funcional ya que se tiene que las personas viven aproximadamente de 4 a 8 años, con mayor influencia a los seis años pues son años más concretos, donde se puede planear muy bien su vida” .

En los resultados obtenidos 38 de las 97 participantes que seleccionaron el problema 1 y 28 de las 97 que eligieron el problema 2 no mostraron una justificación clara al elegir entre los conjuntos de datos. Por ejemplo en el problema 1seleccionaron el juego 2 y mencionaron “porque en el juego 2 se tienen más probabilidades de ganar más cantidad de objetos que en el juego 1”, sin embargo no encontramos una estrategia evidente que represente lo mencionado, además del uso de la palabra *objetos* que no corresponde con el contexto planteado. En el problema 2, las participantes sólo explicaron su elección diciendo “con alguno de los tratamientos se vive más”, pero sin ofrecer argumentos que muestren cómo se usaron los datos.

Conclusiones

En el problema 1 casi 40% de las respuestas fueron confusas; sin embargo en algunas de éstas se advirtió que las futuras profesoras ponían atención a las diferencias entre los valores de cada conjunto de datos, lo cual es punto de partida en la percepción de la variación. Así, en el problema de los tratamientos médicos se presentan varias respuestas en las que se comparan elementos aislados de cada conjunto (los máximos, los mínimos o las modas), y aunque no siempre fueron combinados de manera adecuada, puede sugerirse una estrategia que incluya todos los datos o combinaciones de éstos. En el problema de apuestas probablemente las respuestas en las que se afirma que se gana más o se pierde menos, la atención de las participantes también se enfocó en elementos aislados (en particular en los valores extremos).

La estrategia de sumar las ganancias y luego las pérdidas tiene la característica de que se consideran todos los datos. En el problema 2 varias futuras docentes usan relaciones proporcionales en las que combinan y hacen uso de más de un valor del conjunto de datos, ya sea operando con ellos o mencionándolos de manera explícita. La comparación de las ganancias totales prefigura la respuesta más sofisticada consistente en comparar las medias, lo que no es una estrategia espontánea ni fácil de elaborar por parte de los alumnos (Gal, Rothschild & Wagner, 1989), y la cual pudo observarse en las futuras docentes. En la enseñanza se insiste en la importancia de la proporcionalidad, y por ello considerarla como estrategia indispensable para resolver cualquier problema, y en nuestra investigación fue empleada en la comparación de las razones en el problema 1. Consideramos que no es una estrategia del todo inadecuada, pues las llevó a elegir el juego en el que la pérdida es menor. Esta manera de resolver es más apropiada en el problema 2, en la que comparan proporciones de los valores modales.

Son pocas las respuestas basadas en la consideración de los rangos (6%) o influenciadas por la percepción del riesgo (problema 2). Lo que mostraron las participantes en relación con los dos problemas es que son muy diferentes, pues ninguna de ellas adaptó en el problema 2 la estrategia seguida en el problema 1; esto nos lleva a suponer que el contexto y el formato de presentación de los datos ejercen mayor efecto que la estructura (oculta) del problema. Asimismo, en el problema 1, en general, hubo revisión de los datos, mientras que en el problema 2, en 20 casos se eligió un tratamiento sin ofrecer ninguna justificación que incluyera un procesamiento de los datos debido, quizá, a la dificultad de extraer los datos numéricos de la gráfica (valores extremos de cada conjunto de datos y aparente ausencia de la lista de datos). En cambio, en este problema 2 las estudiantes ponderaron el riesgo en la forma de elegir el tratamiento 1: "se puede vivir 10 años" o tratamiento 2: "al menos se viven 4 años".

De los resultados mostrados se percibe que al igual que en investigaciones previas (Canada & Makar 2006; Mooney et. al, 2014) es necesario promover en las profesoras en formación, conceptos estadísticos como *centro*, *variación*, *distribución, valores esperados.* Las estrategias a seguir deben ser múltiples (discusiones, talleres, uso de la tecnología, resolución de problemas enmarcados en diferentes situaciones, formatos variados de presentación de los datos, entre otros) para que las futuras profesoras se apropien de estos conceptos. Además, las educadoras mexicanas en servicio deben abordar en el aula la agrupación de objetos según sus atributos, cualitativos o cuantitativos; la recopilación y representación apropiada de datos e información, así como su interpretación (SEP, 2011); los procesos anteriores requieren de la consideración de la variabilidad (Franklin, Kader, Mewborn, Moreno, Peck, Perry & Scheaffer, 2007) por lo que es necesario que desarrollen este concepto. Esta investigación aporta información sobre el conocimiento de las profesores en formación acerca de la variabilidad, concepto estadístico importante (Spangler, 2014), y mostramos, de manera incipiente, que los problemas con los cuales hemos explorado el razonamiento de las profesoras en formación conducen a percibir la variación dándole un significado asociado al riesgo para presentar estrategias que las guiaron a usar la *media* y el *rango* de manera significativa y a motivarlas a planear actividades que propicien dar sentido y significado a los procedimientos basados en el uso de la media y la dispersión.

The aim of this investigation is to explore the preservice teachers´ reasoning about variation (variability or spread) when they analyze data in situations that involve risk. In particular, in this communication the responses to two problems of a questionnaire administered to 96 preservice teachers are reported. The problems are of comparing groups of data in situations of risk: stakes in games and the life expected after medical treatments. The questionnaire was applied before the preservice teachers began a course of statistical information processing and the results showed the difficulty found by students to interpret variation in this type of contexts. For these results it is necessary to reflect on the instruction of future teachers about the meanings of measures of center dispersion and dispersion to contribute to an improvement in their academic training.

Introduction

Variation is the underlying cause of the existence of statistics and, given its omnipresence, it is also found in data sets (Watson, 2006). Moore (1990) highlights the importance of measuring and modelling variation while Wild and Pfannkuch (1999) include the perception of variation as part of the fundamental types of statistical reasoning. Additionally, Garfield and Ben-Zvi (2008) consider that "Understanding the ideas of spread or variability of data is a key component of understanding the concept of distribution, and is essential for making statistical inferences" (p. 203). For their part, Burrill and Biehler (2011) propose a list of seven fundamental statistical ideas in which variation is placed in the second position. Regarding the school perspective, Franklin, Bargagliotti, Case, Kader, Sheaffer and Spangler (2015) consider that teachers must identify the characteristics of statistics; they must communicate it clearly and, particularly, they should highlight variability and the role of the context. In the description of variability, they have to consider that data are constituted by a structure (mean or median) around which they vary. To that respect, Canada and Makar (2006) found that, when solving problems on distributions, preservice teachers have an intuitive perception of variation. They describe it using informal language while the mean is rarely used. Other researchers, as Mooney, Duni, VanMeenen and Langrall (2014), state that when exploring on the perception of variability in chance situations, preservice teachers identify a certain amount of variability must be present, but have no certainty about how much. From the preceding researches, it is necessary to provide future teachers with experiences in both data analysis and chance situations in which they can develop concepts as: *center, variation, distribution, expected values* and the relations between them.

To explore the students' comprehension and reasoning regarding the perception, description and measurement of data variation, several contexts and problems have been used; among them are: sampling variability (Watson & Moritz, 2000), chance (Watson & Kelly, 2004), repeated measures, variation in growth of plants (Lehrer & Schauble, 2007; Petrosino, Lehrer & Schauble, 2003) and weather (Reading, 2004). According to these researchers, risk situations provide another scenario to explore the students' reasoning on variability (Sánchez & Orta, 2013). Therefore, the aim of this work is to explore the way in which preservice preschool teachers interpret the spread of data in risk situations, so that they know fundamental statistical concepts towards their professional improvement. For this reason, it is of great importance to include the knowledge of statistical concepts in their education; such concepts will allow them to promote collection, representation and interpretation of information at preschool level (SEP, 2011). In addition, we must consider that these concepts will be taught to their students in other educational levels (Ball, Thames & Phelps, 2008).

Reference Framework

This exploration is located within the field of statistical reasoning whose approach is to understand how people reason using statistical ideas (Garfield & Ben-Zvi, 2008). We seek to propose characteristics to create learning scenarios since the participants of an investigation show the elements they consider important—particularly, the chosen data, operations done, beliefs and knowledge—when they try to justify their responses. Although the persons' responses are often not so explicit as to clearly reveal their reasoning, they still show signs to identify some of their features. In this study, we identified some of the characteristics of the preservice teachers' reasoning when they face risk situations.

Problems are a key component in an investigation on mathematics didactics. When solving them, they must promote the ability of thinking and reasoning in people to provide the researcher with relevant results that contribute with information to the field of work. A problem should also attract those who solve it, so that they engage with the solution and increase the probabilities of understanding the studied concept. In statistics, reasoning must articulate ideas, as median or spread, expressing those using numbers; that is, with real situations based on data. Statistical reasoning is closely related to the contexts and numbers in context involve information (Moore, 1990). Problems regarding decision making under uncertainty are common in statistics. This type of problem has been used to promote and analyze relevant characteristics of people's statistical reasoning. In addition, those situations that demand the comparison of data sets are frequently used to involve students in reasoning with data (Garfield & Ben-Zvi, 2008). In this work, we present two situations involving decision making and data set comparison in which spread is important since it might be associated to the notion of risk which, in turn, might be linked to the uncertainty in an event that involves a threat. These situations arise when there are unwanted results that cause, in consequence, losses or damages. A paradigmatic problem in a risk scenario consists of choosing between two gambling games that show losses and gains (Kahneman & Tversky, 2000). Consider the following problem:

The gains observed in n repetitions of a game A (x_n) and m of game B (y_m) are:
Game A: $x_1, x_2 \ldots ; x_n$

Game B: $y_1, y_2 \dots ; y_m$
In which of the two games would you take part?

A solution to the problem might be: 1) comparing the arithmetic means of both games ($\bar{x}$ and $\bar{y}$); 2) if $\bar{x} \neq \bar{y}$, choose the game whose mean is greater; 3) but if $\bar{x} = \bar{y}$, 3a) choose any game or 3b) analyze the spread of data in each game and choose according to the preferences towards risk. These preferences can be defined as generalization of the attitudes towards risk:

> In general, a preference for a sure outcome over a gamble that has higher or equal expectation is called risk aversion, and the rejection of a sure thing in favor of a gamble of lower or equal expectation is called risk seeking (Kahneman & Tversky, 2000, p. 2).

In a gamble, the spread of gains (including losses) can be considered a measure of risk: greater spread, greater risk. A person averse to risk will choose a data set with lower spread instead of one whose data have a greater spread. In contrast, a risk-seeking person will choose a data set with a greater spread.

Method

The participants in the study were 97 preservice teachers from a public teacher training school in Mexico City who study a Bachelor of Preschool Education (care of children aged 3–6 years). A questionnaire including two problems regarding comparison of data sets (see Figure 1) was used to explore the preservice teachers' ideas.

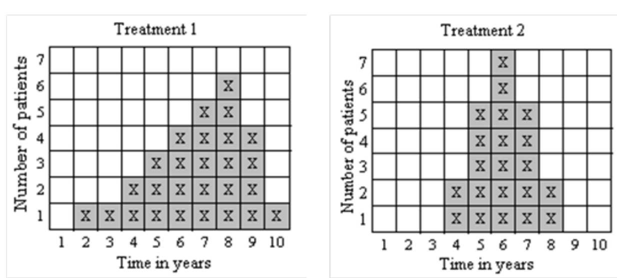
Problem 1.In a fair, the attendees are invited to participate in one of two games, but not in both. In order to know which game to play, John observes, takes note and sorts the results of 10 people playing each game. The cash losses (–) or prizes (+) obtained by the 20 people are shown in the following lists:

Game 1: 15, –21, –4, 50, –2, 11, 13, –25, 16, –4

Game 2: 120, –120, 60, –24, –21, 133, –81, 96, –132, 18

a) If you could play only one of the two games, which one would you choose? Why?

Problem 2. Consider you must advice a person who suffers from a severe, incurable and deathly illness, which may be treated with a drug that may extend the patient's life for several years. It is possible to choose between two different treatments. People show different effects to the medication: while in some cases the drugs have the desired results, in some others the effects may be more favorable or more adverse. The graphs corresponding to the treatments are shown below.



a) Which treatment would you prefer (1, 2 or 3)? Why?

Figure 1. Problems solved by the teachers.

The questionnaire was answered by the preservice teachers before they took the course on statistical information processing. The problems included a section in which a decision-making situation is posed. In problem 1, the gains and losses in two gambles are given and the person is asked to choose the most convenient gamble. In problem 2, the person is asked to graphically choose the times of years lived by two groups of patients after they underwent either of two treatments; the person is asked which the best treatment is. In the first problem, the arithmetic means of the data sets are equal while they are different in the second problem. In both cases, interpreting the spread associated to risk is important to justify the choice.

Below we discuss the responses obtained for each of the problems solved by the teachers. The section starts with the responses to problem 1 and then, those obtained for problem 2. To analyze the responses, firstly we observed the decision the participants made, that is, the data set they chose. Secondly, we categorized the responses based on the strategies of comparison the teachers describe in their justification, as suggested by Birks and Mills (2011).

Results

Problem 1

The normative answer to problem 1 would consist in comparing the means and then, considering the spread (considering it through the range would be enough). In case risk is perceived in both gambles, the option chosen will depend on the risk attitudes of the person solving the problem: those averse to risk would choose gamble 1 while gamble 2 would be chosen by risk-seeking persons. The frequencies corresponding to the options were as follows: 58 (out of 97) preservice teachers chose gamble 1 while only 31 of them chose gamble 2. Only 5 participants responded they would choose any gamble and 3 teachers did not answer. No argumentation for the choices followed the reasoning scheme described in the previous paragraph, even though some arguments came close. A common procedure to all the strategies was adding the gains of each gamble (positive values) as well as the losses (negative values without considering the sign), thus obtaining four values $G1, G2, P1, P2$. The way in which these values were combined produced the following comparisons:

Comparison of the difference between gains and losses. In 30 cases, the strategy consisted in finding the global gain in each of the gambles by comparing the differences between gains and losses: $G2 - P2 = G1 - P1 = 49$. This procedure prefigures the use of the mean. 16 participants chose gamble 1 while 8 preservice teachers chose gamble 2 and 6 answered they would choose any. For example, a student argues: "when doing the operations, the difference in the two gambles between gaining and losing is 49." Here we observe they do not take into account the spread of data nor risk considerations.

Comparison of the sum of gains or losses. 19 teachers based their response whether on the comparison of the sum of the gains (they chose gamble 2 because $G2 > G1$) or on that of the sum of losses (they chose gamble 1 since $P1 < P2$, given that $-P1 > -P2$). Risk was perceived in some of these responses: 9 of the participants chose gamble 1 while 10 chose the second one. One of the participants who chose gamble 1 justified her choice by saying: "There is the possibility of getting a gain since, according to the results of the samples of gamble 1, there were 105 gains and 56 losses, but in the second gamble there were 427 gains and 378 losses. In conclusion, in the first gamble there will be fewer losses than in the second one; although the prizes are better in the second one." Through this argumentation we consider that the choice was based on the comparison of the sum of losses: her perception was that losses are lower in gamble 1. We found risk aversion since, in her justification, the participant says "there will be fewer losses".

Comparison of proportional relationships between gains and losses. In 6 cases, the participants compared proportional relationships between gains and losses, noticing that the one of gamble 1 is greater: $\frac{G_1}{P_1} > \frac{G_2}{P_2}$. That is why they chose this gamble. Given that the means are equal, the previous inequality is reduced to $P1 > P2$. In reality, this strategy aims to choosing gamble 1 because there are fewer losses. As an example, one of the students justified her response by stating: "because from the data, there is a greater probability of winning in this gamble since the number of winners almost doubles the one of the losers and even if the gain was lower than in gamble 2, winning—even if it is a little—is more certain in 1 and I would not choose gamble 2 because although bigger amounts are won, losses are high too." This is an example of both the use of reason between gains and losses and risk aversion, since the argument includes the statement "winning—even if it is a little—is more certain".

Comparison of arithmetic means. Only 2 responses showed the use of arithmetic mean to compare the gambles, and gamble 1 was chosen in both cases. One of the responses showed the arithmetic mean (4.9) and justified the response by saying "the numbers are lower and closer to the mean". In the example we see that besides mentioning the mean, the participant has a notion of spread when she chooses gamble 1, which has values that are closer to the center of the data set.

Problem 2

The normative answer to the second problem can be reduced to the calculation of the means in the life expectancy for each treatment, considering that the data of treatment 1 have a greater mean (6.7) than those of treatment 2 (6). Therefore, treatment 2 could also be chosen if one considers the spread using the range and interprets it as risk. Risk from undergoing treatment 1 (range = 8) might be thought to be greater than that from treatment 2 (range = 4) and that the decrease in the risk might compensate for the difference between the means. In this last case, the choice would be motivated by risk aversion. For this problem, 60/97 of the preservice teachers chose treatment 1 while 37/97 chose treatment 2. In the arguments that justify the participants' choices, we identify the following comparison strategies:

Comparison of centers. In 31 responses, the modal values observed in each graph were compared. In 19 of the responses, the participants chose treatment 1, possibly comparing the modes of the data sets (8 > 6). For instance, one of the teachers justified her response by saying: "there is a greater chance of living longer (8 approx.)". In 12 cases, the teachers chose the second treatment possibly based on the proportion of people who lived six years; for example: "7 persons guarantee that they will live 6 years for sure; however, 6 people live for 8 years in "1". That is for sure but I choose based on the number of persons who were treated". Even though the strategy considers the centers of the data sets, it ignores the data variation.

Comparison of extreme values. In 19 cases, the participants made their choice based on the extreme values. When treatment 1 was chosen, 8 of the responses argued that the treatment would extend the patients' lives for up to 10 years. Two students justified their choice pointing out they would live at least a year. In 9 cases, the students chose the second treatment and they justified their response by saying they would live for four years at least. An example of the type of response in which treatment 1 was chosen was: "The time in years a person lived is longer; a person can live 9 or 10 years; something that does not happen with the other treatment". In the responses where treatment 1 was chosen, the choice might have been motivated by risk seeking since the response states a person can live up to 10 years. In contrast, those responses in which the second treatment was chosen were probably motivated by risk aversion, given that they refer patients live at least for four years.

Comparison of cardinality. Twelve participants who chose treatment 1 based their response on the cardinality of the data set (27 > 21) and, among their arguments, they considered that a higher number of people had lived with that choice. For example: "because there is a greater chance that this treatment works since 27 persons were benefited".

Comparison with range. In six responses, the students referred to range. Although confusingly, they considered the risk; for example: "I prefer to take the treatment that has the higher probability of getting a close result, or at least that ensures you'll live at least two years or a maximum of 10 years". In four responses, the students chose the first treatment while they twice chose the second treatment, arguing that it would ensure a survival period from four to eight years.

Comparison of center and extreme. The students chose the first treatment in four responses. One of these responses expresses a person could live up to 10 years and eight in average (in reality, the response refers to the mode). Treatment 2 was chosen in two responses, probably considering a patient would live four years at least and six years in average. This response was justified as follows: "because in treatment 1, most of the people manage to live eight years and with treatment 2, most only live six years and there is no one who lived 10 years, unlike the first treatment [with which] a person has managed to live for 10 years. So, if a person has already managed for 10 years, the person in need of advice might also live for 10 years". From the response, it is evident that the student observed centers (modal value) and extremes to make a decision. Risk seeking is probably driving the response since the student stated that using the treatment "a person has managed to live for 10 years".

Comparison of center and spread. In a response, the student combined center and spread to justify her choice. The student chose the second treatment and justified her response by stating: "The treatment was more functional since we have that the people live approximately from four to eight years and, more frequently, six years because they are more solid years, where life can be very well planned".

In the results obtained, 38 out of 97 participants who chose problem 1 and 28 out of 97 who chose problem 2, did not show a clear justification when choosing between the data sets. For example, in problem 1, they selected gamble 2 and considered: "because there is a greater possibility of winning a higher number of objects in gamble 2 than in gamble 1." However, we found no evident strategy to represent what was stated. Additionally, the use of the word objects does not correspond to the context laid out. In problem 2, the participants only justified their response by saying "one lives longer with one of the treatments", but provided no arguments to show how the data were used.

Conclusions

In problem 1, nearly 40% of the responses were confusing. However, in some of them we see that the preservice teachers paid attention to the differences between the values in each data set, which is a starting point for the perception of variation. Thus, in the problem of medical treatments, there are several responses which compare isolated element from each set (the maximums, the minimums or the modes) and, although they were not always combined in the correct way, a strategy including all the data or a combination of them might be suggested. In the gambling problem, the attention of the participants was probably focused on isolated elements—on extreme values, particularly—in those responses stating the gains are higher or the losses are lower.

The strategy of adding the gains and then the losses considers all the data. In problem 2, several preservice teachers used proportional relationships in which they combined and used more than one value from the data set by operating with them or mentioning them explicitly.

The comparison of the total gains prefigures the most sophisticated response consistent in comparing means, which is not a spontaneous nor easy strategy to create by the students (Gal, Rothschild & Wagner, 1989), but was observed among the preservice teachers.

When teaching, the importance of proportionality is highlighted; therefore, it is considered a necessary strategy to solve any given problem; in our research, it was used in the comparison of reasons in problem 1. We consider it is not an entirely incorrect strategy because it led the students to choose the gamble in which the loss is lower. This form of solving is more adequate in problem 2, in which the students compare the proportions of the modal values.

There are few responses based on the consideration of the ranges (6%) or influenced by the perception of risk (problem 2). With respect to the problems, the participants showed that they are different from one another, given that no student adapted the strategy followed in problem 1 to problem 2. This leads us to suppose that the context and the format of the presentation of the data have a greater effect than the (hidden) structure of the problem.

In general, the data were reviewed in problem 1 while 20 participants chose a treatment in problem 2 without providing a justification that included an adequate data processing. This situation was likely due to the difficulty of extracting the numerical data from the graph (extreme values from each data set and apparent absence of data list). In contrast, in problem 2 the students considered the risk when choosing treatment 1 "can manage to live for 10 years", or treatment 2, with which patients live for four years at least.

From the results shown, we observe that, as in previous research (Canada & Makar, 2006; Mooney et al., 2014), statistical concepts as center, variation, distribution and expected values in problems, must be promoted in preservice teachers. The strategies to be followed should be multiple (discussions, workshops, use of technology, solving problems with different contexts, and varied ways of presenting data, among others), so that preservice teachers appropriate these concepts. In addition, Mexican preschool teachers in service should deal with grouping objects, according to qualitative and quantitative characteristics, in the classroom. They should also address the collection and the adequate representation and interpretation of data and information (SEP, 2011). These processes demand considering variability (Franklin, Kader, Mewborn, Moreno, Peck, Perry & Scheaffer, 2007); therefore, teachers should develop this concept.

This research contributes with information regarding preservice teachers' knowledge on variability, a relevant statistics concept (Spangler, 2014). We incipiently show that the problems with which we have explored the preservice teachers' reasoning lead to perceive variation. The problems gave variation a meaning associated to risk when the teachers presented strategies that led them to use the mean and the range in a significant way. The problems presented also lead to motivate teachers to plan activities that promote giving sense and meaning to the procedures based on the use of mean and spread.

In the present study we analyze how students reason about or make inferences given a particular hypothesis testing problem (without having studied formal methods of statistical inference) when using Fathom. They use Fathom to create an empirical sampling distribution through computer simulation. It is found that most student´s reasoning rely on data and assimilate natural sampling variation, which are two fundamental ideas of inference. This result represents a significant change in their natural reasoning. An important misconception is believed Fathom simulates samples of the real population instead of a hypothetical one.

Keywords: High School Education, Technology, Informal Education.

Introduction

Literature shows many difficulties on the learning of statistical inference (Batanero, 2000) Castro-Sotos, Vanhoof, Van den Noorgate, & Onghena, 2007). One possible reason is that statistics courses generally focus on teaching procedures and routine concepts and do not offer the opportunity to discuss and understand the fundamental ideas. As a consequence, students reach their first inferential reasoning experience thinking that statistics is only about the computation of numerical values. This has motivated the interest in studying Informal Statistical Inference (IEI) and Informal inferential Reasoning (IIR). Researchers have recently been exploring the idea that if students begin to develop the informal ideas of inference early in a course, they may be better able to learn and reason about formal methods of statistical inference. In this context, the simulation (as opposed to the formal calculation) can be used to begin to teach the process logic and concepts that still need on the contrast of hypotheses (Batanero & Diaz, 2015). However, there are few studies on the RII aimed at students of high school (15-18 years).

Students present a lack of perception of sampling variation (García-Rios & Sánchez, 2014) and a lack of consideration of the data (García-Rios & Sánchez, 2015). This study seeks to show how a sampling distribution simulation activity has the potential to overcome these difficulties. In addition, this proposal presents a simulation by computer that can support the development of inferential reasoning for promoting the understanding of hypothesis tests. Therefore, we are interested in the questions: How students reason on significance testing when they participate in activities using the simulation of Fathom? How would Fathom support the learning of students?

Literature Review

Recently, several studies have focused on the concept of Informal Inferential Reasoning (IIR), as confirmed by the publications of special issues; Statistics Research Journal (Pratt & Ainley, 2008), and Mathematical Thinking and Learning (Makar & Ben-Zvi, 2011). Literature shows two different approaches to study the RII: the first approach focuses on the nature of reasoning about inference given problems and statistical information, while the second approach focuses on the evaluation of the development of the RII as students undergo a course of instruction designed to develop the reasoning. In this paper we focus on the first approach.

Garcia-Rios and Sánchez (2014) show that students have a lack of consideration of data and a low probability language; students often draw inferences based on personal beliefs instead of data and conclusions do not show any degree of uncertainty. In addition, when students based on data,

Galindo, E., & Newton, J., (Eds.). (2017). *Proceedings of the 39th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* Indianapolis, IN: Hoosier Association of Mathematics Teacher Educators.

they have an inappropriate way to determine if a statistic sample is significant; if the statistic is different from the hypothesis tested then it rejects the hypothesis. A plausible cause of these difficulties is the lack of perception of sampling variation (Garcia-Rios and Sánchez, 2015). These authors also observed that Fisher's test of significance comes more natural to students because they establish a null hypothesis (personal model of the population) to compare the sample and intuitively measure their significance (although inappropriate). It is concluded that in order to develop appropriate inferences before formalizing, it is crucial for students to have an informal method to determine a numerical criterion to know when rejecting or accepting the hypothesis and the simulation seems to be a resource that provides such method.

Rossman (2008) provides a characterization of informal statistical inference and makes a distinction between informal and intuitive, although it does not define it, just exemplified it by establishing some essential features of situations and problems of statistical inference and shows how it can informal methods be used to solve them. Zeiffler, Garfield, delMas, and Reading (2008) proposed a definition of the IIR and exposed three types of activities that should be generated by the tasks to develop it; they also propose a conceptual framework to characterize the RII and develop tasks that allow you to examine the natural IIR of students, as well as the development of such reasoning.

Conceptual Framework

In this work, the conceptual framework is understood as a network of related concepts or categories that together provide a general understanding of the phenomenon of research (Miles & Huberman, 1994).

Significance Tests

There are two different points of view about hypothesis testing: a) significance tests introduced by Fisher and b) testing rules to decide between two hypotheses, which was the opinion of Neyman and Pearson (Batanero, 2000). The approximation of Fisher emphasizes the strength of the evidence provided by the data observed against a null hypothesis. The strength of evidence is captured in the p-value, which measures the likelihood of having obtained an extreme result (or more extreme) if the null hypothesis were true. Under this assumption, the sampling distribution is calculated and from this distribution p-value is estimated; if the retrieved value is very small (statistically significant) the hypothesis is rejected.

Informal Inferential Reasoning

Several papers published in the last few years refer to the concepts of ISI and IIR, however there still no consensus as to what exactly these two concepts mean. In an attempt to combine the different perspectives, Zieffler, et al. (2008) defined the IIR as the way in which students use their informal knowledge of statistics to create arguments based on observed samples that support inferences about a population unknown. To emphasize the importance of informal reasoning we remember the ideas set by Bruner in 1960 (see Heitele, 1975) who believes that it is preferable that student begin to study the subject gradually, although initially only understand it either limited or informal, rather than wait until it matures and can teach directly in more abstract or formal. Teaching is not different in a structural way in the various educational stages, but only of a linguistic form and their level of deepening.

Method

This study is part of a Hypothetical Learning Trajectory (HLT) to develop students reasoning at the high school level. In this proposal, we focus on the reasoning of the students on significance testing with the use of technology while they completed a first task of a series of four, without having studied formal methods of statistical inference.

Participants

Thirty-six 11th grade (16-17 years of age) students, grouped in 18 pairs (referred to as R1 to R18) with a computer per couple, participated in the study. The participants had not studied statistics hence they lacked basic knowledge of statistics and never worked with Fathom. This means that the activities carried out have the objective of emerging student's insights on basic knowledge about significance testing and the use of Fathom.

Instruments

Data collection was conducted through a questionnaire applied in computer, in a two-hour class session. The data set are the answers given by pairs of students in a report about the conclusion of a proportion testing hypothesis problem. This report was written on the computer. The problem says "Coca cola claims that majority (more than 50%) of the population drinking cola prefer Coca rather than Pepsi. To check, an experiment where one gave two glasses of soda (one with Coca and other with Pepsi) to 60 people selected randomly from the population was done and they should decide what liked most. The 60 participants 35 people preferred Coke. Is the Hypothesis 'over the 50% of the population who drink cola in Mexico drink prefers that Pepsi Coca" correct?' Make a report were you: a) explain what your conclusion is: b) details how you came to your conclusion step by step: c) say what so sure of your conclusion are".

Process

Fathom's simulation and the problem were presented to students during the first hour to introduce and operate the software; generate random samples and sampling distributions. In the second hour, pair students were allowed to work freely to make a report of its findings (answers) on the computer; the teacher intervened only to answer small personal questions. When reports were finished students can leave class. Fathom simulates 500 samples (size 60) taken from a hypothetical population, where the parameter can be modified by a slider. Samples are represented in a bar graph and in a table (Figure 1). The simulation is used to generate an empirical sampling distribution and measure the likelihood of the observed data with the empirical method (frequency), i.e. the informal calculation of a p-value using frequencies (Rossman, 2008). The sampling distribution is shown in a table and a graph of points.

Results

Principles and techniques of *Grounded Theory* (Birks & Mills, 2011) were used to categorize students responses. This methodology claims that it is possible to develop emerging categories of data collected and analyzed systematically. The constant comparison of the data favors a full development of the categories and their properties (advanced coding) making it analytically powerful and therefore with the capacity to explain the phenomena under study. The categories of analysis that emerged from the data were: *sample, majority in simulation, mode in simulation and proto-significance test*. Each category reflects the different types of inferential reasoning posted in the student's reports. For analysis, responses were coded with the letter R and a number (table 1).

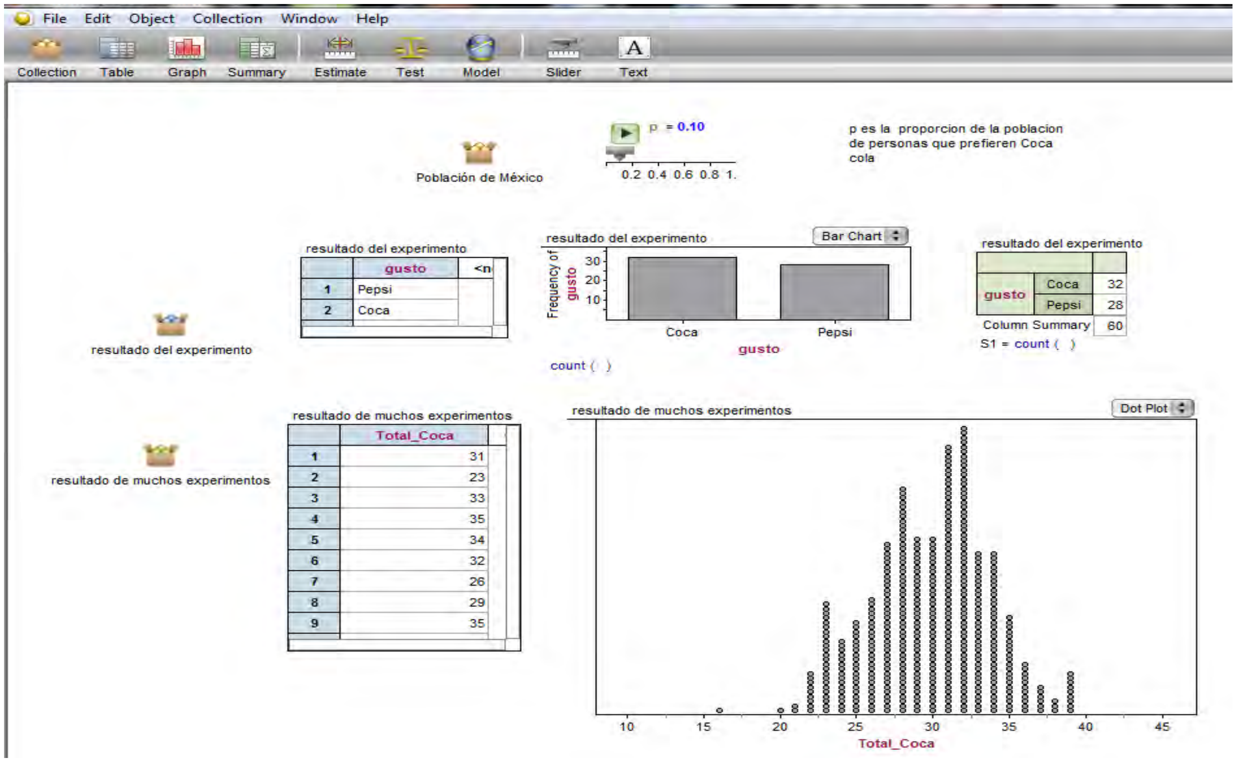

Figure 1. Fathom simulation screen.

The p-value of the statistic (0.58) is 0,098, so the hypothesis P = 0.5 is not rejected at a significance level of 5%. The categories of analysis that emerged from the constant comparison of data and explain the IIR students are: Sample, majority in simulation, mode in simulation and Proto-significance test.

Table 1: Students Reasoning

Category	Pair	Reasoning
Sample (10%)	R1, R3	If sample is bigger than 30 then hypothesis is incorrect
Majority in simulation (69%)	R2, R4, R5, R6, R7, R8, R9, R10, R11, R14, R16, R17	If majority of samples are bigger than 30 then hypothesis is correct
Mode in simulation (16%)	R18, R13, R15	If mode is bigger than 30 then hypothesis is correct
Proto-significance test (5%)	R12	Sample can occur within a population smaller than 0.5 therefore hypothesis can't be prove

Sample

Responses within this category are solely based on sample data and do not consider the simulation results. This reasoning implies an absence of the idea of sampling variation. Therefore, if the proportion of the sample is greater (or smaller) 50%, students conclude that the hypothesis "more than 50% (less than 50%)" is correct. An example of this type of response is the pair R3 who explains in his report: "... from 51% of the population we can say that it is the majority and because the result of the experiment showed that 35 people 60 prefer Coca Cola which is equal to 59% of the total (59% x 60) = 35.4) we can conclude that they are not wrong in what they claim since they are right". In its report, R3 added figure 2.

Figure 2. R3 Report.

Majority in Simulation

In this category the reasoning is to divide the sampling distribution in two regions; samples greater or equal to 30 (50%) represent the region that supports the hypothesis "most prefer Coca Cola" as correct (evidence against the null hypothesis), while less than 30 results represent the region which does not support the hypothesis. Thus, students come to their conclusion determining in which of these two regions are the most of samples. For example, R9 reason "... because if you select the rank of 37 we have 262 surveys... ". These couples add figure 3 and come to the conclusion that the hypothesis is correct. This reasoning suggests that students think that the results of the simulation with Fathom represent the actual population rather than a hypothetical, in addition, assimilate the sampling variation why they resort to determine in which region the most samples are. Some students use parameters greater than 0.5; R11 and R16 used P = 0.51, R4 use P = 0.54, and R10 and R14 use P = 0.6.

Mode in Simulation

The reasoning in this category focused on the mode of the simulated sampling distribution; If mode was greater than 30 (50%) then considered the hypothesis as correct (evidence against the null hypothesis). An example is R13 whom considered that the hypothesis is false, and reason "... our highest value in a survey was 29 people of 60 that liked more Coca-Cola, then from this we see that within that sample less than 50% like Coca-Cola". R13 added Figure 4.

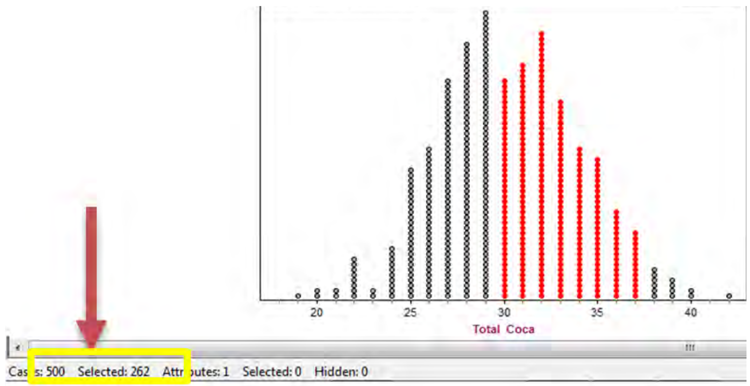

Figure 3. R9 report.

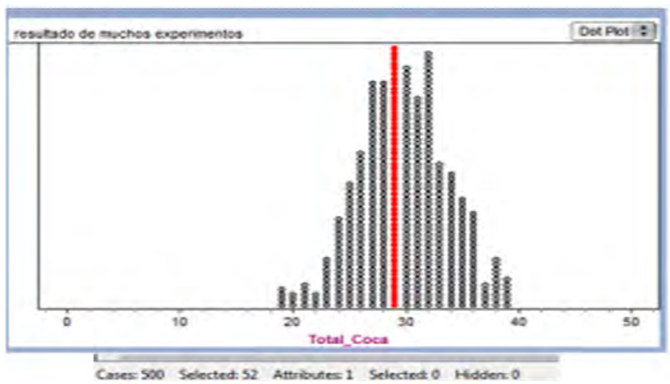

Figure 4. R13 report.

Proto-Significance Test

One interesting answer is the given by R12, whom conclude that it is not possible to test the hypothesis; "we must take a greater percentage of the population in general to the survey so we can conclude that more than 50% of the population actually likes or prefers Coca - Cola, because surveys within a range of 10 values greater and lesser around the expected value must be set" and continue "in the previous survey while the percentage is less than 50% (44%) a value of 26 is expected, I get results up to 16 (being the lowest) and 38 (being the highest) here we see a higher value that that the problem presents, where the majority of the population do not prefer Coca-Cola, so 35 does not ensure that the majority of the population like more Coca Cola". In other words, in a population less than 50% it is possible to obtain the sample; therefore the sample is not sufficient evidence to consider the hypothesis as correct.

Discussion

One of the principles of the constructivist approach applied to teaching is that for any new learning design the knowledge that the student already possesses should be used and articulated. Consequently, if it is to develop the students reasoning, is convenient to have the tools to know what knowledge and reasoning has and what are the false conceptions that limit them or blocked them. The answers to the research questions will give us knowledge to this end.

How students reason on significance testing when they participate in activities using the simulation of Fathom? The first important result is that all the arguments of the students were based on data. This is, no student based his reasoning on personal beliefs, difficulty found in (Garcia-Rios & Sánchez, 2014). The second result to highlight is the assimilation of the idea of sampling variation by the majority of pairs of students (90%). It is considered that reasoning based on simulated sampling distribution have assimilated the sampling variation in some degree, when considering regions (variation of results of samples) and decide to take a statistician; majority or mode. An example of sampling variation assimilation explicit is R14 who wrote "although 50% of the population who likes Coca-Cola has been chosen, there are surveys were Pepsi wins the results". However, this assimilation is not sufficient to choose the outcome of the sample that rejects the null hypothesis (critical value). For a 5% level of significance should be 36, while students consider 30 (50%) or 31 (52%). This difficulty was also found in (Garcia-Rios & Sánchez, 2015).

The difficulties observed in the study are: 1) Sample-based reasoning. (2) A lack of variation to estimate the region that supports the hypothesis. (3) Although students use the simulated sampling distribution they didn't understand their role; responses suggest that students think that fathom simulation represents the actual population rather than a hypothetical.

How would Fathom support the learning of students? The use of absolute values and simulation of surveys made more visible and understandable abstractions such as the sampling distribution and its process. In the traditional teaching of the hypothesis testing a transformation of the statistics (typing or standardization) and the central limit theorem is used to calculate the p-value and determine the critic zone (of rejection) with help of the normal distribution. This is perhaps one of the darker aspects of all the techniques to students. The possibility of putting the notion of sampling distribution in the center of the discussion of a significance test is probably the main contribution of the use of educational software (in this case Fathom). In addition, the students described and explained the observed behavior instead of relying exclusively on theoretical arguments of probability, which often is counterintuitive for students (delMas, Garfield, & Chance 1999). These results show a path to follow for the development of the reasoning in the significance test. First, it must be understood that Fathom not simulates the actual population but a hypothetical; this can help to pass to the next level of reasoning. Secondly, based on the fact that many students assimilated sampling variation, discuss how to choose a sample result (critical value) to reject the hypothesis to verify, this will lead to the idea of p-value.

MANUFACTURING LICORICE: MODELING WITH DATA IN THIRD GRADE

Lyn D. English
Queensland University of Technology
l.english@qut.edu.au

This paper reports on a study of 3rd-grade students' modeling with data, which involves comprehensive investigations that draw upon STEM-based concepts, contexts, and questions, and generate products supported by evidence and open to informal inferential thinking. Within a real-world STEM-based context of licorice manufacturing, students experienced the "creation of variation" as they compared and represented the masses of "licorice sticks" they made by hand (using Play-Doh) and those using a Play-Doh extruder. By generating their own statistical measures, students could observe the features of data distributions including center, range, typical, and middle, at a much younger age than usual. They could draw inferences from the models they created, with awareness of how variation limits the certainty with which predictions can be made. The study supports a potential route for advancing early statistical learning.

Keywords: Data Analysis and Statistics, Modeling

Introduction

This paper aligns with the first conference theme of potential routes for mathematics education for the future, specifically, pertaining to the statistical capabilities of young learners. Despite research revealing how young elementary students are more competent in dealing with statistical problems than is acknowledged (e.g., Lehrer & Schauble, 2012; Lehrer & English, in press), many curricula continue to delay core statistical experiences until the middle and early secondary school years (e.g., *Common Core State Standards: Mathematics*; http://www.corestandards.org/Math). Yet young children are exposed to a vast array of statistical information that can, at times, misinform, rather than inform their receptive minds. The ability to reason effectively with data, including entertaining uncertainty and risk, is integral to making meaningful, informed decisions across all spectrums of life. One cannot participate effectively in debates about community issues such as the environment, health care, and education, without this reasoning ability (English & Watson, 2015; Franklin, Kader, Mewborn, Moreno, Peck, Perry, & Scheaffer, 2007). Foundational statistical experiences need to begin early. By undertaking their own investigations, elementary school students can learn to make critical decisions with data, where variation and uncertainty are ever present.

This paper reports on third-grade students' modeling with data, which involves comprehensive investigations that draw upon STEM-based concepts, contexts, and questions, and generate products that are supported by evidence and are open to informal inferential thinking (Lehrer & English, in press). In the present study, students experienced the "creation of variation" as they compared the masses of "licorice sticks" they made by hand (using Play-Doh) with those made using a Play-Doh extruder kit ("factory-made"; adapted from Watson, Skalicky, Fitzallen, & Wright, 2009). Students chose their own forms of representation in displaying their models for the two forms of licorice production, and identified, compared, and explained the features of their data distributions.

Modeling with Data

There are various interpretations of modeling and modeling with data, as reported by English, Arleback, and Mousoulides (2016). As defined here, modeling with data includes: (a) an appreciation of how and why investigative questions are posed and refined within a STEM context; (b) competence in generating, selecting, and measuring attributes; (c) skills in organizing, structuring, and representing data; (d) an ability to interpret evidence-based models including features of data distributions; and (e) making informal inferences while acknowledging variation in the data, and the uncertainty with which any conclusions can be drawn (cf. Makar, Bakker, & Ben-Zvi, 2011; Lehrer & English, in press). Figure 1 displays these core features of modeling with data. Consideration is given to a selection of these modeling components.

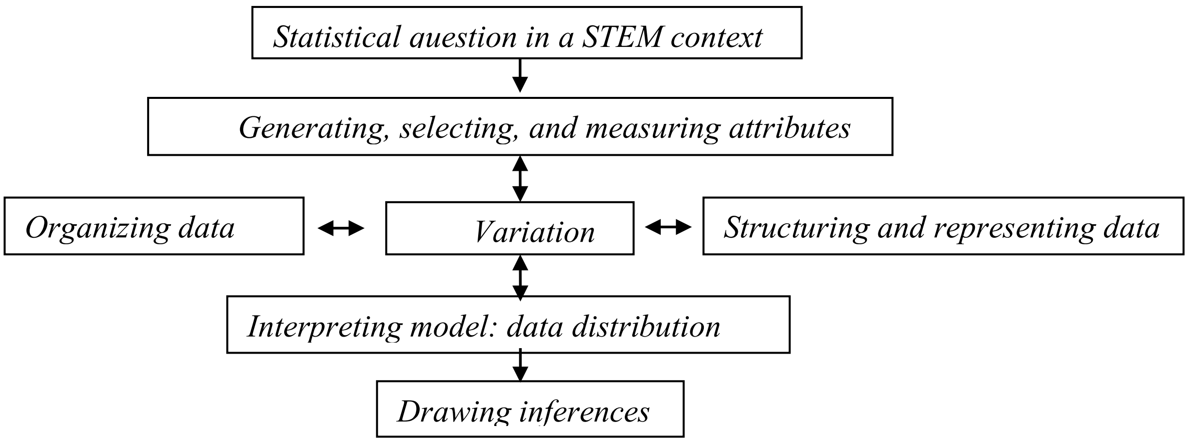

Figure 1. Modeling with data.

STEM Contexts

A statistical question is the starting point for any investigation and immediately raises the issue of problem context and cross-curriculum links. Because data are numbers in context (Moore, 1990), there is no statistics without a problematic situation from another field. Understanding the contextualized nature of data is crucial in developing a facility with statistics. Yet, elementary school curricula tend to give superficial or limited attention to the role of context, especially with respect to whether inferences drawn from the inquiry process align with both the question and context (Lavigne & Lajoie, 2007). With the increased focus on STEM education, including STEM integration (English, 2016) numerous rich contexts arise for undertaking statistical investigations. In the present study, engineering formed the statistical context where students explored the manufacture of licorice and the roles of various engineers (industrial, manufacturing, chemical) in the production process. Such a context highlights the need for quality control in the manufacturing process to reduce product variation.

Variation

Variation is the underlying concept linking all aspects of a statistical investigation; without variation, there would be no need for statistics (Cobb & Moore, 1997; Franklin et al., 2005; Garfield & Ben-Zvi, 2008; Konold & Pollatsek 2002; Moore, 1990; Watson, 2006). In simple terms, variation is “the quality of an entity (a variable) to vary, including variation due to uncertainty” (Makar & Confrey, 2005, p.28). As Watson (2006) highlighted, the reason data are collected and analyzed is to manage variation and draw conclusions and inferences about phenomena that vary. Although there is considerable research on older students’/adults’ awareness of variation there is less so on how this understanding can be developed with young students. This is a major concern especially given that secondary school and university students frequently apply statistical techniques without appreciating or understanding why, when, or how these are applied sensibly to a range of contexts (Garfield & Ben-Zvi, 2008).

Data Distribution

Developing the concept of variation necessitates some understanding of distribution, where patterns in the variability of the data are of interest and are displayed visually (Makar & Confrey, 2005). Exploring learners' concept of variation provides a window into their understanding of distribution. Research has shown that younger students can come to recognize statistics as ways of measuring characteristics of distribution, which guide inferences about the questions posed (Lehrer & English, in press; Makar, 2014). One way to support and advance this early development is to provide children with opportunities to generate statistical measures of center and spread, and to observe how these indicate a distribution's characteristics (Bakker & Gravemeijer, 2004; Konold & Pollatsek, 2002; Lehrer & English, in press). Activities that involve repeated measures yield data distributions that display "signals" (measures of center) and "noise" (measures of variability), which can help students make sense of statistics as measures (Konold & Pollatesk, 2002). It has been argued that when students develop this understanding, they are viewing data through the lens of distribution, in contrast to just a set of data values (Bakker & Gravemeijer, 2004). In today's increasingly data-driven world, young learners deserve access to these core statistical foundations. Future directions in mathematics education need to consider increasing this access in the elementary mathematics curriculum.

Model Representation and Interpretation

Models created through working with data are usually defined as systems of representation, where structuring and displaying data are fundamental; the structure is created, not inherent (Lehrer & Schauble, 2007). Young learners' ability to create and work with a range of representations, including those that extend beyond traditionally accepted formats, is underestimated and needs to be given more recognition and nurturing. In particular, the explicit consideration of variation in relation to representations has not been a key feature of research in the elementary years. Yet, a major foundational component of young students' statistical growth is being able to interpret the meaning, within a given context, of a distribution that displays variation, clusters, modes, and unexpected values; this might not involve conventional text-book types of graphs. Early experiences with a range of representations that effectively display variation in data sets are important but have remained largely neglected in many elementary curricula until recently. Greater insights are needed into how young learners deal with variation in representations that they, themselves, create from their investigations, including how they respond to questions on comparing variation in different data sets, and how they identify and justify the sources of variation that they encounter. With the increasing impact of technology, young students are exposed to more complex and more varied representations that require careful interpretation and critical analysis rather than mere visual inspection.

Drawing Inferences

Informal inference, a precursor to formal inference, has been highlighted as a foundational component that also has not received the required attention especially in the elementary grades. Informal inference is the process of using the evidence provided by data to answer questions beyond the data, acknowledging the uncertainty associated with the conclusion reached (Makar, 2016). Variation is the key to accepting a conclusion with some degree of uncertainty (Franklin et al., 2007). The confidence with which one can form a decision, however, depends on creating a balance between variation and expectation/prediction (Watson, 2006). In the senior secondary courses of study, this balance is expressed in tests of significance or confidence intervals but learning to appreciate variation and its relationship to expectation/prediction needs to begin in the elementary grades with appropriate hands-on experiences and student/teacher questioning.

In addressing these foregoing components of modeling with data, this paper reports on three questions investigated: (1) *How did students represent the models generated for each licorice-*

making method? (2) *How did the students interpret variation and overall data distribution?* and (3) *What was the nature of the informal inferences children drew from their models?*

Methodology

Participants

The activity was implemented in two schools, one a private girls' school, and the other, a co-educational Catholic school. The data in this paper are confined to one class in the former school (mean age of 8.8 years), which was situated in a middle socioeconomic area.

Research Design

The activity was the first that was implemented in a 4-year longitudinal design-based study (Cobb, Jackson, & Dunlap, 2016). This research design caters for complex classroom situations that contain many variables and real-world constraints, supports learning and informs future learning experiences, and facilitates contributions to both theory and practice. Data collection included video-taping of three focus groups as they worked the activity, as well as all class discussions, which were subsequently transcribed for analysis. Focus groups comprised three students of mixed achievement levels selected in consultation with the class teacher.

Activity and Implementation

The activity was created in collaboration with the teacher and formed part of her regular mathematics program in the area of data and probability. The teacher implemented the activity across three school days. The researcher and research assistant were in attendance for the entire activity to observe the students' learning. A detailed lesson description was prepared for the teacher, as was a workbook for students. Students recorded their responses to a number of questions as they worked the activity. Although the students completed the activity in groups, they were to record their own answers and explanations in their workbooks.

The activity comprised several parts including: (a) Reviewing an earlier science activity where students made tubes of lip balm, and discussed variation in their products; (b) Learning about engineers and engineering involved in the manufacture of licorice and foods in general (students viewed a YouTube clip of the American Licorice Co.); (c) Experiencing the notion of variation through exploring packets of manufactured licorice; (d) Investigating questions regarding differences in making licorice sticks by hand (using Play-Doh) and with a Play-Doh extruder ("manufactured"). For each of the hand-made and "manufactured" methods, students identified, measured, compared, and recorded attributes including mass; within-group results were compared; (e) Collating group data on the masses, and representing the group data in a format of choice, for each method; (f) Sharing and interpreting resultant group models from each method with the whole class, including identifying the range and "typical" masses displayed in each group model; (g) Collating all group data and creating a class representation; interpreting the resultant whole-class model of the distribution of the licorice stick masses, for each method.

Data Analysis

For the present paper, data are drawn from the students' workbooks, together with the recorded and transcribed group work and whole class discussions. In conjunction with an experienced research assistant, content analysis (Patton, 2002) was applied in initially identifying, coding, and categorizing the data recorded in the students' workbooks. A further round of refined coding was undertaken to ensure meaningfulness and accuracy. Iterative refinement cycles for video-tape analyses of conceptual change (Lesh & Lehrer, 2000) were applied in reviewing the transcribed focus group and whole class discussions to ascertain the students' learning pertaining to variation, distributions, and inferential reasoning.

Results

This section considers how students represented their models, their interpretations of the variation and data distribution displayed, and the nature of the inferences they drew.

Models Represented

Students represented in various ways their models displaying the licorice-making results. Although forms of bar graphs were most popular, these differed in students' approaches to organizing and structuring their data. For example, many students (78%, N=23) structured their data according to each group member's results (e.g., Monica, Kate, Sarah), while some (13%) ordered the data differently, such as from the "biggest licorice" to "second biggest", to "second smallest", to "smallest licorice" as illustrated in Figure 2. One student displayed each member's heaviest licorice stick only, while another used both tallies and a 3-way table.

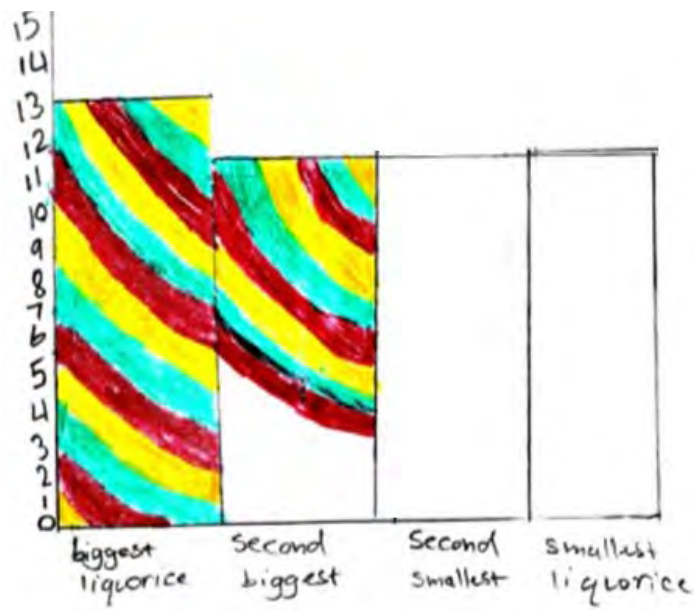

Figure 2. An example of one student's representation for her group's data

Interpreting Variation and Data Distribution

Students were readily able to identify the variation in masses for both the hand-made and factory-made methods, with 83% (N=23) identifying the variation in the former and all students (N=24) for the latter.

Likewise, the students had few difficulties in giving an initial reason for this variation in the hand-made sticks (87%, N=23) with explanations including reference to some sticks being "fatter" or "too thin" or "thicker". They found it more difficult, however, when asked to provide more than one reason.

Sixty-one percent (N=23) were able to offer two acceptable reasons for the hand-made variation, while less than half (48%) were able to give an appropriate third reason (e.g., they simply stated that the sticks "are all different weights"). Over half of the students (63%, N=24) were able to give three appropriate reasons for the factory-made method (58% offering a first reason, 71% a second, and 58% a third).

In collating the group results to form a class plot for each licorice-making method and describing the data distributions, 62% of the students (N=24) offered at least one feature for the hand-made licorice. Of these students, 33% noted multiple characteristics, such as "…lots of spaces and humps and sections and a lot at the start." Those who noted just one aspect gave reasons such as, "very, very lumpy", or "zig-zag." In contrast, all but one student was able to describe the distributional features of the class plot for the second method, with 79% (N=24) describing multiple features, suggesting that their understanding of distribution was developing as they experimented with the licorice-making methods. An example of the class plot for each licorice-making form appears in Figure 3.

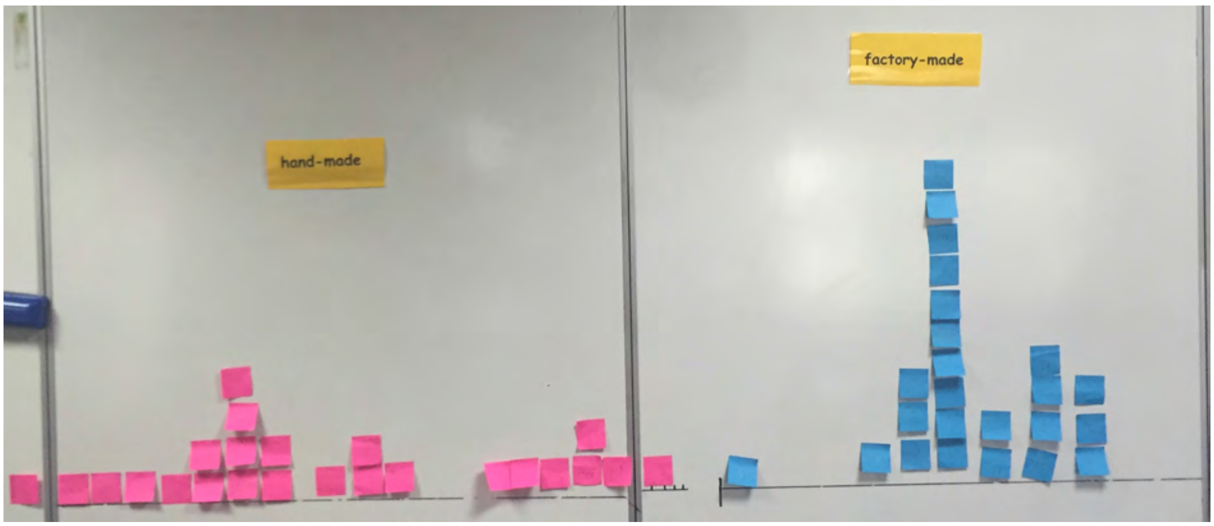

Figure 3. Class plots for each method.

In recording responses to questions about the variation in the masses and the typical mass of the licorice sticks for each class plot, the students again performed better in interpreting the plot for the factory-made licorice. For the hand-made, 58% of students (N=24) could describe the variation in the class plot (e.g., "There's more on 10 and less on 7; there are a lot of people between 8 and 16") and 62% for the factory-made class plot. Although a little over half the students (58%, N=24) could describe the typical mass for the hand-made class plot, 83% (N=24) could do so for the factory-made class plot. The students could readily recognize the difference in the two plots, with 88% (N=24) noting at least one difference. Of these, three students identified multiple differences such as, "Tuesday's (hand-made method) plot had a lot of variation. Thursday's plot (factory-made) had not that much variation. Thursday's plot was a lot taller than Tuesday's plot." The majority of students (71%, N=24) could explain that using the Play-Doh extruder was more accurate in producing sticks of a consistent mass (e.g., "Because it's a machine like, the machine makes them all about the same size and when you're doing them with your hands you can't really tell if they're going to be the same size or not").

Drawing Inferences

On completion of the class models created for each licorice-making method, students were asked, "If you made one more piece of licorice, what do you think (predict) its mass might be? How did you decide?" As part of a follow-up class discussion, the students were also asked, "If another student came into our class and made some licorice, what do you think hers would be (mass of licorice stick)?" Students were readily able to respond to the first question above with 88% identifying an appropriate mass range for the hand-made and 96% for the equipment-made (N=24).

The majority of students could also offer appropriate reasons for each decision, referring to either their own data (42% for hand-made and 33% for factory-made) or the whole class data (29% for hand-made and 46% for factory-made). Their reasons included, “I think because most of mine were around ten and mine were both exactly 1cm wide and 8cm long;” “because it is about the average;” and “I decided because 13g is the typical mass of sticks in the class.”

During class discussions, students frequently referred to chance and uncertainty when explaining what the mass of a licorice stick made by a new student might be. One student explained that, “It might be 13 because most people got … 13 so maybe that’s the typical number.” Another student responded, “I think maybe 12, because if she came in, there’s a chance, because the Fun Factory makes all of them um pretty similar and, and she could make it, but I decided on that [13g] because I think there’s a more likely chance that she would because it won’t always be bigger, she might get it a little smaller than some.” The teacher asked a further question, namely, “Would you expect, say, if we did it again next week and we used the same Play-Doh, and we used the same Fun Factory, would you expect the same plots?” Alesha commented, “I think they might be different because like we could do something, we may have like cut it a bit further or because it’s really hard to get everything exact, so it won’t always be exact.” Monica agreed, “…maybe or maybe not, I sort of agree … you actually don’t know because … when you made three of them like last week they weren’t all the same mass, they weren’t all 15 or they weren’t all 13…”

Discussion

This paper has illustrated how third-grade students can engage in modeling with data involving core statistical concepts and processes, when presented with a motivating context and a meaningful hands-on activity. Using a STEM-based context involving a licorice factory, students were able to explore the important roles of the various engineers responsible for manufacturing high-quality products. The importance of quality control in the real-world provided a valuable context for appreciating how the two forms of licorice making yielded different variations in the sticks produced. By generating and observing “variation in action”, the students could see how variation is an important factor throughout a statistical investigation. They developed an understanding of the reasons behind the greater variation in hand-made sticks and hence, the difference in data distributions of their hand-made and factory-made sticks. Students could identify foundational data distributional features including center, range, typical, and middle, which are usually not introduced until the later grades and then frequently in a computational manner. In line with other research, activities in which students create their own statistical measures of center and spread enable them to observe and understand the features of a data distribution (e.g., Bakker & Gravemeijer, 2004; Konold & Pollatesk, 2002). As Franklin et al. (2007) emphasized, “Statistical education should be viewed as a developmental process” (p. 13) and, as such, these foundational experiences need to commence in the elementary grades.

From the individual and whole-class representations of the models generated, students could draw inferences including predicting the masses of further sticks that might be made. Some awareness of chance and uncertainty was present as the students realized that variation in both licorice-making methods meant that predictions could not be drawn with absolute certainty. Given students’ realization of the uncertainty in drawing conclusions due to variation, the activity can provide foundations for chance explorations. For example, investigations involving the chances of selecting particular candies from factory produced packets can yield unexpected results due to variation in contents. Returning to the conference theme, the present results provide further support for moving mathematics education along a path that capitalizes on elementary students’ early statistical talents. Given the research that has already revealed these talents, greater attention is needed to further advance the field.

Acknowledgments

This study was supported by funding from the Australian Research Council (ARC; DP150100120). Views expressed in this paper are those of the author and not the ARC. Interstate collaborators (Jane Watson & Noleine Fitzallen) are acknowledged, together with the senior research assistant, Jo Macri, and the classroom teacher and her students. Feedback from the paper reviewers is also gratefully acknowledged.

PRESERVICE SECONDARY MATHEMATICS TEACHERS' STATISTICAL KNOWLEDGE: A SNAPSHOT OF STRENGTHS AND WEAKNESSES

Jennifer N. Lovett
Middle Tennessee State University
Jennifer.Lovett@mtsu.edu

Hollylynne S. Lee
NC State University
Hollylynne@ncsu.edu

Amid the implementation of new curriculum standard regarding statistics and new recommendations for preservice secondary mathematics teachers [PSMTs] to teach statistics, there is a need to examine the current state of PSMTs' common statistical knowledge. This study reports on the statistical knowledge 217 PSMTs from a purposeful sample of 18 universities across the United States. The results show that PSMTs may not have strong common statistical knowledge that is needed to teach statistics to high school students. PSMTs' strengths include identifying appropriate measures of center, while weaknesses involve issues with variability, sampling distributions, p-values, and confidence intervals.

Keywords: Teacher Education-Preservice, Teacher Knowledge, Data Analysis and Statistics

Many have argued the need to increase students' understanding of statistics (Shaughnessy, 2007). Accordingly, there has been recent increased emphasis on statistics content in secondary curricula standards in the U.S., informed by recommendations from the National Council of Teachers of Mathematics (2000) and the Common Core Standards for Mathematics (National Governors Association Center for Best Practice & Council of Chief State School Officers, 2010). However, a recent study of 1,249 high school students in the U.S. suggests that students are not developing a conceptual understanding of statistics (Jacobbe, Foti, Case, & Whitaker, 2014). Since many teachers, including preservice secondary mathematics teachers (PSMTs), have likely had minimal experience with statistics in their own K-12 education, they also may not have had many opportunities to develop strong statistical understandings.

The Conference Board of the Mathematical Sciences (2001, 2012) as well as the American Statistical Association (ASA, Franklin et al., 2015), present recommendations for developing statistical knowledge and pedagogy needed by preservice mathematics teachers to teach statistics. However, the lack of research focusing on the statistical knowledge of PSMTs was highlighted and called for in the 2011 International Congress of Mathematics Education Topical Study (Batanero, Burrill, & Reading, 2011). The majority of research on preservice teachers' statistical knowledge has focused on elementary teachers (e.g. Browning, Gross, & Smith, 2014; Hu, 2015; Leavy & O'Loughlin, 2006)). The limited research conducted on PSMTs' statistical knowledge has been small-scale studies, from a small number of institutions on specific statistical content (e.g., Doerr & Jacob, 2011; Lesser, Wagler, & Abormegah, 2014). While some smaller studies have suggested that PSMTs may struggle with statistics (e.g. Casey & Wasserman, 2015), there are no large-scale studies that describe the current state of new teachers' statistical knowledge. This study examines the statistical knowledge of a large cross-institutional sample of PSMTs as they enter student teaching to answer the question: *What are the strengths and weaknesses of PSMTs' knowledge of the statistical content they will be expected to teach*?

Framework

Groth (2013) developed a hypothetical framework for Statistical Knowledge for Teaching consisting of two domains of knowledge teachers need to develop: subject matter knowledge and pedagogical content knowledge. Developing subject matter knowledge and key developmental understandings of statistics is foundational to be able to develop pedagogical statistical knowledge.

Within subject matter knowledge there are three types: common content knowledge, specialized content knowledge and horizon knowledge. Common content knowledge refers to knowledge gained through statistics taught in school and is considered common because it refers to knowledge for daily literacy or in any profession that uses statistics. This study examines the common statistical knowledge of PSMTs since they will soon be expected to teach these common statistical ideas as part of curricula for high school students.

The *Guidelines for Assessment and Instruction in Statistics Education (GAISE) Report: A Pre-K-12 Curriculum Framework* (GAISE, Franklin et al., 2007) describes statistical reasoning students should develop in K-12 and suggests this reasoning develops across three levels A, B, and C. Although there are not explicit definitions given for statistical reasoning in each level, the levels increase in statistical sophistication and become more abstract. The content in Level A represents topics for early or novice learners of statistics (elementary and middle school), Level B represents slightly more advanced statistical content (middle school or early high school), and Level C represents even more advanced content (high school or introductory college courses) (Franklin et al., 2007). The GAISE report recommends that students learn statistical topics through engaging in a statistical investigative cycle consisting of: posing questions, collecting data, analyzing data, and interpreting results. Therefore, when examining PSMTs' common statistical knowledge, it is useful to consider their understandings across these cycle phases and all three GAISE levels.

Methodology

Participating Institutions

This study focuses on PSMTs prepared through university-based teacher preparation programs in the US. Since a random sample of all mathematics teacher preparation programs was unavailable, this study began with a purposeful narrowing on PSMTs who attend institutions in which some faculty have participated in the last 13 years in particular National Science Foundation (NSF)-funded or ASA-funded programs to increase the emphasis of statistics education at that institution. Faculty from 57 institutions participated in the NSF-funded program, Preparing to Teach Mathematics with Technology (PTMT, ptmt.fi.ncsu.edu), and/or the ASA-funded Math/Stat Teacher Education: Assessment, Methods, and Strategies (TEAMS, www.amstat.org/sections/educ/newsletter/v9n1/TEAMS.html) conference between 2002-2014. These institutions were chosen since faculty members received professional development focusing on explicit content and strategies for preparing PSMTs to teach statistics. Our assumption was that PSMTs from these institutions may have had opportunities to engage in statistics content and pedagogy activities in their coursework.

The sample was obtained by contacting all 57 institutions through their undergraduate program coordinator for mathematics education to inquire if the program was interested in participating. Twenty-four programs expressed interest, and 18 participated. The coordinator identified the last mathematics teaching methods course PSMTs take before student teaching, which would constitute the data collection point in either fall 2014 or spring 2015. Of the 18 institutions, all but one were public institutions. The majority of institutions (61.1%) had an Carnegie Classification™ (Carnegie Foundation for the Advancement of Teaching, 2011) enrollment profile of high undergraduate. Approximately 84% of participants attended institutions with a basic classification of Research Universities/Very High, Research University/High or a Master's college and university with a larger program.

Participants

Across 18 institutions, there were 221 PSMTs recruited by their mathematics teaching methods instructor to take the assessment of their statistical understanding, described in the next section, as an assignment as part of the course. Those who took exceptionally less time (10 minutes) than recommended by authors of the assessment were eliminated (Jacobbe, personal communication). This resulted in a sample size of 217 PSMTs. The PSMTs were undergraduate juniors and seniors, or graduate students earning initial licensure; all were enrolled in their last mathematics education course prior to student teaching. The number of PSMTs participating from each institution ranged from 2 to 31, with a mean of 12. Fourteen institutions had 100% participation of PSMTs who were eligible to participate, with the remaining four institutions having between one and four students who did not complete the assignment. The majority of PSMTs were female (71%), and 88% were Caucasian. Almost all (93.4%) reported they had taken at least one statistics course at their institution or had completed Advanced Placement Statistics in high school.

Data Collection and Analysis

To examine PSMTs' common statistical knowledge, the Levels of Conceptual Understanding of Statistics (LOCUS) assessment (Jacobbe, Case, Whitaker, & Foti, 2014) was administered online (locus.statisticseducation.org). The LOCUS instrument assesses understanding of statistics across the three GAISE levels of development and also assesses understanding within each phase of an investigative cycle: formulating questions, collecting data, analyzing data, and interpreting results. Participants took the 30 multiple choice Intermediate/Advanced Statistical Literacy version of the assessment, which was designed for students in grades 10 – 12. The test consists of two level A questions, 11 level B questions, and 17 level C questions. This version has been validated and reliable with students in grades 6-12 to assess statistical knowledge across levels B and C and the four phases of the investigative cycle (Jacobbe, personal communication); while this instrument is not intended as a high stakes assessment of knowledge, it does represent the statistics content PSMTs are expected to teach their students in the near future. Thus, teachers are expected to score fairly high on the assessment. While actual test items cannot be released due to test security, sample items for the four categories at different levels are available on the LOCUS website (locus.statisticseducation.org/professional-development). Each test-taker receives an overall score (percent correct), as well as sub-scores for Level B, Level C, Formulating Questions, Collecting Data, Analyzing Data, and Interpreting Results.

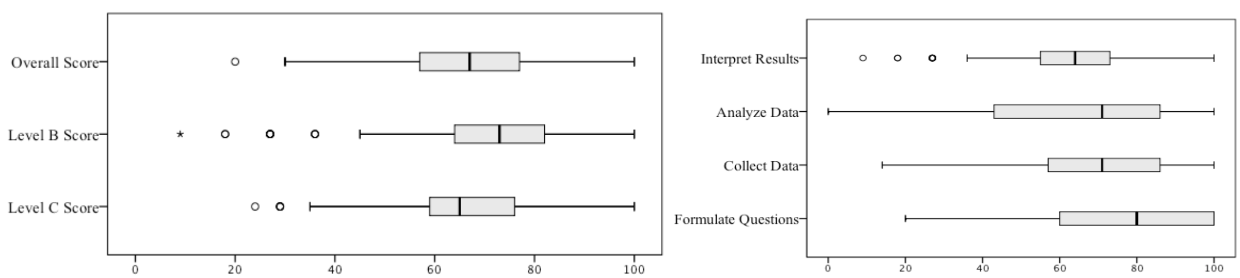
To examine the statistical knowledge demonstrated by PSMTs, descriptive statistics were computed for the overall score and each subscore. Paired samples t-tests were used to test for significance of PSMTs' statistical knowledge between GAISE Levels B and C and a repeated measures ANOVA used to test for significant differences in PSMTs' statistical knowledge between the four phases of a statistical investigation. An item analysis was conducted to closely examine PSMTs' strengths and weaknesses.

Results

Trends in scores on the LOCUS test can help in describing what PSMTs from these 18 universities currently understand about the statistics content they will soon be responsible for teaching. The summary statistics for PSMTs' scores are reported in table 1. With a mean overall score of 69%, and a standard deviation of 14.06, PSMTs do not seem to demonstrate a conceptual understanding of the statistical content they will teach high school students. PSMTs scored, on average, significantly higher on Level B questions than on Level C questions ($t=5.772$, $p<0.001$), demonstrating that their statistical knowledge is weaker as items increase in sophistication. The distribution of PSMTs' scores is shown in figure 1. The boxplots show that for the overall scores and subscores, there are at least some PSMTs who scored between 90-100% correct, indicating that they likely have strong common statistical knowledge of topics they will soon be responsible to teach. However, there is a concern since only one-quarter of PSMTs scored overall above 77%, and a quarter scored below 57% overall. The variation in scores seems somewhat similar for Level C scores. However, higher standard deviation in Level B scores is likely due to the increased quantity of low scoring individuals, indicated as outliers in figure 1.

Table 1: PSMTs' Percent Correct on LOCUS Instrument

	Number of items	Mean	SD
Overall Score	30	68.61	14.06
GAISE Levels			
Level B Score	11	70.85	17.69
Level C Score	17	64.87	14.16
Phases of Statistical Investigative			
Cycle	5	80.37	21.51
Formulating Questions	7	70.40	19.70
Collect Data	7	63.34	22.22
Analyze Data	11	60.48	16.25
Interpret Results			



Figures 1 and 2. Distribution of PSMTs' LOCUS scores

Examining subscores by phases in the statistical investigative cycle, PSMTs scored higher on average on Formulating Questions and lower as the cycle progresses, scoring lowest on Interpreting Results items (Table 1). A repeated measures ANOVA determined that mean scores differed significantly between scores for the four phases [$F(3,648)=64.73$, $p<0.001$]. Post hoc tests using a Bonferroni correction revealed that PSMTs scored significantly lower as the cycle progressed ($p<0.001$). However, there was only a slight difference between mean scores for Analyze Data and Interpret Results ($p=0.32$). The distribution of scores across the four phases is shown in figure 2. The boxplots show that for all four phases, there are again some PSMTs who scored between 90-100%, indicating that those PSMTs likely have the common content knowledge that will be needed when teaching that phase of the investigative cycle. On Formulating Questions items, at least half of PSMTs scored 80% or higher, and a quarter of those scored 100%, indicating stronger understanding for these PSMTs about Formulating Questions. However, half of PSMTs scored below 71% on Collecting Data and Analyzing Data items, and half scored below 64% on Interpreting Results items. Even being conservative, this result is convincing that the majority of these PSMTs do not have the common statistical knowledge that can provide a foundation for teaching students key concepts related to Collecting Data, Analyzing Data, and Interpreting Results.

Item Analysis

Upon further analysis of individual items classified by the statistical investigative cycle, themes emerged concerning PSMTs' strengths and weakness. As previously mentioned, PSMTs scored the highest on average for Formulating Questions items, with no common misunderstanding identified. As an example of their strength in understanding this phase, PSMTs were able to read a description of a study and measurements taken to identify an appropriate statistical question of interest.

Collecting Data. On average, PSMTs scored the next highest on Collecting Data items. PSMTs were able to identify ways to improve a study design given a study and measurements, identify which study design would be best based on a question of interest, and identify a data collection plan based on a study description. Thus, these PSMTs seem to have strong common content knowledge related to the design of a statistical study.

Even though PSMTs were able to develop a data collection plan, they struggled more when asked to identify how to choose a sample to minimize bias. Only 64.5% were able to choose a correct sampling method; instead, 30% chose a convenience sample or a stratified sample that seemed complicated but was not random. Thus, they do not seem to have a strong understanding of the role of an appropriate sampling method within the design of a study. Another common misunderstanding of PSMTs was the conclusion that could be drawn from a specific study design. Figure 3 is a similar item to the one PSMTs were asked on the assessment. Over 58% of PSMTs chose an answer similar to answers (A) and (C) that allowed a researcher to generalize results to an entire population based on a sample of volunteers. These findings highlight PSMTs' need for a deeper understanding related to ways in which study designs and data collection processes impact the conclusions that can be drawn.

Each member of a random sample of 1,000 adult males from the United States was asked a number of questions, including questions about height and annual income. When the responses were analyzed, it was determined that taller men had greater incomes than shorter men, on average, and the difference was statistically significant. Which of the following conclusions would be most appropriate based on these results?

(A) The study establishes that being tall causes men to have greater incomes, on average, and this conclusion can be generalized to all men in the United States.
(B) The study establishes that being tall causes men to have greater incomes, on average, but this result only applies to the men in the sample.
(C) The study establishes that being tall causes men to have greater incomes, on average, than shorter men, and this conclusion can be generalized to all men in the United States.
(D) The study establishes that being tall causes men to have greater incomes, on average, than shorter men, but this result only applies to the men in the sample.

Figure 3. Sample Collect Data item from locus.statisticseducation.org.

Analyzing Data. PSMTs' average scores for Analyzing Data items were the second lowest among the phases, and had the highest variability. PSMTs demonstrated that they understand which measure of center is appropriate for a given context, how measures of center and variation change when data values are changed, and a justification of an association from a two-way table. However, PSMTs demonstrated more difficulty with Analyze Data items that involved understanding of variation in data. Only 43% of PSMTs could identify a histogram containing data that varied the least from its mean. Instead 30% of PSMTs chose a uniform distribution and about 20% thought variability from the mean was the same for all three distributions. PSMTs demonstrated another misunderstanding related to expected variation in sample means when repeatedly sampling from a population. When given the distribution of a population and population mean, 36% of PSMTs could not identify the distribution of sample means. Instead they chose distributions that resembled the general shape of population distribution. These results point to PSMTs' need for more common content knowledge in regards to variation, sample distributions, and distribution of sample statistics.

Interpret Results. PSMTs scored the lowest on average on Interpret Results items. However, on five of the eleven Interpret Results items, 84% or more of PSMTs answered the items correctly. PSMTs were able to compare distributions in a context using the center and spread, demonstrate an understanding of the effect of sample size on a sample mean, and interpret survey results with a given margin of error. These are important concepts often taught in middle and high school curricula. On the other six Interpret Results items, the percentage of PSMTs responding correctly to these items ranged from 21% to 48%, and their misunderstandings were related to ideas of formal inference. PSMTs struggled most with statistical significance, identifying and interpreting a p-value, and explaining confidence intervals. About half (48%) of PSMTs were able to correctly interpret results given a large p-value and fail to reject the null hypothesis (Figure 4). However, 40% of PSMTs chose a conclusion that a large p-value meant they could reject the null hypothesis.

Mario wondered if students who graduated from a nearby college with an engineering degree would have higher yearly salaries, on average, than students graduating with a degree in mathematics. To investigate, he randomly selected ten engineering graduates and eight mathematics graduates. He calculated the mean yearly salary to be $58,421 for the ten engineering graduates and $58,402 for the eight mathematics students. The difference in the sample means of $19 per year resulted in a p-value of 0.478. Based on this information, which of the following statements is correct?

(A) The difference in means is both statistically significant and practically significant.
(B) The difference in means is neither statistically significant nor practically significant.
(C) The difference in means is practically significant, but not statistically significant.
(D) The difference in means is statistically significant but not practically significant.

Figure 4. Sample Interpret Results item from locus.statisticseducation.org.

On another item regarding p-value, PSMTs were asked to reason if a p-value would be large or small for comparing means of two distributions given data on a dotplot. Only 35% of PSMTs were able to correctly identify that the p-value would be small due to the large gap between distributions. Almost 47% incorrectly answered that the p-value would be large due to a large gap between the distributions. These findings demonstrate that PSMTs on average do not have an understanding of what it means to be statistically significant and what a p-value represents, aspects of common content knowledge expected in statistics, and included in many high school curricula.

The item PSMTs had the most difficulty with in Interpreting Results asked the test taker to explain the meaning of a 95% confidence interval for a mean. Approximately one-fifth chose the correct response that a 95% confidence interval represents that 95% of confidence intervals constructed from random samples would capture the true mean. Almost half of PSMTs chose the response that there was a 95% probability that the mean was in between the lower and upper limits of the confidence interval. These misunderstandings highlight the need for PSMTs to have more experiences with interpreting and understanding confidence intervals.

Discussion and Conclusion

Our study was situated within a purposeful sample of PSMTs enrolled in teacher education programs where a faculty member had participated in professional development projects that promoted increasing attention to statistics in secondary mathematics education courses. It is not known exactly how those teacher education programs currently include an emphasis on statistics, nor exactly what these PSMTs experienced at all 18 institutions. Nonetheless, there are several findings of this study that are significant to consider. Our results provide empirical evidence that PSMTs in this study generally do not exhibit a strong common content knowledge of many aspects of statistics needed for teaching high school students, and in particular they struggle more with the later phases of a statistical investigation. Previous research has shown a similar trend with inservice teachers and students measured by LOCUS (Jacobbe, 2015; Jacobbe, Foti, et al., 2014). Thus, PSMTs need more experiences in collecting data, analyzing data and interpreting results to develop a deeper understanding of all aspects of the statistical investigative cycle and to develop common statistical knowledge needed for teaching.

PSMTs exhibit some similar strengths and weaknesses with concepts that high school and introductory college students develop. An important strength that PSMTs demonstrated is that they are proficient at identifying an appropriate measure of center for a given context. PSMTs' strength in understanding measures of center suggests they should be well equipped to assist their future students develop stronger conceptions. PSMTs' weaknesses involve issues with variability, sampling distributions, p-values, and confidence intervals. Many researchers have identified that these topics are also often misunderstood by many students in undergraduate statistics courses (e.g., Aquilonius & Brenner, 2015; Castro Sotos, Vanhoof, Van de Noortgate, & Onghena, 2007; delMas, Garfield, Ooms, & Chance, 2007); thus, PSMTs' common statistical knowledge may be no better than those of other college students not preparing for teaching.

These findings, even though from a purposeful sample, suggest there is a critical need for mathematics teacher education programs to reevaluate the opportunities PSMTs' have to increase their common statistical knowledge. Our results specifically indicate that effort should focus on developing PSMTs' knowledge of variability, sampling distributions, and formal inference, particularly as they are applied in the analyzing data and interpreting results phases of an investigative cycle. While this study only reports on one aspect of PSMTs' statistical knowledge for teaching, the larger study (Lovett & Lee, 2017) provides more details about PSMTs' confidence to teach and the experiences they perceived had contributed to their confidence and understandings in statistics. Additional large-scale studies are needed on all aspects of PSMTs' statistical knowledge for teaching and the impact that teacher education programs have on PSMTs' preparedness to teach statistics.

Texas State University
sigley@txstate.edu

This study investigates the development of pre-service teachers' (PSTs) probability and statistics knowledge in a technological collaborative environment. The teachers collaborated synchronously in an online environment to solve a probability task that involves investigating the fairness of different dice. Teachers used simulations to roll six dice and collect data about them with different sample sizes. The simulations allow users to roll each die up to 1,000 rolls and represent the outcomes in a frequency table, bar graph, and a pie chart. While investigating the fairness of the dice, teachers engaged important statistical and probabilistic concepts to reason about data. Results showed that interactions between experimental and theoretical probability helped teachers further their understanding of distribution, data dispersion, and the Law of Large Numbers. This informs supporting PSTs learning of probability and statistics.

Keywords: Probability, Data Analysis and Statistics, Technology, Teacher Knowledge

Introduction

Today's society relies heavily on technological innovations that make collecting, analyzing, and presenting quantitative data easily accessible. This stresses the importance of preparing students for such reality. As a consequence, mathematics educators are attending more to teaching and learning statistics and probability. The National Council of Teachers of Mathematics (NCTM) suggests that students, starting from elementary grades, should learn how to collect and present data and make decisions based on them (National Council of Teachers of Mathematics, 2000). Students need to develop a meaningful understanding of data variability and to develop an understanding for randomness of different events that can occur in nature, technology, or society.

Different conceptions of probability make learning and teaching of probability a challenge for mathematics teachers. Interpretations of chance and randomness and their relationships with the subjective, theoretical, and experimental conceptions of probability contribute to the challenge of teaching and learning probability (Batanero, Henry, & Parzysz, 2005). Responding to this challenge, mathematics educators turn to technology and simulations to support teaching and learning of statistics and probability. There are different technologies and educational software such as graphing calculators, Spreadsheets, and TinkerPlots that can be used to help students develop important statistics and probability concepts. However, there is a need for studies that provide more insights into how tasks in technological environments can support teachers' and students' learning of statistics and probability (Biehler, Ben-Zvi, Bakker, & Makar, 2013; Garfield et al., 2008). As a response to this need, we investigate the development of PSTs knowledge of probability and statistics while working collaboratively in an online environment to solve probability problem. The PSTs used interactive simulations with multiple representations to determine the fairness of different dice. Our study responds to this question: Using simulations in a collaborative environment, how do PSTs engage theoretical and experimental probability to develop different statistical and probabilistic concepts?

Related Studies and Theoretical Framework

Surveys of the literature of teachers' knowledge of statistics and probability show that in-service and pre-service teachers lack deep understanding of graphical representation of data and important statistical concepts (Eichler & Zapata-Cardona, 2016). In addition, teachers lack theoretical and empirical probabilistic knowledge in general (Batanero, Chernoff, Engel, Lee, & Sánchez, 2016). Professional development programs usually focus on content knowledge. There is a need to help teachers develop flexible understanding of statics in contexts and build connections between theoretical and experimental probability (Batanero et al., 2016; Eichler & Zapata-Cardona, 2016).

Knowledge of statistics and probability includes many important concepts. Statistics deals with aspects related to producing data, either through observation or experimentation, and analyses that aim to find patterns as well as test hypotheses (Cobb & Moore, 1997). On the other hand, probability involves ideas such as randomness, events and sample space, combinatorics, independence (conditional probability), Law of Large Numbers, sampling and sampling distribution, and simulation (Batanero et al., 2016). In general, probability deals with two aspects of phenomena, empirical and theoretical. Empirical probability focuses on data generated from experiments where theoretical probability focuses on expectations beyond empirical data (Batanero et al., 2016).

To support students' learning of statistics and probability, teachers need to acquire deep content and pedagogical knowledge of the subject. Understanding how teachers develop statistical and probabilistic concepts informs the design of tasks in which pre-service and in-service teachers can engage and build their knowledge of statistics and probability.

Methodology and Data Collection

In our study, 12 PSTs interacted synchronously in an online environment to solve a probability task. The online environment, Virtual Math Teams with GeoGebra (VMTwG) integrates GeoGebra with a white board and a chat panel for synchronous discussion. The probability task involves investigating fairness of six different dice. The task has three main components: online collaboration using simulations, watching middle school students' discussing the same task, and analyzing artifacts of middle school students' solutions of the same task. The data for this paper focus on the first two components of the task. Data consist of online interactions of PSTs to solve the probability task, which included their chat logs, GeoGebra activities, and their chat logs reflecting on the middle school students' arguments for the same task. We were interested in studying how the PSTs, using simulations, moved back and forth between theoretical and experimental probability and engaged different ideas to judge the fairness of multiple dice.

The PSTs were provided with simulations for six dice that were weighted differently. They could roll each dice between 1 and 1,000 times to determine whether the dice are fair. The task provided them with three different representations of the data; a frequency table, a pie chart, and a bar graph. As a group, the PSTs were to make judgments about the fairness of each die and provide evidence to support their arguments. The video they watched contained a group of eight seventh graders engaged in a debate about how many times one would have to roll the dice to determine if the dice were fair or not. For analysis, two researchers openly coded the actions of the teachers inside of the tool and their chat logs discussing the fairness of each die and middle school students' arguments. Altogether, four groups of three PSTs were analyzed.

Results

While solving the probability task, PSTs engaged aspects of theoretical and experimental probability in their discussions. Even though the four groups of PSTs had different prior conceptualizations of theoretical and experimental probability, they used similar strategies to response to the task. Our analysis of PSTs actions and chat logs revealed that they relied mainly on three statistical and probabilistic concepts to investigate the fairness of dice. All groups focused on data distribution, data dispersion, and aspects of Law of Large Numbers (LLN). These concepts are related to each other in multiple ways. Because of these relations, PSTs discussions of these concepts were intertwined at moments. The following sections present how PSTs engage each concept while solving the task.

Distribution

The bar graph of the discrete probability distribution of each die allowed PSTs to discuss the experimental and theoretical distribution of data. Some students started with only theoretical understanding of the probability for six-sided dice. They expressed difficulty conceptualizing the notion of investigating the fairness of a die. To them, dice, by definition, have six faces with equal chance of selection. At the beginning of working with the task, a member of the first group asked "what does 'poor quality dice' even mean?" This indicates that this student has a theoretical base for understanding the probability of dice. All groups noticed the normality of data distributions generated from rolling the first die. They described these distributions as "bell curve" and "pretty normal". The normality of the distribution of the first die's data drew students' attention to the notion of distribution and allowed them to reflect on what a fair die's distribution should look like. In addition to bell curve or normal distribution, PSTs described different data distributions with terms such as "even" and "inconsistent". Three groups used "even" or "equal" to describe approximately uniform distributions. These distributions were of data generated from the only fair die in the task.

Dispersion

The second statistical notion to which students attended was dispersion of data. The PSTs attended to extreme values at first and moved to using range as a measure of dispersion. The second die has a low probability for number five. This allowed PSTs to talk about the lowest and highest values in their data. This attention to high and low values was used in investigating dice that followed the second die. After using extreme values to discuss the fairness of dice, PSTs used range to describe the die's performance. They attended to the highest and lowest value and reported the difference between them. While attending the spread of data, the third group demonstrated interactions between experimental and theoretical probability clearly when discussing fairness of the fourth die. A student stated that "at 500, fair dice would be in the range of 83 for each… but 1 is way below that range. i do not think its [*sic*] fair". Starting with an understanding of the theoretical probability of a fair die, the students divided 500 by six to estimate the outcomes of each face of the die. The spread of data is an important concept and relates closely to data distribution and, in our task, the Law of Large Numbers.

Law of Large Numbers

In our task, PSTs were able to change the number of rolls for each die to test its fairness from 1-1000. The simulation used a pseudorandom process to generate data based on certain probability we specified for each face of the die. The groups of PSTs demonstrated different initial and final understanding of LLN. The first three groups started with limited understanding of LLN. That was evident through their choices of how many rolls to use. The first group did not attend to this issue where the second group discussed using a small number of rolls that is a multiple of six. This indicates limited understanding of LLN but could show an understanding of the theoretical chance for each side being one-sixth. One student of the second group commented about the outcomes of each side saying, "obviously it is not going to be perfectly even", which shows that the student has an understanding of experimental probability but did not connect it to the LLN. Without any justification, the third group started with investigating three cases: 100, 500, and 1000 rolls. After testing these cases, a student questioned: "it should be the more you roll, the more equal the graph should look right?" Other members agreed with her. This group is starting to conceptualize the importance of LLN. The last group demonstrated understanding of the importance of LLN and decided to roll the dice 1000 times from the beginning.

Discussion

This study reports on four groups of PSTs interactions in an online collaborative environment to solve a probability task. The task asked PSTs to investigate the fairness of six differently weighted dice through using an interactive simulation for each die. PSTs collaborated synchronously to discuss the fairness of each die. They had the freedom to roll each die between 1-1000 times. At the end of their problem-solving session, PSTs watched a video of middle school students reasoning about the importance of using a large number of rolls in the same task. PSTs' discussions showed significant interactions between empirical and theoretical probability that supported their reasoning of data and investigation of dice fairness. To judge the fairness of dice, they engaged three main ideas: data distribution, dispersion of data, and the Law of Large Numbers. Three groups of the PSTs demonstrated stronger theoretical understanding of probability which align with findings in the literature (Batanero et al., 2016). These groups were able to demonstrate understanding of experimental probability by the end of working on the task.

Except for the last group, the PSTs worked on our task without formal introduction to statistical or populistic concepts related to the tasks. This did not limit them from engaging important concepts that are critical for this task. Their discussions were informal and used non-standard vocabulary. Additionally, we did not ask PSTs to discuss certain ideas when investigating the fairness of the dice. It was interesting to see how all the groups develop similar strategies. This provides important implications for designing tasks that aim to help PSTs develop their knowledge of probability and statistics.

PRESERVICE SECONDARY MATHEMATICS TEACHERS' UNDERSTANDING OF BINOMIAL DISTRIBUTION

Christina Azmy
NC State University
cazmy@ncsu.edu

Dr. Hollylynne Lee
NC State University
hollylynne@ncsu.edu

The binomial distribution is important for its connections to probability, sampling proportion, and inference. This research describes preservice secondary mathematics teachers' understanding of the binomial distribution in the context of an investigative task. A three-tiered framework was developed and used to classify preservice teachers' understanding, with implications for further research on the same or various statistical concepts.

Keywords: Data Analysis and Statistics, Teacher Education-Preservice

Introduction

Statistics education research has made great strides in recognizing common misconceptions and working on best practices to promote students' statistical thinking. To add to research on student thinking in statistics, this research study investigates teachers' understanding of a particular concept, the binomial distribution. The binomial setting is important for its stand-alone use, but also for the opportunity it provides to connect ideas related to probability, sampling proportions, and inference (Kazak, 2010). Thus, the research question is: "How do preservice secondary mathematics teachers (PSTs) understand the binomial distribution?" The frameworks used to analyze PSTs' understanding are the developmental levels described in the GAISE Report (Franklin et al., 2007) and the statistical habits of mind in the Framework for Supporting Students' Approaches to Statistical Investigations (SASI, Lee & Tran, 2015).

Literature Review

The main focus of the task used in this study is to introduce students to the binomial distribution and to encourage conceptual thinking about the probabilities of certain outcomes in that setting. Students have shown evidence of struggling with probability (Batanero, Henry, & Parzysz, 2013), inference (Harradine, Batanero, & Rossman, 2011), and repeated sampling (Harradine et al., 2011); the concrete binomial setting examples can help bridge these gaps. Students will be able to see what constitutes a "weird" or unlikely result by comparing it to an intuitively calculated expected value. For example, students will see that they are unlikely to get six or more questions correct when randomly guessing on a ten-question quiz. The binomial setting in the task also allows PSTs to see how sample size affects experimental probability and its relationship with theoretical probability. Combining ideas of data and probability before approaching formal inference can be useful for students (Kazak, 2010).

Students have intuitions about combinatorics that sometimes conflict with mathematics. For example, they may not attend to order when it is actually important for the question (Abrahamson, 2009; Kazak, 2010). They generally believe that the probability of flipping three heads and then one tail is greater than the probability of flipping four heads in a row, even though these are equally probable when you consider order (Abrahamson, 2009).

The simulation is helpful in allowing students to actually see different "quiz attempts" and the results happen in real-time. It also helps them see the probabilities at work. They would be very shocked to see all ten of the answers be correct, and much less shocked to see none of them correct. The fact that students first "take the quiz" by randomly guessing and then use the computer to simulate many more repetitions follows the recommendation of doing a tactile simulation before using technology (Chance & Rossman, 2006). The TinkerPlots simulator specifically is used in this study because it is possible to actually see the questions being randomly answered, avoiding the "black-box" technology problem (Chance & Rossman, 2006, p. 5). Overall, students should have a concrete idea of the binomial setting after completing the task. Students will develop an informal sense of how to combine data and probability to predict certain results. The level of their understanding is the main focus of this research project.

Framework

The theoretical framework that forms the basis of this research is the SASI framework, which is an extension of the framework in the GAISE Report (Franklin et al., 2007). The GAISE framework combines the investigative cycle and the different levels of student understanding during each phase of the cycle. For example, for the first phase, Formulate Question, the framework describes student thinking at each level, with Level C being the most sophisticated statistical thinking. The levels are not associated with an age or grade level, but rather assess students' current level of thinking. The SASI framework identifies specific statistical concepts, called statistical habits of mind, to which students should attend at different phases of the investigative cycle (Lee & Tran, 2015). The SASI framework was used to pinpoint concepts related to the binomial setting to which students should be attending.

Methods

Data were collected from 12 female PSTs who were enrolled in a 400-level course on teaching mathematics with technology offered at a large public university. They were given a task that asked them to go through the investigative cycle of a statistics problem in a binomial setting. They used the software program TinkerPlots to help them visualize the simulation. The original task (taken from: http://apstatsmonkey.com/StatsMonkey/Statsmonkey.html) was modified to encourage Level B and Level C thinking according to the GAISE framework (Franklin et al., 2007). Written responses to the task were used to assess their level of understanding according to the A, B, C levels of the GAISE framework (Franklin et al., 2007).

Results

The results come from the analyzed data collected in the form of the written responses given by the students on the last section of the task. The GAISE (Franklin et al., 2007) and SASI (Lee & Tran, 2015) frameworks provide a pathway for analysis that involves categorizing PSTs' responses according to Levels A, B, and C, with C being the deepest level of understanding. The GAISE framework focuses on understanding at the different stages of the investigative cycle, rather than on specific statistical topics. For this reason, the framework's structure was used to develop similar levels of understanding specifically for the binomial distribution context. The "statistical habits of mind" (Lee & Tran, 2015) were used to identify concepts on which students should be focused for each level of understanding.

PSTs' responses that indicated a firm understanding of the binomial setting had some common characteristics, and attended to related statistical habits of mind. Those with correct responses 1) include a *context* where it is possible to know that every event has the same probability and that all events are independent, 2) attend to *variability* when predicting likely/unlikely values, and 3) pose *statistics* questions appropriate for a binomial setting. PSTs' responses with all three characteristics were considered to have a Level C understanding (n=4). PSTs with two of the three were considered to have a Level B understanding (n=3). Responses that included none or only one of the three, but were still in the realm of the binomial setting (e.g. outcomes are success or fail, probability is involved, expected value is used) were indicative of a PST with a Level A understanding (n=5). Sample responses are shown in Table 1.

Table 1: Task Questions and Sample Responses from each Level of Understanding

Questions from Task	Level C Response	Level B Response	Level A Response
1. What is another binomial setting you can think of that fits these characteristics? (i.e., the four conditions of the binomial setting)	1. Flipping a coin a set number of times (ex: 30) success (head) failure (tails) fixed observations (30) observations are independent, P(correct)=.5	1. Rolling a die 15 times to see if "1" appears. (1/6 chance each time & each is independent).	1. Cards-standard deck
2. In the setting you have chosen, pose an interesting question you can answer using experimental and theoretical probabilities	2. John and his brother are betting that whoever's end of a coin appears most, has to do the others dishes for the week. Who will have to do the dishes if John chooses heads and his brother chooses tails and they repeat the process 30 times?	2. Does one number appear more often, or is there a higher probability for 1 # than for others.	2. What is the probability of pulling a heart suited card in 10 pulls from a deck.
3. If you define the number of successes to be a random variable Y, what values of Y do you expect to be most likely? Why?	3. y=15, the numbers closest to 15 because as you repeat the task many times, the totals should be close to the actual probability. (.5)(30)=15	3. Y=# successes. 2 or 3 because there's a 1/6 chance & 15 rolls --> 2.5 (1/6)^2=.0278 --> low but possible. lower y more likely to occur.	3. between 2-3 because the probability is 25% (shows work for 52/4=13)
4. What values of Y do you expect to be least likely? Why?	4. The numbers further away from 15, on both ends (+ or - 15) because you are straying away from numbers that are reasonable from the probability	4. Numbers from 5-6 because the probability of rolling a 1 5-6 is (1/6)^5=.000129 which is extremely low. The higher y is, the less likely it will happen.	4. 5-10 would be least likely for the same reasons as other example

It is not enough to judge that a PST is able to state that all observations in a binomial setting have the same probability of success. PSTs should also be able to produce or identify a context in which it is possible to know that is the case. In the Level C example given to item 1, this PST was able to produce an example on her own that satisfies the conditions. In contrast, the Level A example gives a situation with too little detail to infer that she has produced a satisfactory binomial setting. This is also true for the condition that all observations are independent. PSTs should be able to produce or identify a context in which that is true.

PSTs with a deep understanding should also have an awareness of the likelihood of specific outcomes. This includes attending to variability when predicting likely or unlikely values. Although the binomial setting allows for theoretical probability calculations, PSTs should understand that data sampled from simulations or real-world contexts will not match theoretical probabilities. When PSTs were asked to predict values, many calculated the expected value. For example, the Level C example answer to item 3 provides the "actual probability" (when she has calculated expected value) and suggests that likely outcomes will lie around that value. She has attended to variability, but not combinatorics. The Level B example provides a rare appeal to theoretical probability, but leaves out the combinatoric component and independent probabilities of failures. The sample Level C answer to item 4 shows consideration for variability, using language like "the numbers closest to" and "the numbers further away." In contrast, the Level B PST chooses two numbers deemed likely and two numbers unlikely.

Finally, PSTs should be able to produce an investigative question that requires a statistical, not mathematical, answer, appropriate for a binomial setting. For example, the item 2 Level C Example provides an appropriate statistical question in her binomial setting that can be answered using theoretical probability calculations, or simulations. In contrast, the Level A Example provides a basic probability question that does not depend on the binomial setting.

Discussion

Without overgeneralizing from this small sample, the results allow deeper insight into the types of understanding involving the binomial setting, especially in the context of an investigative task. In general, the binomial distribution has not been a focus of much research, even though it is a foundation for the concept of sampling proportions. The framework used for this study can be used to inform future research on the topic, and serve as a model for similar frameworks for a variety of statistical concepts.

The PSTs' responses to questions on the binomial setting after the investigative task show a majority of Level A and Level C understanding, with fewer in the middle. The tactile and electronic simulations, and the real-world context of the task, may have aided the strong responses. It was beyond the scope of this research to investigate PSTs' exposure to binomial distribution prior to the lesson; follow-up research should consider this aspect. In general, PSTs did exhibit struggles with applying the four conditions of the binomial setting to novel situations, attending to variability when predicting outcomes, and producing statistical questions that went beyond basic probability. This echoes research on student misconceptions.

This study reports psychometric evidence for the use of the Middle Grades Self-Efficacy to Teach Statistics (SETS-MS) instrument for both middle and high school pre-service mathematics teachers. Results indicate the reliability from scores is similar for both groups, and there were no statistical differences in the subscale means between the groups. This evidence suggests the instrument is appropriate for use with either population of pre-service mathematics teachers. Suggested SETS-MS uses include measuring self-efficacy after the implementation of recommendations from the ASA's SET report (Franklin et al., 2015). The impacts of these results are discussed within the paper.

Keywords: Data Analysis and Statistics, Teacher Beliefs, Middle School Education, Teacher Education-Preservice

While the National Council of Teachers of Mathematics has long advocated for the inclusion of statistics and probability in high school mathematics curricula (National Council of Teachers of Mathematics, 2000), the adoption of the Common Core State Standards for Mathematics (CCSSM; National Governors Association Center for Best Practice & Council of Chief State School Officers, 2010) has increased the emphasis on statistics in these grade levels. Mathematics teacher education programs are faced with the challenge of preparing pre-service teachers (PSTs) to teach statistics. With the release of the American Statistical Association (ASA)'s *Statistical Education of Teachers* report (SET; Franklin et al., 2015), we are at a crossroads in mathematics teacher preparation in both research and practice. While the recommendations for appropriate content and supports for each certification/licensure level in the *SET* report are an initial start, researchers and mathematics educators still need to evaluate the practices in teacher education programs that increase teacher efficacy to teach statistics and develop teachers' statistical habits of mind using psychometrically-sound measures.

The two grade-level-specific versions of the Self-Efficacy to Teach Statistics (SETS) measure teacher efficacy to teach middle and secondary students the skills to conduct specific statistical tasks, based on the *Guidelines for Assessment and Instruction in Statistics Education* (GAISE) *Pre-K-12 Report* (Franklin et al., 2007) and the CCSSM. The Middle Grades version (SETS-MS; Harrell-Williams, Sorto, Pierce, Lesser, & Murphy, 2014) aligns with the CCSSM standards for grades 6-8. The SETS-MS instrument was validated with PSTs seeking licensure that included some portion of grades 5-8. However, the grade levels covered by some states' secondary licensure/certification include some middle grades in addition to high school, so the SET-MS instrument needs to be evaluated using high school PSTs as well.

Thus, the purpose of this study was to compare psychometric performance of the SETS-MS instrument using two samples of PSTs, one that is seeking licensure/certification that includes at least one of grades 5-8 (referred to as "middle grades" in this paper) and one seeking high school licensure/certification that focuses on grades 9-12 (referred to as "high school"). Specifically, the study sought to answer the following research questions about the differences between middle grade and high school PSTs: Do the scores and reliability of the scores from the two SETS-MS subscales differ? Does the distribution of item response category usage differ? Additionally, is there evidence of measurement invariance?

Methods

Participants

The participants came from two separate studies using the SETS instruments. The first study included a convenience sample of 309 PSTs whose intended licensure/certification was referred to as the "Middle Grades" PSTs. Data were collected across four different large public institutions of higher education in four states (IN, TX, OK, KY) in the US. Approximately 78% of the participants were female and predominately self-identified as Caucasian (88%).

The second study included 290 PSTs from 20 universities in the United States with secondary mathematics teacher education programs, referred to as the "High School" PSTs. While two universities were selected from convenience, the other 18 institutions spanning 14 states in the U.S. were selected because at least one faculty member participated during 2002-2014 in a program (funded by either ASA or NSF) to increase the emphasis of statistics education of teachers at that institution. Similar to the first study, the participants were predominately female (70.3%) and approximately 82% self-identified as Caucasian. While these percentages seem high, they follow national trends and are similar in demographics to pre-service teachers in other studies on teacher efficacy (Duffin, French, & Patrick, 2012; Knoblauch & Woolfolk Hoy, 2008).

Instrument

The SETS-MS has 26 items using a 6-point Likert scale, with 1 = *not at all confident* and 6 = *completely confident*. Harrell-Williams et al. (2014) provides information regarding instrument development and evidence for reporting two subscales for the SETS-MS instrument, identified as "Reading the Data - Level A" and "Reading Between the Data - Level B".

Analyses

The analyses in this paper fall under two categories: those done at the subscale level and those done at the item level. Cronbach's alpha was calculated as reliability estimates for scores from the two aforementioned subscales comprised of the 26 middle grades SETS items. MANOVA was used to determine if the means of the two correlated subscales scores differed for middle grades and high school PSTs.

Three item-level analyses were completed. Item means, classical test theory measures of item difficulty, were obtained for each PST sample. Chi-squared tests of homogeneity of proportions compared the distribution of response categories percentages across the groups for each item. The Benjamini–Hochberg procedure (1995) controlled the false discovery rate for the 26 Chi-squared tests, using a false discovery rate of 0.05. Lastly, differential item functioning (DIF) was assessed across the pre-service teacher groups using the Wald test method in IRTPRO (Cai, du Toit, & Thissen, 2011), with item estimation occurring within each subscale. In general, DIF was assumed to exist if any of the Wald test p-values were smaller than 0.05. The Benjamini–Hochberg procedure was also employed in the DIF analysis to minimize the false discovery rate.

Results

Subscale Analyses

The Cronbach's alpha reliability estimates for the subscales exceeded 0.90 for both the middle grades and high school PSTs (see Table 1), indicating very little measurement error in the subscale scores and almost no difference in the reliability across groups. According to the MANOVA results, the mean subscale scores for Level A and Level B were not significantly different across the two groups, $F(2,596) = 0.037$, $p = 0.964$.

Table 1: Subscale-Level Results

		Middle Grades PSTs			High School PSTs		
Subscale	Number of Items	Cronbach's Alpha	Mean	SD	Cronbach's Alpha	Mean	SD
Reading the Data (Level A)	11	.92	4.54	.91	.93	4.55	.81
Reading Between the Data (Level B)	15	.94	4.11	.98	.93	4.10	.84

Item-Level Analyses

For the Level A items (items 1–11), the item means ranged from 4.26 to 4.86 for the high school PSTs and from 4.28 to 5.01 for the middle grades PSTs. For Level B, the item means ranged from 3.45 to 4.72 for the high school PSTs and from 3.62 to 4.65 for the middle grade PSTs. The observed difference in item means indicates the two groups were likely responding differently to some items. The chi-squared tests of homogeneity of proportions in response category usage revealed that middle grade PSTs responded differently than high school PSTs on 13 of the 26 items. Five of these items were from Level A (items 4-7, 10), while eight were Level B items (items 12, 14-19, 22). The majority of these items addressed creating or using specific visual displays to summarize, describe or compare distributions (dotplot, histogram, boxplot). In most cases, the middle grades PSTs were using the higher response categories (5 or 6) with higher frequency than the high school PSTs, for whom 5 was the category with the highest frequency. All *p*-values for the Wald tests for evaluating differential item functioning across the two groups of PSTs were 0.82 or greater, indicating that the items did not perform differently across the groups when participant self-efficacy levels were taken into account.

Discussion

The current SETS-MS instrument seems appropriate for use in a mixed licensure/PST audience. The results showed no statistical differences in mean scores or reliability at the subscale level between middle and high school licensure/certification candidates. The differential item functioning analysis indicated when participants' level of self-efficacy was taken into account, the items performed in the same manner. There were slight differences in response category usage at the item level with middle grades PSTs using 5s and 6s with more frequency, while high school PSTs used 5s. However, there was not enough difference across all PSTs to come through as a difference in means in the scores of either the "Reading the Data (Level A)" or the "Reading Between the Data (Level B)" subscales. This suggests that middle school PSTs feel more confident in teaching graphical representations than high school PSTs. Since reading and interpreting graphical representations are present in middle grades and high school CCSSM, to increase their confidence, high school PSTs need more opportunities in their coursework to engage with graphical representations.

A limitation of this study is that both samples were not a random sample of PSTs at either licensure/certification level or across the entire US. However, a complete list of all institutions that prepare middle and high school PSTs was not available. Most studies in mathematics education have been conducted at a small number of institutions, while our data included 23 institutions from 16 different states, collectively. Furthermore, the demographics of our participants reasonably mirror national demographics in race and gender for PSTs.

Conclusion

As suggested changes to preparation of middle and high school mathematics teachers, as described in the ASA's *SET* report (Franklin et al., 2015) are implemented nationally, the hope is that PSTs will be more prepared and confident to teach statistics. The evidence provided in this study indicates that the SETS-MS instrument is a psychometrically-sound instrument for mathematics educators to use in measuring changes in their PSTs, as teacher preparation programs implement recommendations in the *SET* report. For example, when using the SETS-HS instrument to evaluate high school PSTs statistics teaching efficacy, Lovett (2016) found that taking Advanced Placement Statistics in high school had a positive influence on their statistics teaching efficacy. As a future direction of research, similar studies can be carried out psychometrically comparing PSTs to inservice teachers' scores on the SETS-HS.

WHAT CONTEXTUALIZED SITUATIONS ARE MADE AVAILABLE TO STUDENTS USE STATISTICS IN MATHEMATICS TEXTS?

Travis Weiland
University of Massachusetts Dartmouth
tweiland@umassd.edu

In our modern information age societies that are drenched in data, statistical literacy is a crucial literacy for citizens to be able to actively engage in their society and government. Statistical literacy is intended to be developed through the instruction of statistics concepts in school mathematics classrooms. However many mathematics teachers have little to no prior experience with statistics, which means many teacher need to draw upon resources to help teach statistics concepts one of which is their textbooks. The objective of this study is to investigate what contextualized situations are available for students for the use of statistics by two major high school mathematics textbook series.

Keywords: Data Analysis and Statistics, Curriculum Analysis, High School Education

Problem Statement

Statistics and data based arguments are common in people's everyday lives today and are used in a number of powerful ways including to guide government policy, business decisions, influence public opinion, and to influence consumers in making purchases. Societies today are drenched in data (Steen, 2001) and this trend is only increasing in our current information age. Statistical literacy has become a crucial literacy for citizens today (Franklin et al., 2007).

In the context of schooling in the United States, the development of statistical literacy is supposed to come from the teaching of statistics concepts in middle and high school mathematics classes (Franklin et al., 2007; National Governors Association Center for Best Practices [NGA Center] & Council of Chief State School Officers [CCSSO], 2010). Unfortunately, most mathematics teachers have had little to no prior experience with statistics (Shaughnessy, 2007). So how then do teachers with little experience in statistics teach statistics concepts to their students? One very likely resource for teachers to rely on is their textbooks. Scholars have reported on the influence of textbooks on shaping classroom instruction and students learning (Fan, Zhu, & Miao, 2013). In line with the conference theme of crossroads, the broad objective of this study is to consider what kind of contextualized situations high school mathematics textbooks give students access to explore with statistics and to consider a possible change in route of the types of contextualized situations used in mathematics textbooks for the use of statistics.

Background

In statistics, "data are not just numbers they are numbers with a context" (Cobb & Moore, 1997, p. 801). This makes the consideration of context central to statistical enquiry (Wild & Pfannkuch, 1999). This is also a departure from the mathematics commonly taught in school where numbers are frequently presented and used in their abstract form without any connection to context (Gattuso & Ottaviani, 2011). In statistics the analysis of data cannot be considered without thinking about the context of the data (Cobb & Moore, 1997; Franklin et al., 2007; Wild & Pfannkuch, 1999). Context determines how and what data to collect, as well as how to analyze the data and interpret the results. This results in a constant interplay between considering a statistical problem and the context of the problem (Wild & Pfannkuch, 1999). For an instructor to teach statistics concepts well they must know more than just the relevant theory, but they must also have a vast supply of relevant contexts with which to see and apply the theory too. In mathematics on the other hand a knowledge of theory is generally enough to create problems and examples on the spot (Cobb & Moore, 1997). Due to such disciplinary differences the consideration of context in school mathematics classrooms is important.

In spite of the influence of textbooks on the enacted curriculum of the classroom there is surprisingly little work specifically focusing on investigating the statistics content of school mathematics texts in the context of the U.S. Much of the previous research has been focused on analyzing the proportion of middle and elementary school texts that focus on statistics content and their alignment to the GAISE Framework (Bargagliotti, 2012; Jones et al., 2015; Pickle, 2012). Only one study focused on the statistics content of high school mathematics texts, which was a dissertation looking at the learning trajectories related to bivariate data in a single text (Tran, 2013). Based on this review of the literature there seems to be a significant lack of research on the statistics content of high school mathematics textbooks

Methodology

Research Question

The specific research question to be considered in this study is: *how are the contextualized situations appropriate for the use of statistics formed by the statements of two major high school mathematics textbook series?*

Selected Texts

In a survey of a nationally representative sample of U. S. mathematics teachers, Banilower et al. (2013) found the top two companies making up the market share of high school mathematics texts are Houghton Mifflin Harcourt with 35% (SE=1.6), Pearson with 30% (SE=2.0). The data for this survey was collected during the initial transition to the CCSSM (NGA Center & CCSSO, 2010). Therefore, I chose to extrapolate the survey results and select Houghton Mifflin Harcourt and Pearson's most recent and CCSSM aligned textbook series to study predicting that they would still make up a majority of the market share. For Pearson I analyzed their Algebra 1, Geometry, Algebra 2 Common Core curriculum (Randall et al., 2015) and for Houghton Mifflin Harcourt I analyzed their Algebra 1, Geometry, and Algebra 2 curriculum (Kanold, Burger, Dixon, Larson, & Lienwand, 2015). All lessons with statistics standards as the explicit focus were included as well as lessons on modeling that included modeling data sets with variation. Counting rules and the development of theorems on the mathematics of probability were excluded, consistent with the GAISE framework (Franklin et al., 2007) recommendations.

Archeology

For this study I drew upon Foucault's (1972) methodology of archaeology, which is focused on the study of discourse to interrogate the "regimes of truth" or knowledge, constituted by the rules or regularities of statements in discourse. From this perspective a discourse consists of a regulated set of rules that are generally taken for granted, and also constrain and "specify what is possible to speak, do, and even think, at a particular time" (Walshaw, 2007, p. 19). Statements in discourse operate in different ways one of which is, "materiality (which is not only the substance or support of the articulation, but a status, rules of transcription, possibilities of use and re-use)" (Foucault, 1972, p. 115). For this study the operation of materiality was considered in terms of the contextual situations in which the use and re-use of statistics is formed as appropriate or normal. From this perspective regularities in the contextualized situations (e. g. rolling dice, test scores, profit, personal characteristics, science, etc.) presented in high school mathematics textbooks influence and regulate in what contextualized situations that teachers and students use statistics in the future.

The focus in this analysis was on the regularities in the types of contexts that were presented in the text and in what form data based information was provided for each (if at all). The forms in which the data were presented that were considered included the types of variables described in the contextualize situations (quantitative or categorical), what sample size was described (if any), whether raw data, summary statistics, or representations were provided with the contextualized situation, and finally whether or not real data was provided with the contextualized situation. I operationalized real data as data that was provided with a citation of its source. The analysis of the texts was done through an iterative process of multiple readings of the data.

Findings

In analyzing the two textbook series a number of strong regularities came out in the types of contextualized situations that were presented for investigating with statistics, which I used to create contextual categories (see Table 1). There was little variation from Algebra I to Algebra II texts within both series and there was also a significant amount of overlap in the categories between the two series.

Table 1: Contextual Categories

Pearson Contextual Categories	HMH Contextual Categories
Entertainment/Sports/Exercise	Entertainment/Sports/Exercise
School/Testing	School/Testing
Science/Weather	Science/Weather
Personal Characteristics	Personal Characteristics
Voting/Personal Preferences	Voting/Personal Preferences
Transportation/Travel	Census/Population data
Business/Economy/Sales	Transportation
Manufacturing/Product Quality	Business/Sales
Food/Farming/Agriculture	Manufacturing/Product Quality
Rolling Dice/Random Draw	Food
Making Decisions/Fair Decisions (Only Algebra II)	Pets/Animals
	Work/Salary/Savings
	Random Draw/Flip coins/Roll dice (Only Algebra II)
	Health/Medical (Only Algebra II)
	Fair Divisions/Outcomes (Only Algebra II)

In considering the forms in which the data based information for each task was presented, contexts were presented in a wide variety of forms. Some statements included no data-based information, while others only provided descriptive statistics such as the measures of center or spread for a situation. Some statements presented data in representations, which included histograms, bar graphs, line graphs, scatterplots, box and whisker plots, data tables, frequency tables, and two-way tables. Some statements presented ordered or raw data. A mixture of any number of these forms was also observed. No statements from the Houghton Mifflin Harcourt text contained real data, while Pearson did present some statements with real data. In the statements only one or two variables were presented with any regularity, if any were at all. For those statements that did present data, the mean sample size was 11(7.4) ranging from 3 to 50 in the Pearson textbooks and the mean sample size was 12 (10.5) ranging from 3 to 100.

Discussion

It is promising that so many categories of contextualized situations were present in the textbooks as it has been pointed out in the past that statistics is often taught abstractly and focused on decontextualized calculations in mathematics classes (Gattuso & Ottaviani, 2011). However, the promise ends there as the contexts in which the texts construct as appropriate for the use of statistics generally go no further than those typical of small talk, such as the weather, sports, or personal preference, or related to work or business. The types of contextual situations presented in the texts are predominantly neutral with almost no controversial issues like those that citizen's face in their daily lives being presented. Some of the most prevalent issue societies are facing today including immigration, race, gender identity, women's rights, climate change, water access and quality, gun rights, gentrification, urbanization, wealth distribution, poverty, and government spending are not at all present. Essentially these texts are not constructing statistics as useful for one to make sense of the world around them. This means there is serious need for curriculum to be created that fosters students to make sense of the world around them through statistics.

ELEMENTARY PRESERVICE TEACHERS' UNDERSTANDING OF VARIABILITY AND USE OF DYNAMICAL STATISTICAL SOFTWARE

Yaomingxin Lu
Western Michigan University
luyaomingxin@gmail.com

Keywords: Data Analysis and Statistics, Elementary School Education, Middle School Education, Teacher Education-Preservice, Technology

A major component of the statistical thinking involves understanding and describing variability in data. Moore (1997) points out the importance of both variability and the measuring and modeling of variability in statistics learning. However, Reading and Shaughnessy (2004) claims that there was a lack of attention to the measurement of variability, which results in a gap in students' concepts of variability. Moreover, the Guidelines for Assessment and Instruction in Statistics Education (GAISE) (2007) has suggested that the use of technology will help students develop a better sense and understanding of variability through more engaged data analysis tasks in upper elementary and middle school grades. However, little research has been done regarding how K-8 pre-service teachers (PSTs) have developed an understanding for variability for themselves in preparation of teaching the topic to children. What experiences are being developed that prepare K-8 PSTs to understand variability while exploring data with technological tools such as dynamic statistical software?

This study analyzed tasks used in a statistics course designed for elementary/middle school PSTs that focused on developing PSTs' understanding of measures of variability. A case study methodology was used with data collected from the statistics content course in Western Michigan University, where dynamic statistical software, TinkerPlots, was used almost daily in class. PSTs' class works and classroom observation notes were analyzed and coded based on Garfield and Ben-Zvi's (2005) framework of seven components that comprise a deep understanding of variability. Based upon the preliminary findings from tasks and class sessions examining variability in data, specifically that of making sense of the mean absolute and standard deviation measures, we see that PSTs are beginning to develop a more meaningful understanding of the measures of variability with the help of dynamical statistical software such as TinkerPlots. TinkerPlots provided several means for students dynamically engaging with the data while thinking about spread. Such work is needed in order to help our pre-service teachers be current in their understanding of the use of technology tools in the teaching and learning of statistics.

A major challenge for students is to apply what they have learned in mathematics classrooms in other contexts, and it is a task for their teachers to prepare them to do so. In this poster we describe the ways in which students applied their knowledge of the concept of slope and how that knowledge evolved within a science lesson on density. The lesson was part of an integrated science, technology, engineering, and mathematics (STEM) unit where students studied the physical properties of minerals as they worked toward designing a process for sorting minerals using those physical properties. In the lesson studied, students compared the densities of two minerals by examining the scatterplots of mass vs. volume for several samples of two different types of minerals. The unit and lesson were specifically designed to support students in developing meaningful understanding of both science concepts such as density and mathematics concepts such as proportional relationships and slope (Moore et al., 2014).

The participants in this study were four groups (13 total) of eighth grade and two groups (six total) of sixth grade students at schools in two different mid-western states. Students were interviewed about their understanding of linear relationships in data and the specifics of slope both before and after the observed lesson. These task-based interviews presented students with a scatterplot of data and a graph showing linear relationships in context and asked them to interpret and answer questions about each. Additionally, audio and video recordings were captured during their group work sessions, and the lessons were observed by the researchers.

Students began the unit with a variety of understandings about slope and linear relationships in data. Some students began with very little knowledge, while other students were able to demonstrate fairly sophisticated understanding of the concepts. After the lesson on density and slope, most students demonstrated a better understanding of the concepts or were able to articulate what they had already demonstrated more clearly. Additionally, several of the students were able to point directly to things that they had done during the lesson which helped them to better understand the interview tasks. However, not all students were able to apply what they had learned or demonstrated in one context in the other contexts. This was true both for students who were able to demonstrate knowledge during the interviews but not during the lesson and visa versa. This observation is consistent with research arguing for the situated nature of learning (e.g. Lesh, 2010; Cobb, 1999). Implications for teaching and curriculum design are addressed.

CONTEXT AND VARIABILITY: HOW DATA CONTEXT SHAPES PRESERVICE TEACHERS CONCEPTIONS OF VARIABILITY

Kit Clement
Portland State University
cclement@pdx.edu

Keywords: Data Analysis and Statistics, Teacher Education-Preservice, Teacher Knowledge

This project builds on by research done by Thanheiser et al. (2011), which investigated elementary preservice teachers' (PSTs) statistical thinking. In one of the tasks given to PSTs, they were asked to provide prices of seven potato chip bags with a specified average. The PSTs tended to provide data close to the average; however, the authors noted that the potato chip prices context may have influenced responses to be close to the expected value, as prices are often the same across stores. The authors asked "would PSTs construct data sets with a wider variability if the context was not restrictive?" (Thanheiser et al., 2011, p. 545) We hope to not only answer that question, but also provide further insight into how PSTs perceive variability of different contexts. In practice, educators should choose a data context in a purposeful way, and this research aims to improve on this practice by improving the education of PSTs in relation to statistics and the data context. Wild and Pfannkuch's (1999) framework on statistican inquiry highlights both the omnipresence of variability in statistics while also noting that statistical reasoning requires shuffling between the statistical and contextual realms of thought.

Our research question is "How does data context affect how preservice teachers think about variability?" To answer this question, we designed a mixed-methods study including a survey and interviews with a subset of the survey respondents. We adapted the task from the previous study into three tasks, all which prompted students to come up with seven data points from a population that has an average of 23, but each of the tasks was placed in one of three data contexts: hourly wages, college t-shirt prices, and no context. The survey also included questions to probe PSTs for their reasoning. Our sample was 66 students enrolled in math courses for PSTs at a Pacific Northwest university, and we randomly assigned each PST to one of the three versions of the survey.

Survey responses indicated that the wage data context elicited students to provide data with more variability than the t-shirt context. One student in the hourly wage context group writing "I thought about just writing numbers 20-27 in the boxes… this would be easy, but I didn't think this was a realistic salary range. So I changed it to counting by 2's to widen the range ever so slightly." However, our initial review of interview responses indicate that there are several wrinkles in this conclusion, and we will present further results from the interviews to better explain the between group differences noticed in the surveys.

SURVEYS OF ATTITUDES ABOUT STATISTICS: AN ANALYSIS OF ITEMS

Douglas Whitaker
University of Wisconsin-Stout
whitakerdo@uwstout.edu

Kylie Gorney
University of Wisconsin-Stout
gorneyk7416@my.uwstout.edu

Keywords: Data Analysis and Statistics; Affect, Emotions, and Attitudes; Teacher Beliefs

Attitudes toward statistics are considered important outcomes of introductory statistics courses because they have been linked with student achievement and because they inform people's lasting impressions of the discipline (Gal, Ginsburg, & Schau, 1997; Ramirez, Schau, & Emmioğlu, 2012). These attitudes have been studied since the 1950s, and dozens of instruments have been created during this time (Nolan, Beran, & Hecker, 2012; Ramirez et al., 2012). Over this 60-year period, there has been substantial evolution in the discipline's understanding and conception of attitudes. These surveys are generally described and reported on in isolation, but few studies have made comparisons across instruments. One notable exception is Nolan, Beran, and Hecker's (2012) meta-analysis that examined the reliability and validity of 15 instruments designed to measure the attitudes of post-secondary statistics students. However, this meta-analysis focused on the surveys and their subscales without examining the original items used in the surveys. Statistics education is at a crossroads with an increase in research with populations other than undergraduate students, i.e. teachers and pre-service teachers. To chart a route forward, this study examines the original items used on survey instruments from the past 37 years to 1) provide a more robust understanding of attitudes about statistics as enacted in the literature and to 2) clarify how constructs that have used common labels (e.g. "values," attitudes," and affect") have been operationalized by different surveys.

The data for this study were the individual items included on the operational or final versions of surveys of statistics attitudes (broadly conceptualized). The final or operational versions of 17 surveys were found by searching the literature, requesting original dissertations, and contacting authors. The data analysis will proceed in two phases. First, the items will be analyzed using an inductive process as described by Hatch (2002); the result of this iterative phase will be a set of codes representing constructs (and subconstructs) measured by the items from the surveys. Then, each of the survey items will be categorized using these proposed codes by the research team. Inter-rater reliability will be assessed, and the team will meet to discuss and resolve disagreements. The development and description of constructs will address the first goal of this study, and the categorization of items using the codes will address the second.

With an increasing focus on statistics education research with new populations, a rich description of attitude constructs and subconstructs that have been valued and assessed in the literature will inform future instrument-development projects. Describing how different surveys assess nominally-similar constructs will also benefit researchers seeking to use or interpret surveys with groups other than undergraduates, such as K-12 students and in-service teachers.

BARRIERS TO ENGAGEMENT IN MATHEMATICAL DISCOURSE: MALIGNANT POSITIONING IN THE SECONDARY MATHEMATICS CLASSROOM

Richard Robinson
The Citadel
rrobins4@citadel.edu

Robin Jocius
The Citadel
rjocius@citadel.edu

In this study, we demonstrate how a teacher draws on validating storylines as support for the malignant positioning of students within classroom interactions, which reflects broader storylines about honors versus non-honors students, mathematical proficiency, and differential access to powerful mathematics.

Keywords: Classroom Discourse, High School Education, Research Methods

Objectives and Purpose of the Study

In this paper, we develop an integrated theoretical approach to examine mathematical discourse in a high school classroom. Drawing on theories of positioning and the social forces that shape interactions, we discuss the *storylines*, or patterns of interaction based on commonly shared narrative conventions (Davies & Harré, 1990), at play within the moment-to-moment interactions between a secondary mathematics teacher and her students. The goal of this work is two-fold: (1) to demonstrate how validating storylines serve as support for enacted subject positions; and (2) to illustrate how malignant positioning can limit students' engagement in mathematical discourse.

Theoretical Framework

In this study, we draw on positioning theory to uncover the ways in which teachers and students make sense of one another's actions within the classroom, something we argue is an integral part of mathematical meaning-making. As Davies and Harré (1990) describe, positioning is "the discursive process whereby selves are located in conversations as observably and subjectively coherent participants in jointly produced story lines" (p. 48). Taken together, storylines and positions are used to interpret actions within discourse. The way in which an action gets interpreted by others depends on the storylines (and related subject positions) that others believe to be in play. One of the key theoretical assumptions of our study is the belief that discourse shapes the positions that are available to participants, even as these positions shape the discourse.

In order to more accurately describe the discursive work that teachers and students do in the mathematics classroom, we distinguish between several different types, or what van Langenhove and Harré (1999) called "modes," of positioning, including intentional and malignant positioning. For example, on the first day of school, a teacher may clearly outline her expectations for the year in order to intentionally position students as having a right to succeed but a duty to work hard. Such intentional positioning can be considered part of the discursive work people do every day in order to create identities, relationships, and practices, and even to privilege one way of knowing over another (Gee, 2014).

The term "malignant positioning" has been used to describe the way in which Alzheimer's patients can be stripped of their social persona and rights in order to be characterized as having less ability and status (Kitwood, 1997; Sabat, 2003). As Harré and Moghaddam (2003) explain:

> To say that someone cannot quickly bring to mind certain words is to predicate a certain psychological attribute to that person. However, to slide from that attribution to positioning someone as no longer having the right to make life decisions for him or herself is an act of positioning. (p. 8)

Galindo, E., & Newton, J., (Eds.). (2017). *Proceedings of the 39th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* Indianapolis, IN: Hoosier Association of Mathematics Teacher Educators.

We define malignant positioning as acts of positioning that limit the rights and duties of individuals or groups. In the mathematics classroom, for instance, to say that a student cannot quickly bring to mind the solution to a problem is to predicate a certain attribute to that student regarding their mathematical competence. However, shifting from that attribution to positioning the student as no longer having the right to engage in powerful mathematics, or mathematics with "clout" (Bruner, 1986), is an act of malignant positioning. Sometimes, the attribution in question is institutionalized (e.g., tracking students into non-honors and honors courses). As our findings show, when teachers draw upon "validating storylines" (Sabat, 2003) to justify acts of malignant positioning, students become entrenched in positions with limited rights to powerful mathematics and minimal duties (expectations) as students of mathematics.

Methods of Inquiry

This study was conducted in Ms. Mason's Algebra II classroom, which was located within a large suburban high school that enrolled approximately 1888 students at the time of this study. According to information provided by the school district, 22.89% of the school's students qualified for free and reduced lunch and the teacher to student ratio was approximately 26:1. Ms. Mason, who has 7 years of teaching experience, was chosen due to her willingness to provide access to her classroom over an extended period of time, which was crucial to gain insight into how teachers and students position themselves and one another within mathematical discourse.

Data Collection and Analysis

Our goal in analyzing classroom discourse was to examine teacher and student interactions from multiple and complementary perspectives. Sources of data included video recordings of 11 classroom sessions (approximately 90 minutes each), interviews with the teacher and focus students, and mathematical artifacts created by the teacher and students. Data analysis proceeded in three overlapping phases: (1) initial, collaborative coding of all classroom videos; (2) micro-analysis of focal interactions; and (3) triangulation across data sources. The first phase of data analysis involved viewing and coding classroom video from all 11 class sessions. Using qualitative coding procedures informed by grounded theory (Strauss & Corbin, 1990), we employed open coding to identify concepts and themes for further analysis and axial coding to organize and integrate categories.

The initial coding process (Phase 1) allowed us to identify focal interactions for more detailed micro-analysis (Phase 2). Using a scale (Herbel-Eisenmann et al., 2015) as the unit of analysis, we focused on particular utterances and exchanges at the levels of 10^0-10^2, words and interactions among people (Lemke, 2000). In order to examine the ways that participants drew on storylines to validate positioning acts in moment-to-moment interactions, we foreground these communication acts while backgrounding attention to storylines. The third phase of analysis involved triangulating our analysis across data sources. In addition to checking and confirming findings and interpretations across class sessions, we analyzed and coded video interviews and artifactual evidence. By looking across multiple scales, including lessons (10^3), lesson sequences (10^4), and units (10^6) (Lemke, 2000), we were able to examine the relationships between positions and storylines (Herbel-Eisenmann et al., 2015).

Results

To illustrate instances of malignant positioning and the effects of this positioning on students' engagement in mathematical discourse, we focus on sample interactions between Ms. Mason and her students at the 10^2 level, words and interactions among people (Lemke, 2000). In the following exchange, Ms. Mason stands at the board, introducing a lesson on how to analyze the behavior of a rational function near a vertical asymptote.

Galindo, E., & Newton, J., (Eds.). (2017). *Proceedings of the 39th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* Indianapolis, IN: Hoosier Association of Mathematics Teacher Educators.

Ms. Mason: If this was an honors class, what I would have you do is pick x points between -4 and 4 and plug them into the equation. Then, I'd have you pick x points below negative 4 and above negative 4 and plug them into the equation=

Student: (shift forward, hands coming up in questioning gesture to shoulders): So, why wouldn't we do=

Ms. Mason: =So now what we're going to do, we're going to look at the calculator. [Pause]. We've got enough to get us started, because I need at least these things labeled on the graph.

The preceding example illustrates how positions and storylines are mutually constituted within the everyday workings of the classroom. In Line 1, as Ms. Mason explains her process for graphing the local behavior of rational functions using the "honors vs. non-honors" storyline, she concurrently introduces an associated set of subject positions that are now made available to others within the conversation. As she positions the students in the room as "non-honors," not capable of achieving the same level of rigor that she would demand of more capable "honors" students, she narrows what is *logically possible* (students algebraically determining local behavior of function near vertical asymptotes) into what is *socially possible* (the calculator doing the work of determining local behavior) (Harré & Moghaddam, 2003). When a student attempts to challenge this position in Line 2, asking "Why wouldn't we do," Ms. Mason cuts her off and instead proposes an alternative: "So now what we're going to do, we're going to look at the calculator." The discussion continues:

Ms. Mason: I'm not going to accept this. I'm not going to accept this. You're going to have to be more specific. Some of you, on the cumulative test, when you had a parabola, you did this (*shakes student's paper*). Nothing labeled. I will not accept that. You have to give me something. I will not accept random swooshes (*puts paper down on desk*). This isn't Nike. I need specifics.

Student: Why are they=

Ms. Mason: =Get your calculators out. All right. You need to write this in your notes, because this is extremely important when you work with rational functions.

Student: Why are they not there?

Ms. Mason: They're not actually lines, they're boundaries. Kind of like a fence. Keeps you from crossing.

Student: What did you say this was for?

Ms. Mason: So, this is rational functions. So, here's what you need to star. This is really crucial—put all of numerator in parentheses and put all of denominator in parentheses. If you don't do that, you are not going to get the right graph. All right?

In the preceding exchange, Ms. Mason draws on a validating storyline (honors vs. non-honors) in an act of malignant positioning that limits the rights and duties of these "non-honors" students. Instead of investigating mathematical understandings through the use of multiple representations (i.e., numerical or algebraic) as honors students might, non-honors students rely heavily on calculators and follow explicit instructions to get the "right" graph. In this case, the larger educational storyline about differential access to powerful mathematics validates the positions at play in the moment-to-moment interactions between Ms. Mason and her students.

Discussion

In a recent commentary, the NCTM Research Committee (2016) suggested that education researchers have a right and duty to "intervene to shift these storylines and positionings and to have greater impact on policy, practice, and public perception" (p. 103). We agree that researchers can play a key role in transforming conversations about the teaching and learning of mathematics. However, we also believe that it is equally important to examine the ways in which storylines unfold

Galindo, E., & Newton, J., (Eds.). (2017). *Proceedings of the 39th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* Indianapolis, IN: Hoosier Association of Mathematics Teacher Educators.

in the moment-to-moment interactions between teachers and students in classrooms. In these spaces, more than mathematics is being created—students create positions and are positioned by others as certain kinds of people: a good student, a bad student, a class clown, an honors student, or a non-honors student. As Morgan (2012) argues, "the challenge is to connect such classroom-level analyses to a developed understanding of the broader context" (p. 192). In this study, we demonstrate how malignant positioning emerges within the mathematics classroom and reflects broader storylines about honors versus non-honors students, mathematical proficiency, and differential access to powerful mathematics. Moreover, we highlight the teacher's role in the ongoing negotiation of such positionings, providing insight for those seeking to remove barriers to mathematical engagement within their own classrooms.

CHANGES IN STUDENT PERSPECTIVES: WHAT IT MEANS TO BE "GOOD AT MATH"

Jennifer L. Ruef
University of Oregon
jruef@uoregon.edu

This paper describes how a cohort of sixth-grade mathematics students shifted their collective understanding of being "good at math" from passive recipiency to active agency.

Keywords: Equity and Diversity; Affect, Emotion, Beliefs, and Attitudes; Teacher Beliefs

For many students, school in general, and mathematics classes in particular, are places to learn that they are not smart. In some cases, student interests and abilities are discouraged as counter to the classroom model of good student. Cobb, Gresalfi and Hodge's "normative identity" accounts for the "general and specifically mathematical obligations that delineate the role of an effective mathematics student in that classroom" (2009, p. 58). Thus, normative identity can be thought of as the set of markers by which a person could identify accomplished learners—if you asked individual students what it means to be good at math, what is the consensus? Traditionally, the normative identity of "good at math" has been limited to being fast and accurate (Horn, 2007). Classrooms that are student- and inquiry-centered often value not only accuracy, but also: bravery in taking risks; embracing uncertainty; collaboration; communication; using misconceptions as springboards for discussion; the use of multiple representations; and being helpful (Boaler, 2015; Ruef, 2016). There is ample evidence telling us that teachers' beliefs about "good at math" matter (e.g. Gresalfi & Cobb, 2011). But students also need and benefit from a more open vision of mathematical success (Cohen & Lotan, 2014). When there are more ways to be successful, more students succeed. This paper describes the shifts in normative identity for 62 middle school students, finding that perceptions of what it meant to be "good at math" shifted from the restrictive normative identity of smart, fast, and correct, to the more inclusive identity of brave, mistake-making, and able to share one's thinking.

The school in this study embraces public sensemaking—the communal act of sharing individual student thinking in a public manner, with the goal of better understanding and refining a mathematical argument. Research has shown that public sensemaking has the potential to powerfully impact student learning (Cohen & Lotan, 1997; Stein & Smith, 2011). Risk-taking is related to "growth mindset"—the belief that one gets better at mathematics through effort—as opposed to remaining stuck a "fixed" innate level of ability (Dweck, 2006; Ruef, 2016).

Related to growth mindset, Boaler links "closed" vs. "open" mathematics to student opportunities to see themselves in the mathematics they do, and mathematics as relevant to their lives (Boaler, 1998). Closed mathematics refers to tightly procedure-bound and rule-based mathematics, which supports a culture of quick and accurate calculation. Open mathematics refers to opportunities to explore, create, collaborate, and invent new methods to make sense of mathematics. Sun (2015) found that teachers' implicit messages of what it means to do mathematics are more impactful than explicit messages about having a growth mindset. In other words, practicing what one preaches matters—it does not work to tell students to have a growth mindset when the teaching and learning environment is infused with closed mathematics.

Methods

This report is a subsection of a larger study, which followed a cohort of 62 sixth-grade mathematics students across most of the 2015-2016 academic year. The students were divided into three classes, and all shared the same mathematics teacher, Ms. Mayen. The students identified as: 76% Latinx, 15% African American, 8% Asian, and 1% Filipinx. They attended City School, a San

Galindo, E., & Newton, J., (Eds.). (2017). *Proceedings of the 39th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* Indianapolis, IN: Hoosier Association of Mathematics Teacher Educators.

Francisco Bay Area middle school that serves a diverse student body drawn from a large urban setting. According to the school's website, more than 91 percent of students qualified for free lunch. Ms. Mayen identifies as Latina, trained at a prestigious teacher preparation program, and was in her second year of teaching at the time of the study. All names in this study are pseudonyms.

Data included pre- and post-surveys constructed from 26-item Likert-scale and three short answer items (Table 1); field notes; analytic memos; classroom video; interviews with students and Ms. Mayen; and three sets of exit tickets. The post-survey was administered on March 18, 2016, to accommodate the schedules of both the participants and the researcher. Analysis of interviews, video, exit tickets, and field notes included coding for a-priori and emergent codes. The analysis was iterative, with emergent themes tested for counter examples, and refined through comparison to additional data (Charmaz, 1995). Coding was validated by comparison with trained raters, resulting in an average inter-rater reliability ratio of 87 percent.

Analysis and Findings

"Good at Math" in August

On the first day of school, students reported that someone who is good at math is compliant; smart; helpful; gets good grades; gets answers quickly; and is focused or pays attention in class (Table 1). This normative identity paints a portrait of "passive recipiency" with markers of success that map to a traditional classroom, including paying careful attention and following rules, and getting answers quickly and accurately (Boaler, 1998; Ruef, 2013; Horn, 2007). Asked to describe someone who is "good at math," Jazmin wrote "They follow directions; do their homework. Teacher's favorite student." Mia shared "They finish their work faster than other people do." These responses were coded as "compliant" and "speed/fast." Several students valued peers who help others with their mathematical work. This maps to reports from September student interviews wherein several students referenced the role of helpers in the classroom, from supporting presenters at the board to collaborating on seatwork. Krystal shared that "A person who is good at math is really smart. They are good at math and help others at math like teachers. They do hard problems." Notice that she sees the role of a smart and helpful student as being similar to that of a teacher. This was a common theme among responses—"smart" is a resource to be shared by helping others. While helping is positive, this early version was laced with the notion that smart and helpful people show how to complete procedures, which reinforced the idea that "smart" meant "knowing the rules."

"Good at Math" in March

This "good at math" portrait included being focused; making mistakes; having a growth mindset; being compliant; explaining well; being smart; presenting one's thinking, and being helpful (Table 1). There is evidence of a shift toward a normative identity of "active agent." The shift makes sense when compared to the norms and culture the classes had co-established with Ms. Mayen (Ruef, 2016). Of particular note is the importance of making mistakes and explaining well. The reason for the growth in valuing mistakes may be attributed to Ms. Mayen consistently valuing them as important for learning and understanding mathematics, which showed up in the student responses on exit tickets and survey responses. Barney wrote "How you know someone is good at Math is if they help and they make a lot of mistakes." Ms. Mayen and her students worked hard to establish a culture centered on efforts to share and understand one another's thinking (Ruef, 2016). It follows that the students valued presenting one's thinking publicly, helping, and explaining well.

Not one student referenced grades on the post-survey, and while students answered the pre-survey with rigidity in following the "rules" of filling in dots, students modified the Likert-scale portion of the post-survey. Some added doodles, one sketched a block letter **YET** (classroom shorthand for growth mindset), and some circled rather than shading in dots. This may be an

Galindo, E., & Newton, J., (Eds.). (2017). *Proceedings of the 39th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* Indianapolis, IN: Hoosier Association of Mathematics Teacher Educators.

indication that students felt greater agency to exercise creativity in answering the surveys. Montse invented a new word, “mistakealable,” to describe math—for her, math is a place where making mistakes is an important part of the learning process. The biggest shifts apparent in the Likert-scale items illuminate changes in the students’ collective vision of doing mathematics (Table 2). Based on results from the paired t-tests of the pre- and post-surveys, students came to value open mathematics, creativity, and the power of consensus to determine the validity of an answer. They disagreed most strongly that “in math, the most important thing is to get the correct answer.”

Discussion

It is clear that Ms. Mayen’s students shifted their beliefs about what it means to be “good at math,” but how and why? These students came to see being brave in presenting at the board as a necessary precursor to sharing their thinking. Relatedly, sharing their thinking supported deep understanding of each other’s perspectives. Perhaps most importantly, making mistakes was central to the work of being a good at math. This short report focuses on the shifts that occurred rather than the mechanisms that drove those changes. I have reported elsewhere on the careful work done in concert between Ms. Mayen and her students to establish the norms and culture of the classroom, which were essential to developing safe ground for the risk-taking that public sensemaking demands (Ruef, 2016). Ms. Mayen inherited, sought out, and augmented a mathematics curriculum that was made up primarily of open mathematics tasks. Further, she negotiated and reinforced norms that supported public sensemaking. It is therefore not surprising that collectively, her students took up the view that math class was about open mathematics and growth mindset, and that they would be successful if they were active agents (Ruef, 2016; Sun, 2015).

In closing, I share two collective stories drawn from these normative identity composite sketches. In the beginning of the year, Ms. Mayen’s students seemed to believe this narrative: Mistakes are bad. If I make a mistake, I am bad at math. By March that story had change to this: Mistakes are good. If I make a mistake, I am good at math. Ms. Mayen’s students re-engineered their understanding of what it means to be smart, and in so doing, opened more doors for themselves and others to identify as successful mathematics students.

COLLEGE STUDENTS' GENDER AND RACIAL STEREOTYPES OF MATHEMATICIANS

Many individuals are negatively affected by stereotypes of mathematics and mathematicians, which further prevent their interest in pursuing mathematical careers. This paper assesses college students' stereotypes of mathematicians with regards to race and gender. In this study, we asked 179 college students to "Draw a Mathematician." We also conducted four focus group interviews with a total of 12 participants, in which we asked them to view photos of individuals and determine which they believed to be a mathematician. Through our analysis of the data, we have found that many college students do have certain stereotypes of mathematicians.

Keywords: Affect, Emotion, Beliefs, and Attitudes; Equity and Diversity; Gender; Post-Secondary Education

Stereotypes about mathematics and mathematicians affect how individuals view those who enjoy mathematics and those who enter mathematical careers. As a result, these stereotypes can also influence certain students' mathematics performance, perseverance, and career choice in the field. It is likely that negative stereotypes more greatly affect women and certain minorities, who are already underrepresented in the field of mathematics. Therefore, it is important to know what stereotypes of mathematicians currently exist and how they are viewed by society.

Scholars began studying stereotypes of scientists as early as the 1950's (Mead & Metraux, 1957) and have continued to do so in more recent years (Thomas et al., 2006). Around the turn of the century, scholars also began studying students' stereotypes of mathematicians. For example, Rock and Shaw (2000) collected drawings of "mathematicians at work" from kindergarten through fourth-grade students and found that while the majority of kindergarteners and first grade students drew female figures, the second through fourth grade students drew almost an equal number of male and female mathematicians. In a similar study with middle school students in five different countries, Picker and Berry (2000) also had students "draw a mathematician at work" (p. 70). Picker and Berry found many common themes amongst the drawings. In particular, they noted that many students drew white, male mathematicians. These mathematicians were often wearing glasses, had facial hair, were either balding or had unruly hair, and were dressed in unfashionable clothing.

While some work has been done on children's stereotypes of mathematicians, we know much less about college students' stereotypes of mathematicians. Given that it is during the college years when many individuals are making choices directly relevant to their future careers, we find it critical to know more about college students' stereotypes of mathematicians, especially those stereotypes related to gender and race.

Methods

This research study was conducted in two phases. During the first phase of the study, 179 college students completed a survey in which they were asked to "draw a mathematician." Colored pencils were provided to the students for use in their drawings. Of the 179 participants, 66 (37%) identified as male, 112 (63%) identified as female, and 1 identified as neither. The majority of the participants identified as Caucasian (79%). More than half (58%) of the participants were college freshmen, with another 28% as sophomores. A large variety of majors were represented, with majors from every

Galindo, E., & Newton, J., (Eds.). (2017). *Proceedings of the 39th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* Indianapolis, IN: Hoosier Association of Mathematics Teacher Educators.

college at the university, and the participants had completed anywhere from zero to six mathematics classes at the collegiate level.

During phase two, we conducted four focus group interviews with a total of 12 volunteers who had participated in the first part of the study. For the focus group interviews, we presented the participants with 16 photos of individuals and asked the participants to determine which individuals they believed were mathematicians and which were not, and to explain their reasoning. The participants were initially asked to do this independently. After each participant recorded their decisions about each of the photos, we led a group discussion about what they had determined. The focus group interviews were audio and video recorded and later transcribed.

Results from the Survey

Of the 179 participants who completed the survey, 87 (49%) drew a male mathematician, 37 (21%) drew a female mathematician, 6 (3%) made sure that both genders were represented, 43 (24%) drew a figure that had an indeterminable gender (such as a stick figure with no hair or clothes), and 6 (3%) drew something other than a person or left the page blank. What we found even more interesting, however, are the results when we analyze our data by the gender of the participant. Therefore, Table 1 contains the data for the male participants and Table 2 contains the data for the female participants. For the one individual who identified as neither male nor female, the drawing of the mathematician was a male.

As can be seen by Tables 1 and 2, both genders drew male mathematicians more often than any other category, however, male students were substantially more likely to draw a male mathematician than female students were. Furthermore, only 3% of male students drew a female mathematician, while 31.5% of female students drew a female mathematician. Similarly, only one male student ensured that both genders were represented while 5 female students made sure that both genders were represented in their drawings.

Table 1: Male Participant Drawings **Table 2: Female Participant Drawings**

Male Participant Drawings			Female Participant Drawings		
Gender of drawings	**N**	**%**	**Gender of drawings**	**N**	**%**
Male	37	56.1	Male	49	43.8
Female	2	3.0	Female	35	31.5
Both genders represented	1	1.5	Both genders represented	5	4.5
Indeterminable gender	24	36.4	Indeterminable gender	19	20.0
No person drawn/blank	2	3.0	No person drawn/blank	4	3.6

We also investigated the implied race of the mathematicians in the drawings, which we compared to the stated race of the participants. To determine implied race of the drawings, we used the colored pencil shading of the face to ensure consistency. For shading options, we developed four categories, which included: no shading, brown, yellow/orange, and other. Of the 173 surveys that had drawings of people, 155 (90%) did not shade their mathematician, 7 (4%) shaded their mathematician brown, 10 (6%) shaded their mathematician yellow/orange, and 1 drawing we coded as "other" because the participant had drawn multiple stick figures with each figure being a different color (red, orange, green, purple, etc).

We further analyzed these results by race of the participants. Table 3 presents the results for Caucasian participants and Table 4 presents the results for the participants who identified as a racial minority or as multi-racial. In our interpretation, no shading could be classified as Caucasian and brown shading could be classified as African American or multi-racial. It is hard to determine what yellow/orange shading is meant to represent, but given that mostly Caucasian participants chose to shade their mathematician as yellow/orange, it is possible that this, too, was intended to represent a

Galindo, E., & Newton, J., (Eds.). (2017). *Proceedings of the 39th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* Indianapolis, IN: Hoosier Association of Mathematics Teacher Educators.

Caucasian mathematician. If that were the case, then 97% (134 of 138) of Caucasian participants who drew a person, drew a Caucasian mathematician.

Table 3: Caucasian Participants Drawings **Table 4: Minority Participants Drawings**

Caucasian Participant Drawings			Minority Participant Drawings		
Shading of Face	**N**	**%**	**Shading of Face**	**N**	**%**
No Shading	125	90.6	No Shading	30	85.7
Brown	3	2.2	Brown	4	11.4
Yellow/Orange	9	6.5	Yellow/Orange	1	2.9
Other	1	0.7	Other	0	0.0

Results from the Focus Groups

During phase two of the study, we held focus groups with two to four participants at a time, asking them to look at actual photographs of individuals and determine whether or not they think each individual was a mathematician. We had a total of 12 participants in our focus groups, three men and nine women.

We selected 16 images to use for the focus group interviews. We purposely chose images that encompassed many different stereotypes of mathematicians. Of these 16 images, eight were male and eight were female. Four images were of racial minorities. We had an image of an Asian male, an Asian female, an Indian male, and an African American female.

Each image was selected to be a mathematician by at least one participant during the focus group interviews. No image was selected by more than nine participants. In our analysis, we classify whether or not an image was considered to be a mathematician by the participants if more than 50% of the participants (at least seven out of 12) chose it to be a mathematician. Based on this criterion, eight of the 16 images were selected to be mathematicians. Of the eight selected as mathematicians, four were men and four were women. Therefore, male images and female images were equally selected to be mathematicians by our participants. When considering race, the images of the Asian male, Asian female, and African American female were all selected to be a mathematician. The image of the Indian male was not.

During the interview discussions, participants rarely brought up the topic of gender on their own and when we specifically asked about gender, most participants stated that gender did not play a role in their decisions. However, a few participants did admit to using different criteria for men as they did for women. While it was not completely clear from their comments how they used the criteria differently, it is clear that they recognized that they were using different criteria for different genders.

Although discussion on gender had to be solicited by the interviewers, many participants brought up the topic of race on their own. For example, some participants wrote comments such as “racial stereotyping” or “he looks Indian and smart” as their reason for selecting certain images to be of mathematicians. This occurred for the images of both the Asian male and Asian female, and the Indian male. No comments about race were written for the image of the African American female, though she was selected to be a mathematician by eight of the 12 participants. One thing we found interesting was that the Indian male was only selected to be a mathematician by three of the 12 participants. One reason for this might be because we specifically chose a photo of an Indian male who was playing the drums, to put into conflict the racial stereotype of individuals from India being good at mathematics with the stereotype that mathematicians do not have hobbies or interests outside of mathematics (Piatek-Jimenez, 2008). While many participants said they considered that he might be a mathematician, they also stated that because he was playing the drums in the photo was why they determined he must be a musician instead.

Galindo, E., & Newton, J., (Eds.). (2017). *Proceedings of the 39th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* Indianapolis, IN: Hoosier Association of Mathematics Teacher Educators.

While gender and race seemed to play some role in these participants' decisions about the photos, there were three other criteria that appeared more compelling to them. First, in order to be considered a mathematician, the individual needed to be "dressed professionally" but not be "too dressed up." If the individual was wearing a t-shirt or polo shirt, it was assumed that they were not a mathematician. Yet, if they were wearing a formal dress or a sports coat, that also led our participants to assume that they were not a mathematician. Secondly, the setting of the images influenced our participants' decisions. For example, the woman who was camping and the man playing the drums were rarely selected to be a mathematician, with the backdrop of the image often being provided as the reason. Finally, one of the most cited reasons that participants gave for their decision was whether or not the individual in the image reminded them of someone they know. If the image reminded them of a past mathematics teacher, then they assumed the image was of a mathematician. If the image reminded them of someone else they knew, a past history teacher for example, then they determined the image was not of a mathematician.

Discussion

During phase one of our study, when we asked college students to "draw a mathematician" we found that they mostly drew images of white males. This was true amongst our female participants as well. However, during the focus group interviews, exactly half of the male images were selected to be mathematicians and exactly half of the female images were selected to be mathematicians. In other words, gender appeared to play a much smaller role when the college students considered actual photos of real people. These results suggest that while a male may be the first image that comes to many people's minds when they hear the word "mathematician," they recognize that both men and women become mathematicians and use additional criteria when making assumptions.

While differentiated races were almost nonexistent amongst our participants' drawings of mathematicians, race played a more prevalent role during the focus group interviews. Our participants were not shy about admitting their stereotypes that Asians and Indians are smart, and therefore more likely to become mathematicians. We found, however, that the stereotype that mathematicians do not have hobbies outside of mathematics appears to be stronger than the racial ones, at least for many of our participants. Our participants appeared to feel more strongly that a mathematician would not play the drums than they did about someone from India having to be a mathematician.

FROM TRAJECTORIES, DEFICIT, AND DIFFERENCES TO NEURODIVERSITY: THE CASE OF JIM

Jessica H. Hunt

Rachel Lambert
lambertr@chapman.edu
Chapman University

Cognitive differences intrinsic to children with learning disabilities (LDs) have historically led to deficit assumptions concerning the mathematical experiences these children "need" or can access. We argue that the problem can be located not within children but instead as a mismatch between instruction and children's unique abilities. To illustrate this possibility, we present the case of "Jim," a fifth-grader with perceptual-motor LDs. Our ongoing analysis of Jim's fractional reasoning in seven equal sharing based tutoring sessions suggests that Jim leveraged his knowledge of number facts and alternative representations to advance his reasoning.

Keywords: Cognition, Elementary School Education, Equity and Diversity

Over their school-age years, many children tend to experience difficulties with fractions. For children with learning disabilities (LD), the difficulties can become persistent and grow into unique learning challenges. As a result, researchers continue to focus on ways these children develop *understandings* of fractions as quantities (Hunt, Westenskow, Silva, & Welch-Ptak, 2016) to provide evidence of and access to the potentially rich mathematics in which these children *can* engage.

Unfortunately, these illustrations stand in sharp contrast to the current literature base and policy recommendations for mathematics instruction for children with LDs. Previous research clearly illustrates instruction for these children have been dominated by basic concepts (Kurz, Elliott, Wehby, & Smithson, 2010). A recent review (Lambert & Tan, 2016) of articles researching the mathematics learning of Kindergarten through 12th grade students found significant differences between the mathematical teaching practices used with children with and without disabilities. Mathematical teaching and learning were informed largely by constructivist and sociocultural perspectives with children *without* disabilities. For children *with* disabilities, mathematical teaching and learning were informed primarily by medical and behavioral perspectives. The distinction is concerning as it suggests two categories of mathematics learners who "need" different kinds of mathematics.

Our work both builds on and critiques work on learning progressions (or learning trajectories). Original discussions of trajectories (Martin, 1995) stressed their hypothetical nature and did not separate actualized trajectories from the teachers and children involved in specific instances of learning. Currently, the term suggests an expected course of development or simplified learning path in a concept area, such as early fractions. When considering children with LDs, who may use different or more informal ways of reasoning than educators might expect, we are concerned that educators might use progressions to direct children to move across the levels or stages of a progression without paying attention to the reasoning that children employ and work to support children to explore, revise, and advance that reasoning.

From Explicit and/or Leveled Instruction to Neurodiversity

Attempts to remediate, or "fix," children through procedural training or steering thinking through predetermined pathways or conceptual steps seems problematic if educators wish to provide access to and support reasoning that children with LDs *do* possess and build from it (Hunt et al., 2016). In fact, we contend that these kinds of approaches to remediation may work in part to disable these children more so than their learning differences. Disability Studies (DS) recognizes that although individuals

Galindo, E., & Newton, J., (Eds.). (2017). *Proceedings of the 39th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* Indianapolis, IN: Hoosier Association of Mathematics Teacher Educators.

have natural biological variations, it is the social effects of difference that disable rather than the impairments themselves (Siebers, 2008). From the DS perspective, the behavioral/directive tradition apparent in much of the instruction these children experience portray learning differences as deficits *within individuals* that results in viewing difference as something to be fixed as opposed to a natural strength that can be leveraged in instruction. Neurodiversity (Robertson & Ne'eman, 2008) positions cognitive differences as not only natural biological differences, but as potential strengths. For example, individuals with LD demonstrate cognitive strengths in three-dimensional reasoning and creative problem solving (Eide & Eide, 2012). Using this lens, we sought to understand the fractional reasoning of one fifth grade children with perceptual-motor LDs as he worked in fractional tasks meant to support two ways of reasoning fundamental to early fraction knowledge: partitioning and iterating (Steffe & Olive, 2010). We utilized equal sharing (i.e., equally sharing an object or objects among a number of people, where the result is a fractional quantity) because it invites multiple means of reasoning and representation. The research question was, "What ways of partitioning and iterating does a fifth-grade child with LDs display in equal sharing tasks?"

Method

"Jim"

"Jim" (age = 12 years) attended elementary school in the Northwestern United States. He was identified by his school system as having a learning disability in mathematics. Jim's performance on the mandated standardized state measure of math performance was at a failing level in 3rd, 4th, and 5th grade, which suggests sustained low achievement in mathematics. His reading scores were at average levels. Jim had received over two years of additional support in fraction concepts and operations that included shading pre-partitioned models and procedures for operations. Finally, Jim evidenced significant difficulties with visual motor integration (i.e., coordination of visual perception and motor skills at 2nd percentile).

Teaching Experiment

Data collection was collected in seven sessions of a teaching experiment (Steffe & Thompson, 2000). Sessions took place during school hours and were in addition to the child's regular math class time. The first and second author attended all tutoring sessions and collaborated throughout the ongoing analysis of teaching episodes. The first author was the researcher-teacher. The second author acted as a witness (e.g., took extensive field notes, observed the interactions to provide an outsider's perspective during on-going analysis). All authors are engaged in retrospective analysis of the data (described below). Researchers collected three sources of data: transcribed video recordings, written work, and field notes.

Tasks, teaching moves, and representations. We prepared problem tasks, representations, and possible teaching moves based on previous evidence of how children with LD might reason in equal sharing tasks (e.g., 3 people share 4 items, Author). Tasks were planned to be dynamic (i.e., adaptable to the child's current conceptions) and presented to Jim in realistic contexts that we changed according to his preference. In each task, the number of sharers ranged from two to ten and the number of objects shared ranged from three to 13. The problem-solving tasks were designed so that Jim could use a variety of strategies and representations (e.g., drawings, Cuisinaire rods) to reason about the mathematics. Teaching moves were broadly defined as responsive to the child's thinking (e.g., extending, supporting).

Data Analysis

Ongoing analysis of critical events (Powell, Francisco, & Maher, 2003) in the child's thinking and learning were noted and discussed before and after each session. The focus was on generating

Galindo, E., & Newton, J., (Eds.). (2017). *Proceedings of the 39th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* Indianapolis, IN: Hoosier Association of Mathematics Teacher Educators.

(and documenting) initial hypotheses as to what conceptions could underlie the child's apparent problem solving strategies during these critical events. These hypotheses led to planning the following teaching episode. We are currently using retrospective analysis to delineate Jim's informal conceptions of fractional quantities, how his reasoning shifts during each tutoring session, and what his conceptions were during the final session. We are also currently working to identify possible indicators of Jim's conceptual growth using the constant comparison approach (Leech & Onwuegbuzie, 2007). Reported results are tentative.

Preliminary Results

Initial Reasoning: Session One

Jim had just solved several tasks involving whole number partitive division. Excerpt a begins with an extension of the partitive division situations.

Excerpt a: Share 7 granola bars between 3 friends

J: [gives two whole items to each person] And of course there would be one left over. [draws a long bar; carefully marks a small dot at the top middle of the bar and draws a line straight down; then uses the same mechanism to mark each of the two parts into two more parts]. Ok, so they each get a slice of the one that's left. And there's another piece left [begins to partition the fourth part into four parts using the same mechanism].

T: Oh. So [labels each part], so if this is my part, and this is yours, and this is Nita's, you say you have this piece left. And we cut it up again. Any way to do it, so we don't have to keep cutting?

J: [attempts to partition two additional times by spinning the paper and draw a line from one of the corners] I really don't know of any other way to do it.

T: Ok. Any way to know what to call that parts you made?

J: [pauses for 5 seconds] I'm not sure.

In the first session, Jim evidences what we call a *midpoint partitioning strategy*. His partitioning seems to be supported by a careful identification of the midpoint of the length and a unilateral partition. The strategy does not yet seem to be linked with the number of sharers in the situation, a consideration of the magnitude of the parts created, or an iterative consideration of the parts to the whole. In other problems in the session, Jim continues to use the midpoint strategy regardless of the number of sharers. It is unclear whether Jim was conflating partitions with parts (i.e., three lines as opposed three parts), yet Jim's alternate strategies provide counter evidence of this possibility. It is interesting to us that, throughout the session, Jim seems to view the midpoint as the only valid partition at this point. In later sessions, Jim continued to evidence this strategy in his work in equal sharing tasks, regardless of the number of items or the number of sharers.

Session Four

In session four, Jim began to connect his number knowledge to his midpoint partitioning strategy to bring about an early iterative reasoning. Excerpt b shows Jim's reasoning in a task involving five sandwiches and four sharers.

Excerpt b: Share 5 sandwiches between 4 people

J: [draws 5 boxes on the paper; makes a lengthwise and widthwise partition to create four parts in each box. Numbers and names each part].

T: Tell me about your drawing.

J: Well, I made lots of tiny pieces.

T: Oh. How many?

Galindo, E., & Newton, J., (Eds.). (2017). *Proceedings of the 39th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* Indianapolis, IN: Hoosier Association of Mathematics Teacher Educators.

J: [pauses for 5 seconds and looks at his drawing] Well, there are five boxes and four tiny pieces in each. Four times five is 20 and 4 + 4 + 4 + 4 + 4 is 20 [points to each box as he counts].
T: Ok [points to drawing]. How much of a sandwich would I get, do you think?
J: [Looks at drawing] Well, you get five tiny pieces out of all of the 20 pieces of sandwiches.
T: Oh ok. How about for one sandwich?
J: Hmm. Well, [mutters 'four times one is four'] four of the tiny pieces is a whole sandwich because four times one is 4, and one part and one part and one part and one part is a sandwich [points to one part; taps table four times]. And then one more. So a whole sandwich and a piece.

Jim shows three subtle shifts in his reasoning. First, his way of partitioning seems to have changed to a repeated halving, perhaps due to his self-prompted change of representation from a bar to a square representation. Second, he partitions *each* square into the number of sharers (as opposed only the last item). Partitioning each item also seems to support the final shift which involves a nascent iterative consideration of the parts to the whole. This reasoning seems further supported by Jim's leveraging of his whole number fact recall to support his reasoning of each person's share as first a share of a subset of the total number of 'tiny pieces' he creates and then as a rudimentary coordination or iteration of the part to the whole. We are further examining how Jim's use of multiple modalities (i.e., changing representations, verbal number facts, gesturing) support his partitioning and iterative reasoning in later sessions, especially in tasks where partitioning proves difficult (e.g., requests to share between 3 or 5 shares).

Discussion

Jim's significant initial misunderstandings about fractions would typically be addressed by behavioral interventions in special education focused on memorizing procedures. In this study, we explore how close analysis of previous understandings based on research in fraction learning can be the framework of an intervention, particularly when the student is understood not as deficient, but as always already having knowledge of the mathematical topic. These two excerpts highlight one of the multiple shifts we document in Jim's understanding of fractions. We argue further that these shifts in understanding were supported by 1) problem solving in contexts, 2) access to multiple modalities, and 3) instruction that builds from careful attention to previous understandings.

Mathematics education must include students with disabilities in research, not simply adding these learners to already developed studies, but by engaging with new perspectives that such students bring. Part of a larger study, this paper documents two dilemmas that the authors were faced with when investigating the mathematical engagement of two fifth graders with autism in a standards-based mathematics classroom. Using neurodiversity, we analyze how the unique engagement of these two students challenges preconceived notions of students with autism in mathematics, as well as how we conduct mathematical research.

Keywords: Equity and Diversity; Affect, Emotions, Beliefs and Attitudes; Research Methods

Introduction

Mathematics educational research rarely includes students with disabilities (Lambert & Tan, 2017). In this paper, we focus on two students with autism learning mathematics, and we draw on a political and theoretical movement initiated by people with autism called *neurodiversity*. Instead of understanding autism as a deficit, neurodiversity understands the cognitive differences of autism as a natural and beneficial aspect of biological diversity (Robertson & Ne'eman, 2008). From this perspective, we assert that increasing the participation of students with autism in mathematics will not only help the students, but will help mathematics. Furthermore, we argue that including students with disabilities such as autism in mathematics education research will help educational research in mathematics by expanding both concepts and methods. This paper presents a theoretical argument for including students with autism in mathematics educational research by analyzing how including two students with autism has expanded both theoretical and methodological practices in mathematics research.

Conceptual Framework

This brief research report is based on emerging data from a larger project arguing for a shift from designing intervention around content to intervention in participation (Lambert & Sugita, 2016). Building proficiency in mathematics for <u>all</u> learners means sustained and deep participation in practices such as problem solving, reasoning, and critique, otherwise known as the Standards for Mathematical Practice in the Common Core State Standards for Mathematics (CCSS-M, 2010). Yet, very little is known about how students with disabilities, particularly with autism, engage in the Standards for Mathematical Practice, as the topic is significantly underrepresented in special education research (Maccini, Miller, & Toronto, 2013).

Taking a situated view of learning, we use the terms participation and engagement interchangeably and define participation as the actions of individuals in particular activity systems, which are one or more individuals interacting with each other and with particular sets of material and ideological resources (Greeno & Gresalfi, 2008). Activity systems are understood through

Galindo, E., & Newton, J., (Eds.). (2017). *Proceedings of the 39th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* Indianapolis, IN: Hoosier Association of Mathematics Teacher Educators.

documentation of the norms of participation that construct the taken-for-granted activities and assumptions of the cultural space. Additional information on the activity system are obtained from interviews with students and teachers.

The majority of research on autism is not focused on academics (Gevarter et al., 2016). Oswald et al., (2015) argue that the lack of research in mathematics that includes learners with Autism Spectrum Disorder (ASD) stems from assumptions that individuals with ASD are higher performing in mathematics than their non-disabled peers. Some research has supported this connection between autism and mathematical talent (Baron-Cohen, Wheelwright, Burtenshaw, & Hobson, 2007). Yet Wei and colleagues (2013) found that while a larger percentage of individuals with ASD in college major in STEM fields (34%) than non-ASD students, individuals with ASD are far less likely to attend college, when compared to other disability categories. From a neurodiversity standpoint, we recognize that individuals with autism have unique ways of processing the world that may provide particular strengths in mathematics. However, we also assert that explanations for persistent low achievement for individuals with autism in mathematics (Wei et al. 2013) must explore the relationship between the student and the mathematics classroom.

Methods

We have situated this paper in a larger study of a fifth-grade classroom that includes four students who receive special education services. The larger study investigates shifts in student participation in the mathematical practices, particularly MP1 (problem solving) and MP3 (discourse) over the course of one academic year. In this short paper, we explore emerging data, focusing on the initial mathematical understandings and participation of two students with autism. Using *neurodiversity* as a theoretical tool, we explore several issues:

1. What does it mean to include neurodiverse individuals in mathematics educational research? What challenges are presented? What can be gained from such work?
2. How do current conceptions of participation privilege neurotypical learners? How can we broaden these notions?

Findings

In this section, we will present two dilemmas that we faced in our initial work on this project, particularly around the two students with autism. We will introduce our two participants, then present the dilemmas, and explore what the findings might mean for broadening mathematics education to include all learners. Andrea and John are the two students of focus in this study. Andrea is a 5th grade girl with an Individual Educational Plan for autism. She identifies as white and Asian. John is a 5th grade boy with an Individual Educational Plan for autism. He identifies as Latino.

Dilemma 1: Interviews

This research included student interviews. In our initial plan, we assumed these would be individual. However, after consulting with the teacher, we were concerned that both Andrea and John would have significant difficulties with this participation structure. In the lead author's first visits to the classroom, Andrea was both very excited about the research, and also clearly uncomfortable with the new adult and the idea of being filmed. John had a history of being very reserved at school, taking months to speak to previous classroom teachers. After discussing this with the teacher, we decided to interview all students in pairs, created by the teacher. We felt that this would make these students more comfortable in the interview. In addition, we planned to allot extra time with each of these interviews. We did not video-record Andrea's interview, and we began that interview by providing a comic book related to her interests. The comic book seemed to help Andrea relax and answer the interviewer's questions.

Galindo, E., & Newton, J., (Eds.). (2017). *Proceedings of the 39th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* Indianapolis, IN: Hoosier Association of Mathematics Teacher Educators.

We were sensitive to the reality that our interviews might feel like evaluative assessments to students, which might trigger negative emotions because of past experiences being taken into rooms with unfamiliar adults and being asked questions. Children with disabilities in schools are routinely assessed by unfamiliar adults, and these events are often confusing, leaving them with memories of failure and stress (Connor, 2005). Even as we planned to ask questions that we felt were not stressful, we recognized that the situation might mimic other evaluative experiences. We changed our research plan to adapt to this need. The lead author also used play as a relationship building device, engaging in talk around the comic book with Andrea in order to help her transition into the interview and feel comfortable. We wonder how much these shifts in methods would assist other students.

While these two individuals with autism prompted our switch to paired interviews, we wonder if this new structure made other students more comfortable as well. Or, alternatively, did paired interviews introduce additional layers of stress for students, as we found in one interview in which a student seemed to ask for permission to speak, not from the interviewer, but from the other student. We believe that when we worked to make the interview more inclusive of the two students with autism, we looked far more carefully at the emotional and social implications of interviews, assessing the dialogical discursive implications of the triad (Riessman, 2007). Including the students with autism made us question the interview structures that we had taken for granted.

Dilemma 2: What counts as participation?

In our first day of video recording, Andrea and John were seated right next to each other, right in the front of the classroom next to the teacher's whiteboard. The teacher first led the class in a numeracy routine called a number string, and then asked students to solve a Cognitively Guided Instruction (CGI) story problem on equal sharing (Empson & Levi, 2011).

Their participation in this mathematics lesson was quite dissimilar. During the number string, Andrea raised her hand for each problem, and more than once shouted out an answer. When called on, she shared her strategy, explaining how she broke apart a multiplication problem into parts (using the distributive property). Each of her answers were correct. For the CGI equal sharing problem, her first exposure to that problem type, Andrea drew out the sharers and the brownies that were to be shared, partitioned the final brownie into fourths, and accurately identified all fractional parts. Her strategy was non-anticipatory, with coordination at the end resulting in a accurate answer. She solved this very quickly, within 3-4 minutes, and then began clearing out her desk, and then transitioned to reading a comic book. She did not speak in any small group situation, nor did she share a strategy for the CGI problem. Andrea demonstrated understanding of the targeted mathematical concepts of the lesson, and was able to engage in whole group strategy sharing, although she did not participate in small group discussion.

John did not verbally participate in the number string. However, throughout the number string, his attention seemed rapt towards his teacher and the board on which she represented student strategies. Like Andrea, this was his first exposure to an equal sharing problem. Also like Andrea, John used a non-anticipatory strategy with coordination at the end. While Andrea solved the CGI problem quickly, John worked slowly, carefully drawing out each portion as he portioned, twice representing all the shared pieces and the sharers. His partitioning was accurate but he did not accurately name the quantity in fractional terms. When solving the CGI math problem, he did not speak to any other students, nor did he during opportunities to speak to a partner during a share. During the share that followed the CGI story problem, he did raise his hand very slightly in response to a question about which strategy he used. At all times, however, his attention seemed wholly focused on his teacher and her representations on the white board. Similarly, when he solved his CGI problem, he focused completely on his work, drawing and redrawing his solution for the entire work time. He worked longer on his paper than any other student in the room.

Galindo, E., & Newton, J., (Eds.). (2017). *Proceedings of the 39th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* Indianapolis, IN: Hoosier Association of Mathematics Teacher Educators.

Conclusion

What do we learn from these differences in participation? Andrea provided more evidence for her mathematical understanding during this lesson. She moved from intense attention on the mathematics, to cleaning out her desk, always moving. John, on the other hand, was quiet and still, but appeared to be attending wholly on the mathematics. However, because he did not speak, we felt unsure of his level of engagement and/or understanding at times. In both cases, we felt that our tools for measuring mathematical understanding during the lesson (documenting discourse and collecting student work) were inadequate to the task of understanding their mathematical understandings. Should we devalue the quiet engagement of John? Or the intermittent attention of Andrea? Their differences in engagement remind us that there is not one way of learning mathematics, and no one way of being autistic, and that as we include students with autism in mathematics education, as we must, that we recognize and respect unique ways of engaging in mathematical practices.

In this mixed methods study, we examined how middle level students' self-efficacy towards STEM changed after participating in a week long summer day STEM Camp. Findings revealed differences in students' STEM self-efficacy exist among students who received a scholarship to attend STEM camp compared to those who did not. Continuous opportunities for authentic STEM opportunities to support more equitable education for students from low socioeconomic backgrounds are recommended.

Keywords: Equity and Diversity; Affect, Emotion, Beliefs, and Attitudes

Introduction

As the demand for science, technology, engineering, and mathematics (STEM) professionals continues to rise, calls from policy makers for improved diversity in mathematics and science education aim to broaden participation in STEM fields (NSF, 2010). Some studies cite the "STEM Pipeline", or limited access to rich academic coursework in K-12 education, as the cause of the shortage and lack of diversity (e.g., Fox & Hackerman, 2003). However, with PK-12 students in school less than 20% of their time awake (Afterschool Alliance, 2011), access to academic coursework is not enough to shift toward equitable representation in STEM fields. We must rely on partnerships beyond the formal school setting to motivate underrepresented groups and build their STEM self-efficacy.

In this study, we investigated the impact of an out-of-school environment, See Blue STEM Camp, on student's STEM self-efficacy. More specifically the research question underlying this study is *How does participation in the See Blue STEM Camp influence students from diverse socioeconomic backgrounds STEM self-efficacy of STEM?*

Conceptual Framework

Self-efficacy is defined as one's judgment about their ability to plan and execute a course of action to successfully complete a specific goal (Bandura, 1986). Because self -efficacy is a significant predictor of task motivation and performance beyond ability (Bandura & Locke, 2003), high self-efficacy is a key predictor of performance and persistence in STEM. Self-efficacy is developed through four primary sources: mastery experience, vicarious experience, social persuasion, and physiological reaction (Bandura, 1997; Pajares, 2005). In STEM, students must have access to 1) high-level STEM experiences in order to achieve mastery, 2) STEM role models similar to the students, 3) feedback and encouragement from influential people, and 4) a chance to build confidence through discussion in all environments (see Figure 1).

Traditionally underrepresented groups in STEM have less access to STEM learning experiences (Peters-Burton et al., 2014) and lower levels of self-efficacy (Hernandez et al., 2013), which perpetuates the cycle of blocked access to STEM fields (Carter, 2006). Out-of-school environments, such as the See Blue STEM Camp, have been shown to increase STEM interest and post-secondary matriculation (e.g. Mohr-Schroeder, Jackson, Schroeder, Miller, Walcott, Little, Speler & Schooler, 2014; MacPhee et al., 2013). However, there is limited knowledge regarding the development of

Galindo, E., & Newton, J., (Eds.). (2017). *Proceedings of the 39th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* Indianapolis, IN: Hoosier Association of Mathematics Teacher Educators.

STEM self-efficacy in students of low socioeconomic backgrounds in K-8 education (e.g., Lubienski, 2007). This study aims to contribute to the literature by investigating the self-efficacy of this population of students.

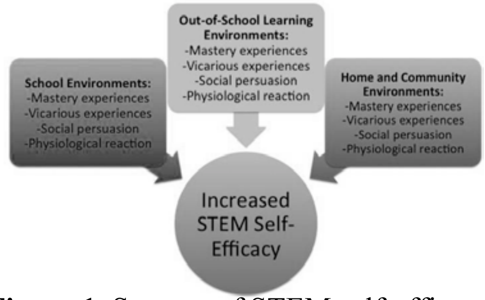

Figure 1. Sources of STEM self-efficacy.

Method

In this sequential, mixed methods design (Creswell & Plano-Clark, 2007), we examined middle level students' STEM self-efficacy before and after participating in See BlueSTEM Camp.

Participants. Participants (N=346) were rising fifth- through eighth-grade students from the southeastern region of the United States who attended a week-long STEM summer camp in either 2015 or 2016. Students participated in STEM content sessions, where they engaged in authentic, hands-on experiences in STEM that fostered the practices of engineers, mathematicians, and scientists. The camp targeted underrepresented groups in STEM (e.g., females, students of color, and students of low socioeconomic backgrounds). Scholarships were offered to students based on financial need. For this study, there were 72 (~21%) scholarship recipients.

Data. Students were administered the STEM-Career Interest Survey (Kier et al., 2014) at the beginning and end of STEM camp. The 44-item survey was based on a 4-point Likert scale. Semi-structured interviews, lasting around 3-5 minutes, were conducted with a sample of participants to discuss their concepts and connections to STEM before, during, and after camp. A total of 155 students (45%) were interviewed with 23 (6.6%) of the interviewed students receiving scholarships. Interviews were digitally recorded and transcribed.

Data Analysis. Exploratory factor analysis (EFA) was conducted on 346 matched pairs using weighted least squares with adjusted means and variance (WLSMV) estimator in *Mplus v.7.11* (Muthén & Muthén, 2013) to show unidimensionality was tenable, as supported by a ratio of the first eigenvalue to the second eigenvalue larger than three (Embretson & Reise, 2000). Then, omega reliability coefficient (McDonald, 1999) was calculated using bootstrapping method to obtain confidence intervals for the pre- and post-survey data using the WLSMV estimator to determine whether a raw score total could be used (i.e., the larger the omega, the greater the reliability in using raw score totals for analysis). Finally, the Wilcoxon Signed Rank Test was used to test whether change in students' responses from pre- to post-survey was statistically significant for the scholarship and non-scholarship students. To analyze the qualitative data, we used an inductive content approach to identify patterns and themes (Grbich, 2007). The themes were discussed until consensus amongst the categories was obtained.

Results and Discussion

In this study, we examined whether there was a difference in scholarship and non-scholarship students' STEM self-efficacy. The EFA results from the overall population on the survey revealed a single underlying construct related to interest in and awareness of STEM and STEM careers. Using the WLSMV estimator, the resulting omega values for the model results of the pre- and post-survey data were .961 and .969, respectively, with corresponding 95% Confidence Intervals [.961, .971] and [.972, .978] obtained from bootstrapping; thus indicating strong internal reliability and

Galindo, E., & Newton, J., (Eds.). (2017). *Proceedings of the 39th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* Indianapolis, IN: Hoosier Association of Mathematics Teacher Educators.

reasonableness to use raw score totals to pursue further analysis. The Wilcoxon Signed Ranks Test (see Table 1) suggest there is a statistically significant positive difference in students' interest in and awareness of STEM and STEM careers from pre to post for scholarship students, z = -2.62, *p* = .009, and non-scholarship students, z = -7.10, *p*< .001. When differences were tested for each group at the item level, scholarship students showed statistically significant change on some items related to self-efficacy (e.g., item 13 in Table 1). However, the non-scholarship students had more questions that were statistically significant across the survey, which could be attributed to needs scholarship students have that are not met by the camp or are not adequately measured by the instrument. In addition, the smaller sample size of the scholarship students could also affect the results.

Table 1: Descriptives and Wilcoxon Signed Rank Test Results for Self-Efficacy Items and Raw Score Total

	Scholarship (n = 72)			Non-scholarship (n = 274)		
Self-efficacy items	Presurvey Mean(SD)	Postsurvey Mean(SD)	z*	Presurvey Mean(SD)	Postsurvey Mean(SD)	z*
1. I am able to get a good grade in my science class.	3.28(0.63)	3.38(0.62)	-1.61	3.52(0.56)	3.59(0.55)	-2.16**
2. I am able to complete my science homework.	3.35(0.65)	3.35(0.75)	-0.43	3.66(0.55)	3.61(0.57)	-1.42
12. I am able to get a good grade in my mathematics class.	3.40(0.69)	3.51(0.73)	-1.57	3.58(0.60)	3.61(0.57)	-1.17
13. I am able to complete my mathematics homework.	3.48(0.67)	3.63(0.54)	-2.39**	3.64(0.62)	3.61(0.60)	-0.65

Raw Score Total	137.40(18.99)	140.22(21.58)	-7.10**	142.26(18.16)	147.51(19.07)	-2.62**

*test statistics for Wilcoxon Signed Ranks Test, **p < .05, two-tailed

To glean more insight into the scholarship students not specified by the quantitative data, we analyzed qualitative data from the student interviews. Three themes emerged from the data specific to the scholarship population: the thrill of achievement; positive interactions with peers, camp staff, and presenters; and increased confidence in STEM knowledge. Of the 23 scholarship students interviewed, 100% expressed joy over accomplishments they had achieved throughout camp. Building and programming robots and interacting with STEM professionals in their work environment were most frequently cited. Scholarship students communicated surprise at their own abilities to achieve such tasks while the non-scholarship population did not articulate the same sense of awe. Many scholarship students remarked they never had the opportunity to engage in the type of activities they experienced during STEM camp. Therefore, it was challenging for them to relate their successes at STEM camp back to their school environment (e.g., mathematics). Approximately 83% of the students shared how interacting with STEM professionals, camp counselors/teachers, and peers who look like them (sex, race, age, and location) made them feel like they belonged and were a part of the "team." Only three students commented on how their STEM knowledge connected to their families and friends outside of STEM camp. This may indicate that there is a need to provide more STEM experiences to students in order to increase their STEM self-efficacy beyond camp. Finally, 50% of the scholarship students reported a new sense of confidence for participating in classes related to STEM (e.g. mathematics), which strongly supports the statistically significant shifts in their self-efficacy.

Galindo, E., & Newton, J., (Eds.). (2017). *Proceedings of the 39th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* Indianapolis, IN: Hoosier Association of Mathematics Teacher Educators.

Results from this study indicate there were inconsistent increases in self-efficacy in STEM among students on scholarships compared to the ones who were not. The qualitative data indicate this could be due to missing connections between the STEM camp environment and the students' home and school environments. Access to See Blue STEM Camp benefited students from low socioeconomic backgrounds. Mastery experiences, vicarious experiences, social persuasions, and physiological reactions (Bandura, 1997; Pajares, 2005) were all shared, but only within the context of camp. This indicates access is a springboard toward equity in STEM, but it is not enough. Traditionally underrepresented groups need ongoing, year-round access to rich STEM experiences to increase their STEM self-efficacy and encourage them to enter into STEM fields. A singular episode, such as a camp, can make a difference, but more is needed.

Acknowledgments

The See Blue STEM Camp was funded by the National Science Foundation EPSCoR Track III No. 1348281. The authors greatly acknowledge the support of all camp faculty, staff, and students for their valuable involvement.

RELATIONSHIPS BETWEEN LOCUS OF CONTROL, LEARNED HELPLESS THROUGH PISA 2012: FOCUS ON KOREA AND FINLAND

Jihyun Hwang
University of Iowa
jihyun-hwang@uiowa.edu

The purpose of this research is to gather empirical evidence for the attribution theory (Weiner, 1979) about students' learned helpless when doing mathematics. Korean and Finnish students' responses in PISA 2012 were analyzed with the ordinal regression analysis. For all observed cases, Korean students showed higher probabilities to feel learned helpless than Finnish students. Similar patterns between the two countries were found when students attributed their failure to either ability or task difficulty. For the other attributions, different relationships were found. The findings were generally corresponding to what the attribution theory claimed. However, the differences between Korea and Finland showed necessity of cultural factors in addition to the attribution theory to explain students' learned helpless.

Keywords: Learning Theory, Data Analysis and Statistics, Probability

Motivation has been a subject of research in mathematics education for several decades. As a difference between potential and performance, motivation could be one of reasons for underachievement. To resolve students' underachievement due to lack of motivation, researchers have scrutinized students' adaptive and maladaptive behaviors related to appropriate achievement. This research focuses on one of the maladaptive behaviors, *learned helpless* like challenge avoidance, give up, and lack of enjoyment when doing mathematics (McNabb, 2003).

Previous studies also have tried to describe conditions in which adaptive or maladaptive behaviors occurs. Particularly for learned helpless, social cognitive theories (e.g., Rotter, 1966) and the attribution theory (Weiner, 1979) discussed locus of control to answer who are likely to feel learned helpless. Rotter (1966) defined locus of control as "the tendency of people to perceive that outcomes in a particular arena were either within or outside of their control" (McNabb, 2003, p. 418). Diener and Dweck (1978) claimed that they are likely to feel learned helpless if students thought that the outcome is out of their control. Furthermore, Weiner (1979) argued the four attributions grounded locus of control and stability (see Figure 1). According to this theory, students believing their failure is because of their low abilities are likely to avoid challenges and low persistence.

		Locus of Control	
		Internal	External
Stability	Stable	Ability (X_1)	Task Difficulty (X_2)
	Unstable	Effort (X_3)	Luck (X_4)

Figure 1. Four attributions that explain academic outcomes (McNabb, 2003, p. 419).

The purpose of this research is to gather empirical evidence for relationships between the four attribution and learned helpless. The PISA 2012 data was analyzed to compare Korea and Finland. These two countries selected because both showed top-achieving countries, but they are different in motivational issues (e.g., Mullis, Martin, Foy, & Arora, 2012). The questions guiding this research are; (1) what is a probability to feel learned helpless by each attribution via PISA 2012? And (2) what are differences in tendency to feel learned helpless between Korea and Finland?

Galindo, E., & Newton, J., (Eds.). (2017). *Proceedings of the 39th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* Indianapolis, IN: Hoosier Association of Mathematics Teacher Educators.

Method

Data Description

Korean and Finnish data were collected from the PISA 2012 database. The total number of students in the PISA 2012 database is 8,829 for Finland and 5,033 for Korea. However, a large portion of students did not answer students' questionnaire. Data of students who had completed student questionnaire were gathered and analyzed instead of dealing with missing data. Thus, the final sample sizes were 2,789 for Finland and 1,681 for Korea.

Variable Selection

Specific five variables/questions with the four-level Likert scale were selected corresponding to the attribution theory. Table 1 shows details about those questions in the PISA questionnaire.

Table 1: Five Questions for Learned Helpless and Locus of Control

PISA Variable	Variable Code		Question	Coding
ST42Q08	Learned Helpless	(Y)	I feel helpless when doing mathematics problem.	1 Strongly agree 2 Agree 3 Disagree 4 Strongly disagree
ST43Q01	Effort	(X_3)	If I put in enough effort I can succeed in mathematics.	
ST44Q01	Ability	(X_1)	I'm not very good at solving mathematics problems.	
ST44Q04	Task Difficulty	(X_2)	Sometimes the course material is too hard.	
ST44Q06	Luck	(X_4)	Sometimes I am just unlucky.	

Data Analysis

The ordinal regression analysis was employed using SPSS. This regression was appropriate because all questions related to locus of control and learned helpless had four-level Likert scale, which produced ordinal variables. The specific five variables in Table 1 are all ordinal, but it should be noted that real distances between adjacent categories is unknown. I focused on describing the relationships between locus of control and learned helpless rather than conducting hypothesis tests for statistically significant differences between the regression models for Korea and Finland. This is because differences between the two countries may be evident, but not described.

Table 2: McFadden's R^2 for Each Ordinal Regression Model

	Ability	Effort	Task Difficulty	Luck
Korea	0.086	0.046	0.045	0.011
Finland	0.089	0.060	0.049	0.006

I reported pseudo R-squared to evaluate the ordinal regression models because model evaluation is essential in regression analysis. There were no clear recommendations about how to use pseudo R-squared and how to interpret them, this pseudo R-squared can help to evaluate the ordinal regression models in this research at some degrees. Particularly, McFadden's R^2, which has been preferred to other pseudo R^2s (Menard, 2000), was informed in Table 2. It need to be cautious to make a strong conclusion with a single index about goodness of fit although other indices were not available. All models were accepted because there is no evidence that McFadden's pseudo R^2 were zero. It is known that that index can be as low as zero and the value above 0.2 actually indicated excellent fit of models.

Galindo, E., & Newton, J., (Eds.). (2017). *Proceedings of the 39th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* Indianapolis, IN: Hoosier Association of Mathematics Teacher Educators.

Results

The analysis results showed that Korean students were likely to feel learned helpless in the following cases: students strongly agreed that their failure was due to their abilities; students disagree that they are able to success in mathematics with enough efforts; students strongly agree that course materials were difficulty; and students' failure in mathematics was because of misfortune. In those cases, the probability to agree or strongly agree with learned helpless was greater than 0.6. Korean students showed very high possibility of learned helpless when students only strongly agreed that their failure was due to their ability (0.837), task difficulty (0.771), or even misfortune (0.628). However, if students had any degrees of disagreement that they can success in mathematics with their sufficient efforts, they reported learned helpless (0.673 for "disagree" while 0.766 for "strongly disagree"). In addition, students' answers about their ability made the widest range of probabilities of learned helpless (from 0.114 to 0.837) while those about luck had the narrowest range (from 0.345 to 0.628).

Finnish students showed different patterns in the relationships between learned helpless and locus of control from Korean students. Finnish students were very likely to feel learned helpless in the two following cases: students strongly agree that they are not good at mathematics; and students moderately disagree that they can success in mathematics with enough efforts. Only these two cases of Finnish students showed higher probabilities than 0.6. The most interesting finding about Finnish students is the relationships between efforts and learned helpless. Students had the highest probability (0.611) in the relationships between learned helpless and efforts. However, if students strongly agree with that statement, the probability decreased to 0.359. Furthermore, Finnish students' answers about luck was independent from learned helpless.

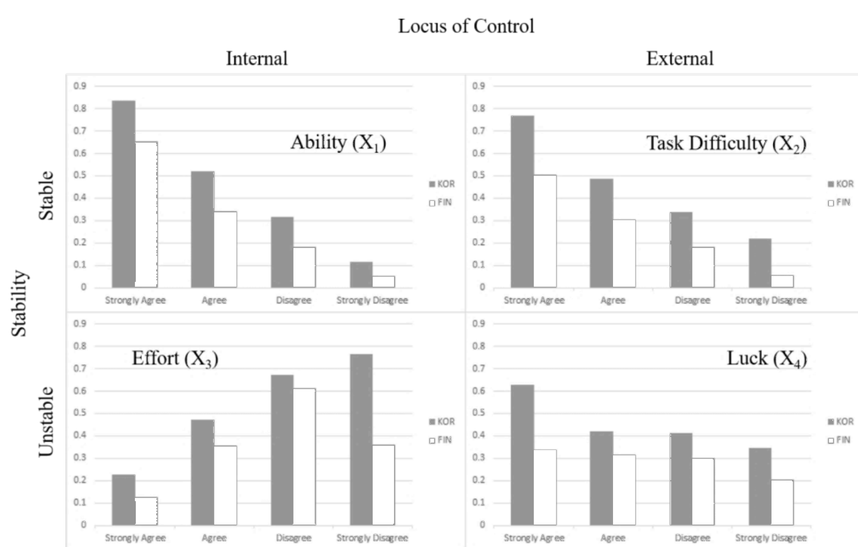

Figure 2. Probabilities to agree or strongly agree to feel learned helpless in Korea and Finland.

Figure 2 showed probabilities that Korean or Finnish students agree or strongly agree to feel learned helpless in learning mathematics. Whatever Korean students answer about their locus of control, they had greater chances for learned helpless than peers in Finland. Most cases for the Finnish students showed probabilities less than 0.5 to feel learned helpless while Korean students are very likely to do with strong beliefs about attributions to failure.

Similar patterns between two countries were found in the relationships of ability or task difficulty to learned helpless. As students' responses for learned helpless shifted from agreement to disagreement, the probabilities considerably decreased. Figure 2 shows that it is reasonable to assume

Galindo, E., & Newton, J., (Eds.). (2017). *Proceedings of the 39th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* Indianapolis, IN: Hoosier Association of Mathematics Teacher Educators.

a monotone relationship between students' learned helpless and strength of agreement that ability/task difficulty attributes to failure in both countries. The gaps of probabilities from strongly agreement to strongly disagreement were greater in Korea.

However, Korean and Finnish students showed different patterns in relationships of effort or luck to learned helpless. Particularly, Finnish students' beliefs about luck could be unconnected to their feeling of learned helpless. All responses about luck had similar probability for learned helpless from 0.203 to 0.340. However, if Korean students strongly agreed that they failed because they were unlucky, they were likely to feel learned helpless with the chance of 0.628. Moreover, Korean students showed monotone increasing probabilities of learned helpless from strong agreement to strong disagreement that they can success with enough efforts. As seen in Figure 2, Finnish students had a considerably different pattern, in which the highest probability was for moderate disagreement.

Discussion and Conclusion

The findings, particularly about the Finnish students, are matched to the claim of Diener and Dweck (1978). Student who attributed their failure to ability were most likely to feel learned helpless in both countries. For the other attributions, Korean students reported high probabilities for learned helpless, which were different from Finnish students. The attribution to luck is independent from feeling learned helpless for the Finnish students while the Korean students who agreed that they failed because of misfortune are likely to feel learned helpless.

However, Korean students had higher probabilities to feel learned helpless in all analyzed cases. The dissimilarities between Korea and Finland indicated that learned helpless cannot be explained only by the attribution theory. Particularly, the relationships between attribution to efforts and learned helpless differed most. This probably indicated that social and cultural factors can mediate the relationships between the attributions and learned helpless. The findings suggested further research to scrutinize social factors in addition to psychological ones. In addition, more comparisons among countries can contribute to better understanding about the attribution theory and learned helpless in learning mathematics.

STUDENT AND SCHOOL LEVEL CORRELATES OF MATHEMATICS PERFORMANCE IN THE UNITED STATES REGARDING PISA 2015

Halil Ibrahim Tasova
University of Georgia
halil.tasova25@uga.edu

Oguz Koklu
University of Georgia
kokluoguz@gmail.com

Muhammet Arican
Ahi Evran University
muhammetarican@gmail.com

İbrahim Burak Ölmez
University of Georgia
i.burakolmez@hotmail.com

The purpose of this study was to investigate the effects of a set of variables that may explain the relationship between mathematics performance and equity. The Programme for International Student Assessment (PISA) 2015 data for the United States sample was analyzed using the hierarchical linear modeling (HLM) to determine student and school level correlates of mathematics performance. Based on the results, disparities in performance by students' background characteristics (e.g. socioeconomic status, gender) together with mediator factors (e.g. learning time, school location, class size etc.) and their implications for policy are discussed.

Keywords: Equity and Diversity, Data Analysis and Statistics, Policy Matters

Regarding mathematics education as a civil rights issue, Schoenfeld (2002) argued that mathematical literacy should be a goal for all students (p. 13). In accordance with Schoenfeld's argument, to examine countries' mathematics performances and their levels of educational equity outcomes, researchers have focused on analyzing large-scale international assessments such as PISA and the Trends in International Mathematics and Science Study (TIMSS). In this study, we investigated the relationship between the U.S. students' mathematics performance and equity-related factors in education by conducting the HLM analysis to the PISA 2015.

Theoretical Framework

According to the PISA equity framework, equity is defined as "providing all students, regardless of gender, family background or socioeconomic status, with high-quality opportunities to benefit from education" (The Organisation for Economic Co-operation and Development [OECD], 2016, p. 202). As extensively discussed in this framework, students' socioeconomic status and immigration background are two important factors regarding their school performances, and each country's education system should be more inclusive and fair to ensure high student performance. Hence, equity-related factors are to be associated with student achievement mainly because improving learning opportunities would increase student performance overall. In this study, we framed our investigation according to the PISA equity framework, and addressed the following research questions: (1) To what extent are background characteristics (i.e., socioeconomic status, immigrant background, gender) and mediating factors (i.e., access to educational resources, opportunity to learn, stratification policies) associated with the mathematics performance of students in the U.S. in PISA 2015? and (2) To what extent are school-level characteristics associated with the effects of background characteristics? Thus, this study aimed to provide evidence-based insights for policy-makers and researchers regarding the equity factors that are associated with students' mathematics performance in the U.S.

Galindo, E., & Newton, J., (Eds.). (2017). *Proceedings of the 39th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* Indianapolis, IN: Hoosier Association of Mathematics Teacher Educators.

Methods

The data for this study consisted of 15-year-old students' responses to the PISA 2015 Background Questionnaire and the Mathematics Test, and the PISA 2015 School Questionnaire.

After removing missing data, the final dataset in this study consisted of 4293 students from 159 U.S. schools. Because the PISA 2015 data were nested (i.e., students are nested within schools), HLM was used as a statistical technique so that the results could provide important empirical evidence on the decomposition of variance of performance by student- and school-level variables (Raudenbush et al., 2011). We followed two-level HLM by incorporating plausible values and sampling weights into the analysis so that each sampled student and school were represented accurately (Rutkowski et al., 2010). After building the unconditional model and the random-coefficients model in the HLM analysis, the full-contextual model that contains significant student- and school-level variables was developed.

Results

The results of the final model with statistically significant student- and school-level variables on student mathematics performance are shown in Table 1. In addition, it is important to note that this final model explains 65% of the variance between schools and 20% of the variance within schools.

Table 1: Final Estimation of Fixed Effects

*p<0.05 **p<0.01 ***p<0.001

Student-level variables. This section provides the extent to which background characteristics were associated with the mathematics performance of U.S. students according to PISA 2015. The gender gap within schools was found to be large (boys performed better), even after controlling for other variables ($\gamma_{10} = -23.43$, $p<.001$). Economic, social, and cultural status (ESCS), learning time, achievement motivation, and student's enjoyment of collaboration are positively associated with mathematics performance ($\gamma_{80} = 22.9$, $\gamma_{30} = .05$, $\gamma_{40} = 9.94$, and $\gamma_{50} = 10.03$, respectively, $p<.001$ for each). Moreover, mathematics performance was found to be lower on average for students whose

Galindo, E., & Newton, J., (Eds.). (2017). *Proceedings of the 39th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* Indianapolis, IN: Hoosier Association of Mathematics Teacher Educators.

teachers were reported as unfair by the students compared to the performance of those whose teachers were perceived as more fair (γ_{70}=-5.20, p<.001).

School-level variables. Considering the associations between school-level variables and mathematics performance, the school average ESCS, namely the school socioeconomic composition effect, was highly significant in predicting mathematics performance (γ_{03}=38.15, p<.001). Moreover, the model predicted that students in public schools scored higher than students in private schools after demographic and socioeconomic factors were controlled (γ_{04}=-37.84, p<.001). Students in urban schools performed less favorably than students in rural schools (γ_{01}=-5.21, p<.051).

Cross-level interactions. In terms of the significant cross-level interactions between background characteristics and school-level variables, the interaction of gender with a shortage of education staff (γ_{11}=-4.98, p=.010) showed that the negative effect of being a female student on mathematics performance was particularly higher for the students in schools whose capacity to provide instruction was hindered to a great extent by a shortage of education staff. The significant cross-level interaction between learning time and school socioeconomic composition effect indicated that the positive effect of the total learning time on performance was stronger for students who attend schools with a less advantaged social profile than those attending advantaged schools (γ_{31}=-.05, p=.014). Furthermore, the significant cross-level interaction of enjoyment of cooperation with percentage of immigrant students in schools demonstrated that the positive effect of enjoyment of cooperation on mathematics performance was stronger for students who attended schools with a higher percentage of immigrants (γ_{51}=.22, p<.001). In addition, there was a significant interaction between teacher unfairness and school location (γ_{71}=1.24, p<.001). The results suggested that the negative effects of high teacher unfairness on performance were stronger for students attending rural schools than those in urban schools.

Moreover, there was a significant interaction between ESCS and school location, class size, and the school socioeconomic composition effect. For school location, the positive effects of high ESCS were stronger for students in rural schools than for students in urban schools (γ_{81}=-3.67, p=.013). For the average class size in schools, the positive effects of high ESCS were stronger for students attending schools with a higher average class size (γ_{82}=.47, p=.091). For school socio-economic intake, the positive effects of high ESCS were stronger for students who attend schools with a more advantaged social profile than those attending less advantaged schools (γ_{83}=13.18, p<.001).

Conclusions and Implications

Results from this study indicated that the differences in mathematics performance observed across socioeconomic groups were significant. However, the U.S. has been successfully reducing the adverse effect of socioeconomic status on performance between 2006 and 2015 (OECD, 2016). The initiatives promoting equal opportunity (e.g., the No Child Left Behind Act and Common Core State Standards for Mathematics) might have played a major role on this reduction (Kitchen & Berk, 2016). On the other hand, the U.S. performance on mathematics was comparatively weak among the OECD countries. Thus, according to the PISA policy framework, policy-makers might consider more universal policies to raise standards for all students to improve performance along with equity (OECD, 2013). In addition, we found that school location and average class size influence the equitable distribution of achievement by socioeconomic status among students in a school. This result suggests that, beyond the universal policies, policy-makers and administrators should decrease the average class size in schools and focus on interventions specifically designed for rural schools.

OECD (2016) identifies *resilient students* as the ones coming from a disadvantaged socio-economic background, but scoring among the top quarter in a country/economy. Based on PISA 2006 and 2009 data, one factor for becoming a resilient student in science appears to be increased amount of time that the student spends in science class (OECD, 2011). Our study pointed out the

Galindo, E., & Newton, J., (Eds.). (2017). *Proceedings of the 39th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* Indianapolis, IN: Hoosier Association of Mathematics Teacher Educators.

same result for mathematics by providing evidence that the positive effect of learning time on mathematics performance is stronger for students in schools with lower ESCS than those attending schools with higher ESCS. The result implies a way to help students to overcome the adverse effects of their social background and, thus perform better in mathematics. A way of having disadvantaged students spend enough time in class is making mathematics courses compulsory. For example, in the U.S. in 2006, compulsory attendance made disadvantaged students score 40 points more in science, which is the equivalent of a full year of schooling (OECD, 2011). The result suggests that providing more opportunities for disadvantaged students to learn in class may be an integral way of fostering resilience.

Moreover, our analysis showed that girls tend to underachieve in mathematics in the U.S. Results from PISA 2015, however, showed that there is no significant difference between boys and girls in China, Singapore and Massachusetts in mathematics (OECD, 2015). This result shows that gender gap does not depend on student's innate differences in ability. In this study, the significant cross-level interaction of gender with schools' resources might reveal a potential way of narrowing the gender gap. That is, administrators should consider increasing the number of educational staff because the schools that were in need of teacher and assisting staff found to have a larger gender gap in favor of boys. In addition, another PISA data showed that girls tend to perform better in mathematics when they try to solve mathematics problems independently (OECD, 2015). Thus, teaching strategies that demand more of students might provide better learning opportunities for girls.

Future studies should continue focusing on the relationships between student and school correlates of mathematics performance by considering the random effects as well as the fixed effects because the magnitude of those relationship might vary from one school to another. Moreover, similar HLM analysis could be conducted using other international assessments such as TIMSS data to validate the findings.

SUBJECT LEVEL ZOOM: A NEW LENS FOR STUDYING STUDENTS' PERCEPTIONS OF THE USEFULNESS OF MATHEMATICS

Tracy E. Dobie
Northwestern University
t-dobie@northwestern.edu

This paper involves a methodological exploration into approaches used to assess students' perceptions of the usefulness of mathematics. I argue that it is crucial to attend to the level at which we ask students to report perceptions of usefulness. I present the construct of subject level zoom and a case study of one student to consider issues that might arise in measuring usefulness at the level of an academic subject versus a task or topic within that subject. Finally, I highlight important implications for both research and classroom practice moving forward.

Keywords: Affect, Emotions, Beliefs, and Attitudes; Research Methods

Introduction

In recent years, increasing emphasis has been placed on the usefulness of mathematics (National Governors Association Center for Best Practices, 2010). Existing research has illustrated that finding ways to enhance perceptions of usefulness (also referred to as perceived utility) is a worthwhile pursuit, as one's perceptions of usefulness are positively associated with academic achievement (Durik et al., 2005; Hulleman et al., 2008), course enrollment (Durik et al., 2005; Updegraff, Eccles, Barber, & O'brien, 1996), and interest in a subject (Hulleman et al., 2008). However, upon examining the ways in which perceptions of usefulness are measured in these studies, an unaddressed yet potentially important distinction arises. While perceived utility is conceptualized in the literature as a reason for doing a particular *task*, students are often asked about their perceptions of usefulness of an entire *topic* or *subject* area. While we might be interested in knowing students' perceptions at each of these levels of focus, I argue that it is crucial to explicitly attend to this distinction for two reasons: First, students' perceptions of usefulness might vary depending on whether they are considering the utility of a task, topic, or subject. Second, academic-related outcomes might differ depending on the level at which students perceive usefulness. In this paper, I consider this possibility, first briefly describing the existing literature and then presenting a new construct and a case study to consider potential implications of using measures with different levels of focus.

Sketching the Landscape

The expectancy-value model highlights the ways in which one's values and beliefs influence one's achievement-related choices and performance (Eccles & Wigfield, 2002). In this model, the degree to which one values a task directly influences achievement-related outcomes. Utility value, broadly defined as the degree to which a task is "useful and relevant for other aspects of [one's] life" (Harackiewicz, Rozek, Hulleman, & Hyde, 2012, p. 1), is one component of task value. However, many studies that measure utility value question students' perceptions of usefulness of entire academic subjects, rather than tasks (Anderman et al., 2001; Battle & Wigfield, 2003; Fennema & Sherman, 1976; George, 2006; Parsons, 1980; Xiang, Chen, & Bruene, 2005). For example, Anderman et al. (2001) asked students to respond to statements such as, "In general, how useful is what you learn in math?" In contrast, other studies zoom in on the usefulness of particular techniques or topics and ask participants to respond to statements such as, "This technique could be useful to me in daily life" (Canning & Harackiewicz, 2015).

Galindo, E., & Newton, J., (Eds.). (2017). *Proceedings of the 39th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* Indianapolis, IN: Hoosier Association of Mathematics Teacher Educators.

Subject Level Zoom

To consider potential issues resulting from this varying level of focus, I present the construct of *subject level zoom*. Subject level zoom refers to the grain size at which we examine a phenomenon related to an academic subject. In regards to the topic of usefulness, while researchers have previously questioned individuals about their perceptions of utility at multiple levels, the level of zoom has not been acknowledged as a factor that might influence individuals' reported utility value. I propose, however, that students' ideas about the usefulness of particular tasks or topics in mathematics might differ from their perceived usefulness of the subject of mathematics. Furthermore, perceiving utility at these different levels might differentially influence achievement-related outcomes. Below I present a case study that speaks to this issue.

A Case Study: Katie

Katie is a 13-year-old female who identifies as Hispanic. She is a member of a seventh-grade honors mathematics class at a school in a working-class suburb of a large Midwestern city. On a survey about usefulness, Katie reported that she thinks math is the most useful subject because "it mostly has everything in it and you learn a lot in math too." In her responses to a modified version of the Fennema-Sherman Usefulness of Mathematics scale (Doepken, Lawsky, & Padwa, 2004; Fennema & Sherman, 1976), Katie's mean rating was 3.83/5 across the 12 items, which corresponds to viewing mathematics as useful. Given these responses, one might conclude that Katie's perceived utility of mathematics is relatively high, which is likely to positively impact her mathematics achievement. However, applying the lens of subject level zoom highlights that Katie answered these questions about utility at the level of the subject. Will Katie's reported perceived utility differ if she considers the utility of particular topics within the subject of math?

During an interview, Katie was asked about six mathematics topics that her class explored during the year. Her responses regarding whether she expected to use the topics outside of class and if so, where, can be viewed in Table 1.

Table 1: Katie's Views on the Usefulness of Specific Mathematics Topics

Mathematics Topic	Use of Topic in Life (Katie's perspective)
Commission and Mark-up	"Commission and markup can be but I don't think it is—for like cashier work. 'Cause they're, like-they're, like, using a much, like, money they have to give or something. I don't know, yeah."
Adding and multiplying fractions	"Um, I don't think you use this for any jobs, I'm not sure."
Writing equations	"Um, no? I'm not sure."
Finding equivalent ratios	"Well, maybe those are like, for math teachers. But yeah, that's all."
Making graphs	"Uh... um, like, maybe making a graph for uh... for let me see, like-like for science? Like something-something that works for science. Like a job that is for science."
Calculating perimeter and area	"For construction, 'cause you need to see how much perimeter has and what area you're gonna use."

Zooming in to consider Katie's perceptions of usefulness of particular mathematics topics paints a more complex picture than seen earlier. For two topics – writing equations and adding and multiplying fractions – Katie could not think of any particular uses in life. While Katie did report that the other four topics "can be" or are "maybe" useful for particular jobs, she did not actually imagine herself pursuing any of those lines of work. For example, after Katie reported that she could imagine

Galindo, E., & Newton, J., (Eds.). (2017). *Proceedings of the 39th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* Indianapolis, IN: Hoosier Association of Mathematics Teacher Educators.

making graphs in “a job that is for science,” she was asked whether she was imagining that for herself or for others, and she clarified that she meant “just other people.” She was asked the same question after she reported that calculating perimeter and area would be useful “for construction,” and she again said that she imagined that for “other people.” Furthermore, at the end of Katie’s interview, she was asked whether she knew what she wanted to do for work when she got older, and she replied that she has “two choices” – either a lawyer or a veterinarian – and will “probably not” need mathematics for either. It is worth briefly mentioning that while Katie focused specifically on usefulness for jobs, the interviewer did not ask her to do so. Katie could have referenced ways in which she might use these topics for a variety of different purposes, yet for five of the six topics she spoke solely about uses – or lack thereof – for jobs. The potential significance of this will be considered in the next section.

Discussion and Conclusion

In this paper, I highlight a potential crossroads in research on usefulness regarding the way in which we measure students’ perceptions of utility. While a range of items has previously been employed to measure perceived utility of tasks, techniques, and subjects, I argue that we must begin to explicitly distinguish between these types of measures and their potential outcomes in our research. This work has important implications for mathematics education moving forward, as perceived utility is often used as a lever for enhancing student achievement and interest.

Drawing on the construct of subject level zoom and the case study of Katie, I propose two reasons for attending to the level at which we measure perceived utility. First, it might be the case that adolescents use different criteria to assess the usefulness of an academic subject than to assess the usefulness of specific tasks or topics within that subject. For example, Katie reported that math is useful for many things; however, when she was asked about how she might use particular mathematics topics, she only considered the topics in terms of their applicability for specific jobs and was unable to report any jobs in which she herself expected to use the topics. Katie’s responses raise the question of whether she always considers jobs when assessing usefulness, or if she only applies that criteria when considering the usefulness of particular topics. If asked to assess the usefulness of a particular mathematics task, would Katie consider its utility for future jobs, or might she consider other features, such as the task context or the form in which the task is presented? Reflecting back on Eccles and Wigfield's (2002) expectancy-value model, this potential difference in criteria considered raises another question: Will Katie’s perceived utility of the subject of mathematics positively influence her academic-related choices and outcomes, as the model suggests, if she is unable to view individual topics as useful?

As this question highlights, the second reason for attending to subject level zoom is that academic-related choices and outcomes might be differentially affected depending on the level at which students perceive usefulness. For example, it might be the case that many adolescents will report that mathematics is useful since they frequently hear such messages from valued adults, including parents and teachers. However, this belief might not improve students’ interest in mathematics or course enrollment because they do not see various aspects of classroom mathematics – including particular topics or tasks – as useful. In contrast, it might be the case that perceiving usefulness in particular tasks or topics is less likely to influence students to pursue a career in mathematics than perceiving usefulness in the subject of mathematics overall. Instead, perceiving usefulness in those tasks and topics might positively influence students’ engagement in the mathematics classroom and interest in the subject. In other words, different perceptions of usefulness might have very different outcomes for students’ performance, engagement, and achievement-related choices. Current research by the author is building on this work to examine the relationship between students’ perceptions of usefulness of different types of tasks and their engagement on those tasks.

Galindo, E., & Newton, J., (Eds.). (2017). *Proceedings of the 39th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* Indianapolis, IN: Hoosier Association of Mathematics Teacher Educators.

Moving forward, we must attend to the choices we make in measuring usefulness since they drive the interventions we create. This work will have direct implications for practice, as teachers regularly strive to help students see mathematics as useful. Conducting research that sheds light on the effects of different levels of perceived utility will allow teachers to more effectively influence students' perceptions of usefulness in order to improve mathematics achievement, interest, and classroom engagement.

THE CROSSROADS BETWEEN HIGH SCHOOL AND COLLEGE LEVEL MATHEMATICS: PERSPECTIVES OF TEACHERS, INSTRUCTORS AND STUDENTS

Elizabeth Kocher
The Ohio State University
kocher.3@osu.edu

At the intersection between high school and college, is the mathematical knowledge students have learned enough to ensure their future mathematics success? This study looks at the expectations gap or the disconnect between what students know leaving high school and the actual knowledge and skills they need to be successful in college from the perspectives of high school teachers, college instructors, and remedial college mathematics students. Survey data from the high school and college instructors revealed agreement on seven of the top ten most important skills for student success. Remedial students' survey and interview data indicated they view their remedial placement as beneficial, yet identified the procedural emphasis of their high school teaching as contrary to how they best learn mathematics.

Keywords: Post-Secondary Education, High School Education, Teacher Beliefs

Objectives and Purpose of the Study

Throughout the United States, high school students who take a college preparatory curriculum are often surprised when they are placed into a remedial mathematics course in college, as they assume their high school courses have adequately prepared them to enroll in college level courses. The term "expectations gap" has been used to describe the disconnect between what students know leaving high school and the actual knowledge and skills they need to be successful in college (Achieve, 2010, p.7). This expectations gap is most noticeable the large percentage of students who require remediation upon entering college. In mathematics, 26 by % of the students who took the college preparatory mathematics courses of Algebra I, Geometry and Algebra II, needed to take remedial mathematics coursework in college (ACT, 2007). In fact, 17% of students who had taken one additional, advanced math course in high school required remediation (ACT, 2007). Of concern is that high schools are not giving students the adequate preparation needed for college even if they are taking college preparatory courses (Hoyt & Sorensen, 2001). Two specific research questions frame this work.

1. What are the expectations of high school teachers regarding mathematical college readiness and how do they correlate to the expectations of college readiness held by college instructors?
2. How do students placed in remedial mathematics courses view this placement and their prior mathematics teaching and learning?

In exploring these questions this study attempts to identify and clarify the expectations held by students, high schools, and colleges in regards to mathematical college readiness, thereby providing knowledge necessary to better preparing students for this transition.

Perspectives

The first research question asked in this study examines any discrepancies in expectations held by high school and college mathematics teachers concerning the skills necessary for college success in mathematics. Many college faculty members nationwide think that students are not adequately prepared for the intellectual demands and expectations of post-secondary education (Conley, 2008; Corbishley & Truxaw, 2010). The ACT (2009) found in their *National Curriculum Survey* that 91%

Galindo, E., & Newton, J., (Eds.). (2017). *Proceedings of the 39th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* Indianapolis, IN: Hoosier Association of Mathematics Teacher Educators.

of high school teachers feel their students are prepared for college-level work in their content area, but only 26% of the college instructors said their students arrived prepared. A survey of college professors found that 65% rated graduates' basic mathematics skills as "fair" or "poor" (Achieve, 2004). Any discrepancies in perception will be evidenced by what mathematics is ultimately taught and emphasized.

Although a strong conceptual foundation in mathematics is needed at the college level, one observation of entering college students is their lack of conceptual understanding in mathematics (Richland, Stigler, & Holyoak, 2012). "College-ready students possess more than a formulaic understanding of mathematics. They have the ability to apply conceptual understandings in order to extract a problem from a context, solve the problem, and interpret the solution back into the context" (Conley, 2008, p.8). It appears that many students have gained only a procedural understanding of mathematics at the high school level, and have been able to get by with this limited knowledge up to this point (Kajander & Lovric, 2005; Richland, Stigler, & Holyoak, 2012).

Methods

Research questions are answered using an explanatory sequential mixed methods design (Creswell, 2015). The research design includes both survey data (quantitative) and semi-structured interview data (qualitative). This mixed methods design integrates both data types and draws interpretations using the strengths of both sets to understand the research problem.

Question One

The first part of this study involved evaluating high school teachers' and college instructors' expectations for college readiness. Survey instruments asked participants to rate the importance of 57 factors for mathematical college readiness. A Likert scale ranging from 1 - not important, to 5 - extremely important, was used to rate each factor. An option to add any additional factors that were not mentioned in the survey was included, as well as the ability to list the five factors or skills they found to be the most important for college readiness.

The population for the first research question involved college instructors who teach remedial or beginning college-level mathematics courses at a large Midwestern university and high school mathematics teachers from the top 25 feeder high schools to this university who teach a college preparatory mathematics course. Approximately 415 high school teachers and 15 college instructors were contacted with 57 high school teachers (14% response rate) and 9 college instructors (60% response rate) responding to the survey.

Question Two

The second part of this study gathered and evaluated the views of students who have been placed into and taken a remedial mathematics class. An on-line survey was emailed to 2,638 remedial students, with 109 responding and 84, or 3%, completing the survey. Survey questions focused on how student's viewed their high school and college mathematics experiences as well as how students perceive they learn mathematics. Questions based on conceptual and procedural learning/teaching styles were used to determine how students felt these aspects affected their mathematical understanding.

Semi-structured interviews with a subset of the surveyed students added additional insight and clarity to the survey findings. Data gathered from the interviews was analyzed for common themes using a general inductive approach. Interview data from 13 students was used to validate, explain, and enrich the quantitative survey results in more depth.

Galindo, E., & Newton, J., (Eds.). (2017). *Proceedings of the 39th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* Indianapolis, IN: Hoosier Association of Mathematics Teacher Educators.

Results

Instructor Expectations

Findings from the high school teacher/college instructor surveys revealed that both groups rated "develop thinking skills" as the most important factor for students to learn in high school to be considered ready for college level mathematics. In fact, seven of the top ten highest rated factors were the same for both groups. Table 1 outlines these seven factors identified by each group and the average Likert scale score it received. Both groups also agreed on three of the five lowest rated factors: (a) "student journals", (b) "breadth over depth" and (c) "only teach/learn the procedures and process". Further analysis of the survey data revealed that the largest difference in mean importance occurred with "advanced math content knowledge" (1.339) followed by "reading ability" (1.000), "specialized curricula (AP, IB, etc)" (0.965), "cooperative learning" (0.959), and "memorize basic concepts" (0.947). In all cases the high school teachers ranked these topics as more important than college instructors and placed them on average approximately one entire importance level higher.

Table 1: Most Important Factors for Mathematics Success in College

Factors/Skills	Mean of High School Teachers	Mean of College Instructors
Develop thinking skills	4.74	4.67
Strong foundation of basic math skills	4.70	4.44
Understanding the concepts	4.56	4.11
Improve study skills and habits	4.47	4.44
Alternate representations (graphing, algebraic)	4.44	4.22
Time management skills	4.44	4.22
Providing regular feedback	4.42	4.33

High school teachers and college instructors were also asked to list in order of importance the five factors they feel are most important for college readiness in mathematics. "Understanding concepts", "perseverance", "problem solving", "critical thinking" and "number sense" were common themes in the high school teachers' list. Unfortunately with such a small college instructor sample, identifying any themes in the college instructors' list was not possible, although some themes identified by the high school teachers were also found in the college instructors' lists.

Student Perceptions

Student survey findings indicate that only 35% of the students felt their high school math background adequately prepared them for college level mathematics. Seventy-two percent of students say they were taught mathematics in high school using mostly computational problems. This is in opposition to 77% of the same students who said they need to understand the ideas and concepts in order to do well in mathematics. Over 78% of the students felt that their college math instructor explained the concepts first, with 81% stating that connections were made between different mathematical ideas and concepts in their college mathematics course.

In the interviews statements such as "I remember a lot of high school was just memorize" and "concepts were the biggest thing that I lacked until I got up here" were often mentioned. A common theme throughout the interviews was one of sense-making and understanding. One example came from a student who said when talking about high school, "I didn't understand why I'm doing it. I just knew how to get the answer. I didn't know why I was getting answers." A second student mentioned that in high school he felt like he "kind of learned bits and fragments" of math, but that his first semester in his remedial college math course "I was able to kind of connect the ideas and the big picture math concepts." Another interviewee, Alvin, also mentioned everything coming together for him in his remedial math course.

Galindo, E., & Newton, J., (Eds.). (2017). *Proceedings of the 39th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* Indianapolis, IN: Hoosier Association of Mathematics Teacher Educators.

I learned a lot in that course. And it was like I had seen all the parts that were shown to me but I was shown how they actually worked. So it's like I had this machine I'd been working with my entire life that I had no clue how it worked and then someone finally showed me where all the parts go. Which was, pretty nice!

Conclusions

Overall both high school teachers and college instructors held very similar views on what constituted mathematical college readiness. This was nice to see, as more disjoint views between these groups has been noted in the past. Of interest is that "advanced math content knowledge" had the greatest variability of any college readiness factor in this study.

Remedial students view their high school mathematics courses as being more procedural or computational, while they interpret their college mathematics courses as more conceptual in nature. Although they were not pleased they had to take a remedial mathematics course, 78% of the remedial students think they were accurately placed into their remedial course, and almost 81% thought taking their remedial course was beneficial. Additional analysis revealed time away from school/mathematics and memorization of steps instead of understanding of concepts were barriers to success, as well as contributing factors for students' remedial placement.

DEVELOPING STEM LITERACY VIA AN INFORMAL LEARNING ENVIRONMENT

STEM is "standards-based, meta-discipline… where discipline specific content is not divided, but addressed and treated as one dynamic, fluid study" (Merrill, 2009, p. 49). STEM literacy is the synergy of applying the knowledge and skills of STEM to "increase students' understanding of how things work and improve their use of technologies" to solve the greatest challenges of our era (Bybee, 2010). The purpose of this study is to examine the development of STEM literacy in rising middle grades students in an informal learning environment.

The See Blue STEM Camp is a week-long summer day camp for students (N=216) in incoming grades 5-8. The camp focused on authentic hands-on sessions where students were given opportunities to engage in a variety of STEM fields through the use of the eight Standards of Mathematical Practice (CCSSO, 2010) and the eight science and engineering practices (NRC, 2011). The language of these practices reveal an extensive overlap to support students solving complex problems and participating in authentic learning experiences, thereby increasing their STEM literacy. Data included pre- and post-surveys as well as interviews conducted throughout STEM camp. Data were qualitatively analyzed using the constant comparative approach (Glaser, 1965). Coding was used to generalize patterns (Strauss & Corbin, 1990).

Prior to participating in camp, most students gave a definition of STEM that focused on just one of the subjects that comprise STEM (e.g. an equation or science equipment), or by writing the words that make up the acronym. In interviews, students often defined STEM by listing the four individual subjects and struggled to give a broader conception of how STEM applied to their lives. After participating in See Blue STEM Camp, a majority of students defined STEM by copying the images from the camp logo or writing the words "Science, Technology, Engineering, and Math" with connections between the four siloed subjects. Over 50% of students included smiley faces, "fun," and other positive words or phrases. Nearly 15% students described STEM as a concept beyond its individual components and emphasized problem solving. This indicates students' conceptions of STEM started to evolve through attending camp. Their STEM literacy grew and progressed as they experienced the potential of the STEM field. These findings give insight into how we can move forward in developing STEM literacy for students. In order for students to develop their STEM literacy, they need to explore and experience STEM *overtime*. We must provide continued, extended opportunities and adequate time to build the STEM literacy of the next generation.

FIXING A CROOKED HEART: EXPRESSING AND EXPLORING MATHEMATICAL IDEAS IN AN INFORMAL LEARNING ENVIRONMENT

Lara Heiberger
Vanderbilt University
lara.jasien@vanderbilt.edu

Ilana Horn
Vanderbilt University
ilana.horn@vanderbilt.edu

Playing and *doing mathematics* are often conceived of as mutually exclusive activities. One is dominated by positive affect and free choice, while the other is often perceived as highly abstract and predetermined. We wonder how children's play can provide an entrée into mathematical thinking? In play, children ask "what if…?" as they imagine new possibilities, and they often persist at solving problems. These activities resemble mathematical practices like *make sense of problems and persevere in solving them* or *look for and make use of structure*, potentially bridging children's spontaneous activity with desired activities in ambitious math teaching. We specifically ask: (1) How are mathematical ideas and practices expressed informally in children's play? (2) How is the body involved in children's sense-making during play?

Conceptual Framework

The math children use in a playful math learning context draws differently on meaning-making resources than either school math or mathematicians' math, requiring differing amounts of the following for meaning-making: situational meaning, personal meaning, disciplinary meaning.

Data Collection and Analysis

This study was set at a mathematical playground at the Minnesota State Fair called Math On-A-Stick. Our primary data collection strategy involved head-mounted Go-Pros on 345 children to collect video data on table-top activity. We engaged in data reduction using grounded theory (Corbin & Strauss, 1990) to identify *episodes of persistent problem-solving*. For this study, we present an analysis on one eight year-old female ("Elly"), selected for her unusually persistent problem-solving in play. Using interaction analysis (Jordan & Henderson, 1995) we examined Elly's talk, gesture, object use, with particular attention to how she used her body.

Findings

Elly defined an aesthetic goal of "making a heart" with colored plastic eggs in a 6x5 crate.

Mathematical Ideas and Practices in Play: (1) Everyday notions of "crookedness" and "middle" indicated *attention to and an increasingly refined understanding of structure* of both the symmetry of her heart and the parity of the grid of egg crate. (2)The playful nature of her activity allowed her to *persist in her problem-solving* as well as *maintain ownership* of the problem-solving process even with her mother's attempted interventions.

Role of Body in Sense-Making during Play: The use of *bilateral coordinated movements* aided her in realizing the problem of "middle," that she needed to rotate the crate so she could have a "middle," and continued be used to fix her "crooked" heart and achieve symmetry.

Implications

Elly's play involved approximations of mathematical practices like *make sense of problems and persevere in solving them* and *look for and make use of structure*. Children's personally relevant goals in mathematical environments can support the authentic use of math practices.

ANALYZING THE RELATIONSHIP BETWEEN CLASSROOM ENVIRONMENT AND STUDENT BELIEFS IN 8TH GRADE STUDENTS

Jennifer Ericson
University of Massachusetts Amherst
Jericson@umass.edu

Keywords: Affect, Emotion, Beliefs, and Attitudes; Middle School Education

Student perception of mathematical abilities plays an important factor in in a student's decision to continue in their selection of rigorous course work and to study in the STEM fields (Tyson, Lee, Borman, & Hanson, 2007). Females are less likely than males to pursue a career in the STEM fields (National Science Foundation, 2014). There may be a relationship between the perceived mathematics classroom learning environment of high school students and their self-concept (Tosto, Asbury, Mazzocco, Petrill, & Kovas, 2016). Students need to feel competence, relatedness, and autonomy in the classroom to persist in challenging situations and to have higher achievement and interest levels (Gottfried, Marcoulides, Gottfried, & Oliver, 2013). This study examined the relationship between students' perceived competence and feeling of relatedness and autonomy as mediated by gender and autonomy of problem solving.

Methodology

TIMSS 2015 8th grade mathematics background questionnaire files were analyzed to answer the research questions. Scaled variables for relatedness and perceived competence were derived from questions 18 and 19 of the student questionnaire and had Cronbach alpha scores of 0.87 and 0.89. A linear regression analysis was performed with the dependent variable of competence and independent variables of relatedness and gender. An ANOVA analysis was performed with the dependent variable of competence and independent variables of autonomy to problem solve and gender.

Findings

Students' perception of relatedness in the classroom accounts for nearly 18% of the variability in their perceived competence. Being a female negatively affects perceived competence but not relatedness. Increased frequency of autonomy in problem solving increased competence perception, more so for males.

GIRL TALK: USING GAME DESIGN AND ROBOTICS TO THINK, REASON AND COMMUNICATE MATHEMATICALLY

Joy Barnes-Johnson	Jacqueline Leonard	Adrienne Unertl
Princeton Public Schools	University of Wyoming	Clark Elementary School
drjoy@emc2groupllc.org	jleona12@uwyo.edu	auertl@uinta1.com

Female student sets the robot to run the program. The robot partially navigates the course but doesn't knock the block down. At the "turn" in the course, the robot plays a short sound. F: And the crowd is cheering.

Keywords: Informal Education, Classroom Discourse, Gender, Equity and Diversity

In spite of well substantiated claims that culturally relevant pedagogies (CRP) help students develop voice and identity in diverse learning contexts, CRP remains a less-explored means for engaging a diversity of students in game design and robotics programs (Ladson-Billings, 1995; Leonard et al., 2016; Shah et al., 2013). Part of a larger study of middle school extra-curricular programs, the present analysis investigates girls' "math talk", cultural relevance, spatial visualization, computational thinking and problem solving during game design instruction. Building on the work of Sullivan & Heffernan (2016), our research supports the notion of learning progressions in technology education. Adding to their model, our data show that students' proportional reasoning is a critical step between sequencing and causal inference on the way to learning how to think about robotic systems, codes and their interplay. When students engaged in conversations or were asked to explain their programming choices, they often related numeric values within the code to specific measureable behaviors and outcomes, leading to increased understanding of causal relationships. While all students (individuals and within groups) developed similar communication habits around coding, girls tended to talk more frequently and openly about the connections between their rather haphazard codes, their observed results and connections to other phenomena, real or imagined. This observation is validated by our finding that girls had higher posttest scores (M=4.56; Std. Dev. 0.47) than boys (M=4.19 Std. Dev. 0.65) on the 21st century skills survey when pretest scores were used as a covariate. While the scores were not significantly different, the data show a trend that girls are more likely to verbalize their thinking than boys. Facilitated by a video journaling dimension of the program required by the teacher, the research team was able to document pathways to learning for students, chronicle changes in their reasoning and organize the development of computational thinking by analyzing qualitative data (journal videos, observation/field notes and focus group interviews). A rubric was developed that describes indicators of computational thinking as emergent (level 1), moderate (level 2) or substantive (level 3). An additional evaluation tool was developed to conceptualize how students engage the Next Generation Science Standards (NGSS) science and engineering practices most directly related to authentic communication of scientific ideas.

EVALUATING COLLEGE STUDENTS' CONFIDENCE JUDGMENT OF FRACTION

Yanqing Ding
University of Central Missouri
yqd668@hotmail.com

Deborah Moore-Russo
University at Buffalo, SUNY
dam29@buffalo.edu

Keywords: Affect, Emotion, Beliefs, and Attitudes; Assessment and Evaluation; Rational Numbers

A confidence judgment expresses how sure students are about the accuracy of their own answer to a test item. It plays a critical role in students' ability to successfully self-regulate their own learning (Dinsmore & Parkson, 2013). It also provides instructors with information to guide their instructional decisions regarding remediation (Stankov et al., 2012).

Knowledge of fraction concepts (e.g., decimals, percentages, ratios, rates, and proportions) and fraction arithmetic are essential skills for students' future success (Siegler & Lortie-Forgues, 2015) in probability (Garfield & Ben-Zvi, 2007) and other topics. However, half of middle and high school students and even many college students (Siegler & Lortie-Forgues, 2015) lack fraction sense and struggle with fraction applications to mathematics or real world settings. Erroneous fraction ideas have been found to exist in both conceptual understanding and procedural fluency (Panaoura et al., 2009). The present study investigates college statistics students' confidence judgments on fractions prior to their introduction to the study of probability. We look to identify fraction notions associated with high and low confidence.

Participants in this study were 57 college students from the statistics (GER) classes in a public 4-year college. Using a Rasch rating scale model, we analyzed their confidence ratings on a 5-point scale for all items on a 30-item instrument. The person and item reliability of the confidence construct were 0.93 and 0.90 (Ding & Moore-Russo, forthcoming). The study uses the item difficulty estimates from Rasch analysis to identify which fraction concepts are "easier" and "more difficult" for the participants to agree they are "completely confident." We found participants have increased confidence in their responses to the items about part-whole fraction, its applications, and fraction arithmetic computations. These items had a relatively lower item difficulty level. The study finds that 38% of items are at the above-average difficulty level, for which participants display low confidence. The fraction concepts underlying these items include fractions involving variables (e.g., TIMSS 2011 item M032662) and fraction division operation sense, etc. The findings reflect participants' procedural knowledge is more solid than their conceptual understanding of fractions and fraction arithmetic. The findings have implications for teaching and learning in developmental mathematics, college mathematics, and statistics.

NARRATIVES OF MATH, SCHOOLING, AND IDENTITY IN THE MATHOGRAPHIES OF BROOKLYN YOUTH

Emma Gargroetzi
Stanford University
egroetzi@stanford.edu

Keywords: Equity and Diversity, High School Education

Mathematics education is at a crossroads in terms of how we address issues of equity, moving from demographic-based measures of access and achievement to the pursuit of new understandings of how mathematics learning itself can be a racializing or minoritizing event (Gutierrez, 2013). We know that the terrain of mathematics learning can be particularly difficult for students from historically marginalized groups, at least in part because of the problematic discourses that circulate about these students with regard to success, failure, and questions of belonging in mathematics. At the same time, we have a deeply under-theorized understanding of how young people make sense of themselves in this space (Martin, 2009).

One way that people make sense of their lives and articulate a vision of the self is through stories. This study examines student narratives through the stories told in *mathographies* – written autobiographical narratives about a person's experiences learning mathematics. The data for this study consisted of 54 mathographies written by students in two differently tracked high school math classes in a large, diverse, public high school in Brooklyn, NY. The mathographies were examined using discourse analysis with a focus on positioning (Davies & Harre, 1990) in order trace the ways in which students positioned themselves and others by drawing on, or contesting, existing discourses of mathematics achievement, participation, and belonging in school as well as the broader social world. The research questions guiding the study were: (1) What is the typology of mathematics identities that emerge in a diverse urban high school? And (2) How do students draw on a range of available discourses - including of mathematics, schooling, race, immigration, and family - to position themselves as certain types of mathematics students?

Findings show that students draw extensively on discourses of schooling as they position themselves as students worthy of their teacher's investment. Students take up student positions that posit worthiness along axes of ability, effort, and resilience. They contest deficit narratives about themselves and their families; and they simultaneously reproduce dominant discourses of schooling by drawing heavily on institutional evidence of achievement, such as exam scores and homework compliance, and through stories of parental investment. These findings suggest that the mathematics education community must look closely at how it is implicated in the widespread reproduction of an American schooling context in which exam-based achievement scores, and the ability to out-perform others in order to get ahead economically, overshadow opportunities for participation and engagement on other grounds.

GROUPWORK AND HIGH SCHOOL IMMIGRANTS

Amanda E. Lowry
Rutgers University
amanda.lowry@rutgers.edu

Keywords: High School Education, Equity and Diversity

This poster presentation expands on prior research about bilingual students and English Learners (ELs), which has focused on how they best learn mathematics (Domínguez, 2011; Khisty & Chval, 2002; Moschkovich, 1999; Secada, 1991; Setati, 2005; Setati & Adler, 2000; Turner, Domínguez, Maldonado, & Epsom, 2010; Zahner, 2012). The purpose of this study was to explore how high school immigrants', who are also ELs, prior educational experiences influence their preferences for learning mathematics, specifically Algebra 1, in a new educational setting. Each of the three participants involved in this case study were interviewed and asked questions about their educational experiences in their home countries, how they best learn math, and how they prefer to be taught math. In analyzing this data, participants brought up ideas on working with others during math classes and whether they preferred to work independently or in a group. This poster shows this portion of the data analysis of the greater study.

Each of the participants' home countries is different, as is their experiences with formal schooling. While none of the participants has had interrupted schooling, they have been educated in the U.S. for varying amounts of time and have been in different types of schools in their home countries. The participants have shared different experiences with working with peers in both their home countries as well as in their U.S. high school. Each of the participants prefers to work individually. With varying prior experiences with working with peers in mathematics, participants have differing views about why they do not want to work with or the potential for working with peers to solve problems in the mathematics classroom. The analysis of these response shows some relationship between prior educational experiences and preferences for working with others in the classroom, however the sample size is quite small so generalizations cannot be made.

PROVIDING ACCESS TO ALGEBRA FOR STUDENTS WITH AUTISM BY ELIMINATING BARRIERS CAUSED BY MATHEMATICS ANXIETY

Nicole Birri
University of Cintinnati
osterlnl@mail.uc.edu

Casey Hord
University of Cincinnati
casey.hord@uc.edu

Samanta Marita
University of Cincinnati
samantha.marita@uc.edu

Keywords: Instructional Activities and Practices, Algebra and Algebraic Thinking, Equity and Diversity

Proposal

Students with autism spectrum disorder typically achieve below their peers without disabilities due to the common characteristics of autism (Fleury et al., 2014). In addition, these students often experience high levels of anxiety (Bellini, 2004; Kim, Szatmari, Bryson, Streiner & Wilson, 2000), which can make access to and success with mathematics especially challenging. Specifically, mathematics that requires higher level thinking and mathematical reasoning is difficult for students with autism due to deficits in executive functioning (Barnhill, Myles, Hagiwara, & Simpson, 2000; Mayes & Calhoun, 2003). To provide access to abstract, secondary mathematics for students with autism, teachers need to utilize support strategies that eliminate barriers by reducing anxiety and addressing difficulties with executive functioning.

The researchers conducted an exploratory case study (Creswell, 2013) to describe teaching strategies to support executive functioning to reduce anxiety and increase the algebraic reasoning skills of a secondary school student with high functioning autism. We transcribed five teaching sessions, coded the data, organized the data into emerging themes, and utilized an independent rater to monitor interpretive validity during data analysis. The teacher utilized calming routines during strategically timed breaks within longer sessions of engaging in challenging mathematical reasoning. For example, when the student became anxious, she preferred to calm down by solving procedurally repetitive mathematics problems (at a skill level that she had already developed) and practicing deep breathing exercises. Then, when relaxed, the student would vigorously engage in challenging mathematics (e.g., Pythagorean Theorem and graphing inequalities) including problem solving, justification, and participation in discussions connecting her work across mathematical and other contexts. Findings from this study suggest that teachers of students with high functioning autism may be able to set high expectations for these students to access challenging mathematical content as long as part of their instructional approach includes strategies for reducing anxiety and addressing difficulties with executive functioning.

HOW STUDENTS FROM THE BIOLOGICAL AND LIFE SCIENCES SOLVE CALCULUS TASKS INVOLVING ACCUMULATION

William Hall
North Carolina State University
wlhall@ncsu.edu

Keywords: Advanced Mathematical Thinking

The crossroads of mathematics and biology are more important than ever as advanced quantitative techniques have become standard in biology (NRC, 2003). Additionally, 30% of Calculus I students intend on careers in the biological and life sciences (Bressoud, 2015). Furthermore, researchers have called for studies that investigate how students from the many disciplines that require calculus think about and use calculus concepts (Rasmussen, Marrongelle, & Borba, 2014). Existing research concerning the definite integral and accumulation is based primarily in physics and engineering contexts (e.g. Jones 2015) and little is known about how students from the biological and life sciences reason about such tasks. This topic is particularly important given the prevalence of modeling via differential equations in the biological and life science. Therefore, I sought out to answer the research question: How can we characterize the ways individuals in the biological and life sciences solve calculus tasks involving accumulation?

Methods

This qualitative study included task-based interviews with twelve undergraduate students majoring in the biological and life sciences. During the hour-long interviews, students were asked to solve five calculus tasks involving accumulation. Interview data was transcribed and open-coded in accordance with principles from constructivist grounded theory (Charmaz, 2000).

Results and Discussion

Results indicate that students developed local theories of how to solve the interview tasks. Students made conjectures concerning a solution strategy and then assessed the reasonableness of said strategies via their understanding of the problem context. In one task, students used the problem context (climate change) to judge whether their assumptions and mathematical approach were accurate. Familiarity with the problem context, as well as the representation of the rate of change function, affected how the students reasoned about accumulation. One significant implication of these results is the importance of using a wide variety of contextual settings in university calculus courses to better serve the undergraduate calculus community.

THE IMPACT OF A DRAWING INTERVENTION ON THE SPATIAL VISUALIZATION SKILLS OF SIXTH-GRADE STUDENTS

Teresa A. Schmidt
Middle Tennessee State University
Teresa.Schmidt@mtsu.edu

Keywords: Elementary School Education

Background and Research Question

This study investigated the usefulness of a particular drawing intervention, *Quick Draw,* to better understand how sixth-grade students of varying abilities approach and interact with spatial visualization tasks, using a quasi-experimental, mixed-methods design. The concept of spatial intelligence has changed over time from being thought of as an innate ability to skills that can be developed (NRC, 2006; Sarama & Clements, 2009; Sorby, 1999). Studies of spatial ability and skills have grown from simply identifying mechanical ability to being a predictor of success in such academic fields as science, technology, engineering, and mathematics (Hegarty & Waller, 2005; Sorby, 1999). The power of spatial intelligence and its many subcomponents are an underappreciated and underutilized cognitive ability within many classrooms (NCTM, 2000; NRC, 2006; Sorby, 1999).

Method and Results

The research subjects were in a sixth-grade teacher's mathematics classes, and through pre-testing, four case study participants (two high and two low spatial ability students) were identified. A multiple holistic case study approach provided information concerning the differences amongst subgroups (high or low spatial ability) regarding their approach and interaction with spatial visualization tasks. The testing instrument for both pre- and post- testing consisted of a combination of five modified spatial visualization tests. Students participated in six weeks of *Quick Draw* interventions as five-minute warm-up activities to track their progress and to determine how their spatial abilities improved. Students briefly viewed a *Quick Draw* figure and were asked to draw what they saw, and follow-up discussions ensued. In a review of all of the data sources (quantitative and qualitative) three distinct differences were identified between the groups. One was how groups viewed the intervention activities' impact on other academic areas; two, the use of correct geometric terminology. However, the most distinctive difference was how groups appeared to view the figures. Students with high spatial visualization skills appeared to view images holistically, whereas students with low spatial visualization skills appeared to view images as components.

INFORMAL STEM LEARNING: IMPACTING BLACK FEMALES SELF-EFFICACY AND INTEREST IN STEM CAREERS

Crystal Morton
Indiana University, IUPUI
cranhill@iupui.edu

Demetrice Smith-Mutegi
Martin University

Keywords: Equity and Diversity; Informal Education; Affect, Emotion, Beliefs, and Attitudes

In most K-12 schools, Black girls face limited access to STEM course offerings and rigorous STEM learning experiences (Perry, et al. 2012). Black girls are often placed in mathematics classrooms dominated by non-engaging and non-rigorous curriculum devoid of meaning and any real connections to their lived experiences (Hill, 2010). With the growing interest in STEM at both the national and international level, as well as the persistence in racial disparities in educational achievement, it is crucial that educators provide learning experiences that support the positive development of Black girls as STEM learners. Previous research suggests that there is a relationship between informal STEM learning, self-efficacy and interest in STEM careers. For example, according to the Afterschool Alliance (2011), informal STEM learning experiences contribute to improved attitudes toward STEM fields and careers, increased STEM knowledge and skills, and higher likelihood of graduation and pursuing a STEM career. Kerr and Robinson Kurpius (2004) found that girls of color who participated in informal STEM activities increased their exploration of STEM careers, achievement and self-efficacy.

Building on this work, this study explores the impact of a four-week informal STEM program that utilizes a socially transformative curriculum model which values and draws connections between Black girls lived experiences and STEM content. To better understand the relationship between informal STEM learning and Black girls' self-efficacy and interests in STEM careers, we are conducting quantitative analyses of pre-post survey data from 55 Black girls (ages 9-17) who participated in the summer STEM program over two years.

Initial findings suggest that having access to socially transformative STEM curriculum in an informal setting increased participants' self-efficacy, interest in STEM careers and that learning in an informal setting with socially transformative STEM curriculum can help counter some of the detrimental effects Black female students may experience in more traditional settings.

MOTIVATION AND SELF-REGULATION IN CALCULUS

Carolyn Johns
The Ohio State University
johns.125@osu.edu

Keywords: Affect, Emotion, Beliefs, and Attitudes; Metacognition

Recent studies have attempted to identify student characteristics that predict success in calculus (Hieb, Lyle, Ralston, & Chariker, 2015; Worthley, 2013). Prominent has been the use of Motivated Strategies for Learning Questionnaire (MLSQ) to measure motivation and learning strategies. Hieb et al. found ACT scores, algebra skills test scores, intrinsic goal orientation, time and study environment management, and test anxiety to be good predictors of student success in a first-year engineering calculus course. Worthley's model of calculus success incorporated variables such as math placement test scores, test anxiety and self-efficacy. While these studies indicate motivational and self-regulatory factors may impact success, they do not examine the interactions between success/failure and motivational/ self-regulatory factors without the added element of mathematics ability of incoming students. Our research aimed to examine the relationship among these constructs.

In autumn 2016, 545 Calculus I students at a large midwestern university were given the Calculus Concept Readiness (CCR) assessment (Carlson, Madison, & West, 2015) and the MLSQ. In addition, final grades as a percentage were collected.

In analyzing MSLQ results, each student's subscale average score was calculated. First, correlations with bootstrap 95% confidence intervals were ran between MSLQ subscales and final course grades. Then, controlling for CCR scores, partial correlations with bootstrap 95% confidence interval were calculated between each MSLQ subscore and final numerical grade. Using Bonferroni Correction, a significant *p*-value of .002, eight of the MSLQ subscales significantly correlated with final course grade: intrinsic goal orientation, task value, control beliefs, self-efficacy, test anxiety, elaboration, metacognitive self-regulation, and effort regulation. After controlling for CCR scores, only five of the subscales significantly correlated to final grade: instrinsic goal orientation, task value, self-efficacy, test anxiety, and effort regulation.

Results indicate that without controlling for incoming ability, additional motivational and self-regulatory characteristics correlated with final grade, implying these student characteristics may need to be addressed to assure success.

PRETENDING WOGS ARE LOGS: EXPLORING CONTEXTUAL EFFECTS OF EQUAL SHARING WORD PROBLEMS IN FOURTH-GRADERS

Katherine Foster
Concordia University
kathe_fo@education.concordia.ca

Helena P. Osana
Concordia University
helena.osana@concordia.ca

Keywords: Problem Solving, Cognition

Grounding mathematics word problems in realistic contexts (e.g., situations that involve everyday items, such as pizzas) can elicit informal, yet meaningful, strategies that enhance problem solving. These effects are observed when compared to problems that contain so-called idealized representations – i.e., arbitrary elements, such as alphanumeric notation, that do not trigger real-world knowledge as readily (Belenky & Schalk, 2014). What is less understood is the effect of different *types* of real-life problem contexts. Cutting a pizza into equal slices involves concepts and actions learned informally outside of school. In contrast, partitioning 12 m of rope entails measurement concepts (e.g., standard units) that are learned formally in school. When students' everyday knowledge is not activated, their strategies tend to suffer (Weyns et al., 2016).

Method and Results

In the present study, we examined students' performance on equal sharing problems as a function of context type. Fourth-grade students ($N = 36$) in 4 public schools in Canada solved 8 equal sharing problems with fractional remainders. Four problems were couched in *everyday* contexts that readily cue routine actions (e.g., slicing pizza), and two in *measurement* contexts (e.g., partitioning 12 m of rope) that cue formal school knowledge. Two problems contained items with no real-world referents ("wogs") and thereby constituted *idealized* problem contexts. We assessed the students' performance by scoring the appropriateness of the strategies they used.

Contrary to predictions, we found no difference between performance on the word problems with everyday contexts and those with idealized contexts. Video recordings and the students' drawings revealed that they ascribed everyday meaning to the idealized items ("I am going to pretend that a wog is a log."). Students' performance on the problems with the measurement context was significantly lower than performance on both the everyday problems (p =.008) and the idealized problems (p = .017). Descriptive analyses revealed that the measurement context appeared to impede the generation of meaningful strategies. Struggling to conceive of length as a quantity that could be partitioned, students relied on computation learned in school and guessing.

Conclusions

Our findings show that not all realistic contexts are equal. Some may contain elements that block the activation of informal knowledge that would support problem solving (Weyns et al., 2016). Children can be extremely resourceful in constructing meaning where it otherwise does not appear, but more research is needed on the conditions that elicit productive meaning making.

UNDERSTANDING SCHOOL LEADERS' DISCOURSE IN REGARD TO MATHEMATICS ACHIEVEMENT

Jhonel Morvan
Brock University
jhonel.morvan@brocku.ca

The notion of discourse in school mathematics has been of considerable interest to researchers. Scholars largely associate mathematical discourse to classroom practices (Moschkovich, 2007) and tend to overlook the political dimensions of discourse that are largely the prerogatives of school leaders. There is a significant body of literature pointing to the fact that school leaders are critical in supporting effective schools (Fullan, 2011). Further, school leadership is widely considered to impact student achievement and success (Leithwood, Patten, & Jantzi, 2010). Despite that evidence, not much attention seems to be given to school leaders' discourse on math achievement even though it is well known that school leadership discourse impacts school culture (Webster, 2012).

This poster presents findings from a pilot project involving 10 school administrators and systems leaders representing 2 different jurisdictions: 5 from the Northern Haiti and 5 from the French-language schools in Ontario. The participants from Haiti were from private schools (religious and secular) and the ones from Ontario were from both the catholic and public systems. The research examines school leaders' discourse in the context of math achievement for all students. What are some of the commonalities of school leaders' discourse when it comes to math achievement? What do these leaders perceive to be success factors, roadblocks and challenges to students' math achievement? To what extent their discourse is a reflection of implicit inequities in school math? Do they allude to deficit assumptions in their understanding of math achievement for all students?

Using primarily semi-structured interviews, this research used a qualitative framework to explore some of these questions. Early analysis of the transcripts yielded to several themes including the importance of teachers' impact, the students' and teachers' attitudes effect, the fixed mindsets regarding math achievement and the challenge to make math meaningful to students. These four themes are examined in light of literature arguing that "effective school leadership is needed to support the transformation of teaching practice and school culture" (Vale, Davies, Weaven, Hooley, Davidson, and Loton, 2010, p. 47).

This research offers insights on school leaders' discourse related students' math achievement and addresses a gap in the literature (Herbel-Eisenmann, Choppin, Wagner, and Pimm, 2011, p. 5). This project initiates a framework for further studies on how school leaders' discourse interplay with math achievement. As scholars examine equity issues in school math and as policymakers discuss ways to increase math achievement for all students, it is critical to also consider how school leaders can be supported in developing discourses compatible to more equity in school math.

WRITING TO LEARN MATHEMATICS: A STRATEGY FOR PROMOTING REFLECTIVE ABSTRACTION FOR STUDENTS WITH LEARNING DISABILITIES

Kaitlin Bundock
Utah State University
Kaitlin.bundock@udu.edu

Jessica Heather Hunt
North Carolina State University
Jhunt@ncsu.edu

Beth Loveday MacDonald
Utah State University
Beth.macdonald@usu.edu

Keywords: Learning Theory

An estimated 6%-14% of students in the United States have persistent difficulties in mathematics and may be identified as having a learning disability (LD). These students often have difficulty connecting approximate number systems with symbolic number systems (Mazzocco, Feigenson, & Halberda, 2011), as well as challenges holding and storing information in short and long term memory. These specific difficulties, evidenced by challenges with foundational skills (i.e., counting on and subitizing), may relate to problem solving abilities.

We use Piaget's (2001) construct of reflective abstraction to explain how students cognitively reorganize information through reflection on their activity and its effects as they learn mathematics. First, students notice that the expected results of actions do not align with actuality, and try to resolve this perturbation by reorganizing their actions. Second, students compare mental activity records and their effects across similar situations (Simon, Tzur, Heinz, & Kinzel, 2004). Through repeated exposure, students internalize the concepts and processes used to select and execute appropriate strategies to solve problems. However, it is common for students with learning disabilities to struggle with identifying whether a solution to a given problem is reasonable and with keeping track of and reflecting on specific problem solving processes (Cuenca-Carlino, Freeman-Green, Stephenson, & Hauth, 2016).

Writing to Learn (the use of writing activities to aid learning in other content areas) can help students develop metacognitive strategies (Bangert-Drowns, Hurley, & Wilkinson, 2004). Reflective abstraction can be aided through metacognitive strategies (Simon et al., 2004). Therefore, WTLM may help students with LD engage in reflective abstraction. Psychological theories support the use of writing to develop connections between representations and the ability to communicate thought processes; both tenants are central to Piaget's theories on metacognition (Fox & Risconcente, 2008). In this poster session, we propose WTLM as an instructional strategy to promote reflective abstraction for students with LD, review the evidence for the use of WTLM to promote reflective abstraction, and provide suggestions for classroom applications as well as future research.

EXAMINING THE INTERACTIVE POSITIONS AND STORYLINES OF AN EMERGENT BILINGUAL LEARNER

Erin Smith
University of Missouri
emsxh3@mail.missouri.edu

The U.S. storyline of emergent bilinguals has historically failed to highlight the mathematical and linguistic assets of this group; instead, it has primarily focused on providing support. To disrupt this narrative, a case study of one elementary teacher, Ms. Bristow, is presented. Ms. Bristow's discursive practices and pedagogy illustrate how she fostered the storyline of mathematical competence for an emergent bilingual Latina by positioning her in ways that called attention to her mathematical thinking. Ms. Bristow's creation of mathematical goals and participatory expectations provided the foundation for classroom interactions that enabled the student's storyline to come to fruition and be appropriated by peers.

Keywords: Equity and Diversity, Classroom Discourse

Although emergent bilinguals (EBs) are a diverse group of students with a wide array of mathematical and linguistic competencies, they are not positioned in the U.S. narrative as such (de Araujo, Smith, & Sakow, 2016). Frequently, EBs are positioned in ways that do not focus on their mathematical competencies, but on their linguistic deficiencies. Such narratives have repercussions in the classroom and can determine ways teachers interact with EBs (Wood, 2013; Yamakawa, Forman, & Ansell, 2009; Yoon, 2008).
