Discourse is critical to mathematical learning (National Council of Teachers of Mathematics, 2014) and classroom discourse can facilitate or restrict this learning (e.g., Esmonde & Langer-Osuna, 2013; Turner, Dominguez, Maldonado, & Empson, 2013). Discourse that is used to control or silence EBs ultimately diminishes opportunities to learn mathematics and acquire English while maintaining the status quo (Battey & Leyva, 2016; Yoon, 2008). Therefore, teachers must be attentive to the ways their discursive practices and mathematical and participatory expectations influence EBs mathematical learning in the classroom.

Positioning theory offers one way to examine how teachers' discursive practices can facilitate mathematical learning for EBs and offer counter-narratives of who is mathematically competent. Through discursive practices, teachers position students in ways that contribute to their storylines as mathematics students. When teachers position students in ways that value their mathematical competencies and diverse cultural assets and experiences, a storyline of mathematical competence can be fostered. All too often, however, Latin@ EBs are shut out of such storylines (Brenner, 1998; Gutiérrez, 2008). To understand how teachers can establish storylines of mathematical competence for Latin@ EBs, a single case study was conducted of a teacher who had learned about positioning.

Positioning and Mathematical Learning

In mathematics education, positioning theory has been used to analyze social interactions at the individual (e.g., Yamakawa et al., 2009), class (e.g., Esmonde & Langer-Osuna, 2013; Turner et al., 2013), and national (Herbel-Eisenmann et al., 2016) levels. Although this research has demonstrated the importance of positioning to mathematical learning, mathematical identity, access to mathematics, and the field of mathematics education, it has not yet identified how classroom teachers establish storylines of mathematical competence for EBs.

In this study positioning theory (van Langenhove & Harré, 1999) was employed as a conceptual and methodological framework to examine discursive practices between a teacher and a Latina EB.

Galindo, E., & Newton, J., (Eds.). (2017). *Proceedings of the 39th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* Indianapolis, IN: Hoosier Association of Mathematics Teacher Educators.

Positioning theory is composed of three central components: communication acts (Herbel-Eisenmann, Wagner, Johnson, Suh, & Figueras, 2015), storylines, and positions. *Communication acts* are the ways people verbally or non-verbally communicate (e.g., gestures) (Herbel-Eisenmann et al., 2015). *Storylines* are the "broad, culturally shared narrative that acts as the backdrop" (Herbel-Eisenmann et al., 2016, p. 104) to social interactions. Oftentimes these refer to the categories that people give others in specific situations, such as teacher/student or man/woman, that define the expectations and conventions of interactions in the situation (Herbel-Eisenmann et al., 2015). Within each social interaction there are multiple storylines at play all drawn from and on participants cultural, historical, and political backgrounds and experiences that occur on different scales (e.g., utterance, episode, state, national, etc.) and define the expectations and conventions for interactions in the situation (Herbel-Eisenmann et al., 2015). For example, in the U.S. the storyline of mathematical success is often characterized by speed and accuracy, as opposed to deep conceptual thinking. Manifested in the classroom, this storyline is established by the teacher and fostered through communication acts in socially recognized ways (e.g., rewarding quick, correct answers).

The socially recognized ways people employ storylines are referred to as *positions*. Within storylines, people are metaphorically positioned or have a position, which refers to one's "moral and personal attributes as a speaker" (Harré & van Langenhove, 1991, p. 395). This position is relational, directly tied to the power one has compared to others, and is dynamic—each communication act results in a re-positioning of oneself and others. Moreover, one can position him/herself (reflexive position) or can be positioned by others (interactive position) (van Langenhove & Harré, 1999).

A teacher's position in the classroom situates them as the catalyst and leader for the establishment and maintenance of norms that determine EBs positions and storylines in mathematics (Yackel & Cobb, 1996). Furthermore, since peers reinforce positions and storylines designated by the teacher, he/she must position students in ways that call attention to and highlight EBs unique cultural backgrounds and knowledge bases in order to have opportunities to participate and learn (Turner et al., 2013; Wood, 2013; Yoon, 2008). Thus, within any classroom, teachers' positioning plays a key role by determining *who* has the right and duty to participate and learn. As a result, this study sought to answer the question: *In what ways does an elementary teacher use communication acts to interactively position and foster storylines of EBs in the mathematics classroom?*

Methodology

To answer the research question of this study, data are drawn from a large, longitudinal professional development intervention study that spanned three years and included four female, monolingual third grade elementary teachers. The intervention focused on EBs development of mathematics and language, enhancement of mathematics curriculum materials, and productive classroom interactions (see Chval, Pinnow, & Thomas, 2014 for more information). Over the course of the year, the researcher met with each teacher 9-12 times to discuss the themes in the context of lesson planning or debriefing. In addition, the researcher pushed each teacher to create mathematical goals for each EB in their classroom.

The present study used a single case study design (Stake, 1995) to examine one teacher, Ms. Bristow. Ms. Bristow taught in a Midwestern city with an approximate population of 115,000 in a school that was predominately white (>70%) with less than 10% of the student population Latin@ and over half of students receiving free and reduced lunch. At the start of the intervention Ms. Bristow had two years of elementary teaching experience with no prior education in pedagogy for EBs or experience teaching EBs. Thus, the first year of the study coincided with her first opportunity to teach EBs. Thereafter, in each year of the study, Ms. Bristow had 1-4 EB Latin@s.

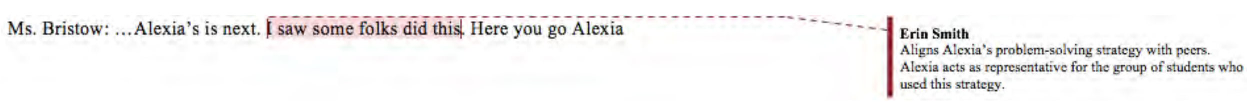
Data Selection and Analysis

To understand the ways Ms. Bristow constructed storylines for her EBs through interactive positions a subset of the data was analyzed—the first full month of the third year of the study. This subset was selected for two reasons. First, the establishment of storylines to facilitate EBs mathematical learning are heavily influenced by the teacher. Consequently, the teacher lays the foundation for future classroom interactions in the first month of the school year. Second, Ms. Bristow began learning about positioning and its importance in the classroom at the start of the intervention. Hence, after two years she had developed a greater knowledge base and mastery of positioning practices.

In the third year of the study, Ms. Bristow had one EB Latina, Alexia, who had relocated from a southwestern state two and a half weeks before the start of the school year. Ms. Bristow described Alexia as a quiet, shy, and reserved student who was often seen on task. Mathematically, Ms. Bristow explained Alexia had background knowledge that differed from her peers and, as a result, would bring up unfamiliar topics to peers in class.

Data analysis was conducted on a subset of data collected in September—the first month of the study (in the third year). Videos and transcripts of whole-class mathematics instructional interactions between Ms. Bristow and Alexia were analyzed. Classroom observations occurred five times, on September 6, 7, 15, 22, and 27. All classroom videos were reviewed and each instructional interaction between Ms. Bristow and Alexia was transcribed. Each transcription included verbal and non-verbal communication acts. In addition, transcripts of audio recorded one-on-one professional development intervention sessions were analyzed. These 40-50 minute sessions occurred on September 8 and 27.

The transcripts of Ms. Bristow's communication acts were open coded (Strauss & Corbin, 1990) at the utterance and turn taking levels to identify the interactive positions of Alexia (see Figure 1). These positions were analyzed sequentially to identify and construct the storylines Ms. Bristow fostered for Alexia as a mathematics student in the month of September.



Ms. Bristow: …Alexia's is next. I saw some folks did this. Here you go Alexia

Erin Smith
Aligns Alexia's problem-solving strategy with peers. Alexia acts as representative for the group of students who used this strategy.

Figure 1. Example of a coded communication act in a classroom transcript.

Findings

Ms. Bristow established and fostered Alexia's storyline as a mathematics student in multiple ways. First, she constructed pedagogical goals and participatory expectations for Alexia focused on her mathematical thinking and learning. Second, she employed communication acts to interactively position Alexia in whole class interactions where her mathematical thinking could be demonstrated. These interactive positions resulted in peers' appropriation of Alexia's storyline of mathematical competency.

Mathematical Goals and Participatory Expectations

In the intervention, the researcher consistently asked Ms. Bristow to create short and long term goals for her EBs at the start of the school year, but did not identify or specify the types of goals that these should be (e.g., what mathematical content, language competencies, and/or social competencies). This act of explicit goal setting for specific children facilitated Ms. Bristow's use of communication acts to position EBs in the mathematics classroom.

In September, Ms. Bristow described the goals she created for Alexia in her first meeting with the researcher on September 8.

Researcher: So what would be your goals for Alexia for this year?
Ms. Bristow: I think I want her to be a kid that is able to have strong mathematical thinking without just having to rely on just a set of rules. You know? I want her to be able to approach

> problems and be able to think of lots of different ways to solve a problem. And I don't...sometimes I worry with her that she will get trapped in an algorithm for everything because of the drilling that I think she is getting.

Ms. Bristow could have identified many different types of goals, however, as evidenced in her response the storylines and positions she wanted to facilitate for Alexia in her classroom were focused on her mathematical thinking. Specifically, a desire to increase Alexia's flexibility in mathematical thinking ("think of lots of different ways to solve a problem"), increase her mathematical reasoning abilities, and reduce her reliance on algorithms. These goals strictly attended to Alexia's mathematical thinking and learning and did not include or refer to her status as a language learner or newcomer in the school and community. In this way, Ms. Bristow began to construct a storyline of mathematical competence through her pedagogical goals, which were reified through classroom interactions.

Ms. Bristow was aware of the importance of participation for EBs' mathematical learning based on her involvement in the intervention. Consequently, Ms. Bristow intentionally positioned and solicited participation from Alexia in ways that would facilitate her mathematical learning. This was also described in the September 8 meeting with the researcher.

> As far as her [Alexia] participating, I try to get her to participate in some capacity in every lesson. I try to give her the opportunity to choose a partner that she is comfortable with. Because she is a little bit more reserved. And, I use her name in the problems. I used one of the problems that she had written in that word problem that the kids did with each other... I am trying to make her feel like a part of the class community and utilize her work and her name in as many different things as I can. I am trying to make her feel included.

Ms. Bristow clearly described the actions she took at the start of the school year to enhance Alexia's participation and mathematical learning. This included the incorporation of her name in mathematics problems, the option to select a partner, and the use of mathematics problems Alexia had written. What is most notable about Ms. Bristow's participatory expectations was her goal to seek out Alexia's participation in *every* mathematics class. Such actions worked to create a classroom community where Alexia—a newcomer and the only EB—could be successful in.

In addition to the above quotes, the analysis of video data demonstrated Alexia's participation took multiple forms. Ms. Bristow invited Alexia to the board to share her mathematical ideas, called on her in whole class discussions to explain her thinking, and displayed her work on the board to discuss in front of the class. To illuminate these practices, classroom examples are presented.

Sharing Ideas at the Board

Ms. Bristow commonly invited students to the board during discussions to share their mathematical thinking. In contrast to other teachers (e.g., Brenner, 1998; Yoon, 2008), Ms. Bristow frequently extended this invitation to Alexia and did not allow her to be a bystander. These actions were seen in the first day of classroom observations for the study, September 6. On this day, Alexia was invited to the board at the start of the lesson to share her mathematical ideas about a problem the class discussed. This communication act (i.e., Ms. Bristow's invitation to the board) interactively positioned Alexia in three ways: as a student who possessed mathematical ideas; as a student who would be an active participant in the global classroom conversation of mathematics; and as a student who was in the role of a teacher—a physical and metaphorical position of power. Together, these positions worked to establish the storyline of mathematical competence for Alexia publicly and counter deficit views of Latin@ students in mathematics (Gutiérrez, 2008).

What Are You Thinking?

At the start of the school year, Ms. Bristow established the expectation that *all* students—Alexia included—would share their ideas frequently and publicly. On the same day that Alexia was invited to the board to share her mathematical ideas (September 6), Ms. Bristow asked Alexia to share her mathematical thinking at the close of a lesson. In this lesson, students had played a game with a peer where they drew four cards each, made the greatest number they could, and then compared their numbers to determine a winner. The whole class discussion was framed around an example from a pair of students. To start the discussion, Ms. Bristow stated,

> Okay so…I have got two cards that I wanted to talk about today. Okay. Let's see…okay so Lamar and Adam. I thought that this was an interesting one. Adam got 9,760 and Lamar got 9,761 Why is that an interesting one? Why might that be an interesting one? Alexia what do you think?

At the start of this discussion, Ms. Bristow immediately asked Alexia what she thought about the selected numbers. This is an interesting question to pose Alexia as it asked her to not only consider how to compare the two values, but also the pedagogical decisions of Ms. Bristow (i.e., Why this example? What is important about this pair of numbers? What can we learn from them?). In this way, Ms. Bristow's communication act interactively positioned Alexia in two ways: as a student who can compare numbers in the thousands and as a student who can consider the pedagogical importance of this specific example. These two positions actively contributed to and reified Alexia's storyline of mathematical competence.

The next day, Ms. Bristow continued to invite Alexia into the classroom conversation of mathematics by soliciting her mathematical thinking. On September 7, Ms. Bristow began the lesson by modeling a game students would play with a peer where each player draws six numeral cards and makes two two-digit numbers "that, when added, give you a total that is close to 100." In the demonstration, Ms. Bristow first drew the cards, 1, 1, 5, 8, 3, 4 and wrote "_ _+_ _=__" on the board. Then, she invited the class to identify the best numbers to use, stating "Is there a number you could make or a combination you could make with just using those four of the six cards? Alexia, what are you thinking?" Like the day before, Alexia was the first student to be called on after Ms. Bristow initiated this whole class discussion. Ms. Bristow's question is interesting because it does not ask Alexia what are two numbers she could use, but what she was *thinking*. This communication act positioned Alexia as a student with mathematical thoughts who could strategically compose values to win the game. Moreover, it was the second time in *this* class that Ms. Bristow had asked Alexia what she was thinking. Furthermore, the questions posed to Alexia to describe what she was thinking were not low level or required a simple response, but challenged her to think critically and exercise a second language. Such instructional decisions may be directly tied to Ms. Bristow's pedagogical goal of developing strong mathematical thinking and reasoning skills for Alexia.

Sharing A Problem-Solving Strategy

Ms. Bristow often used student work (displayed on the board) at the end of a lesson to provide an opportunity to reflect on or share peers mathematical thinking. On September 15, Alexia was one of three students asked to discuss their problem-solving strategy (see Figure 2) of the peer written problem, "Sarah looks in her desk. She found 23 crayons, 14 pencils, and forty-nine crayons. How many crayons did she find in all?"

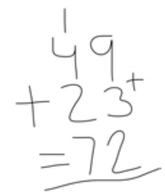


Figure 2. Alexia's problem-solving strategy.

Ms. Bristow: …Alexia's is next. I saw some folks did this. Here you go Alexia.
Alexia: *((comes to board))* I crossed out this. I crossed out this *((refers to "14 pencils"))* because if you say how many crayons are, did she find in all it doesn't say the pencils, so I crossed that out and I wrote this for this problem. *((points to algorithm))* First I wrote down the problem, then I put a plus sign here *((points to plus sign on right))* because I wanted to see 9 plus 3 is what. And it was, it was 12, so I put a 1 up there *((points to carried 10))* and I put a 2 there *((points to sum of ones column))*. Then I added these up 1 plus 4 plus 2 is 7 and I got 72.
Ms. Bristow: Questions and or compliments for Alexia. Keri
Alexia: Keri
Keri: I like how you thought about the, the answer.
Alexia: Mary
Mary: I like how you re-grouped.
Ms. Bristow: So that 1 where you say, that you put that 1 on top, what does that 1 representing? Is that one thing? Or what is that 1?
Alexia: It represents the 10 and so this is the tens place *((points to tens column))* I put it in the tens place.
Ms. Bristow: Yeah, so she actually took that 12 and put 2 of those loose ones on the side and then that one group of ten and added it to the 40 and 20 to make 70 and then we have the 2 loose ones to add to it. Alexia, I really appreciate you sharing. Thank you so much. *((class claps))*

This interaction represents another way Ms. Bristow solicited Alexia's participation. In this instance, Alexia was provided an opportunity for extensive mathematical talk. As a result, she was provided a chance to explain how she considered the information presented in the problem, determined what was erroneous, and then calculated her answer through an algorithm.

This opportunity to share her thinking was unique in the way it leveraged and elevated Alexia's status in the classroom and contributed to the storyline of mathematical competence. First, Alexia was one of only three students asked to share their thinking in this class. In this way, Ms. Bristow signaled Alexia was a competent mathematical student and her thinking was worthy of attention and discussion by her peers. Second, Ms. Bristow prefaced Alexia's discussion with the statement, "I saw some folks did this." As such, Ms. Bristow aligned Alexia's mathematical thinking with her peers and simultaneously enabled her to represent the group of students who used this problem-solving approach.

Regarding Alexia's mathematical thinking, Ms. Bristow also used this interaction to probe and clarify her ideas further in front of the class with her inquiry of the carried ten. This allowed Alexia to elaborate on her problem-solving strategy through mathematical discourse and illuminate how she understood the mathematical representation of the algorithm. An instructional decision that may be directly tied to Ms. Bristow's mathematical goal of increasing Alexia's flexibility in mathematical thinking and a reduction in the reliance of algorithms. Following Alexia's response, Ms. Bristow re-voiced her contribution, which acted to amplify her thinking to ensure all students had heard it and, reinforced her position as a student with valuable mathematical ideas.

This interaction also illuminates how Alexia's peers perceived her mathematical thinking and began to appropriate the storyline of mathematical competence. This is most evident in the targeted compliments Keri and Mary provided on Alexia's mathematical thinking. Unlike the two peers who also presented their mathematical thinking, Alexia was the only student who received compliments. This act of public recognition—a practice Ms. Bristow cultivated—is an example of how her interactive positioning of Alexia was taken up by peers, which fostered her mathematical success.

Discussion and Conclusion

Ms. Bristow offers a case of a monolingual elementary teacher who used of her position of power to construct a storyline of a mathematical competence for Alexia, a Latina EB, through communication acts and interactive positions. An examination of the data revealed Ms. Bristow initially established mathematical goals and participatory expectations focused on Alexia's mathematical thinking—not on her status as a newcomer Latina EB—that grounded future classroom interactions. Moreover, Ms. Bristow did not isolate Alexia in the classroom, allow her to be a spectator, or ask closed or simplified questions, but regularly invited her to share her mathematical thinking publicly, which provided opportunities for Alexia to use mathematical discourse—a critical aspect of mathematical learning. These communication acts worked to establish and foster Alexia's position in a storyline of mathematical competence and counter the narrative—and teachers' beliefs—that Latin@ EBs need mathematical support (Chval & Pinnow, 2010; de Araujo et al., 2016; Polat & Mahalingappa, 2013).

Given the growth of EBs nationwide, it is imperative teachers understand the connection between their communication acts, positions, and mathematics success and how their role in the classroom can be leveraged to create and manage storylines of mathematical competence for students that counter deficit views. Case studies—such as Ms. Bristow—can be used to illuminate how specific language practices and pedagogy can be employed by teachers to establish storylines of mathematical competence early in the year that position EBs for mathematical success.

INTRODUCING MATHEMATICS TO INFORMATION PROBLEM-SOLVING TASKS: SURFACE OR SUBSTANCE?

Ander Erickson
Western Oregon University
ericksona@wou.edu

This study employs a cross-case analysis in order to explore the demands and opportunities that arise when information problem-solving tasks are introduced into college mathematics classes. Professors at three universities collaborated with me to develop statistics-related activities that required students to engage in research outside the classroom. This paper will focus on one aspect of the study: a comparison of how the teachers balanced mathematical content with information-problem solving in the tasks that they created. These tasks incorporated mathematics in a variety of ways, ranging from tasks in which the mathematical component was crucial to others where mathematics served solely as a marker of credibility. This research has the potential to provide tools for understanding how to productively incorporate information-literacy instruction into the mathematics classroom without losing sight of mathematical goals.

Keywords: Instructional Activities and Practices, Post-Secondary Education, Technology

Introduction

Mathematics students increasingly occupy an environment in which they enjoy immediate access to varied sources of information outside of the classroom. They can look up vocabulary terms on Wikipedia, find context for a statistics problem by accessing governmental statistics directly, and track down discussions of test problems on various Q&A web-sites. While mathematics instruction has historically been focused on sequestered problem-solving (Bransford & Schwartz, 1999), or the ability to solve problems without any outside aid, an increasing number of mathematics teachers have been actively encouraging students to engage with information-based problems (Walraven, Brand-Gruwel, & Boshuizen, 2008) or those problems that require "students to identify information needs, locate corresponding information sources, extract and organize relevant information from each source, and synthesize information from a variety of sources" (Walraven et al., 2008, p.623). I have previously argued (Erickson, 2015) that the use of information-based problems is not just preferable, but that it is also necessary if mathematics instruction is to help prepare students for the quantitative arguments that they may expect to encounter in their everyday lives (Paulos, 1988; NCED, 2001).

This paper presents a cross-case analysis (Stake, 2013) of three different undergraduate mathematics teacher who work with their students on statistics-focused tasks that require the students to seek out, evaluate, and make use of information that they find online. The use of information-based problems have been studied in the context of science education (Hoffman, Wu, Krajcik, & Soloway, 2003; Wiley, Goldman, Graesser, Sanchez, Ash, & Hemmerich, 2009) and history education (Britt & Aglinskas, 2002) before. These studies reported on experiments that took place apart from classroom instruction and so those who crafted the problems did not need to answer as to whether the problems provided evidence of learning, were congruent with the goals set out in the course syllabus, or incorporated the disciplinary topics to be covered in the class. Accordingly, the present study is unique for two reason: a) it takes place in the context of mathematics instruction, and (b) it was incorporated into ongoing mathematics courses. The analysis of the design and implementation of these information problem-solving math tasks provides a window into the balance teachers must strike between mathematical content and information literacy practices. In particular, the analysis addresses the following research questions:

1. How does mathematical content function as a component of an information-based problem introduced into a mathematics class which is meant to prepare students for the mathematics that they will encounter in their everyday lives?
2. What opportunities are students given to employ their mathematical knowledge through their work on these information-based problems?

Theoretical Framework

Three different conceptions of literacy have emerged which each highlight the importance of introducing information-based problems to mathematics instruction. (1) A move to attend to how reading and writing is conducted in the disciplines and to use this as a way of thinking about how to teach those disciplines means that mathematics teachers must think more carefully about how those who work in STEM fields locate and evaluate mathematical resources (Schleppegrell, 2007; Moje, 2007; Shanahan & Shanahan, 2012). (2) Quantitative literacy, sometimes described as a mathematical proficiency that can serve any individual in their everyday life, has been embraced as an educational goal, particularly at the undergraduate level (Cullinane & Treisman, 2010; Watson, 2013;MORE CITATION) and seen realization in courses offered by many colleges for non-STEM majors who need to fulfill a mathematics requirement as part of their liberal arts education. (3) Researchers in the information sciences have been arguing for the importance of instruction in order to facilitate college and high school students' ability to effectively research topics online (Rader, 2002).

While the importance of information-based problems for disciplinary literacy is easy to justify as long as one accepts that information-seeking is an important part of practice in the disciplines, it requires a little more unpacking to explain why this type of instruction might have a place in mathematics instruction. One way to begin such an explanation is to imagine an applied mathematics problem -- say students are given an editorial in which the author argues that federal guidelines on fuel efficiency will end up costing the country more money than it will save (Diefenderfer, 2009). Students are asked to read the editorial and then provided with several guiding questions that encourage the students to analyze the numerical argument contained in the article while noting some of the additional information that might be required prior to coming to a final verdict on the validity of the editorial's argument. While this activity is a legitimate applied mathematics problem, the real-world context (see Figure 1) suggests other directions that such a problem could be taken.

If a reader were to actually want to determine whether the editorial's claim was true or not, they would want to locate the relevant *epistemic community* (Haas, 1992), or that community that possesses the expertise to tentatively rule on the truth of the claim. In other words, they would need to engage in the practice of rational dependence by finding experts on whom the students have good reason to rely. The problem as originally stated does not afford the students an opportunity to engage in this practice. They are not asked to seek out and evaluate those sources of information that might either corroborate or challenge the argument found in the editorial. An *information-based problem* (Walraven et al., 2008)*,* on the other hand, requires that the student seek out and evaluate sources outside the classroom. In order to come to a better understanding of an information-based problem, the student must "identify information needs, locate corresponding information sources, extract and organize relevant information from each source, and synthesize information" (Walraven et al., 2008, p.2) in a process called *information- problem solving*. My inquiry can be framed, then, as a question about how mathematics teachers and their students cope with the introduction of information-based problems, and whether and how these problems afford opportunities for the practice of mathematical problem-solving skills.

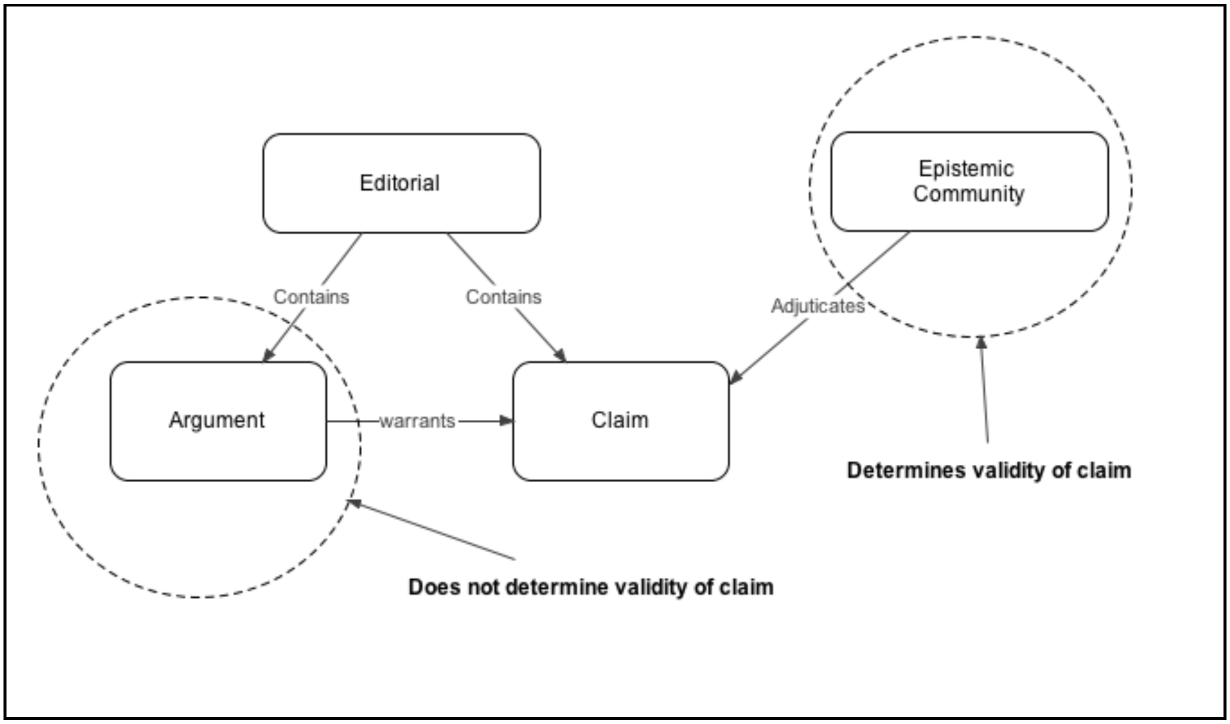

Figure 1. Relationship between editorial, claim, and epistemic community.

Methodology

I began this work by contacting instructors of terminal mathematics courses for non- STEM majors because my reading of the literature and interviews with mathematics educators suggested that this would be the most accessible site for this type of work. There were thirteen educators at ten different institutions who responded to this call and, while they all expressed interest in the idea when I explained it to them, I ended up with 4 collaborating instructors as the others were not able to work with me due to either institutional or timing constraints. I met with each of these four collaborating teachers and explained the rationale behind information-based problems and we worked together to design a couple of activities in which this type of problem would be introduced to their students. The analysis is focused on the three sites (see Table 1) where the instructors had the greatest role in designing and implementing the problems.

At Phi University students were assigned to argue one side in a classroom debate. To prepare, they were required to research their topic and provide some statistical evidence supporting their side of the issue. At Rho University we developed a two-part activity where students were asked to look for articles in which a conjecture about causation was being studied (e.g., vaccines and autism). They were asked to locate the quantitative evidenced used to claim that the two variables were or were not correlated, and then engaged in a small-group discussion with their peers about the topic. Their groups tried to come to a consensus on the issue at stake and then shared their verdict with the rest of the class. The students at Delta University also worked in small groups, but here they were asked to create a presentation in which they would analyze the way that statistics were used in a research article for the rest of the class. The focus of this analysis would be on the sampling methodology, but they were free to talk about other facets of the article if they so chose.

Table 1: Research Sites

University Name*	Course Name*	Students	Topics	Structure
Phi University (Research)	Topics in Mathematics	22 entering Freshman, Liberal Arts Majors	Gun Control, Marijuana Legalization, Single-Sex Education, Death Penalty	Debate Format
Rho University (Regional)	Quantitative Reasoning	14 Juniors and Seniors, many are prospective Nursing students	Autism and Vaccination, The Mozart Effect, Gun Control, Health Care Reform	Small-group Discussions
Delta University (Doctoral)	Mathematics in Today's World	24 Juniors and Seniors, many are prospective Nursing and Education students	Autism and Vaccination, Gun Control, Murder Rate, Vehicular Accidents, Employee Prospects	Small-group Presentation

*These are pseudonyms

This study takes the form of a multi-case analysis (Stake, 2013) derived from the activities described above. The *quintain*, or the phenomenon of interest for this cross-case analysis, is the introduction of information-based problems to an undergraduate mathematics course. The data for this study includes pre- and post-interviews with the instructors at each of the three sites, supplementary interviews with teaching assistants and students, field notes taken while observing instruction prior to the introduction of the information-based problems, video and audio-recordings of the in-class component of the activities, and copies of the work that the students submitted. These data sources informed the writing of individual case reports which were, in turn, used to develop the cross-case analysis. Following Stake (2013), I developed themes based on my research questions that I then used as an analytical lens for the development of case reports for each of the three sites. After writing up the case reports, I cross-referenced case-specific observations (see Table 2 for relevant examples) with the themes of the larger study. This allowed me to warrant theme-based assertions and used those to inform the final cross-case assertions about the introduction of information-based problems to undergraduate mathematics classrooms. The cross-case assertions related to the students opportunities to interact with mathematical content in the information-based problems will be presented below.

The teachers with whom I collaborated were taking on a unique challenge when they decided to introduce information-based problems to their mathematics classroom. While they agreed that their students would benefit from an opportunity to engage in information problem solving, they had to continue to teach their students mathematics through these problems. I intentionally provided very little guidance on this front and the teachers at each of the three locations approached the challenge in distinct ways. In order to describe the role that mathematical work played in these problems I describe the implemented problems as *academic tasks*, a term that encompasses both the perspective of the students as they try to meet the requirements of their assignment and the teachers as they manage the work of their students. I refer to academic tasks using the technical sense employed by Doyle and Carter (1984) where tasks are broadly understood as the "situational structures that organize and direct thought and action" (Doyle & Carter, 1984, p.130) in the classroom and more specifically as components of the curriculum that direct students to use *operations* on *resources* in order to achieve a *product* which is validated by a system of *accountability.* The different role of mathematics in each of the cases is clarified by articulating where it sits within the overarching academic task with respect to the component operations, resources, and product.

Table 2: Examples of Case-Specific Observations from Rho University

Case-Specific Observation A: In the first session, students were searching for articles and then looking for a correlation coefficient within the articles, but they rarely found a correlation coefficient.
Case-Specific Observation B: Students preferred to work with information resources that contained mathematics that they could understand.
Case Specific Observation C: In the first session, the teacher prioritized the identification of a particular piece of mathematical content, the correlation coefficient, to the exclusion of any discussion of the credibility of sources.

Results

The mathematical aspect of the debates at Phi University was fairly circumscribed; it almost existed as a freestanding task of its own within the larger task of the debate. Tim (a pseudonym for their professor) had decided that his students would provide a statistical chart or diagram as part of their argument and that this would tie the problem into the unit on statistics that the class was in the process of covering. In particular, the students would have to create their own graphic rather than downloading it from elsewhere,

> I made the decision at some point that I didn't want them to just download graphics off the internet because I was worried that if they did that, they would download a bunch of fancy graphics that they didn't really quite comprehend and then it would be too much information for anybody in the audience to comprehend too. And so I figured the way around that is that I would have them do it, they read the section on how to present data, that's section two of that chapter, how to present data, ideas on how to present data, and so let's make them do it. I think that was a good decision. (Tim, 8/14/13, Lines 73 - 79)

I refer to the creation of graphics as an *almost* freestanding task because it still was predicated on some information-seeking in order to locate the sources containing the statistics that would inform the graphics. One way to put this is that the operations that were part of the debate task (for example, using a search engine, scanning search results) provided the resources that would be used for the mathematical task. I refer to the mathematical work as an academic task of its own because it theoretically could exist independently of its role in the debate as long as equivalent resources were made available. Conversely, a debate could have taken place without students having to make use of statistical diagrams. Nonetheless, by introducing this mathematical task, Tim was able to simultaneously avoid the introduction of graphics that could be too mathematically demanding for his students and to create a relatively well-defined mathematical task within the larger information problem-solving task which he would subsequently be in a better position to appraise as mathematical work.

At Rho University, Anne (a pseudonym for their professor) also created a mathematical task that was part of a larger information problem-solving task, but in this case the mathematical work was necessary, at least as Anne conceived it, for the credibility assessment that constituted the larger task.

As with the students at Phi University, the students at Rho were to submit a product that included the mathematical work (i.e., the identification and interpretation of a correlation coefficient or confidence interval) alongside more ambiguous information problem-solving work (i.e., an assessment of the credibility of the different sources). It was also the case that the search for those mathematical markers could only occur after the students searched the internet in order to collect sources. Thus, we again have a situation where the information-seeking operations on the internet was used to provide resources for the students' mathematical work. There was one small but significant difference in the case of the second problem; those students were required to only collect sources that contained confidence intervals and so the mathematical operation of identifying a confidence interval became part of the information-seeking work. The subsequent classroom discussion constituted another part of the task, or perhaps a second task, which was much more ambiguous in terms of both its product and its operations. By breaking the information-based problems into two distinct activities, Anne was able to collect and evaluate concrete evidence of mathematical work with the written assignment and make that same mathematical work available as a resource for the students' discussions of credibility.

The first problem at Delta University as developed by Ivan (a pseudonym for their professor) was structurally similar to the mathematical sub-task at Phi University in that the students had to first find a source which they would then use as a resource for their mathematical work. The product at Delta University was the students' analysis of the sampling strategy used by poll or research article that they found. The second problem at Delta University was similar as well, but the use of sources was complicated by the fact that the students could not just pick a source and then analyze its contents. Instead, the students were held accountable for finding the data needed for their calculations which meant that their mathematical knowledge needed to mediate their information-seeking work in a way not seen in any of the other cases. By structuring the problems in this way, Ivan made the students' mathematical work the core of the product that they shared with the class. This was reflected in the type of feedback that Ivan provided for his students, he focused much more on the students' mathematical work than either of the other cases.

Looking across the cases (see Table 3 for cross-case observations) it was notable these students only questioned the source of the statistics when explicitly instructed to do so as part of the activity. When the statistics served as evidence for a point-of-view, as in the case of Phi University, students were only concerned with effectively communicating the information that they found to their peers in order to support their argument. Further, when the statistics were being used as evidence, students used the presence of statistical information as a token of credibility for the information source as a whole, and not as an element of the information source deserving critique in and of itself. Ironically, the activities at Phi and Rho University, in which actual mathematical work was very limited, were felt to be very successful by the Tim and Anne, while Ivan expressed some frustration with his activity. This appeared to be at least partly due to the opportunity the presentations afforded for Ivan to observe gaps in his students' knowledge of basic statistical concepts, an opportunity that did not exist at either of the other two locations. In a subsequent interview with Ivan, he expressed some satisfaction that he was able to realize that students did not fully understand some of the more basic statistical concepts that he had been trying to teach them and said that he would incorporate a similar activity into future iterations of the course in order to discover whether students could apply what they were learning to real-world scenarios.

Table 3: Cross-Case Observations About the Role of Mathematics in the Information-Based Problems

Cross-case Observation 1: Students only adopted a critical stance towards the statistics that they found when explicitly demanded by the problem.
Cross-case Observation 2: Students successfully drew on elements of a statistical knowledge base throughout the three cases, but those information-based problems in which mathematical work was prioritized presented a greater opportunity for revealing gaps in student knowledge.
Cross-case Observation 3: The students' mathematical knowledge sometimes conflicted with their ability to assess the credibility of a source. On the one hand, if the students are not asked to engage with the mathematics in question, then it may only serve as a superficial marker of credibility rather than providing insight into the mathematical argument. On the other hand, if a source contained mathematics that the students did not understand, then they might not use that source.

Discussion & Conclusion

These three cases afforded me the opportunity to see some of the ways that a practicing mathematics teacher can dispense their obligation to teach the discipline to their students while assigning non-traditional information-based problems. In all three of the cases, the students had to engage in some initial information-seeking in order to collect sources that would serve as a resource for their mathematical work. In the first case, this work was its own mathematical task, contributing to the larger information problem-solving task but not strictly necessary for its completion. In the second case, the mathematical work was a distinct task but it also served as a resource for the following discussion. In the third case, the result of the mathematical work was actually the product of the information problem-solving task and the students' information-seeking and evaluation played a supporting role.

This analysis of the dilemmas faced by mathematics instructors who wish to create opportunities for their students to build their information literacy skills is not intended to dissuade teachers from using information-based problems that bring students into contact with real-life quantitative claims nor to discourage the introduction of information problem-solving to mathematical tasks. Rather, it suggests that pedagogical choices must be made thoughtfully and deliberately if they are to meet their intended goals.

Acknowledgments

I would like to gratefully acknowledge the help of the necessarily anonymous mathematics professors who graciously agreed to work with me as well as the support and feedback of Patricio Herbst, Pamela Moss, Elizabeth Moje, and Deborah Ball.

At the crossroads of our prior research on prospective teachers' feedback to mathematics-learners and our mathematics teacher educator feedback practices, we study written feedback as part of relational practice. Using self-study methodology and an analysis of our narratives and conversations about written feedback, we identified factors that frame and motivate our written feedback. We argue that, assuming the central goal of teacher education is the development of relational practice, written feedback should support prospective mathematics teachers' skills and knowledge relevant to tasks involved in teaching mathematics and extend prospective teachers' views of mathematics teaching and learning by drawing on their experiences, insecurities, problems, and views of mathematics teaching and learning.

Keywords: Instructional Activities and Practices, Teacher Education-Preservice

Grossman et al., (2009) asserted that development of a relational practice is a central goal of teacher education and illustrated that mathematics teacher educators (MTEs) engage in activities in support of this goal. Buhagiar (2013) suggested that MTEs' practices serve as models for future mathematics teachers (teacher-learners). Thus, MTEs' activities should model relational practice, described by Fletcher (1998) as including "empathy, mutuality, reciprocity, and a sensitivity to emotional contexts" (p. 174). This paper focuses on MTEs' written feedback as one activity that models elements of relational practice. Feedback is a significant part of an assessment system and impacts learning and performance (Hattie & Timperley, 2007; Shute, 2008). Therefore, MTEs' written feedback and factors that frame and influence that feedback warrant study to improve understanding of written feedback as a model of relational practice.

Findings from a prior analysis of feedback that teacher-learners provided to mathematics-learners (i.e., K-12 mathematics students) through letter exchanges (e.g., Crespo, 2002) included a description of the ways mathematics teacher-learners used praise and attended to the learners' mathematics in their responses (Kastberg, Lischka & Hillman, 2016a). These findings raised questions about our MTE feedback practices. We wondered if our written feedback would stand up to the scrutiny leveled at teacher-learners. Did our feedback attend to ways teacher-learners saw learners' mathematics and build on their personal understandings of mathematics teaching and learning or did we direct teacher-learners to what we saw in mathematics-learners' work?

Considering this question brought us to a crossroads as we became conscious of a "living contradiction" (Whitehead, 1989) between our feedback practices and our expectations for teacher-learners' written feedback. In an effort to improve our feedback practice and identify ways in which such a practice modeled relational practice, we asked *What factors frame and motivate our written feedback as a model of relational practice?*

Literature Review and Theoretical Framework

Existing meta-analyses of quantitative studies of feedback (e.g., Hattie & Timperley, 2007; Shute, 2008) identified factors that mediate its effects, such as complexity of tasks and characteristics of praise on performance. Recent research (e.g., Evans, 2013) draws from a broader array of theoretical perspectives (e.g., socio-cultural, socio-critical, constructivist) not well represented in prior feedback discourse. From a synthesis of studies in higher education, Evans hypothesized a "feedback landscape" that "illustrates a two-way process in which feedback is moderated" (p. 97) by a collection of relational and information variables that include learners' "beliefs about learning and expectation of the learning environment" and teachers' "knowledge of the student" (p. 98). Evans' view of feedback applied to mathematics teacher education involves understanding written feedback as an element of relational practice.

There is much research on feedback in general with little attention to written feedback provided by MTEs to teacher-learners. Studies of feedback in teacher education have focused on feedback given during practicum (White, 2007), teacher-learners' perceptions of feedback (Dowden, Pittaway, Yost, & McCarthy, 2013), and self-studies focused on written feedback (Kitchen, 2008; Pittaway & Dowden, 2014). In *mathematics* teacher education, only Buhagiar (2013) explored written feedback. He reported that MTEs' feedback varied significantly and suggested beliefs about teaching and learning as the source of the differences.

Relationships with learners are important elements in effective feedback practices (e.g., Evans, 2013; Hattie & Timperley, 2007), allowing MTEs to leverage understandings of teacher-learners (Grossman et al., 2009) and contexts in which they work in support of teacher-learners' development of practices and understandings of mathematics teaching and learning. Kitchen's (2005a, 2005b) description of *relational teacher education* as teacher educators "knowing in relationship" (2005a, p. 18) is used to understand factors that frame and motivate MTEs' written feedback as a relational practice. Like Fletcher (1998), Kitchen drew from notions of empathy and vulnerability to describe relational practice and identified seven defining characteristics: understanding one's own personal practical knowledge, improving one's practice in teacher education, understanding the landscape of teacher education, respecting and empathizing with preservice teachers, conveying respect and empathy, helping preservice teachers face problems, and receptivity to growing in relationship. These categories are used as an analytical framework to explore factors that influence written feedback as a relational practice. Descriptions of each category are shared in the findings section.

Mode of Inquiry

To identify factors that frame and motivate our written feedback as a relational practice, we undertook a self-study. Identified by Borko, Liston, and Whitcomb (2007) as a form of practitioner research, self-study is aimed at improving one's practice (LaBoskey, 2007) and is characterized by openness, collaboration, and reframing (Samaras & Freese, 2009). Self-studies situate questions in existing research literature and suggest implications for "the larger audience of teacher-educators" (Borko, Liston, & Whitcomb, p. 9). Self-study involves the construction of narratives of experiences and conversations with critical friends sharing alternative perspectives on practice, described by LaBoskey as data in self-study methodology. This self-study was undertaken with the goal of improving our written feedback. We began by analyzing our written feedback using Hattie and Timperley's (2007) framework (see Kastberg, Lischka, & Hillman, 2016b for findings related to this analysis). This paper focuses on factors that framed and motivated our feedback, using transcripts of eight recorded online conversations about written feedback findings (May-December, 2015) and two self-constructed narratives (Clandinin & Connelly, 2000) as data. The first narrative described our feedback experiences as leaners and the second narrative described our experience creating opportunities for teacher-learners to provide written feedback to mathematics-learners (May and December, 2015). This data allowed for reframing experiences by taking the perspective of another on one's practice.

Narratives and discussions were coded using Kitchen's (2005a) characteristics of relational practice. Evidence of *knowing in relation to self and teacher education* was coded using Kitchen's (2005a) first three categories and evidence of *knowing in relation to teacher-learners* the remaining categories. Descriptions and exemplars are shared in the findings.

Blind review precludes specificity, so a sketch of the actors and context is included here.

Pseudonyms are used for the authors in the remainder of this paper. The authors work at three different institutions with Sandy and Jean both mid-career MTEs working with elementary teacher-learners and Pamela an early-career MTE working with secondary teacher-learners. All teacher-learners engaged in letter-writing activities, with MTEs providing written feedback.

Findings

Knowing in Relation to Self and Teacher Education

In restorying our experiences, we gained “self understanding” (Kitchen, 2005a, p. 19) of reasons for assignment structures and types of written feedback we provided.

Understanding one’s own personal practical knowledge. Kitchen (2005b), defined personal practical knowledge as “the ways in which past experiences inform present practice and intentions for the future" (p. 199). We unpacked our experiences as learners, mathematics teachers, and MTEs and considered how they informed our practices. Discussions focused on assignment structures and what teacher-learners’ approaches to feedback could teach us.

An example related to assignment structures involved exploring whether feedback on letters supported the teacher-learners to develop their views of mathematics teaching and learning or just to complete the task as we had conceptualized it. We wrestled with the question of whether the teacher-learners could use our feedback. Sandy and Pamela provided feedback on teacher-learners’ reflections on feedback provided in letters to mathematics-learners, while Jean had provided feedback on teacher-learners’ draft letters and requested revisions. Looking back at our experiences giving written feedback, Sandy and Pamela wondered whether the teacher-learners could make sense of the feedback.

> Sandy: I think that one of the fundamental assumptions that we operate under, [is that] if we give feedback, [teacher-learners] are actually going to operationalize it and use it. But the reality of the situation is that we know that really doesn't happen. In part, that is our own fault because … we don't provide opportunities to revise your work in light of feedback. When we do, Jean's work shows us that they attend to the letter of the law. “Oh, you told me I needed to add this … so I did those things.” (November 12, 2015)

We questioned whether we were supporting only those teacher-learners whose work aligned with our views. Retelling our experiences as MTEs, we developed empathy for teacher-learners trying to fulfill course demands while extending understandings of mathematics teaching and learning.

Our discussions of teacher-learners’ approaches to feedback focused on a contrast to our own pedagogical principles and strategies used in written feedback. We wondered if interpersonal relationships with teacher-learners would encourage them to use our feedback. Teacher-learners’ responses to mathematics-learners served as examples of relationship development. For example, some teacher-learners first attended to mathematics-learners as people and only highlighted elements of the learners’ mathematics after addressing unique characteristics of the mathematics-learner. In contrast, our written feedback focused on supporting the teacher-learners to complete the task at hand. Looking forward, we discussed if we should, or could build more personal connections into our written feedback.

> Pamela: Ok, then maybe I need to think differently about mine [feedback], because I looked at the few tasks that I have had a chance to look at and I’m thinking that I don't really attend to the PT [teacher-learner] as a person. … But I think I do a lot of that in class, it’s just not in my written comments. So I struggled with that one. (June 4, 2015)

Pamela’s comment illustrates that interpersonal relationships with teacher-learners may be developed face-to-face. We then wondered if our written feedback would be more effective if attending to interpersonal relationships before sharing feedback on the task and process.

Improving one's practice in teacher education. Kitchen's (2005a) category "improving one's practice in teacher education" includes exploring experiences and using insights gained to improve practice, such as teacher educators trying to communicate "understandings and structure meaningful lessons" (p. 23). Efforts to improve our feedback practices focused on the purpose of assignments, such as desiring to have teacher-learners explore mathematics-learners' reasoning.

> Pamela: My intent was just to have them thinking about [mathematics-learners'] thinking.
> Sandy: Yeah me too.
> Pamela: I wanted them to interact with a [mathematics-learner] because they don't have a field experience in the course. So I wanted student interaction. (July 28, 2015)

By comparing and contrasting our course activities, institutional contexts, and feedback practices, we proposed changes to our assignments and feedback practice. Pamela and Sandy drew insight from Jean's approach where feedback had resulted in teacher-learners' improving final versions of letters. Proposed improvements included providing feedback on drafts of teacher-learners' responses, initiating class discussions of MTE feedback, and adjusting letter exchange time-lines to allow teacher-learners to revise.

We evaluated proposed changes to our feedback practice based on whether a change was productive for teacher-learners and efficient for us. For example, we wanted to reduce time between the submission of work and teacher-learners' receipt of written feedback, but struggled with how to construct feedback quickly that attended to individual needs of teacher-learners.

Understanding the landscape of teacher education. Kitchen (2005a) identified the need to "frame individual challenge within a larger institutional and societal challenge" (p. 27) as "understanding the landscape of teacher education." We discussed motivations behind decisions about structuring assignments and crafting written feedback that included program assessments for accreditation, field structures, class size, the practices of supervisors in practicum, and the Common Core movement. Our feedback was part of teacher-learners' experiences in teacher education programs facing increased scrutiny and demands that graduates be expert teachers. In particular, Jean's motivation in developing the letter exchange between teacher-learners and mathematics-learners was for teacher-learners to develop ideas about providing written feedback, in response to data analysis from a program assessment related to accreditation that showed a need for improvement in the area of teacher-learners' feedback to K-12 students.

For example, Jean and Sandy shared stories about efforts to meet demands of accreditation organizations including preparing teacher-learners to collect "data" from their practices.

> Sandy: … because my [colleagues] are asking me for examples of my teacher-learners' work that I think are particularly good and that show that they can collect and have analyzed data and can make decisions about what to do next. (August 10, 2015)

Our conversations revealed the challenges in creating meaningful learning opportunities for our teacher-learners (e.g., constructing written feedback on mathematics tasks) while preparing them to document their work as required for accreditation.

Knowing in Relation to Teacher-Learners

Kitchen (2005b) described the last four elements of relational practice as modeling "respect for teachers as curriculum makers" (p. 200) with focus on the MTE/teacher-learner relationship.

Respecting and empathizing. Central to respecting and empathizing with teacher-learners is "a genuine belief that each prospective teacher must construct her or his own meaning as a curriculum maker" (Kitchen, 2005b, p. 201) by recognizing and supporting the needs of teacher-learners while encouraging them to probe issues of mathematics teaching and learning.

Discussions focused on gaining insight into teacher-learners' experiences and concepts of teaching. Knowing about teacher-learners' stories of experiences in schools could help us understand their views of mathematics teaching and learning. Yet, we typically had not asked teacher-learners about their experiences. When we did, we did not use that knowledge to inform our written feedback. For example, Sandy asked teacher-learners to reflect on their experiences as learners, but described still wondering about the sources of teacher-learners' insights.

> Pamela: So then how do you build on [teacher-learners'] own knowledge and experiences, when you haven't found out what those are?
>
> Sandy: I never really tried to understand where [teacher-learners] were coming from. So when I read Jean's [feedback] and then I read mine I was going: "Ok, well this feedback [responses to mathematics-learners] that they are giving could be interpreted so many ways." I wish I knew how [teacher-learners] were thinking about it. I had them do the reflections, so you would think I would know. But they would make statements about … the students' thinking, that I was just like: "I wonder where this is coming from." (August 10, 2015)

Not knowing the teacher-learners' motivations and experiences that may have influenced their interpretations of learners' mathematics made developing meaningful feedback difficult.

Although supporting teacher-learners' efforts to build conceptions of teaching and learning was a goal, we considered how to address their need to survive in practicum. We realized teacher-learners' responses to mathematics-learners, were a function of their conceptions *and* efforts to complete course assignments. To construct productive feedback, we conjectured about teacher-learners' conceptions of teaching and learning from evidence of their experiences. For example, Jean started asking "how are you doing?" (November 12, 2015) in individual meetings with teacher-learners before launching into feedback about lesson plan drafts. This simple question encouraged teacher-learners to relay stories from field experience that revealed not only their concerns with practicum, but informed Jean's understanding of their concepts of teaching and learning. Looking forward we developed other ways to gather evidence of such experiences.

Conveying respect and empathy. Describing his efforts to convey respect and empathy, Kitchen (2005b) suggested teacher educators can demonstrate their feelings by "acknowledging insecurities" (p. 204) and helping teacher-learners face challenges in programs of study. Further, teacher educators can express commitment through listening and responding mindfully.

We were uncertain about challenges teacher-learners faced since we had not invited teacher-learners to share experiences with us. To gain insights, we discussed our own experiences as teacher-learners and recalled challenges trying to "fit" into mentor teachers' classrooms. Using this experience, we considered our programs and course activities and the potential in these contexts for teacher-learner challenges. For example, in looking back to our letter-exchanges, we discussed the challenge of engaging with mathematics-learners whom teacher-learners did not know. This activity structure seemed misaligned with possible teacher-learners' views of teaching and learning situated in nurturance and care.

We discussed how to respond mindfully when teacher-learners shared challenges and insecurities. We wondered whether praise would count as part of a mindful response because without praise, teacher-learners might read our written feedback as lacking care or concern. Jean looked back at shifts in her written feedback from using "smiley face kind of stuff" in her written feedback to giving "specific comments" and whether this had impacted her relationships with the teacher-learners (August 10, 2015).

> Jean: But then, I wonder if that shifted relationship building because there just seems to be a difference between [teacher-learners] that I have had recently versus [teacher-learners] that I

remember from say years ago. (August 10, 2015)

Hypothesizing about challenges our teacher-learners faced was easy; knowing how to construct written feedback addressing the challenges was difficult.

Helping teacher-learners face problems. Kitchen (2005b) described helping teacher-learners face problems as identifying and supporting teacher-learners to confront tensions between their constructs of teaching and learning and the practical realities of classrooms.

Discussion focused on problems that could arise when a teacher-learner's goals did not align with her practices. Sandy described asking teacher-learners how to confront errors in mathematics-learners' work: "When I addressed dealing with incorrect responses with my [teacher-learners] … They were very sensitive to children being told that they are wrong. [Teacher-learners] really think there is no place for it" (July 28, 2015). Sandy strove to honor teacher-learners' perspectives, but felt the practice they described was inconsistent with their goals for mathematics teaching. The teacher-learners' position on error-handling was consistent with their determination to attend to mathematics-learners as people, yet seemed inconsistent with their goal of supporting the development of learners as mathematicians. Sandy recognized this tension with teacher-learners' perspectives on errors as a potential learning opportunity for them, but did not know how to use feedback to help the teacher-learners confront this tension.

Pamela's feedback was typically in the form of questions addressing what she identified as teacher-learners' problems of practice. For example, sharing a teacher-learner's response about being more clear and specific with mathematics-learners, Pamela illustrated how she used questions to help the teacher-learners face problems.

> My response was "I want you to consider whether it is the clarity and specificity that is important or the information on which you ask the students to build their thinking. How are you asking students to think about their own responses?" (Pamela, July 28, 2015)

Pamela hypothesized teacher-learners' conceptions of teaching and learning were surface-level and questions in her feedback would encourage teacher-learner reflection, even when directly disagreeing with teacher-learners' claims to help them unpack problems of practice. As Sandy wondered if her relationships with teacher-learners could withstand this approach, Pamela maintained that interactions with teacher-learners allowed giving critical feedback, asserting teacher-learners would attend to feedback due to collegial relationships with the teacher-learners.

Receptivity to growing in relationship. Kitchen (2005b) described receptivity as identifying one's own problems rather than "the 'expert'" (p. 206) defining the problem to be faced. MTEs discovery of new meaning and development of professional practice is then based on being receptive to needs of teacher-learners.

We discussed receptivity as components of our relationships with teacher-learners, yet having our own identities and values seemed to interfere with the development of our relationships at times. We discussed wanting intellectual relationships with teacher-learners.

> Sandy: I'm engaged with you because of the possibility of learning something new.
> Pamela: Because of the intellectual possibilities, not the interpersonal possibilities.
> Sandy: I want to know [teacher-learners] in an academic and an intellectual way, but I don't even think I do because I'm not taking up the ideas that they provide … except in the most superficial way.
> Jean: … Knowing them in an academic and intellectual way. So is there a way to think about empathy in terms of that … I mean what would that look like? (September 24, 2015)

We agreed our love of mathematics influenced our conversations and relationships with teacher-learners. Sandy felt teacher-learners might need more than our focus on mathematical thinking.

> What makes your classroom work are those relationships and those moments you have with the students where … you are connecting as human beings and the student is going, "Oh yeah, she gets me and I can talk to her." (Sandy, September 24, 2015)

Our discussions took up the need for human connection with teacher-learners, but the tension involved the power we had over their grades and the way that influenced the relationship.

> Pamela: But that is the challenge, I want them to get to the point where they are pushing back a little bit. (August 24, 2015)

Pamela viewed teacher-learners' questions about her motives and practices as an indicator of a mature relationship. We viewed human connection as important to demonstrating and supporting receptivity to growing in relationship through discussion of feedback.

Summary

Evidence of knowing in relation to self and teacher education showed assignment purposes and structures were factors motivating our written feedback. Improvements to our practice were viewed through a lens of efficiency, while considering mindfulness in our feedback. Program accreditation influenced the design of activities on which we provided feedback, responding to external demands of society and our respective institutions for teacher-learners to demonstrate proficiencies. We were not consciously attending to these factors as we wrote feedback, but they impacted our attention to what and how feedback was provided. Considering improvements, we turned to the teacher-learners' feedback as an example of attending to learners as people first.

Evidence of knowing in relation to teacher-learners revealed that we knew little about the experiences, challenges, and problems teacher-learners faced. To convey respect and empathy we attended to elements of teacher-learners' work on assignments, but without attending to teacher-learners' views of mathematics teaching and learning. To build relationships, we relied on in-person interactions to encourage teacher-learners to attend to our written feedback. Our love of mathematics and desire to have intellectual relationships with teacher-learners motivated attention to mathematics in our feedback, without attention to insecurities and problems of practice with which teacher-learners wrestled.

Discussion and Conclusion

Findings revealed factors that framed and motivated our written feedback as a model of relational practice. Our written feedback was influenced by knowing in relation to self and teacher education, and knowing in relation to teacher-learners. Discussions of our written feedback as a relational practice revealed attention to skills and knowledge relevant to tasks involved in teaching mathematics. This focus is essential for effective feedback (e.g., Evans, 2013), yet falls short when feedback is considered as a model of relational practice. Evidence that our written feedback was motivated by "empathy, mutuality, reciprocity, and a sensitivity to emotional contexts" (Fletcher, 1998, p. 174) was thin, suggesting a way forward in improving our written feedback. Considerations of teacher-learners' experiences and views of mathematics teaching and learning are needed to build written feedback as a relational practice.

Attention to the written feedback of our teacher-learners was a source of inspiration as we considered potential insights from the experiences of teacher-learners. Yet we recognized that it is necessary to move beyond the responses teacher-learners provided for course assignments focused on developing skills and knowledge. Aligned with the finding of Pittaway and Dowden (2014) that personal experience with feedback influences teacher educators' written feedback, our feedback experiences motivated activity design and ways in which we structured feedback. Further, our views of mathematics teaching and learning motivated our feedback, as suggested by Buhagiar (2013), and in some cases interfered with our relationships with teacher-learners.

As MTEs seek to contribute to teacher-learners' relational practice by modeling, the conceptions of the learner should be a central factor. Yet as part of an assessment system, feedback can focus on task performance without attention to the particularities of the learner. With relational practice as a goal, moving beyond the development of skills and knowledge needed to complete tasks in the work of teaching, toward gathering insights about and ways to use views of mathematics teaching and learning in our practice provides a way forward. Written feedback seen through the lens of relational practice should include empathy and build from experiences of learners in an effort to meet course, program, and learner goals.

REALIZATION OF A LANGUAGE-AS-RESOURCE ORIENTATION IN LANGUAGE IMMERSION MATHEMATICS CLASSROOMS

José Manuel Martínez
Michigan State University
mart1580@msu.edu

Researchers have argued for an orientation to language as a resource that values bilingualism in mathematics classrooms. However, little is known about what mathematics teachers can do to translate a language-as-resource orientation into productive classroom practice. In this study, I analyze video data from two language immersion classrooms to understand pedagogies that are possible in contexts where bilingualism is seen as a resource. I argue that teachers' purposefully devised discursive practices used students' languages in ways that enhanced mathematical learning opportunities. I provide examples from the classrooms and discuss implications for research in bilingual classrooms where a language-as-problem orientation dominates.

Keywords: Classroom Discourse, Equity and Diversity

Mathematics teachers in bilingual classrooms deal with competing language-related orientations. While some orientations regard bilingualism as a problem to avoid or overcome, others regard them as a resource. Mathematics education researchers have drawn on what Ruíz (1984) called language-as-problem and language-as-resource (Planas, 2014; Planas & Civil, 2013; Setati, Molefe, & Langa, 2008). An orientation toward language as a problem creates a hierarchy, namely, one language dominates communication while devaluing other non-dominant languages. This orientation emphasizes lack of proficiency in the community's dominant language as a handicap and, ultimately, marginalizes users of non-dominant languages. In contrast, an orientation toward language as a resource questions language hierarchies by valuing and encouraging bilingualism. Mathematics education researchers have analyzed implications of a language-as-resource orientation to mathematics classrooms (Planas & Civil, 2013; Planas & Setati-Phakeng, 2014). These studies have focused on student-student interactions, describing the benefits of allowing students to speak in their preferred languages. Less is known about what else, besides allowing students to use more than one language, teachers can do.

In language immersion classrooms, learning a language other than the community's dominant language is regarded as useful, and learning mathematics in such language is seen as possible. Therefore, language immersion classrooms provide opportunities to observe discursive practices that are possible when teachers look pass limiting language orientations. In this study, I explore different ways in which teachers translate the language-as-resource orientation in which their classrooms are embedded into specific discursive practices. I argue that teachers purposefully devised discursive practices that used both students' languages in ways that enhanced students' mathematical learning opportunities. I ask the following research question: What discursive practices do teachers in language immersion classrooms enact to enhance mathematical learning opportunities? Understanding this question may illuminate what teachers in bilingual classrooms embedded in contexts that hold a language-as-problem orientation can do to disrupt restrictive language practices.

Theoretical Framework

Instead of regarding discourse as a stretch of speech, Peirce (1989) viewed discourse as guiding what is considered possible:

> Discourses, in a poststructuralist theory of language, are the complexes of signs and practices that organize social existence and social reproduction. In this view, a discourse delimits the range of

possible practices under its authority and organizes how these practices are realized in time and space. (pp. 403-404)

Besides regarding language as part of discourse, this view also sees it as a mechanism to create, reproduce and enforce discourse. Language delimits and is delimited by the practices that a discourse organizes as possible. Those who participate in such practices are privileged while those who do not are marginalized, since “when participants cannot find subject positions for themselves within a particular discourse, they may be silenced” (Peirce, 1989, p. 405). Peirce (1989) proposed that teachers engage in a *pedagogy of possibility*, that is, a pedagogy that encourages teachers to reconsider which language discourse practices are possible. For the purpose of this study, the notion of a pedagogy of possibility draws attention to creative teacher practices that are consistent with a language-as-resource orientation. Attending to instances of intentional productive use of languages may support teachers in bilingual mathematics classrooms to develop pedagogies that are consistent with a language-as-resource orientation.

Teachers’ regulatory role may silence students’ use of their preferred languages, potentially muting all contributions from particular students (Planas & Civil, 2013). Alternatively, teachers may enhance learning opportunities through the strategic and intentional use of students’ languages. Following previous research on language-as-resource in mathematics classrooms, I focused on learning opportunities: “By referring to learning opportunities, we avoid fundamental claims about whether or not mathematics learning has actually taken place, but instead put the focus on the opportunities for communication and participation created by learners as well as by teachers” (Planas & Civil, 2013). I define *bilingualism-as-enhancer* as the strategic use of more than one language to enhance learning opportunities.

Methodology

Two Spanish immersion classrooms participated in this research. One was a third-grade classroom, with 14 students from middle class families. The teacher, señora Abad, is a US-born Latina, who considers both English and Spanish as her native languages. The second was a second-grade classroom, with 23 students from economically struggling families. The teacher, Ms. Griffin, is a US-born Caucasian teacher, whose native language is English. Both teachers conducted mathematics class in Spanish. All students’ native language is English.

Data Sources

I draw on audio-recorded interviews with each teacher and mathematics class video recordings. While video-recording class lessons using a handheld camera, I focused on the teacher during whole class discussions, and then alternated focus on different groups during small group tasks. I video recorded eight lessons of a geometry unit in señora Abad’s class, and three lessons of a number sense unit in Ms. Griffin’s class. Unstructured interviews took place after video recordings. The teachers and I discussed the interplay between language and mathematics in video recorded segments. All interviews were fully transcribed.

Data Analysis

Following Powell, Francisco and Maher’s (2003) video analysis model, I annotated videos to identify focal episodes. I engaged in repeated attentive viewing, which included watching the videos three time to refine interpretations and redefined episodes I interpreted as *bilingualism-as-enhancer*. Then, for each teacher I selected one lesson that seemed to provide more examples than other lessons of the role of using more than one language in enhancing the teaching and learning of mathematics. This process resulted in 10 focal episodes: 6 from señora Abad’s class, and 4 from Ms. Griffin’s.

Second, each teacher and I analyzed the video of their lesson collaboratively. In-depth focus on one video is consistent with the study's purpose of illustrating possible discursive practices, without claiming that what I describe is an exhaustive list. The teachers and I discussed interpretations of the role bilingualism played in supporting mathematics learning opportunities. I transcribed these discussions and the focal video episodes. I added quotes from the discussions with teachers to specific parts of the video transcripts. Finally, following a constant comparative method (Glaser & Strauss, 1967), I coded discursive practices in the transcripts and identified emerging themes. I followed Young's (2008) view of discursive practice in language immersion contexts. This view attends to the interplay between orientations at the societal level and interactions at the classroom level: "The aim of discursive practice is to describe both the global context of action and the communicative resources that participants employ in local action" (p. 3). This definition resonates with this study's purpose of attending to societal language orientations—*language-as-resource* in particular—in relation to what teachers do to enhance mathematics learning opportunities.

Findings

There were two main teacher discursive practices that relate to bilingualism-as-enhancer: (1) choosing the language that more transparently represents a mathematical idea, and (2) supporting students' inference of mathematical terminology. In this section, I present an example from the classrooms and an interpretation of what motivated the practice that illustrates bilingualism-as-enhancer. The transcript conventions are: **Emphasis,** <Speaker slows down>, *Translation*, and --- silence.

Choosing the Language that Represents a Mathematical Idea more Transparently

As Ms. Griffin's class (second grade, Spanish immersion classroom) worked on a mystery numbers task, each student wrote a number that no one else could see. Each student wrote clues for the rest of the class to figure out the number. For one of the cards, Ms. Griffin read out loud one clue at a time. The teacher solicited guesses and explanations from students. After each clue, the class discussed whether they had enough clues to come up with one unique number. In the following example (see Table 1), Ms. Griffin had read the clue, "Tengo tres dígitos" (*I have three digits*). After discussing this clue, she read and wrote on the board the second clue, "Soy impar" (*I am odd*). She asked for examples of odd numbers. Ms. Griffin asked Dereck and Karen—two African American students who had started in the Spanish immersion program that academic year—what they thought.

Ms. Griffin and I interpreted this episode as an example of intentionally choosing the language that represents a mathematical concept in a more transparent way. The teacher tended to use English to support the participation of students new to the Spanish immersion program, like Karen and Dereck. In this episode, however, she chose Spanish to support students' understanding. She used the Spanish words par (*even*) and impar (*odd*) because she could relate one word with the other and with the mathematical concept with which the class was engaging. It seemed like rather than not knowing whether a number was even or odd, Karen and Dereck had a hard time remembering to what set of numbers the word *odd* refers and to what set of numbers the word *even* refers (lines 3-4 and 20-22). In English, the words even and odd have different etymologies, and they seemed arbitrary and unconnected. In Spanish, the words par and impar seemed related and more transparent as the prefix im indicates negation: not even.

We interpreted this example as bilingualism-as-enhancer because the use of the two languages helped students clarify and express a mathematical idea. Applied linguists have highlighted the role semantic transparency plays in communication (Bell & Schäfer, 2016). Semantic transparency refers to whether the form of a word makes its meaning explicit. For example, the word *shoemaker* can be considered transparent because parts of the word (shoe and maker) describe its meaning, and those parts are easily discernible. In Ms. Griffin's example, the words even and odd seemed opaque for students, whereas par and impar seemed transparent. Although there might be other ways to support students' sense making of the words and concepts of even and odd, in this case the possibility of alternating between the two languages enhanced the learning opportunity.

Table 1: Discussing Odd and Even Numbers

Line	Speaker	Spoken utterances	Translation	Actions
1	Ms. Griffin	Dereck, ¿**im**par dice even or	*Does* impar *say* even or	Underlying im
2		odd?	odd?	
3	Dereck	Are three, five and seven even		
4		or odd?		
5	Ms. Griffin	¿Qué dice par? ¿Alguien	What does even say? Can	
6		puede explicar esto?	someone explain that?	
7	Javier	Par tienes algo que puedes	*Even you have something*	Gestures separating her
8		dividir.	*you can divide*.	hands
9	Ms. Griffin	Sí. En números iguales	*Yes. In equal numbers*	Holds two fingers
10		La clave dice soy **im**par. Soy	*The clue says 'I'm odd.'*	
11		impar dice soy **no** par.	*I'm odd says I'm not even,*	
12		¿Qué número debe de	*In what number does it*	Pointing at last of the
13		**terminar** en el lugar de uno?	*have to end in the ones*	dashes that represent
14			*place?*	each of the three digits
15	Dereck	**Im**par	*Odd*	
16		**No** par	*Not even*	Shakes head
17		Three		
18	Ms. Griffin	So, si este termina en tres, ¿es	*So if this one ends in three,*	Writes 3 on the board
19		par o impar?	*is it even or odd?*	
20	Karen	One, three and seven are		
21		something, and two, four, and		
22		six are something.		
23	Ms. Griffin	Remember, par means	*Remember, even* means *you*	
24		<puedes dividir en números	*can divide into equal*	
25		iguales.>	*numbers.*	
26		<And **im**par means **no** par>	And *odd* means *not even*	
27		Is three par or **no** par, **im**par?	Is three *even* or not *even*,	
28			odd?	
29	Karen	So two is par, and one, three,		Miss Griffin writes
30		five, and nine are **im**par		numbers under Impar
31	Dereck	And seven		
32	Ms. Griffin	And seven		Writes 7 on the board
33	Dereck	And two, four and six are par		

Supporting the Inference of Mathematical Terminology

Señora Abad's class (third grade, Spanish immersion classroom) was finishing a geometry unit focused on classifying two-dimensional (2D) shapes according to the shapes' attributes. During the final lesson of the unit, the class focused on three-dimensional (3D) figures. Señora Abad wanted the class to draw on what they knew about 2D figures to name 3D figures. Her goal was to draw attention on 3D figures' attributes, how the names of the figures represented some of those attributes, and the relationship between the 2D figures and the 3D figures. After a class discussion comparing and contrasting 2D and 3D figures, señora Abad projected on the board an image of a pentagonal prism.

Table 2. Naming 3D Shapes

Speaker	Spoken utterances	Translation	Actions
Señora Abad	¿Cómo tú piensas que se	*How do you think this is*	Points at drawing of
	llama esto? Voy a darte un	*called? I'm going to give you*	pentagonal prism
	minuto para pensar.	*a minute to think. Maybe*	
	Tal vez algunos saben la	*some of you know the English*	Holds a pentagonal
	palabra en inglés. Tal vez	*word. Maybe you remember*	prism
	recuerdas algo que aprendiste	*something you learned in*	
	en figuras **bi**dimensionales.	*two-dimensional figures*	
	¿Frank?		
	Largo	*Long*	Moves hand
Frank			horizontally
	Es largo ¿verdad? ¿Qué más	*It's long, isn't it? What else*	Moves hand
Señora Abad	ves en esta figura?	*do you see?*	horizontally
	Cinco esquinas	*Five corners*	
Frank	Cinco lados	*Five sides*	
Gloria	Ah. Ves <cinco lados>	*Oh. You see <five sides>*	Points at 5 sides of
Señora Abad			the pentagonal face
	Cinco pirámide	*Five pyramid*	
Mike	Tiene cinco lados. OK. ¿En	*It's got five sides. OK. How is*	
Señora Abad	qué se parece a una pirámide	*it similar and how is it not*	
	y en que **no** se parece a una	*similar to a pyramid?*	
	pirámide?		
	No tiene triángulos	*It doesn't have any triangles*	
Mike	Tiene **pentágono**	*It has* ***pentagon***	
Gloria	Ah. Ah-ha.	*Ah. Aha.*	
Señora Abad	Pentágono pirámide	*Pentagon pyramid*

Gloria	¿Por qué?	*Why?*	
Señora Abad	Tiene un pentágono y es	*It has a pentagon and it's like*	
Erika	como un prismo	*a prism*	
	¿Es como un prisma?	*It's like a prism?*	Moves hands
Señora Abad	Como una prisma	*Like a prism*	horizontally
Erika			

Señora Abad and I interpreted this episode as an example of supporting the inference of mathematical terms and phrases. Instead of providing definitions or translations, the teacher encouraged students to experiment with language and come up with terms and phrases that made sense to them. Mathematical ideas and words students already knew informed their guesses. By making and explaining informed guesses, the class explored mathematical concepts such as the attributes and names of 3D shapes. Simultaneously, the teacher expected students to author and assess mathematical ideas, therefore enhancing students' mathematical agency. The teacher conjectured that if she had conducted the task in English, perhaps Gloria would have said that the shape was a pentagonal prism from the beginning. In that case, *pentagonal prism* might have been a memorized expression that some students in the class would not relate to the figures' attributes. Bilingualism seems to have motivated the teacher and the students' exploration of the figures' attributes and how the name of the figure represents those attributes.

We interpreted this example as bilingualism-as-enhancer because students are used to using language creatively to figure out how to express their ideas. In this classroom, the coinage of words emerged as students recurrently asked señora Abad how to say certain words in Spanish in different subjects. To raise students' linguistic awareness and autonomous use of language, señora Abad started to ask students to make informed guesses. Applied linguists refer to lexical inventions as expressions that look and sound like a word in the language, but that are not formally defined or used (Dewaele, 1998). For example, Frank's 'pentágono prismo' (line 33) sounds like Spanish, although the expression formally used in Spanish is 'prisma pentagonal'. In the example, the teacher intentionally promotes lexical invention as a strategy to reinvent mathematical ideas. The bilingualism in this classroom motivated the inference of mathematical terms and phrases, and the discussion about the connection between those expressions and specific concepts.

Discussion

Researchers have argued that an orientation of language-as-resource at the societal level plays out in classroom language use. Few studies, however, have explored teachers' role in translating a language-as-resource orientation into classroom practice. In this study, I have explored two language immersion mathematics teachers' discursive practices that seem consistent with a language as resource orientation. I have drawn on a pedagogy of possibility as a theoretical framework to focus attention on teachers' intentional efforts to devise creative ways to use languages in their mathematics classes.

I have proposed the notion of bilingualism-as-enhancer to foreground two related issues. First, bilingualism-as-enhancer focuses on the bilingual dimension of debates about language orientations. Second, it draws attention to the possibility of enhancing mathematics learning opportunities when teachers purposefully integrate mathematics and communication in more than one language. This purposeful integration requires a pedagogy of possibility in which teachers expand and explore possible discursive practices. I have focused on teachers, extending previous studies that have focused on bilingual mathematics students' language use.

I described two overlapping discursive practices that exemplify bilingualism-as-enhancer: (1) choosing the language that represents a mathematical idea more transparently, and (2) supporting students' inference of mathematical terminology. These discursive practices illustrate how teachers can enhance mathematics learning opportunities by drawing on students' languages. I have presented teachers' perspectives on the use of these practices to describe their reflective process of exploring their particular pedagogy of possibility.

This study contributes insights on how language orientations at the societal level may play out at the classroom level as discursive practices. Language orientations play a role in whether teachers enhance or silence particular languages. At the same time, classroom discursive practices also inform language orientations at the societal level. Examples of bilingualism-as-enhancer may inform teachers in contexts where bilingualism is regarded as a problem to explore the benefits of specific bilingual discursive practices, developing their own pedagogies of possibility.

REVEALING LAYERED MATHEMATICAL LEARNING GOALS THROUGH AN EXAMINATION OF MINDSET

James C. Willingham
James Madison University
willinjc@jmu.edu

This exploratory case study investigated the role of mindset in the establishment of an elementary teacher's mathematical learning goals at different layers of her classroom and curriculum. Data from the critical case of a teacher displaying characteristics of the growth mindset and engaging in the processes of teaching change provided evidence for a unique goal structure that could prove useful to a variety of mathematics teachers and mathematics teacher educators. This layered goal structure featured goals at global, trajectory, and content levels that provided opportunities for further operationalization of the teacher's mindset.

Keywords: Instructional Activities and Practices, Research Methods, Teacher Beliefs

Introduction

In bridging the perceived divide that exists among the theories, research, and practices of mathematics education, we must begin by addressing ideas that are shared and fundamental to each of these facets of the discipline in a way that leverages the unique strengths of each. One such idea involves the mathematical learning goals established by teachers as they interact with learners across the days, weeks, and months that constitute the academic year. As others have observed, this is perhaps the most fundamental idea shared between the unique faces of our discipline, as "until learning goals are expressed clearly, further analyses are impossible" (Hiebert, Morris, Berk, & Jansen, 2007, pp. 50-51).

A growing body of literature documents that a teacher's establishment and sharing of appropriate learning goals is an essential component of learning mathematics in the classroom (National Council of Teachers of Mathematics [NCTM], 2014). The specific challenges that are experienced by both teacher and learner are defined by these learning goals (Hiebert & Grouws, 2007), and the degree to which these challenges are overcome is greater in classrooms in which these goals are clearly and explicitly defined for all involved (Haystead & Marzano, 2009; NCTM, 2014). Despite the array of knowledge regarding the value of mathematical learning goals, their genesis and interaction with an individual's beliefs about the teaching and learning of mathematics are difficult to measure. Additionally, theories that describe these goals in terms of teaching are in notoriously "short supply" (Hiebert & Grouws, 2007, p. 373). The research reported here attempts to bridge this gap by examining the influence of a teacher's mindset, operationalized through the tenets of self-regulation theory, on the mathematical learning goals she pursues in the classroom. In doing so, it establishes a crossroads between two important theoretical perspectives and the daily operation of the elementary mathematics classroom and promotes the synergy among these factors that is the theme of this year's conference.

Purpose

A complete model of mathematics teacher development must describe the teachers' motivations and dispositions for their teaching as well as the influence of these factors on areas such as the teacher's implementation of learning activities, interactions with students and the classroom environment, and interpretations of professional development experiences (Opfer & Pedder, 2011; Wagner & French, 2010). The principal purpose of this study was to explore one of these motivational factors, the teacher's mindset, within the contexts of the teacher's professional development experiences and classroom practices. However, as the study evolved, it became apparent that the teacher's mindset linked inexorably to the mathematical learning goals she established in her classroom and the manner in which she operated on and monitored progress towards these goals. These premises led to the primary research question of the study reported here: How do characteristics of the growth mindset influence the mathematical learning goals established by a mathematics teacher as she engages in professional development and mathematics teaching? To address this question, the influence of mindset on the teacher's learning goals as she observed, interpreted, discussed, adapted, planned for, implemented, and reflected on a demonstration lesson was examined.

Theoretical Framework

The unique strength of the theoretical framework of a research study is in its ability to provide an underlying structure for the research that allows the researcher to anticipate, understand, and attempt to explain the phenomena under consideration. Additionally, this framework shapes the research design process, and in a single-case study supports the analytic generalizations that are the primary product of the research (Yin, 2014). With this perspective in mind, two important theoretical constructs guided this study: the model of implicit theories, commonly referred to as mindset, provided the primary theoretical lens for the study, while tenets of self-regulation theory operationalized these mindset constructs. The remainder of this section contains descriptions of these theoretical elements.

The Model of Implicit Theories

Situated in their prior research on goal orientation and behavior, Dweck and Leggett (1988) described the social-cognitive model of motivation and personality that developed into the implicit theories framework. In this model, the authors posited that an individual's implicit assumptions about the nature of an ability lead directly to the type of goals he pursues regarding that ability and the behaviors he exhibits when faced with challenges to that ability (Dweck & Leggett, 1988; Dweck, Chiu, & Hong, 1995). These mindsets and their associated goal pursuits thus created "a framework for interpreting and responding to events" (Dweck & Leggett, 1988, p. 260) that promoted observable behavioral patterns when the ability under consideration is challenged. Two implicit theories, the *entity theory* and *incremental theory*, exist in this model.

Incremental theories. The model described individuals espousing an incremental theory as those who view attributes as malleable, with the potential for the related ability to grow over time. Subscribers to this *growth mindset* often establish learning goals that focused on improvement of the ability in question (Dweck, 1986; Dweck & Leggett, 1988; Elliott & Dweck, 1988). When faced with challenging situations related to this ability, individuals with growth mindset characteristics display adaptive, mastery-oriented responses characterized by engagement with the challenges and resilience to failure (Elliott & Dweck, 1988).

Entity theories. Individuals assuming an entity theory tended to view attributes as fixed, uncontrollable entities, for which ability depended on factors over which the individual had no control. Those with these *fixed mindset* characteristics adopted performance-oriented goals to gain positive judgments for skills they had already mastered or to avoid negative judgments regarding talents they had yet to acquire (Dweck, 1986; Dweck & Leggett, 1988; Elliott & Dweck, 1988). When faced with challenges, these individuals displayed helpless responses characterized by lowered performance and avoidance of challenges (Elliott & Dweck, 1988).

Generalization of the model. Although the tenets of implicit theory advanced through research regarding characterization of an individual's own intelligence (Dweck & Leggett, 1988), the authors soon generalized the model to other attributes and domains. Additionally, they predicted that for any attribute of personal significance, "viewing it as a fixed trait will lead to a desire to document the adequacy of that trait, whereas viewing it as a malleable quality will foster a desire to develop that quality" (Dweck & Leggett, 1988, p. 266). Applications of this prediction culminated in the validation of a simple instrument used to assess an individual's implicit theories for a variety of attributes (Dweck et al., 1995). Additional evidence supported the notion that the model holds for generalization to other traits, such as the character and attributes of other people (Erdley, & Dweck, 1993), or mathematical ability (Lischka, Barlow, Willingham, Hartland, & Stephens, 2015; Willingham, 2016; Rattan, Good, & Dweck, 2012).

Self-Regulation Theory and Mediated Pathways of the Growth Mindset

Burnette, O'Boyle, VanEpps, Pollack, & Finkel (2013) conducted a large-scale meta-analysis examining the relationship between implicit theories and self-regulation theory. Their analysis revealed a strong alignment between three key processes of self-regulation theory and the constructs of mindset. Goal-setting processes encompassed the performance versus learning goal orientations; goal-operation processes associated helpless and mastery responses; and goal-monitoring processes aligned the dichotomy of expectations of success and negative emotional responses. More specifically, the results described the relative strength of association for these mediators of incremental theory on an individual's goal achievement across a wide range of abilities, disciplines, and context (Burnette et al., 2013).

These findings aligned with prior research showing that an incremental theory regarding an ability associated with an affinity for learning goals, mastery strategies, and expectations of success regarding that ability, and negatively associated with the pursuit of performance goals, helpless responses, and negative emotions regarding that ability (e.g., Blackwell, Trzesniewski, & Dweck, 2007; Dweck & Leggett, 1988; Dweck et al., 1995). However, this analysis also revealed significant findings regarding the positive strength of association between mastery-oriented responses and expectations of success with goal achievement and the negative relationship between negative emotions regarding an ability and goal achievement. The most significant findings resulted from considering the mediated paths between an incremental theory and goal achievement. For instance, examination of these pathways revealed that the incremental theory's avoidance of negative emotions is more strongly associated with goal achievement than its expectations of success (Burnette et al., 2013).

Methodology

The unique strength of a well-designed qualitative research study is in its ability to answer specific research questions while at the same time testing the boundaries of those questions to discover significant relationships as the research evolves (Yin, 2014). When guided by a well-grounded theoretical framework, this approach allows important and perhaps unanticipated findings to emerge. The remainder of this section describes the design and contexts of the study, which allowed the meaningful goal structures found in the participant's classroom to surface.

The Study's Design

Overview. An exploratory, holistic single-case design (Yin, 2014) supported consideration of how characteristics of the growth mindset influenced an elementary teacher's mathematical learning goals. The study focused on Gale Martin, a second-grade teacher, deemed significant as evidence from her engagement in an ongoing professional development project, Project Influence, indicated that she represented the critical case of a teacher displaying strong growth mindset characteristics and engaging in the processes of teaching change. Over the course of four months of the fall of 2015, the researcher interview and observed Ms. Martin as she engaged in activities including the planning, delivery, and assessment of classroom instruction, classroom teaching, assessment, a demonstration lesson, and other professional development activities.

Data collection. The data collected throughout the study focused on how Ms. Martin's mindset characteristics influenced her other experiences, beliefs, and practices. More specifically, the researcher collected data regarding Ms. Martin's mindset and beliefs regarding the teaching and learning of mathematics, her described and observed mathematics teaching practices, and her adaptation of a demonstration lesson for use in her classroom. Data sources for the study included historical records of her mindset and beliefs, semi-structured interviews, classroom observations, artifacts of the observed and enacted demonstration lessons, reflective journal entries, and artifacts from Ms. Martin's lessons. The researcher collected this data across four stages, including a participant selection process, baseline classroom observations, Ms. Martin's engagement in the demonstration lesson through her professional development project, and her adaptation and enactment of the demonstration lesson in her own classroom.

Data analysis. The researcher then organized this body of data in chronological fashion, corresponding approximately with the data collection stages described above, and completed a simple time series analysis (Yin, 2014). A holistic analysis of themes, "not for generalizing beyond the case, but for understanding the complexity of the case" (Creswell, 2012, p. 101), was performed for the first stage of data through open coding and reduction of these codes into themes consistent with the theoretical framework. The themes emerging from the stage one analysis guided interpretation and coding of the stage two data, after which the stage one codes were revisited for completion. The researcher repeated this process through all four stages of data in order to produce a comprehensive set of themes to guide a written case description.

Research Contexts

The participant. The researcher selected Ms. Gale Martin, a Caucasian female in her mid-thirties, as the critical case for the study. Rationales for this selection included historical survey data indicating persistent growth mindset characteristics, a positive record of changes in beliefs regarding the teaching and learning of mathematics, and observational records indicating a change in classroom teaching practices consistent with the mindset and belief data. Ms. Martin was an elementary mathematics teacher in her second year of teaching second grade and her fifteenth year of teaching elementary school who taught in a rural elementary school of approximately 330 students in a southeastern state. Prior to teaching second grade, Ms. Martin had taught one year of kindergarten, two years of third grade, and 10 years of fourth grade, providing her some perspective in the mathematical content requirements of several elementary grades. During the course of this study, Ms. Martin was also engaged in her third year of ongoing professional development for mathematics teaching.

The demonstration lesson. As part of the study, Ms. Martin observed a second-grade demonstration lesson conducted by the faculty of Project Influence with a lesson goal of "engaging students in thinking about subtraction with regrouping, while potentially representing the process symbolically" (Demonstration Lesson, October 28, 2015). The lesson involved students interacting with the following task in a problem-solving format.

> On Thursday, Tara was at home representing numbers with base-ten blocks. The value of her blocks was 304. When she wasn't looking, her little brother grabbed two longs and a flat. What is the value of Tara's remaining blocks? Use pictures, words, and/or symbols to describe how you solved the problem.

During the lesson, students worked in pairs to solve the problem and participated in extensive mathematical discussions across pairs, small groups, and the whole group under guidance of Project Influence's expert teacher. Approximately 30 kindergarten to second grade teachers observed the demonstration lesson, and demographically, the county, school, and class were extremely similar to those of Ms. Martin.

Results

The unique strength of a teacher's classroom practices exists in their ability to mediate the outcomes of students' learning (Hiebert & Grouws, 2007). During the course of this study, Ms. Martin's students consistently displayed a sense of ownership of their mathematical ideas, communicated their thinking about these ideas to one another and Ms. Martin, explored relationships across their curriculum, and achieved lesson goals with varying degrees of success. This section contains a portion of the results of this study related to different goal pursuits Ms. Martin utilized to facilitate these outcomes.

Overarching Goals

Ms. Martin professed to believe that a focus on student thinking and ownership of their mathematical ideas was one of the most essential elements of her classroom environment, and one that allowed students to learn mathematics effectively. She described her thoughts on the matter, referring to how a student from the previous year's class was ultimately able to be successful in learning mathematics in her class.

> [The student] was able to share her ideas, because she heard somebody else share their ideas. So just building that community of "I am my own person in here, and that's okay. I can show you how I know something. It's just not Ms. Martin's way. I can have my way. So and so can have their way. Yeah, Ms. Martin shows us things, but if I don't see it the way Ms. Martin shows us, then I can still use my way." (Selection Interview, September 9, 2015)

Ms. Martin credited this student's willingness to value and share her own ideas to the fact that she first heard another student share their thinking and the community norms of her classroom.

This relationship between students' willingness to communicate their ideas and their increasing level of understanding of mathematics appeared to be one of the motivating beliefs behind much of Ms. Martin's thoughts regarding the teaching and learning mathematics. She spoke directly to the notion that understanding mathematics and communicating about mathematical ideas were inescapably linked.

> That's why I always tell them, "If you can explain, you can go home and teach mom or teach brother or come to me and show me and explain it in your own words, I think that's how you understand it." That's why I like for them to do a lot of talking, obviously, because I want them to share their ideas with each other and understand it, especially in kid terms. Because there are times when I have said something and a kid will say it differently, and I feel like we've said it the same way. If a kid says it, [other] kids are like, "Oh yeah, that makes total sense." (Selection Interview, September 9, 2015)

It appeared that Ms. Martin believed that this focus on student thinking and communication was essential to student learning and could help to reconcile differences between adult's and children's ways of thinking about and describing mathematics.

Lesson Goals Within a Learning Trajectory

Ms. Martin also spoke explicitly about her learning goals for her implementation of the demonstration lesson and how she believed these goals related to her students' past and future study of mathematics. In describing these learning goals, she referred directly to her students' current understanding of strategies for operating with two-digit numbers, a topic which directly preceded her implementation of the demonstration lesson.

> I would think that my students need to be able to represent the two-digit number in various ways to subtract. . . . I feel like the goals [for the demonstration lesson] are kind of the same, we're just kind of changing, we're moving from two-digit numbers to three-digit numbers. I feel like our goal is the same, can they look at these numbers and understand that I need to maybe represent the number in a different way in order for me to subtract. I guess that really works for this whole unit. (Planning Interview, November 10, 2015)

In this quotation, Ms. Martin established the specific mathematical goals for her enactment of the demonstration lesson as extending students' ability to represent numbers in a variety of ways into using these representations with purpose in the form of regrouping for subtraction. This was a substantial change from the goal of the lesson she originally observed.

Additionally, she described how this goal connected to her students' recent areas of study and her future goals for the semester.

> To me, it's definitely understanding that not only can we represent numbers in different ways, but we can do that when we are subtracting as well. I see where we were several weeks ago where we were really focused on the place value and representing those numbers in different ways. I really hope that they can see the tie-in with that to the subtraction. I really think if they make that big connection, then once we get to the algorithm of regrouping this will be no issue. (Planning Interview, November 10, 2015)

With these words Ms. Martin confirmed the goals described in this section and explained the connections among these goals, her emphasis early in the semester on representations of number and place value, and the future objective of having her students symbolically represent operations and utilize algorithms.

Reinforcing Goals Within a Lesson

The previous section presented explicit examples of Ms. Martin's lesson goals and her willingness to change the goals of a lesson she had observed to suit her lesson and trajectory needs. In addition to these planned changes, Ms. Martin also displayed the ability to adjust her classroom instruction to reinforce the goals she had established for her students. In closing her implementation of the demonstration lesson, Ms. Martin placed a final question on the board, which she read aloud with her class.

> All right, here is your last question. Let's read it together. Guys, listen, we've got five minutes, and this is our last thing. Ready? [Read aloud and recorded on the whiteboard] How could you represent 407 so that 3 longs could be taken away? Write a sentence explaining how you know. . . . You have to write a sentence, but I don't mind if you use a drawing to show it as well. (Classroom Observation, November 13, 2015).

As the demonstration lesson Ms. Martin observed ended with students reflecting on what they had learned from solving the original task, this extension question provided a substantially different close to the lesson that was more aligned with Ms. Martin's lesson goals.

In an interview after this lesson, Ms. Martin's overall assessment of the lesson was that it had been successful and that the majority of students had developed further understanding of the need to represent numbers in different ways in order to support operations such as subtraction.

> I'd say three-fourths of the classroom. . . were [able to address the exit ticket]. I could pick out maybe five or six that were not. I think, for the most part, they were able to. . . . They understood that you had to represent a number a different way in order for them to subtract, which leads to

the whole idea of the algorithm and regrouping. I feel like the trajectory is on target and moving towards the overall goal. (Reflection Interview, December 21, 2015)

This description further illustrates Ms. Martin's commitment to her lesson goal and her ability to adapt her instruction to continue to reinforce her student's progress towards this goal based on ongoing classroom assessment.

Discussion and Conclusion

Utilizing the self-regulation constructs of goal setting, goal operating, and goal monitoring to observe Ms. Martin's operationalization of her mindset in the classroom proved extremely effective. Perhaps one of the most important results of this framework was the revelation of three distinct layers of goals under which Ms. Martin operated throughout the semester. Although hierarchical language describes these goal structures in the following paragraph, this language relates only to the relationships among the goals themselves and not the value Ms. Martin ascribed to these goals as she spoken of them with equal importance (see Figure 1).

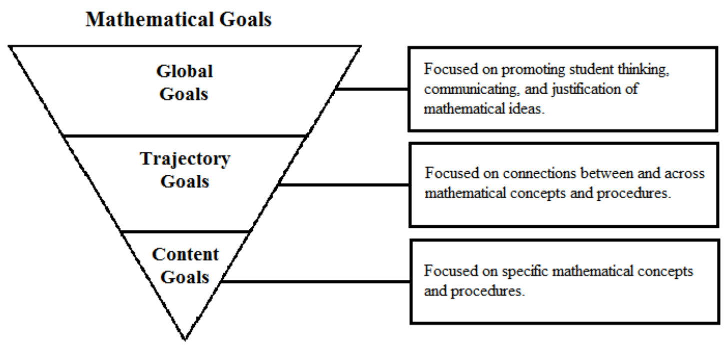

Figure 1. Ms. Martin's Layered Mathematical Learning Goals

At the highest layer, Ms. Martin established *global goals* that spanned the length of the school year. These goals tended to focus on widely applicable student mathematical practices such as thinking independently about mathematical ideas, communicating these ideas to others, justifying this thinking, and critiquing the reasoning of others. In an intermediate tier, Ms. Martin described *trajectory goals* that involved assessing and moving students along an evolving mathematical trajectory by helping them connect various mathematical concepts and representations throughout the semester. She spoke of these goals at the level of sequences of lessons and classroom activities, units of instruction, and conceptually related mathematical topics. These goals appeared to be more fluid than the global goals and evolved as the semester progressed based on her students' current understanding. At the lowest level were Ms. Martin's *content goals*, which aligned roughly with her learning goals within a lesson or brief sequence of lessons and could be adapted as needed within an individual lesson or student encounter.

These layered goals also offered a variety of opportunities to observe Ms. Martin engaging in goal operating and goal monitoring practices on a daily basis. In general, her goal operating practices aligned with utilizing specific instructional strategies to advance individual students, small groups, or the whole class towards her goals for them at different layers. Additionally, she focused heavily on her students' use of mastery strategies throughout her interactions with them. Ms. Martin's general goal-monitoring strategies focused on making students' mathematical thinking visible to her and the students' peers. She then used this thinking as evidence for assessment as she compared students' progress to her learning goals, for facilitation of group discussions, or for discussion and critique from the students' peers.

The most directly useful aspect of Ms. Martin's case for the classroom mathematics teacher is likely the fashion in which she operationalized her mindset through her goal-related practices. Although all classroom teachers may not operate under the tenets of a growth mindset on a daily basis, many of these goal-related practices can be easily adapted to any classroom. Setting goals that support student interactions about mathematics and that focus on mathematical concepts and strategies that transfer are broadly useful. Operating toward these goals by interacting with students via advancing, redirecting, and facilitating strategies appears to require little adaptation to the questioning approaches many teachers already use. Goal-monitoring practices such as focusing on student thinking and evaluating student progress against a mathematical learning trajectory align well with globally accepted assessment practices. These findings, which are useful to a variety of elementary mathematics teachers and mathematics teacher educators, represent the intersection the study's theoretical framework, research design, and observations of classroom practice, and would not be possible without the convergence of these facets.

This study investigates teacher responses to a common set of high potential instances of student mathematical thinking to better understand the role of the teacher in shaping meaningful mathematical discourse in their classrooms. Teacher responses were coded using a scheme that disentangles the teacher move from other aspects of the teacher response, including who the response is directed to and the degree to which the student thinking is honored. Teachers tended to direct their response to the student who had shared their thinking and to explicitly incorporate ideas core to the student thinking in their response. We consider the nature of these responses in relation to principles of productive use of student mathematical thinking.

Keywords: Classroom Discourse, Instructional Activities and Practices

Recommendations for effective mathematics teaching stress the importance of engaging students in meaningful mathematical discourse (e.g., National Council of Teachers of Mathematics [NCTM], 2014). Research has begun to help us understand how to effectively orchestrate discourse around written records of student work (e.g., Stein, Engle, Smith, & Hughes, 2008), but much less is known about how to effectively use the in-the-moment mathematical thinking that emerges during classroom mathematics discourse. One issue related to responding to student thinking is that not all student thinking warrants the same consideration. Rather, student thinking varies in the degree to which it provides leverage for accomplishing mathematical goals. Leatham, Peterson, Stockero, and Van Zoest (2015) described a framework to identify those instances of student thinking—MOSTs—that provide such leverage, but little is known, as of yet, about effective responses to MOSTs. The study reported here investigated teacher responses to a common set of MOSTs. Better understanding such responses will contribute to better understanding the role of the teacher in shaping meaningful mathematical discourse in their classrooms.

Literature Review

Research on classroom discourse has identified patterns in teachers' responses to student thinking. Mehan (1979) coined *IRE*—Initiation, Response, Evaluation—to describe a common pattern of classroom interaction where the teacher's main follow-up to an elicited student response is to evaluate it. An IRE interaction is an example of what Wood (1998) referred to as *funneling,* where the teacher's response is intended to corral students' thinking within predetermined and often narrowly-defined parameters. By contrast, Wood characterized certain other teacher responses as *focusing*; in these responses a teacher "keep[s] attention focused on the discriminating aspects of the solution" (p. 175).

Van Zee and Minstrell (1997) explored what they called a *reflective toss*—a pattern that consists of a student statement, teacher question, and additional student statements. Van Zee and Minstrell argued that changing the evaluation component of IRE to a question could positively impact the nature of classroom discourse by changing students' expectations for participation. These results are not unique; in general, research has found that teacher responses matter. Fennema et al. (1996) found that increases in teachers' focus on student thinking in their classrooms were directly related to improvements in their students' achievement. Kazemi and Stipek's (2001) investigation revealed that teachers in high-press classrooms—classrooms in which the teacher responded to their students' contributions to classroom discourse by pressing the students to further engage in thinking about important mathematics in their contributions—provided their students with increased learning opportunities.

Other researchers have looked at collections of teacher moves that accomplish a particular purpose related to student thinking. Lineback (2015), for example, investigated the construct of *redirection*—"instances when a teacher invites students to shift or *redirect* their attention to a new locus" (p. 419). This work generated a taxonomy of redirections to deconstruct teacher responses and analyze the contribution of different redirection responses to instruction. Bishop, Hardison, and Przybyla-Kuchek (2016) described the mathematical contributions of students, the moves teacher made in response, and the relationship between these contributions and moves, through the lens of *responsiveness*, which they defined as the extent to which teacher responses "mutually acknowledge, take up, and reflect an awareness of student thinking" (p. 1173). Connor, Singletary, Smith, Wagner, and Francisco (2014) developed a framework that includes teacher responses to student thinking that support collective argumentation in the classroom. Their work provides important information for focusing on a particular type of student thinking—that which involves mathematical argumentation.

In the work reported here, we narrow down the type of student thinking to MOSTs and consider the extent to which the teacher responses to those MOSTs accomplish the purpose of *building* on them.

Theoretical Framework

MOSTs (Leatham et al., 2015) are instances of student thinking worth *building* on—that is, "student thinking worth making the object of consideration by the class in order to engage the class in making sense of that thinking to better understand an important mathematical idea" (Van Zoest et al., 2017, p. 36). To take full advantage of these opportune instances of student thinking, one would want to seek to build on MOSTs *in the moment*. Such use encapsulates the core ideas of current thinking about effective teaching and learning of mathematics (e.g., NCTM, 2014), including that student mathematics is at the forefront and that students are positioned as legitimate mathematical thinkers, engaged in sense making, and working collaboratively. These ideas serve as the principles underlying our conceptualization of productive use of MOSTs (see Figure 1).

1. The mathematics of the MOST is at the forefront.
2. Students are positioned as legitimate mathematical thinkers.
3. Students are engaged in sense making.
4. Students are working collaboratively.

Figure 1. Principles underlying productive use of MOSTs (Van Zoest et al., 2016).

We theorize that building on MOSTs is a particularly productive way for teachers to engage students in meaningful mathematical learning. Van Zoest, Peterson, Leatham, & Stockero (2016) put forth a conceptualization of the teaching practice of building on MOSTs (see Figure 2). Together the principles (see Figure 1) and building subpractices (see Figure 2) provide a way to assess the extent to which teacher responses to MOSTs instantiate the practice of building.

1. Make the object of consideration clear (make precise)
2. Turn the object of consideration over to the students with parameters that put them in a sense-making situation (grapple toss)
3. Orchestrate a whole-class discussion in which students collaboratively make sense of the object of consideration (orchestrate)
4. Facilitate the extraction and articulation of the mathematical point of the object of consideration (make explicit)

Figure 2. Sequence of subpractices of the teaching practice of building on MOSTs.

Methodology

The Scenario Interview (Stockero et al., 2015) is a tool to investigate how teachers think about responding to student thinking during instruction. During the interview teachers are presented with instances of mathematical thinking from eight individual students—four each from an algebra and a geometry context. The interviewee is situated as the teacher and asked to describe what they might do next were the instance to occur in their mathematics classroom and to explain why they would respond in that way. The Scenario Interview allowed us to compare teacher responses to a common set of student thinking. The analysis reported here focuses on responses to the four instances, two from each context, in which the student thinking was a MOST. The four MOSTs and their contexts are provided in Figure 3.

Scenario	Context	MOST
G1	Students were sharing their solutions to the following task (a corresponding picture was on the board). *Given two concentric circles, radii 5cm and 3cm, what is the area of the band between the circles?*	Chris shared his solution: "The radius of the big circle is 5 and the radius of the little circle is 3, so the gap is 2, so the area of the band is 4π cm^2."
G3		Pat explained how he got the same answer as Chris (4π cm^2) a different way: "π times r^2 for the big circle is π times 5^2, which is 10π and π times 3^2 is 6π for the little circle. I minused (sic) them and got 4π as my answer."
A2	Students had been discussing the following task and had come up with the equation $y = 10x + 25$. *Jenny received $25 for her birthday that she deposited into a savings account. She has a babysitting job that pays $10 per week, which she deposits into her account each week. Write an equation that she can use to predict how much she will have saved after any number of weeks.*	Casey said, "You could also change the story so the number in front of the x is negative."
A3	The teacher asked, "How do we find the equation given any table?" and put this generic table of values [to the right] on the board for the students to use in their explanation. X | Y 0 | 15 2 | 19 3 | 21 5 | 25	Jamie said, "I found the number in front of the x by subtracting the y-values in the table, 21 - 19, so that number is 2."

Figure 3. MOSTs that formed the basis of the teacher responses and their contexts.

Data Analysis

The data for this study consisted of video recorded interviews with 25 secondary school mathematics teachers from several sites across the United States. These teachers were representative of a set of 44 teachers who participated in our larger project. We used Studiocode (SportsTec, 1997-

2015) video analysis software to segment each interview into the instances of student thinking and the teacher responses to each individual instance—everything a teacher said about how they would respond to that instance. Transcriptions of the videos were used to facilitate the analysis. For the 4 instances and 25 teachers of this study, there were a total of 100 teacher responses. In one of those responses the teacher did not provide a description of how they would respond to the instance because they were not able to envision it happening in their classroom, thus 99 teacher responses were analyzed for this study.

The resulting teacher responses were then coded using the *Teacher Response Coding Scheme (TRC)* (Peterson et al., in press), a scheme that disentangles the teacher move from other aspects of the teacher response, including the Actor and the degree to which the student thinking is honored (Recognition-Action and Recognition-Idea). Figure 4 provides the TRC coding categories and codes that were included in this analysis.

Category	Coding Category Description	Codes
Actor	Who is publicly asked to consider the student thinking	teacher, same student(s), other student(s), whole class
Recognition-Action	The degree to which the teacher response uses the student action, either verbal (words) or non-verbal (gestures or work)	explicit, implicit, or not
Recognition-Idea	The extent to which the student is likely to recognize their idea in the teacher response	core, peripheral, other, cannot infer, not applicable
Move	What the actor is doing or being asked to do with respect to the instance of student thinking	adjourn, allow, check-in, clarify, collect, connect, correct, develop, dismiss, evaluate, justify, literal, repeat, validate

Figure 4. Subset of the *Teacher Response Coding Scheme* (*TRC*) used in this paper.

Results and Discussion

We discuss findings related to specific aspects of teachers' responses to MOSTs as well as interactions among those aspects. We first focus on the Actor and Move and their interactions, followed by the individual Recognition categories and their interactions. In doing so, we highlight how a response might adhere to the principles underlying productive use of MOSTs or contribute to enacting subpractices of building.

Actor and Move

With respect to the actor, the majority of teacher responses (66%) had the *same student* as the actor, meaning that the teacher proposed a move that was directed back to the student who had contributed the original thinking (see Table 1). In about 24% of the instances, the teacher move was directed to the *whole class*.

With respect to the moves, two occurred much more frequently than the others; together, *develop* (37%) and *justify* (18%) moves accounted for over half of the data. In a develop move, the teacher provides or asks for an expansion of the student thinking that goes beyond a simple clarification. In a justify move, the teacher asks for or provides a justification of the instance. Since our data showed that these moves had a *same student* or *whole class* actor, in both cases the teacher was asking for, rather than providing, the expansion or justification.

Table 1: Actor and Move

	Same Student	Whole Class	Teacher	Other Student(s)	TOTAL
Adjourn	0	0	3	0	3
Allow	0	3	2	1	6
Clarify	5	0	0	0	5
Collect	2	4	0	1	7
Connect	1	4	0	1	6
Correct	1	0	0	0	1
Develop	32	5	0	0	37
Dismiss	0	0	1	0	1
Evaluate	0	4	0	0	4
Justify	16	2	0	0	18
Literal	4	2	0	0	6
Repeat	4	0	0	1	5
TOTAL	65	24	6	4	99

Taken together, the Actor and Move findings suggest that teachers might instinctively respond to MOSTs by asking the student who provided the thinking to either expand upon or justify their idea. Because MOSTs are instances that a teacher can build upon to “engage the class in making sense of [student] thinking to better understand an important mathematical idea” (Van Zoest et al., 2017, p. 36), however, asking the student to develop or justify their idea may not always be necessary and may actually limit students’ opportunities to make sense of mathematical ideas. For example, consider scenario A2 (see Figure 3). It turned out that nearly half of the instances of *develop* moves with *same student* actor (15 of 32) occurred in response to this scenario. The most common teacher move in this instance was to ask Casey, the student who made the suggestion, to explain how they would change the story (e.g., “Well what do you mean? What sort of an equation, or what sort of a real life situation can you think of where that would be a negative?” (Teacher 6 [T6]). Contrast this response with a similar one directed instead to the whole class: “Interesting comment… who can come up with a story, a situation that would match what Casey is saying?” (T7). In this case, we would argue that directing the response to the whole class might be more productive, as it would engage all of the students in trying to come up with a situation where the coefficient is negative, likely advancing the entire class’s understanding of the mathematics of linear equations.

Similarly, consider scenario A3. More than two-thirds of the *justify* moves with *same student* actor (11 of 16) occurred in response to this scenario. The most common response to this instance was to ask Jamie why they used the numbers that they did (e.g., “Why did you do the 21 minus the 19? Why didn’t you do the 19 minus the 15?” (T14)). This response would allow Jamie to justify their idea, but does not engage the whole class in thinking about the importance of taking into account the differences between x-values as well as the y-values when calculating the rate of change. Consider an alternate response directed to the whole class, such as: “So [Jamie] got 2 from subtracting those two numbers, so what if I pick 19 and 15? If I subtract those, I get 4. Why did we get two different answers?" (T21). Such a response would allow all of the students to consider the mathematics of rate of change. We argue that teachers who respond to MOSTs by asking the student who shared the original thinking for justification may be focused on the details of the situation, whereas those who ask the whole class for justification may be more focused on the big mathematical picture.

In general, responses that turn the mathematics of a MOST over to the whole class instead of engaging a single student better adhere to principles underlying productive use of MOSTs. Such responses provide all students the opportunity to collaboratively engage in making sense of the mathematics of the MOST. In doing so, they put the students' mathematics at the forefront and position all students as legitimate mathematical thinkers. These responses may also demonstrate an ability to discriminate between those instances that need to be made precise before the teacher can turn them over to students (grapple toss) and those that do not.

Although the goal of building on MOSTs is to have the whole class consider the student mathematics of the instance, there are some cases where directing the initial teacher response back to the same student might be desirable. For example, in scenario G1, it is quite possible that other students in the class would not initially understand Chris' explanation, so the most common teacher response in our data, "ask him to explain by using…pictures and words, like how he came up with the 4π" (T18) may be the teacher helping to make Chris' idea precise before other students are asked to consider it. A move such as this could be an instantiation of the first subpractice of building (make precise)—an important first step in setting the teacher up to engage in the next building subpractice (grapple toss), in which they turn the now-precise student thinking over to the class for consideration.

Recognition of Student Actions and Ideas

The Recognition codes operationalize the extent to which the student who provided the instance would recognize their thinking in the teacher's response. As seen in Table 2, the majority of teacher responses either *explicitly* (54%) or *implicitly* (32%) incorporated the student's words (verbal) or gestures or work (non-verbal). Only 13% of responses would likely *not* be recognizable to the student as incorporating their own actions. Moreover, the vast majority of the responses (75%) remained *core* to the idea in the instance of student thinking. Together the results indicate that a large percentage of the teacher responses were both *explicit* and *core* (43%), meaning that the teachers in this study honored the student thinking by explicitly incorporating the student's verbal or non-verbal actions and staying focused on the student's core ideas in their described response. For example, the response to scenario G1, "I would want to know what he means by gap. Um, and maybe have him illustrate that visually, just to kind of picture that as a class," (T4) is *explicit* and *core* as it incorporates both the student's words (gap) and his ideas (having him illustrate his idea visually). A response such as this aligns with the principles underlying productive use of MOSTs, as it positions the student as a legitimate mathematical thinker by keeping the students' mathematics at the forefront. In general, many teacher responses that are *core* to the student ideas and *implicitly* incorporate student actions also adhere to the same principles, but may be problematic in that it may not be clear to the student(s) what mathematics is under consideration. For example, the response to scenario A3, "So I would want to ask her, 'Why did you do this? What are you thinking? Tell us a little bit more,'" (T24) fails to specify what mathematics the teacher wants to know more about. Among other things, the teacher could be wondering why the student subtracted or why they chose to select the numbers that they did.

Table 2: Recognition of Student Actions and Ideas

		Student Ideas			
		Core	Peripheral	CNI, Other, N/A	TOTAL
Student Actions	Explicit	43	10	1	54
	Implicit	26	4	2	32
	Not	5	1	7	13
	TOTAL	74	15	10	99

Conclusion

Our findings revealed that the teachers in this study most often responded to MOSTs by making a *develop* or *justify* move that was directed to the *same student* who had shared the initial thinking. Additionally, they did so in ways that stayed *core* to the ideas in the student thinking and often *explicitly* incorporated the students' actions.

Responses that either explicitly or implicitly incorporate core ideas of a student's contribution signal that these teachers value the students' contributions. We also see such responses positioning the students as legitimate mathematical thinkers who can make valid contributions to the development of the mathematics in the classroom. Hence the words and idea(s) teachers use in their responses to students' ideas could matter in terms of how students are positioned in the classroom. When the student action that is being considered is explicit, it is easier for the whole class to recognize that student thinking is being honored.

MOSTs are prime opportunities for teachers to enact the building practice, but teachers' tendencies to direct their responses to the student who had shared their idea could prevent them from doing so. As we have illustrated, directing a response to the same student could be productive in cases where the student's idea needs to be made precise before others can consider the idea, but many MOSTs do not require clarification. In these instances, rather than going back to the student, it would be more productive to *toss* the already precise student thinking to the whole class to provide all students an opportunity to collaboratively make sense of the mathematics.

The findings of this study advance research on teachers' in-the-moment responses to student mathematical thinking by moving beyond looking at what moves teachers make, to considering to whom those moves are directed and to what extent those moves would allow students' ideas to be recognizable to them or other students. In doing so, the study builds on the approaches taken in past research on teacher responses to explore more refined approaches that allow the field to look at teacher responses in new ways. Decomposing teacher responses in the way we have in this study has the potential to help teacher educators and researchers focus their development efforts. For example, if the majority of a teacher's responses honor student thinking, but engage only the student who contributed the instance, professional development work with the teacher could focus specifically on understanding the potential in directing a response to the whole class, and when it would and would not be appropriate to do so. Focused efforts such as this would allow professional developers to leverage teachers' strengths and thus develop teachers' practice more effectively.

Acknowledgments

TOWARD MULTIMODAL POETIC ANALYSIS: A CASE OF PROPERTY NOTICING

Susan Staats
University of Minnesota
staats@umn.edu

This paper uses multimodal discourse analysis to show that discursive form, in addition to words, gestures and sound dimensions of speech, is an important linguistic resource for expressing mathematical meaning. During a collaborative task, a student spoke an insight about an algebraic property five times over a few minutes, in slightly different ways. He consistently used repetition of grammar and words, a speech form known as poetic structure. These poetic structures were marked elaborately through discursive modes such as pause, intonation and gestures, suggesting that they form a meaning-making mode that is real to the speaker.

Keywords: Classroom Discourse, Problem-Solving, Algebra and Algebraic Thinking

Introduction

This paper contributes a methodological example to scholarship on language as a resource for learning mathematics. Use of home languages and the interplay of academic and informal discourses are known to be central resources (Barwell, 2015; Planas & Setati-Phakeng, 2014). This paper suggests that the discursive form of students' mathematical statements is also an important resource for learning. Grammatical repetitions within students' sentences are just as important as the words themselves in focusing attention on key issues within a task.

This study reports on a task in which two students, Sheila and Joseph, were asked to find a formula for the perimeter of a string of *n* hexagons. The key issue is that the interior sides of a hexagon string do not contribute to the perimeter. One of the students, Joseph, noticed this property (Pirie & Kieren, 1994), and over the course of about four minutes, stated the property five times before his partner agreed to it. Over these moments, we can consider which discursive strategies Joseph conserved and which he changed as he tried to make his point. Poetic structures, elaborately marked with pauses, changes in intonation and with gestures, were a discursive strategy that Joseph used in each property noticing attempt. This paper proposes that poetic structures can be considered as a discursive mode in multimodal discourse analysis.

What Is a Poetic Structure?

A poetic structure occurs when a speaker repeats a phrase or sentence that was spoken previously, while retaining some of the syntax of the prior statement, and at least one word (Staats, 2016a, 2016b). Repeating grammar helps students talk about math because the syntax establishes relationships among small mathematical ideas or images. Repeating the phrase lets students conserve or modify these relationships. Looking for repetitions that retain at least one word from the previous statement helps the researcher focus on continuity of topic.

Sometimes a poetic structure occurs within one student's turn at talk, as an "internal" poetic structure (Staats, 2016a). Here, Sheila is describing each diagram in Figure 1, from the n = 1 case to the n = 4 case, in which the number of interior sides are 0, 2, 4, and 6, respectively. In the layout of the transcript, I have used indentation to call attention to the grammatical repetitions so that they are arranged roughly in columns, one column for the phrase *would be*, one for *the total number of sides* and one for the number of sides that she sees:

So that would be	like a formula, right?
So this would be	6L,

and then this one would be, uh,
    the total number of sides   minus 2 .
And then this one would be
    the total number of sides   minus 4 .
This would be
    the total number of sides   minus 2, 4, 6

Poetic structures can also occur between students, or "across" students, when one student repeats and perhaps modifies a phrase that another student said in the past (Staats, 2016a; 2016b). For example, a short time after Sheila's statement above, over several of her turns at talk, she spoke fragments of a formula while trying to figure out how to subtract interior sides. At turn 76, she says, *...So, like in statistics the number of cases would be n and that would be your number minus 2...* and at turn 77, she says, *...Number of hexagons would be 1, 2, 3, 4. 4, uh, times 2....* At turn 78, Joseph uses an "across" poetic structure to recombine two of Sheila's phrases in order to request clarification, *Times 2 or minus 2?*

In this way, poetic structure analysis can focus on the form of a single student's mathematical commentary, or it can focus on the relationships of commentary that students share, sometimes over long stretches of a conversation. This study is concerned with the way Joseph used discursive form to explain a property of the hexagon diagrams, and so here we focus on "internal" poetic structures. As we see in the examples above, poetic structures can be shown on the page through indentation and through underlining. In order to conserve space in this research report, in the following examples, I use several forms of underlining instead of indenting to highlight repetitions within Joseph's property-noticing statements.

Theoretical Foundation

In recent research reports, I have outlined a methodological foundation for identifying and interpreting poetic structures in collaborative mathematical conversations. I've shown that poetic structures can facilitate activities such as organizing data, generalization, and shifting from a spoken mathematical formula to a written one (Staats, 2016a, 2016b). In this research report, I discuss how poetic structures contribute to a student's property noticing statements.

In Pirie and Kieren's theory of the dynamic growth of mathematical understanding, three of the early stages are image making, image having and property noticing (Pirie & Kieren, 1994). A student in the property noticing stage can coordinate multiple abstract images or ideas in order to identify a new property of a mathematical object or activity. Martin and Towers have extended this theory to describe collective property noticing, in which the insights are distributed across different students, with no single student expressing the full idea (Martin & Towers, 2015). Throughout the hexagon task, Sheila and Joseph had collaborated closely, and Sheila had voiced many key insights. But in the selections below, Joseph was in an individual stage of property noticing. Joseph seemed to be making a bid to have his insight validated by Sheila and brought into their collective work. The theoretical foundations advanced by Pirie and Kieren on one hand and Martin and Towers on the other allow us to locate Joseph's commentary just at the boundary of individual and collective property noticing. Joseph used multimodal discourse in varying ways over five moments of property noticing to gain collective engagement, with only some success.

Participants and Task

Sheila and Joseph were two undergraduate students who had recently completed a university class in precalculus. They participated in a paid, one hour video and audio recorded problem-solving session. The hexagon task was based on Wilmot et al (2011, p. 287). The task includes diagrams for strings of 1 to 4 hexagons, shown in Figure 1. It asks the students to fill a table of values for n = 1 to n = 5 hexagons with the corresponding perimeters. A correct answer is $p = 4n + 2$. Sheila and Joseph developed an answer of the form $\#H(6) – 2(N – 1) =$ in which H and N both stand for the number of hexagons (Staats, 2016a; 2016b).

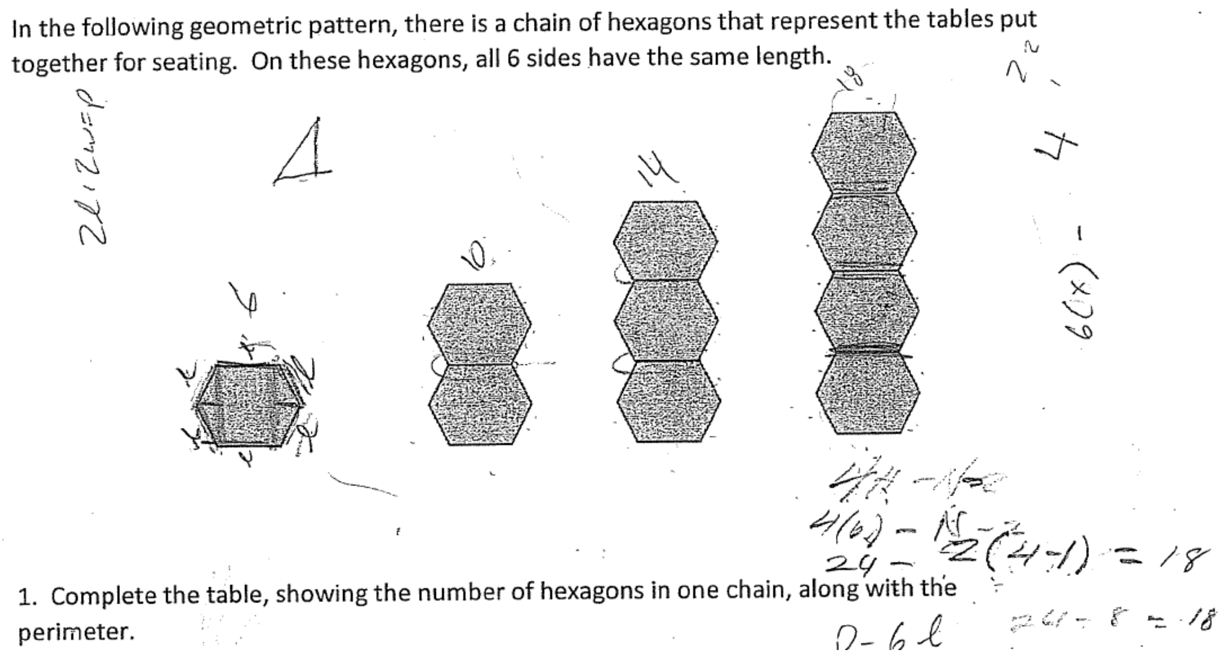

Figure 1. Task diagrams for n = 1 to n = 4 hexagons.

Methods

This study uses multimodal discourse analysis to understand a student's bid to propose a property as a collaborative activity. Because this paper is concerned with patterns in syntax and sound, as well as gesture, I use an approach to discursive multimodality that is drawn from conversation analysis (Bergmann, Brenning, Pfeffer, & Reber, 2012). This approach takes prosody—patterns of sound in language such as pitch, intonation, pause or loudness—combined with gesture and syntactic structures, as interactional modes that allow people to create meaning. Syntactic units are sometimes marked multimodally through prosody and gesture (Szczepek Reed, 2012). Multimodal analysis in mathematics education has shown that prosody, gesture, sounds created through gesture, and rhythm can be coordinated to express mathematical understanding (Bautista & Roth, 2012; Radford, Bardini, & Sabena, 2007). Alibali, Nathan, et al (2014) show that the coordination of speech and gesture is particularly important in linking mathematical ideas, particularly for new material. In this paper, I introduce poetic structure as an additional discursive modality for creating meaning.

When Joseph explains the property and Sheila fails to agree with it, he must explain it again but change something, in other words, he must deploy a new combination of discursive resources. Speakers could shift among many different discursive strategies to try to highlight important information for their idea. I consider four elements of speech that a speaker could combine in various ways to create a new strategy for explanation: introducing academic vocabulary; elements of prosody; gesture; and poetic structures. I represent these elements according to the transcription key in Table 1. This mode of transcription doesn't use punctuation such as commas, periods or question marks unless they are defined in the key as features of the sound. In the selections below, I transcribe Joseph's property noticing statements closely, and I present other statements in ordinary prose with ordinary punctuation. To identify poetic structures within one turn at talk, I looked for phrases that were repeated and that share some grammar and at least one word. If I could identify alternative ways of parsing the statement into poetic structures, I chose the approach that accounted for the longest stretch of words.

Table 1: Transcription Symbols

Symbol	Definition
↑ or ↓	High pitch or low pitch, respectively, compared to nearby words. Could occur at beginning, middle or end of word.
Bold text	Emphasis on a word through loudness, vowel lengthening, or stress
(x.y)	Pause, estimated, in seconds.
Underlining styles	Single, double or bold underlining represent the different poetic structures in one turn at talk
[*italics*]	Descriptions of gestures

Five Attempts to Explain a Property

In this part of the conversation, the students had already developed a numerical method for solving the hexagon problem that corresponds to the formula that they had written, *#H(6) – 2(N – 1)* = . The task now asks them to explain their method in terms of the diagram. After a brief discussion of whether this refers to the table of values or the images of hexagons on the handout, Joseph states a property of the hexagon diagram for the first time in the conversation.

First Attempt, Turn 171

171 J: Then this must be the diagram (1.0) so ↑how can we use ↓this (0.2) to prove our point (1.4) [*Pencil taps vertically on the diagram at each "this."*]

so the **hex**agon has ↑six sides (1.4) but when you put a hexagon in a **chain** they share **two** sides (0.6) so you're taking away **two** sides (0.8) from the chain↓ (1.6) so each time you **add** another hexagon in a chain↑ [S: But it's not asking, this one] you're losing two sides↑ [*During part of this segment, Joseph's hand obscures the paper, so we don't know precisely whether he used small gestures.*]

172 S: This one is not asking about the diagram. It says, how do we know this is true? Why does it work? Because the formula matches the diagram and table.

There are two repeated phrases in Joseph's first statement of the property, which can be summarized as: *you/put, add/hexagon in a chain* and *you're/taking away, losing/two sides*. The beginning and ending of each of these four underlined phrases is fairly strongly marked through prosody, either through pause, intonation or emphasis. For example, *so you're taking away **two** sides* is bounded on either side by a distinct pause. The poetic structure *when you put a hexagon in a chain* is marked as a bounded unit as well, but perhaps less distinctly, with an opening pause and a small level of sound emphasis on the word *chain*. It is important to notice that the beginnings and endings of many of the following examples of poetic structures are marked as a distinct unit, primarily through intonation or pause, and sometimes through less prominent forms of emphasis that are noted with bold text.

The poetic structure in Joseph's first explanation introduces a strategy that he uses in some of the following explanations: a cause/effect or if/then form of argumentation. Fairly often, the first repeated phrase is a cause or action in some sense, and the second one is an effect. This argumentative strategy is conveyed primarily through Joseph's poetic structures.

Though gestures are obscured, it appears from Joseph's hand position that there were probably some small gestures. Still, they did not result in Sheila's acknowledgement of his statement. In the next few turns, the students discuss what it means to explain a method in terms of a diagram. Sheila wonders if they need to draw a new diagram, which leads to Joseph's second statement of the property.

Second and Third Attempts, Turns 177 and 181

177.1 J: ↑I don't think so I ↑think you just have to explain so (1.8) a ↑hexagon has six sides↓ (0.4) [*just before "a hexagon", a heavy tap on the base of the n = 1 diagram*]

177.2 and as you **add** (1.2) an additional hexagon (1.2) [*at "add," light touch on the base; at "additional," light touch on top*]

177.3 you add six↑ (0.8) *[touch base before "six" and touch top after]*
177.4 because they ↑share two sides↑ (0.6) [*circling the top of the n = 1 diagram*]

177.5 you subtract↓ two sides↓ [*pencil is above the page. At "subtract," there's a beat in the air near the top of the hexagon and at "sides," there's a beat near the base*]

177.6 from their total↓ (0.8) number of sides↓

178 S: Um. I think this is, I think this is –
179 J: Which is essentially this.
180 S: The, the number of tables has six sides. And with that multiplied you minus, as they join together they lose one side. So for every-

181 J: One side for (0.2) **one** (0.2) hexagon. [*Overlapping with Sheila's 180 to 181. No gestures; Joseph's hand is away from the paper*].

182 S: -For every, for every two tables, one side is lost. So for the, for the, well, uh, the formula just states it, right? How do you state the formula?

At turn 177, Joseph realized that his property noticing was not taken up by Sheila, and so he made several prominent discursive changes. He used two mathematical poetic structures, each one advancing an "action/result" kind of argument: 177.2-177.3, and 177.4-177.5. Each of these four lines was strongly bounded by prosody, particularly pause, but also with some intonation and emphasis, except the end of 177.5 which was only bounded by intonation and gesture. In 177.2, 177.4 and 177.5, each was accompanied by a two-fold pointing gesture that emphasized the words *add*, *six*, and *subtract…sides*, respectively. Line 177.3 was marked by a different gesture, circling near one side of a hexagon. Generally, the poetic structures in attempt 2 included elaborate coordination with gesture and prosody. Joseph also shifted to the more precise mathematical terminology of *add* and *subtract* with this statement. These layers of multimodal cues suggest that these poetic structures were real to the student, rather than a researcher's analytical imposition.

Once a speaker establishes a unit of speech through a poetic structure, it opens up additional expressive possibilities. If we think of poetic structure repetitions as a kind of rhythm in speech, then prosody and gesture sometimes form a sub-rhythm that highlights words within the poetic structure in ways that enhance the mathematical idea. This is well known for gesture, but multimodal poetic structure analysis shows more clearly that gestures and prosody can express comparisons and contrasts in mathematical entities that are defined through the poetic structure.

For example, a subtle sub-rhythm emerges in 177.2, with a slight emphasis on the word *add*. With this word, Joseph introduces a new strategy in attempt 2, to use more precise computational terminology. The computational word *add* is a new idea, and this is enhanced with prosody (emphasis and pause) and the first part of a two part pointing gesture. In the repetition in 177.3, however, Joseph shifts the emphasis from *add* to *six*, with intonation, pause and a two part pointing gesture. This sub-rhythm controls and shifts focus within the poetic structure words. It shifts the hypothetical action on the diagram of *add/additional hexagon* and towards the computational technique of *add/six*. The poetic structure of 177.4 and 177.5 also contains a sub-rhythm that is coordinated with the repeated words of the poetic structures. Rising intonation on *share/sides* is contrasted with falling intonation on *subtract/sides*, which, like 177.2 and 177.3, emphasizes a shift from action to computation but also realizes that cause/effect argumentation structure. The sense of cause/effect was heightened as the circling gesture at 177.4 shifted to a two part beat gesture on *subtract/sides*. Within elaborately marked and bounded poetic structures, sound and gestures help Joseph to highlight mathematical actions and relationships.

Sheila's response to turn 177 was ambiguous: *as they join together they lose one side*, and so Joseph clarified again at turn 181. With each attempt to explain the property, Joseph uses a different combination of discursive tools. Here, his statement, *One side for one hexagon,* relied on a prominent poetic structure with no gestures. His strategy in attempt 3 was minimalism, to explain using as few words as possible. A poetic structure allowed him to do this. A subtle sub-rhythm used pauses and a small bit of emphasis to highlight the clarification of ***one*** *hexagon*.

Fourth Attempt, Turn 185

183 J: Well they want you to use the diagram. So using this we have to explain how that formula works. So there are six sides, which is, which corresponds to –

184 S: Let's see. Let's do 4. For every, for all these tables, four tables, there's only three intersections [*Joseph takes a piece of paper and writes "4."*]

185.1 J: But they **all** lose two sides at an intersection (1.6) so (0.4) a **hex**agon has six sides, right↑ (0.6) so 4 times 6 is 24↑ [*Joseph has now written 4·6 = 24*] (1.2)

185.2 um but each (1.0) table when each table touches the other one (1.2) [*Joseph has taken a second piece of paper, and at "when," he holds his hand up with palm down*]

185.3 they lose two sides↓ [*At "lose," he closes his palm into a fist*]

186 S: Oh, that doesn't work out mathematically.

Joseph's fourth attempt to assert property noticing used poetic structures less prominently, possibly because he was in the middle of introducing the new modality of writing mathematical formulas. The small level of repetition that exists still expresses the cause/effect argumentation structure, and this is supported through gesture. The open-handed gesture at 185.2 seems to be a gesture of asserting, and the closed fist at 185.3 seems to grasp a conclusion.

Fifth Attempt, Turn 187

187.1 J: Because ↑here's one and ↑here's one (0.8) **here's** one **and here's** one (0.4) **here's** one **here's** one (0.4) so you lose **six** sides (0.8) [*Joseph's hand has obscured the view again, but we can hear him scratching over the interior pairs of sides, and we can see him moving from the bottom pair to the middle pair to the top pair, making the marks that are visible on the interior sides of the n = 4 case in Figure 1. His hand comes away after the last "here's one."*]

187.2 so **24** (0.8) [*He writes a negative sign in 4·6 = 24 -]*

187.3 would be the number of ↑sides if they weren't touching (0.4) but because they're ↑touching (0.4) you lose six↓ [*He writes 6 after the negative sign*]

187.4 and that comes down to 18. [*Joseph has now written 4·6 = 24 – 6 = 18.*]

188 S: Yeah. Okay, go ahead and write it down. You're better at that than I am.
189 J: I'm just more visual.

The first part of turn 187 has a strong poetic structure based on *here's one and here's one*, in which the beginning and ending is marked and bounded off with prosody and a combination of gesture and drawing. Alibabi, Nathan, et al (2014) consider this action as a "writing gesture," though this is distinguished from writing linguistic or mathematical text. The various gestures that Joseph made near the base and top of a hexagon in several previous statement were here made lasting and tangible through a writing gesture.

At 187.2, when Joseph writes the minus sign, *4·6 = 24 -*, he creates a sense of incompletion. We could consider this as a sub-rhythm that is not completed until he writes the *6* as he says a part of the poetic structure at 187.3, *you lose six* and then completes the calculation of *18*. There is a slight dramatic feel to this moment, because he performs the subtraction while he completes the poetic structure. Another sub-rhythm is associated with the poetic structure at this moment, the rising and falling intonations on *touching* and *lose six*. The poetic structure, writing mathematical text, pause and intonation are all coordinated to reproduce the cause/effect argument that Joseph used throughout his property noticing statements. At 188, Sheila responded with a long, thoughtful sounding *Yeah*. It sounded as if she decided that she agreed with Joseph.

Conclusion

Across his five property-noticing statements, Joseph combined expressive modes into distinct discursive strategies that finally achieved acceptance if not extended collective engagement. Poetic structures were present in all attempts, prominently so in four of them. The poetic structures were very commonly marked near the beginning and end through prosody, especially pause and changes in intonation. This analysis shows that as syntactic units are repeated, they may continue to be marked multimodally, amplifying their expressive quality.

Poetic structures put units in parallel position into relationships of similarity— *as you add an additional hexagon/ you add six*; and of difference— *because they ↑share two sides*↑ *you subtract*↓ *two sides*↓. Bautista and Roth have similarly observed that sounds produced through gesture mark important mathematical similarities or differences (2012). Joseph capitalized on poetic structures to add layers of sub-rhythms through gesture, pause and intonation that did quite a lot of the mathematical work in Joseph's five property noticing statements. The co-occurrence of poetic structure and several modalities is strong evidence that poetic structures are not simply abstract grammatical mappings applied by a researcher, but rather, highly expressive tools of meaning-making. Poetic structure analysis is a powerful method to trace the moment-by-moment construction and expression of precise mathematical ideas through informal language.

USING DISCOURSE ANALYSIS TO UNDERSTAND VARIATION IN STUDENTS' REASONING FROM ACCEPTED WAYS OF REASONING

John Gruver
Michigan Technological University
jgruver@mtu.edu

In this study, I use a systemic functional linguistics approach to examine mathematics classroom discourse with the aim of providing a plausible explanation of how students could actively participate in productive classroom discussions without adopting ways of reasoning that were accepted in the classroom community. In this way, I work in the crossroads of a research tradition examining classroom interaction and a research tradition that examines student learning. I found that even though particular ways of reasoning about exponentials and logarithms were advanced and accepted in the classroom discourse, the way these ways of reasoning were talked about in the class did not preclude students from maintaining less sophisticated ways of reasoning Specifically, I argue that the two exponential ways of reasoning were not explicitly contrasted, which may have contributed to students seeing them as essentially the same strategy.

Keywords: Classroom Discourse, Teacher Education-Preservice

Introduction

It is not uncommon for a novice teacher to be surprised by his or her students' poor performance on an exam or assignment after class discussions had seemed to have been going well (see, for example, Price & Valli, 2005). This surprise is not unreasonable. At times, students can be integral participants in productive class discussions that seem to advance the mathematical agenda, yet later still be confused or grappling with a concept that was thoroughly discussed in class. To understand this phenomenon in greater detail, I took the lens of the emergent perspective (Cobb & Yackel, 1996) to examine classroom interactions.

The emergent perspective coordinates social and individual aspects of the classroom community to explain students' learning. Specifically, it coordinates classroom social norms, socio-mathematical norms, and mathematical practices with their individual correlates. In this study I focused on the relationship between classroom mathematical practices, which are specific ways of reasoning that become adopted in a class community, and its correlate of individual students' personal ways of reasoning. According to the perspective, this relationship is indirect and reflexive. Accepted practices arise as individual students posit ways of reasoning. These are then discussed within the class community and are either collectively accepted or rejected. In this way, individual students' conceptions and ways of reasoning give rise to accepted mathematical practices. Then, students' conceptions are influenced as they continue to participate in established math practices. In this way the relationship is reflexive. It is also indirect, meaning that there is not a one-to-one mapping between accepted math practices and students' ways of reasoning. This is acknowledged by the perspective in at least two ways. First, a math practice is not defined as the conceptions held by the majority of students, but as the social status of a way of reasoning in the classroom community. Second, Cobb and Yackel (1996) were careful to point out that participation in a practice influences, but does not determine students' ways of reasoning.

Despite the fact that this acknowledgement of variation in thinking existed from the inception of the theory, the research community still does not have many images of the nature and extent of this variation, much less a well-developed theory of why these variations occur. Of those scholars that have explicitly investigated the reflexive relationship between individual cognition and the emergence of mathematical practices (e. g. Rasmussen, Wawro, & Zandieh, 2015; Stephan, Cobb, &

Gravemeijer, 2003; Tabach, Hershkowitz, Rasmussen, & Dreyfus, 2014), Stephan et al. (2003) gives the best image of the nature and extent of individual variation as they tracked two students' participation in a class community as various math practices emerged. While they documented significant variations in individual ways of reasoning from established practices, these differences seemed to resolve themselves through continued participation in the class. One explanation for this is that the individual ways of reasoning that varied from accepted practice did not yield correct answers, and thus, made it problematic to continue participation in class discussions while using their personal way of reasoning. This encouraged the students to reevaluate their way of reasoning and, eventually, to adopt ways of reasoning more consistent with the math practice. In contrast, my previous work (Gruver, 2016) found that mathematically significant variations in thinking can persist, even after instruction has ended. This finding shows that significant variations do not always work themselves out naturally through the course of instruction. This underscores the importance in further understanding these variations and their causes; this is the focus of the current study.

Nature of Variations From the Established Practice

In a previous study, I documented the ways that individual ways of reasoning varied from accepted classroom mathematical practices. I first determined which practices were established in a classroom of 29 prospective teachers and then compared those practices to the individuals' reasoning during a post instruction interview. I determined which practices were accepted in the class by analyzing students' arguments using the documenting collective activity method (Cole et al., 2012; Rasmussen & Stephan, 2008). Of the seven students interviewed, I found that four of them reasoned in ways that were different in mathematically significant ways from the established practice. In this section, I describe the established practice and the ways students reasoned in the interview.

The math practice emerged as students were developing an exponential number line, which would later be used to investigate exponential and logarithmic relationships. Early on, the students developed a number line in which powers of 10 were equally spaced. However, the spaces between the powers of ten were subdivided linearly. In this way, their number line had an exponential structure at the macro level, but a linear structure between the powers of 10. Eventually, this initial way of subdividing was eventually overturned in favor of a method that produced a fully exponential number line. The math practice, *Subdividing the Number Line,* consisted of two ways of reasoning that were accepted in the classroom community. These two methods for subdivision were cognitively distinct, but produced the same answer. The first method, *Subdividing Segments by Reasoning Linearly About Exponents* is characterized by students writing the number they wished to place on the number line in the form 10^b, ignoring the 10, and then determining the location of the number as if they were simply placing the exponent on linear number line. In other words, $10^{1.5}$ would go halfway between 10^1 and 10^2, because 1.5 would be halfway between 1 and 2 on a linear number line. The second method to subdivide the number line that became normative in the class was *Preserving the Multiplicative Relationship within the Segments.* This way of reasoning emerged as students noticed a constant multiplicative pattern at the macro level. Specifically, they noticed that the equally spaced powers of ten increased by a factor of ten. This differs from a linear number line where equally spaced points would increase by a constant sum rather than a constant factor. They then extended this pattern to apply to subdivisions. Thus, to determine the value of the half way point between 10^1 and 10^2, they would notice that between these two points there is an increase of a factor of 10; then, since the half way point divided the segment into two subsections, they would need to find a number that when multiplied by itself yielded 10. That number is the square root of ten. Thus, the midway point is 10 times the square root of ten. These two ways of subdividing segments on a number line emerged around the same time in class, but the first was talked about as a way to efficiently determine the value of subdivisions while the second was used as a way to explain why reasoning linearly with the exponents makes sense.

Three of the students coordinated these two ways of reasoning in the post interview. This means that while they may have determined the values of various points on an exponential number line using the numeric pattern in the exponents, they could also use multiplicative reasoning to justify their placements. However, the other four were not able to use the second way of reasoning, the multiplicative pattern, even when probed.

Since more than half the students interviewed did not include multiplicative reasoning in their interview responses, observers were left with the question: How could the students intellectually engage in class discussions, but not personally adopt ways of reasoning consistent with the classroom math practice? A partial response to this question will be developed in this report. In particular, I will focus on the nature of the classroom discourse as multiplicative reasoning was developed in this class to address the research question, *How might the nature of the discursive interactions in both whole class and small group settings give a plausible explanation for students' variations from the emergent math practice?* In answering this question, I examine the intersection of classroom interactions and individual student learning. This work is at the crossroads of two research traditions and contributes to a new path forward for using discourse analysis to give insights into the nature of individual knowledge construction.

Method

Data collection occurred in a math class for prospective secondary teachers (PSTs). The purpose of the course was to deepen the PSTs' mathematical knowledge of secondary topics. The current study focuses on a single unit where the PSTs explored exponential and logarithmic relationships. This unit was three weeks long. The class met twice a week for an hour and a half each time. Thus, the unit included nine hours of instruction spread over six days. Data included video and audio taped class discussions and approximately 1 hour problem solving interviews with seven students. The purpose of these interviews was to determine students' individual ways of reasoning about the content explored in class. These students were distributed among two small groups of four students each. The small group interactions of these seven focus students were also video and audio recorded.

To analyze the discourse, I used a modified version of Herbel-Eisenmann and Otten's (2011) method for thematic analysis (Lemke, 1990; Herbal-Eisenmann, 2011), a systemic functional linguistics (SFL) approach (Halliday, 1978; Halliday & Hasan, 1985). Central to this method is the assumption that words derive their meaning from their relationships to other words used in the discourse. To determine this meaning researchers examine the semantic relationships between words expressed in classroom discourse. For example, if a student said, "500 is at the midpoint," They are expressing a relationship between "500" and "midpoint." In particular, they express a located/location relationship. This helps determine the meaning of both 500 and midpoint, namely that 500 is something to be located and midpoint is a location.

I used this method to examine moments in the classroom where subdivision of an exponential number line was discussed to develop networks of semantic relationships between lexical items, words or phrases that came up repeatedly in the discourse. I developed a network for each method of subdivision based on arguments given in class as well as networks based on canonical arguments, those that are representative of how an expert might argue. Comparing the various networks revealed subtleties in the discourse and the meanings of various words.

I then analyzed discourse where students reflected on and talked about the methods of subdivision themselves. In these instances, students would explicitly refer to a particular method of subdivision as a method of subdivision. This contrasts with the other episodes of discourse where students were simply using a particular method. This means that in these instances of discourse, students were referring to a whole network of semantic relationships as a single lexical item. In SFL, this is called condensation (Lemke, 1990). In the episodes where students reflected on methods of subdivision, they tended to express semantic relationships in a different way than when they used the methods. In these episodes they tended to use equivalence and contrast strategies (see Lemke, 1990, p. 226) to show whether they thought two strategies were the same or different. This occurred during four episodes, though only two will be examined in this report. In the first episode, they contrasted linear and exponential methods using the discursive device of *parallel environments*. This means the speakers placed lexical items so that they have the same function in the grammar of two phrases. For example, a student might say, "in a *linear method* you do abc, but in an *exponential method* you do xyz". Here, the two methods are serving the same function in the grammar, in that they are both methods whose steps are being described. Furthermore, the methods are being contrasted and positioned as distinct, as one does something different in each instance. In the second episode, students explicitly said the two methods of subdivision were the same.

Results

Analysis of the four episodes in which students explicitly talked about the methods of subdivision themselves provided evidence for the following result: *When speaking, students distinguished between linear and exponential ways of reasoning, but did not distinguish between reasoning linearly with the exponents and multiplicative ways of reasoning.* In fact, students seemed to think of both of these methods as the same. In these instances, students may have referenced other lexical items, but these will be ignored as this analysis focused on references to the methods themselves.

Background to Episode 1

Students developed an exponential number line over the first three days of a six-day unit. On Day 1, they were asked to create a timeline that represented the history of the earth. Several approaches emerged on Day 1, but by Day 2 the teacher had encouraged them to focus on and develop a particular approach in which the timeline had a macro exponential structure, meaning powers of ten were equally spaced. However, to place events they subdivided the space between powers of ten linearly. Eventually, over Days 2 and 3, this method of subdivision was rejected and the two methods that were ultimately accepted were developed. The four episodes in which students in class reflected on the methods of subdivision occurred over these two days.

The first episode occurred near the end of Day 2. Students had already placed two dates on the timeline, the Renaissance and the Ordovician Periods, using linear reasoning to subdivide the space between two powers of ten. Presumably to problematize this way of reasoning, the teacher asked the students to place the Renaissance again, but using 1 and 1,000 and endpoints instead of 10^2 and 10^3. As part of her question, she specifically asked if 500 would end up in the same place. This led to the realization that using the different endpoints resulted in a different placement for the Renaissance. The students then considered the idea that the method they were using to subdivide was problematic. As they reflected on their method they contrasted how they subdivided the segments with the macro exponential structure, using the discursive device *parallel environments*. This contrast helps support the main claim in this paper, that over several discussions in class linear and exponential strategies were contrasted in the discourse, while the two exponential strategies for subdivision were not.

Discussing the Problem of the Renaissance Moving

The first instance of using *parallel environments* to contrast the linear relationships with exponential relationships came up as Nathan described why their linear method might be problematic:

> Yeah, so ultimately, the issue is, it seems like we're trying to apply a method that's completely linear in nature, when our graph [timeline] is not, it's exponential. That is, that's the problem, so that means that right there, the solution will not work, because why would it?

In this quote, Nathan referenced the idea that they were using a "method that's completely linear in nature" and a "graph… [that's] exponential." While Nathan argued that there was a mismatch between the nature of the method and the nature of the graph, Danna provided even more detail as to what the problem might be. She argued that a linear placement would not work, highlighting that it inaccurately predicts the placement of the known point 10^3.

> I started with first doing basically what we did up here [the linear way of reasoning]. So, we looked at the difference between 10^4 and 10^2, which was 9,900 years. And half of that [points to halfway between 10^4 and 10^2] should have been the 48 or should be…4,950, but we know that it's actually 10^3, so that right there told me linear doesn't work and it pushes the halfway mark closer to the 10^4 side. So applying the 500 to this one, I knew it was going to be closer to 10^3, just `cause, 500 it's halfway if it's linear, but when it's exponential, you know it's not, based on this [points to the number line that she used to argue "linear doesn't work"]. Then, I realized you can do it this way.

Again, Danna used the discursive device *parallel environments* to contrast linear and exponential ways of reasoning. She began using the linear method to predict the placement 10^3, a year whose placement was already determined from the macro pattern. She then extrapolated, "500 years, it's halfway if it's linear, but when it's exponential, you know it's not." Here the linear and exponential relationships have a similar grammatical function, in that she basically said, if it's linear, then 500 is halfway, but if it's exponential, then 500 is not halfway. She did this again when she said, "We were trying to look at it linearly in between each chunk, but the entire timeline is exponential." Here, she contrasted linear and exponential ways of reasoning by saying that in each chunk the structure was linear, but the structure of the whole timeline was exponential.

Background for Episode 2

Talk about methods of subdivision continued on Day 3. The day began with a student, Lacey, introducing the first way of subdividing that eventually became normative. She determined that the halfway point between 10^2 and 10^3 should be $10^{2.5}$, using the subdivision method of *Reasoning Linearly with the Exponents*. While discussing this task, Nathan justified her placement by introducing the second way of subdividing that eventually became normative, *Preserving the Multiplicative Relationship within the Segments*:

> Well, the way I did this one was I was looking at it where, in the more general sense, each tick was, …each thing apart on the bigger one is the same distance… multiplicatively apart, so we're going to do the same thing here. We have two so, we have two sections that when multiplied all together are 10. So, each side we'd had better have the square root of ten, because that's the only thing that's gonna give us 10 when we multiply it again, so I…just took the, I just figured it was, the distance away was 10^2 and then times the $\sqrt{10}$, which is 3.162. So I got 3.162 times 10^2.

Here, Nathan argued that by extending the multiplicative pattern that existed at the macro level, one can find the halfway point to be 100 times the square root of 10, or $10^{2.5}$, as Lacey had said. Presumably because the teacher noticed this was a distinct way of reasoning, she asked the students to talk about it in small group, specifically asking them to explain where they see the square root of ten coming up. However, during their small group discussions, the students said that Nathan's method and Lacey's method were the same.

Reactions to Nathan's Ideas.

In both small groups that included focus students, they failed to see the difference between Nathan's and Lacey's ways of reasoning about the subdivisions. In the first group, instead of engaging with the ideas of factors and multiplication, one student, Tanya, started the discussion of square roots by talking about the exponents. She said, "Well, the exponent one half is the square root right? ... So if it's 10^2, multiplied by $10^{1/2}$, right? So it's 100 times the $\sqrt{10}$." Here we see Tanya following the teacher's prompt to attend to the square root, however Tanya is arriving at the square root in a much different way than Nathan did. Instead of continuing the multiplicative patterns that existed at the macro level, she is arriving at the square root via a previously known rule that $10^{.5}$ is $\sqrt{10}$. This allowed her to still preserve her linear ways of reasoning about the exponents, while at the same time explaining where the square root is coming from as the teacher asked. This made it so she did not have to distinguish between the two ways of reasoning. This analysis is consistent with her groupmates' comments. Kathy said, "[Nathan's way of reasoning is] the same thing, because if you're doing 10^2 times 10 to the square root that's the same thing as .5." Rachel concurred saying, "He just thought of it as square root instead of…one half." Kathy summarized by saying, "Yeah, it's the same thing, he just wrote it differently."

In the second group, the students also continued to focus on exponents. However, instead of engaging with Nathan's idea, they explicitly said they did not understand it and ignored it. Farah said, "Well, I don't understand what [Nathan] said, but this is how…I thought of it." She then continued with her own idea.

In these small group interactions, the students explicitly said Nathan's and Lacey's way of reasoning were equivalent. Even though the teacher prompted them to attend to the square root, an idea that was central to Nathan's idea and absent from Lacey's, the students treated this as simply a notational difference. Tanya began by asking "the exponent one half is the square root right?" Rachel echoed this connection when she said, "He just thought of it as square root instead of…one half." This interpretation may have allowed them see Nathan's idea as simply another expression of Lacey's ideas rather than a new idea worthy of examination.

Summary

Analysis of the discourse in the four episodes where students reflected on methods for subdivision provide evidence for the claim: *When speaking, students distinguished between linear and exponential ways of reasoning, but did not distinguish between reasoning linearly with the exponents and multiplicative ways of reasoning*. In the first episode, when students discussed the problem of the point representing the Renaissance moving, they distinguished between linear and exponential ways of reasoning. They talked about subdividing the segments as a linear process while the macro structure was exponential in nature. This contrast between linear and exponential came up again in the third episode when students contrasted halving the values on the line with halving the values of the exponents. While this contrast is important, it does not help to disambiguate between the two exponential ways of reasoning. Furthermore, when the students talked about Nathan's multiplicative way of reasoning in small groups, they referred to it as the same as Lacey's method, which relied on linear patterns in the exponents. Thus, it is possible that students participating in the class discussion could see the two exponential methods as the same, which leaves little intellectual encouragement for students who can reason successful by focusing on the exponents to adopt multiplicative ways of reasoning.

Discussion

This study focused on how the nature of the classroom discourse can help explain how students could participate in a classroom where multiplicative ways of reasoning were developed and accepted by the class community, but not adopt those ways of reasoning as individuals. Through discourse analysis I discovered that exponential and linear ways of reasoning were contrasted, but reasoning multiplicatively and reasoning linearly with the exponents were not. This may mean that students thought there were primarily two ways of reasoning, a wrong way and a right way—linear reasoning and exponential reasoning. Thus when students heard multiplicative explanations, they may have thought that what they were hearing was no different from reasoning linearly with the exponents, since both were exponential.

It is reasonable to think that strongly contrasting linear and exponential methods in the classroom discourse is a desirable outcome, since previous research on exponential reasoning suggests that making the transition from linear to exponential reasoning is difficult (Berezovski, 2004; Liang & Wood, 2005). However, tackling this issue in this classroom seemed to background the subtler difference that exists between the two methods for subdividing exponentially. Being able to distinguish between the two methods is key to developing conceptual understanding of the relationships among numbers on the exponential number line. To develop this understanding, students need to coordinate the two methods of reasoning linearly with the exponents and continuing the macro multiplicative pattern. If students think of these as the same, then they can simply reason linearly with the exponents to get the right answer, without thinking exponentially at all. This means that, ironically, since the only contrast between methods of subdivision that existed in the discourse were between exponential and linear methods, students were able to participate in classroom discourse about exponential subdivision while reasoning only linearly.

This work raises the question of how to encourage students to see the differences between two ways of reasoning, especially when both ways of reasoning yield the same answer, so that they can then explore their relationships. In this paper, I have argued that the two exponential ways of reasoning were not explicitly contrasted, which may have contributed to students seeing them as essentially the same strategy. As such, an implication for teachers of this specific unit is to consider asking students to explicitly name and contrast the two exponential strategies. This would make it problematic for students who thought of the two methods as the same to continue to participate in the discourse. This may encourage them to disambiguate between the two methods, positioning them well to explore the relationships between them.

More generally, teachers teaching any unit should think about various ways of reasoning that may arise in the class and if they should be named and contrasted. However, it should be noted that determining which methods should be contrasted can be difficult to predict. While the research presented here underscores the point that the two exponential methods of subdividing a number line should be contrasted, this was not obvious before instruction. While the teacher recognized the complexity of transitioning from linear to exponential ways of reasoning and appropriately orchestrated the discussion to contrast those two ways of reasoning, she seemed to underestimate the difficulty students would have with disambiguating and coordinating the two exponential strategies. This highlights that to some extent, familiarity with and competence in executing general discourse moves, such as those involved in orchestrating discussion in such a way that strategies are contrasted, only goes so far in teaching and even highly effective teachers need support garnered through research that illuminates the conceptual difficulties of particular topics and gives insights into how to teach those topics. This suggests that teacher education focused on discourse should be paired with professional development focused on understanding the cognitive difficulties students face as they learn specific topics.

A QUALITATIVE METASYNTHESIS ON CULTURALLY RESPONSIVE TEACHING & CULTURALLY RELEVANT PEDAGOGY: UNPACKING MATHEMATICS TEACHING PRACTICES

Robert Q. Berry, III
University of Virginia
robertberry@virginia.edu

Casedy A. Thomas
University of Virginia
cat6hu@virginia.ed

This qualitative metasynthesis synthesizes published research papers using qualitative methodologies focusing on Culturally Relevant Pedagogy (CRP) and Culturally Responsive Teaching (CRT) published between 1994 through February of 2016. Twelve articles were synthesized to understand how researchers interpret mathematics teaching practices that support CRP and CRT in pre-kindergarten through 12th grade. There were six findings: a) caring; b) knowledge of contexts and teaching practices using contexts; c) knowledge of cultural competency and teaching practices using cultural competency; d) critical consciousness; e) high expectations; and f) mathematics instruction/teacher efficacy and beliefs.

Keywords: Research Methods, Teacher Knowledge, and Teacher Beliefs

Since 1994, there has been a large body of research focused on Culturally Relevant Pedagogy (CRP) and Culturally Responsive Teaching (CRT) across all content areas. Mathematics education has benefited from teaching and research using the tenets of CRP and CRT. Much of the research using the tenets of CRP and CRT in mathematics education employs qualitative methodological approaches. However, this work has yet to be synthesized and interpreted using methodologies for qualitative metasynthesis. Aronson and Laughter (2016) conducted research synthesizing CRP and CRT across all subject areas. This research uses a qualitative metasynthesis as a methodological approach for mathematics education research discussed by Thunder and Berry (2016). This research focuses on understanding how researchers interpret mathematics teaching practices that support CRP and CRT in pre-K through 12th grade.

Theoretical and Methodological Frameworks

Gloria Ladson-Billings', *Dreamkeepers* (1994) outlined CRP as a framework and Geneva Gay's *Culturally Responsive Teaching: Theory, Research and Practice* (2000) outlined a framework for CRT. Both CRP and CRT are frameworks for unpacking teacher practices embedded in classrooms as sites for social change and social justice. Both connect cultural framing to academic skills and concepts, build cultural competence through teaching, and use teaching as a way to critique power discourses and representations. Published peer-reviewed research papers between 1994 and 2016 using qualitative methodologies focused on CRP and CRT were sought for this qualitative metasynthesis. Prior to conducting database searches, inclusion and exclusion criteria were developed based on four parameters: topical, population, methodological, and temporal. All papers use CRP and/or CRT as frameworks (topical) and the research focused on mathematics teaching and learning in preK-12 contexts in the United States (population). Qualitative research was the methodological framework for all papers; however, mixed methods research studies were included if the qualitative findings were distinguishable. Subject term searches were conducted using EBSCO to simultaneously search five databases for peer-reviewed journal articles. Figure 1 shows the flowchart of inclusion and appraisal to determine articles for the qualitative metasynthesis.

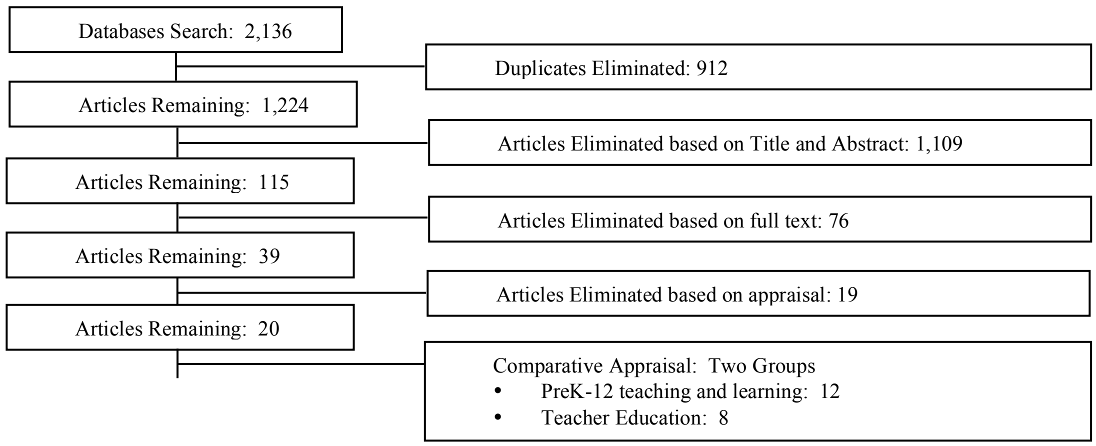

Figure 1. Flowchart of inclusion and appraisal.

The initial EBSCO search produced 1,224 articles. Following our initial search, we worked through a validation process by looking at the titles, abstracts, subject terms, and full text for published peer-reviewed journal articles. This process left further 39 articles fitting the inclusion criteria. Book reviews, reports, chapters, and dissertations are examples of items that were excluded. We then performed individual appraisals for each article, appraising the quality of the research methodologies using the rubric published by Thunder and Berry (2016, p. 329-330). Following their appraisal process, 20 articles were identified. Further, we did a comparative appraisal, dividing the articles into two groups: 1) preK-12 teaching and learning; and 2) teacher education. This qualitative metasynthesis treats the findings from 12 articles focused preK-12 teaching and learning as informants (the 12 articles are marked with an * in the reference). Dedoose, a data analysis software, was used to support data analysis and initial codes were developed and defined. Six initial codes with eight child codes were used to code the data; we re-read, re-coded, and unpacked the data to synthesize and interpret for reporting.

Findings and Excerpts

The six findings focus on teacher practices, classroom interactions, and student experiences. Each finding is highlighted with representative excerpts in Table 1.

1. **Caring** is a continuous cycle of working to establish a rapport, using knowledge gained from that rapport to inform teaching practices, and then, reflecting upon teaching and learning to understand students' mathematical knowledge.
   - Teachers created positive learning environments where students saw themselves as participatory.
   - Teachers took an active role in seeking out knowledge about students and communities.
   - Teachers supported students emotionally and academically by making mathematics content accessible and empowering students mathematically.
2. Knowledge of **context** is related to space and place in the ways teachers gained knowledge of home, community and neighborhoods. Teachers integrated mathematics instruction and knowledge of **context** by making meaning of the mathematics curricula and tasks.
   - Teachers actively engaged in communities to work with students' parents and families.
   - Teaching practices included mathematizing contexts, creating and adapting mathematical problems, utilizing questioning strategies to elicit students' local knowledge, requiring explanation and justification as it relates to context knowledge, and creating project-

based opportunities incorporating funds of knowledge.

Table 1: Findings and Excerpts

Findings	Excerpts
Caring	*When establishing relationships, teachers cannot merely go through the motions because students know when teachers are genuine and really care about them…The teachers realize they must have a relationship before they can make mathematics lessons relevant to the students. They take the opportunity to know their students and discover their motivations and interests. They tailor their instruction with this knowledge.* (Jackson, 2013, p. 7)
Context	*Ms. Finley often ''walk[ed] the neighborhood'', taking time out in the evenings to visit with students and their families. She knew that this type of connection with the community was important, and she was able to weave the knowledge that she gained through these interactions into the mathematical content that was the basis for her lessons.* (Bonner & Adams, 2012, p. 30)
Cultural Competence	*Inga decided to interview some of her students to better understand their experiences with money when shopping for their families. From this, Inga learned about her students in ways she did not expect, finding that those students who shopped with their families were able to quickly solve problems regarding currency…The strategies children use with money are often non-routine, and this might have offered an opportunity to gain a deeper knowledge of students' understanding.* (Wager, 2012, p. 16)
Critical Consciousness	*…the teacher is explaining an adjustment he made to the map's display to make the trends that they are examining more visible…The teacher superimposed the dots over the average income of each census tract with lighter colors corresponding to lower incomes…This display and discussion is part of the group's overall argument that de facto segregation still exists in Los Angeles.* (Enyedy & Mukhopadhyay, 2007, p. 161-162)
High Expectations	*…Ms. Bradley's classroom was highly structured and disciplined, focusing on high expectations and success through "tough love." When a student did not have his or her homework, for example, Ms. Bradley would take the student in the hallway to call his or her parent or guardian. Furthermore, if a student was not participating in the group chants or problem-solving activities, Ms. Bradley would "call him [or her] out and take him [or her] to church," meaning she would stop the lesson and "preach" about the decisions students were making and the importance of academic success…she indicated that this type of culturally connected communication and maintenance of high expectations allowed students to develop racially and culturally "so that they don't have to give up what they are used to for the sake of passing class...* (Bonner, 2014, p. 395)
Mathematics Instruction/Teacher Efficacy and Beliefs	*…Chela loved math. Chela turned this passion for math into a professional strength—she took advantage of all math professional development opportunities and she made mathematics a central part of her practice...Weaving math into daily activities was what Chela did best. As she designed different games or visual supports she looked for the math hook…* (Graue, Whyte, & Delaney, 2014, p. 308)

3. **Cultural competency** was found in the ways teachers developed knowledge and competencies associated with various forms of communication and funds of knowledge.
    - Teaching practices and strategies primarily focused on classroom discourse including storytelling, utilizing call and response, and dynamic forms of interactions.
    - Teachers promoted engagement by incorporating nonverbal communication through proximity and by integrating music and movement into teaching practices.
    - Teachers made mathematics accessible by unpacking and connecting cultural artifacts.
4. While **critical consciousness** and critical reflections are significant parts of the CRP and CRT, only one study (two articles) examined critical consciousness explicitly. Teachers in four studies made reference to critical consciousness and reflection.
    - Teachers and students critiqued and mathematized societal issues.
    - Societal inequities were acknowledged by framing challenges within communities. It was not clear how students were using mathematics as an agent for social change.
5. Teachers must have **high expectations** both for their students and for themselves.
    - Teachers made necessary teaching revisions based on their students' needs, interests, and understandings as they relate to mathematics.
    - Teachers were warm-demanders by establishing learning environments in which students were held accountable and empowered by taking an active role in their own learning.
6. **Mathematics instruction** highly correlates with teaching practices and strategies for both context and cultural competency. This finding is specific to mathematics teaching practices.
    - Teachers utilized technology, incorporating tools and manipulatives in their instruction.
    - Teachers modeled their thinking for students.

- Teachers with high confidence in teaching mathematics and high self-efficacy believed that mathematics instruction should be student-centered, open-ended, inquiry-based, highly interactive, and impromptu, based on students' needs and interests.
- Teachers with low confidence in teaching mathematics, or low self-efficacy struggled with CRP and CRT. This led to limiting tasks focusing on high cognitive demand.

Implications

There are significant gaps in the literature focused on mathematics teaching related to CRP and CRT. The gaps primarily exist around unpacking mathematics teacher actions focusing on CRP and CRT. More work is needed in the field for unpacking teaching practices that promote access, equity, and empowerment. The findings of this research suggest that CRP and CRT teachers know their students and the communities of their students; more work is needed to unpack the continuous cycle teachers use to develop rapport. The findings from this work suggest that mathematical knowledge for teaching positively impacted teachers' lens for CRP and CRT; more work is needed to understand and unpack the interactions of teachers' knowledge of context and culture with knowledge of mathematics and teaching mathematics.

CONSTRUCTION AND JUSTIFICATION OF CENTRAL ANGLE THEOREM IN DYNAMIC GEOMETRY ENVIRONMENT

Xiangquan Yao
The Ohio State University
yao.298@osu.edu

Understanding how students construct abstract mathematical knowledge in classroom setting and the use of various instructional tools in facilitating such abstract constructions have been central themes in mathematics education research. This study used Abstraction in Context (AiC) as a theoretical framework to study studying high school students' processes of constructing and justifying of central angle theorem in dynamic geometry environment. Data analysis revealed that the although the central angle theorem was proposed and verified through dragging and measuring tools enabled by a GeoGebra driven simulation, the need to produce a formal proof establishing its validity was not realized by the group, suggesting that the dragging and measuring features of the dynamics geometry environment may pose challenges for teacher and students to construct abstract formal proofs.

Keywords: Geometry and Geometrical and Spatial Thinking, Reasoning and Proof, Technology

Understanding how students construct abstract mathematical knowledge in classroom settings and ways to facilitate the development of abstract generalizations and justifications among learners has been a persistent theme in research in mathematics education for decades (Mitchelmore and White, 2000). Indeed, as it pertains to abstracting and generalizing regarding geometric properties and relationships, scholars have argued, with empirical data, that the presence of dynamic geometry software (DGS) (e.g. GSP, Cabri, GeoGebra) can provide productive means for allowing students to explore, notice relationships, conjecture about potential relationships and construct generalization regarding geometric properties and relationship, with the understanding that such environments also presents challenges when moving students from inductive verification to deductive formal proof (González and Herbst, 2009). However, a majority of work in this area has considered knowledge construction of individuals or small groups of students in presence of DGS. Not many studies have been reported with a focus on exploring the dynamics of generalizing and justifying within a whole group setting, taking into account the impact of peer-teacher interactions on what might be extracted from the DGS and what is assumed collaboratively. The current study aimed to address this gap and is guided by one question: how do students and teacher in a high school geometry classroom construct and justify central angle theorem while working in DGS?

Theoretical Framework

Hershkowitz, Schwarz, Dreyfus (2001) proposed Abstraction in Context (AiC) as a theoretical-methodological framework to investigate the genesis of abstraction. The core of the model consists of three epistemic actions: *recognizing*, *building-with*, and *constructing*. *Recognizing* a familiar structure occurs when a student realizes that a structure is inherent in a given mathematical situation. Recognizing is often, though not always, at the level of empirical thought. *Building-with* consists of combining existing artifacts in order to meet a goal. When operating at the *building-with* level, the student is not enriched with new, more complex structural knowledge. She or he uses available knowledge to produce a viable solution to the problem at hand. *Constructing* consists of assembling knowledge artifacts to produce a new structure, which could be new methods, strategies, or concepts. The three epistemic actions are dynamically nested in such a way that building-with includes recognizing, and constructing includes both recognizing and building-with. This model has been used to investigate processes of abstraction in a wide range of situations (Dreyfus, 2012). This study will use AiC to examine the process of constructing and verifying central angle theorem in DGS.

Methodology

Data for the study comes from an ongoing program of research which aims to understand how students and teacher in a regular classroom settings interactively work towards constructing and justifying generalizations pertaining to geometric properties and relationships. The participating site is a high school geometry class consisting of 21 students and 1 teacher. All mathematics lessons have been video-recorded daily to capture interactions taking place during instructional activities. All student artifacts have been collected to examine the types of inferences and connections students make individually/collectively based on group interactions.

The data used in this report comes from a particular lesson whose objective was for students to learn central angle theorem. Prior to this lesson students had explored and seemingly learned about (1) all the radii of a circle are congruent, (2) two radii and a chord make an isosceles triangle and the base angles of the isosceles triangle are congruent, (3) inscribed angles subtended by a diameter are right angles. A GeoGebra simulation was created as in Figure 1a for students to explore the relationship between the measure of the central angle and the measure of the circumference angle. In the exploration, the center, point C and the diameter of the circle were locked and point D and E were not fixed. Students were first assigned to work in small groups to explore in the pre-made GeoGebra file and answer the following: (1) As you move D around on the top half of the circumference, what happens to the measure of angle E? (2) As you move E around on the bottom half of the circumference, what happens to the measure of angle O? (3) What do you think is the relationship between angle E and O? And then the teacher initiated a whole-class discussion around their observations.

Findings

When exploring in GeoGebra simulation all the 21 students have *recognized* when moving D around both angle E and angle O become larger or smaller depending on the moving direction and that when moving E around the measures of angle E and angle O stay the same. And when asked the relationship between angle E and O, 18 students had *constructed* the idea that angle E is half of angle O. However, it is unclear students understood why angle E is half of angle O. In the whole group discussion, the teacher asked students to share their observations and tried to help students to see why angle E is half of angle O. The following transcript demonstrates how central angle theorem had been collectively verified in whole group discussion.

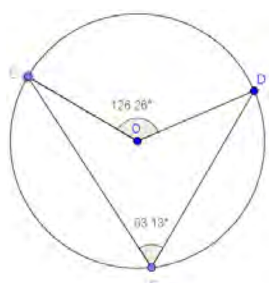

Figure 1a

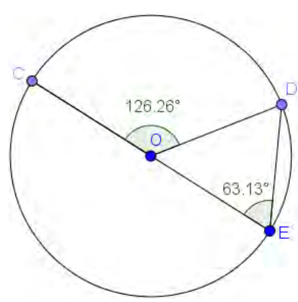

Figure 1b

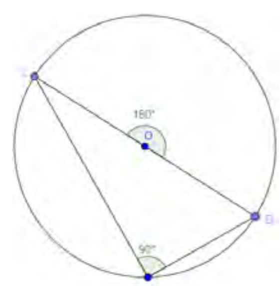

Figure 1c

Teacher: If we move angle D, what happens in general to the two angles that are given to you? (move D around the circle)

SS: They change.

Teacher: Yes, they are changing. So they are not remaining the same. What about when I move around angle E (move E around the circle)?

SS: They stay the same.

Teacher: They stay the same. Ok, let's put this at…here is a good one, because as just said we can move around E and nothing will change even if I make it overlap like this. That means I can make this as a diameter if I want to. Now it's a diameter [move E to make CE as a diameter as in Figure 1b]. What can I say about what's going on here? Think about last week and raise your hand. [no hand raising in 15 seconds] What congruence marks can I put here? [a few hands raising] Chase, what congruence mark can I put here?

Chase: The middle point and from the middle point to the other side [the teacher then put congruent mark on OE and OD].

Teacher: Anything else, Oliva?

Oliva: OD [the teacher put congruent mark on OD].

Teacher: Ok, these are all congruent. So what's going on here now? Does it help us connect? What do you see Jodi?

Jodi: Isn't like since both them are congruent you can put both angles would be equal?

Teacher: So which angels would be the same?

Jodi: The 63

Teacher: This one here 63.13. Now could I find this angle here [point to angle DOE] suppose I don't know this is 126.26 [point to angle DOC]? How would I do that? Andrew, what do I do?

Andrew: add up 63.13.

Teacher: 63.13 plus 63.13 which is 126.26. Is 126.26 already on there? Hmm, so the sum of these two angles give me this [point to angle DOC]. Are these two angles [point to angle OED and ODE] always going to be congruent no matter where I move that?

SS: Yes.

Teacher: Yes, these two should be congruent. So what do you think the relationship between this angle here E and this [point to angle DOC] we call this a central angle because it comes from the center. What do you think the relationship might be between angle E and the central angle? What do you think, Ethan?

Ethan: It's half of the central angle.

Teacher: So the central angle is twice as much as the circumference angle.

Ethan: Yes

Teacher: So even if I have it looking funky like this [move E up] is that relationship still the same? Is the relationship down here still the same [move E down]?

SS: Yes

Teacher: Yes, that will hold. Here is another way we can prove it. Last week when we looked the diameter as the leg of a triangle [move D to make CD a diameter of the circle as in Figure 1c]. What did we say about this angle here [point to angle E]? What would it always be if this is a diameter? Carol, what do you think?

Carol: 90 degrees.

Teacher: So this is 90 [point to angle E] and this is 180 [point to angle COD]. Does that relationship hold? Is the central angle twice the outside angle?

SS: hmm.

To help students understand why angle E is half of angle O, the teacher created the first special case of central angle theorem and then asked students what congruence marks could be put on the diagram (turn #5). The question triggered students to *recognize* that OC, OE and OD are radii of the circle (turn # 6 and #8) and therefore triangle DOE is isosceles. *Building-with* these ideas, students concluded angle ODE and angle OED are congruent (turn #10). The teacher then drew students' attention to connect the sum of the two base angles and the central angle (turn # 13 and #15). And students finally articulated that the circumference angle is half of its central angle (turn #18). The teacher then introduced a second special case to connect central angle theorem with inscribed right triangle (turn #23 and #25). Students *recognized* that E is 90 degrees, which is half of 180 degrees. This special case again verified that a central angle is twice as much as its circumference angle.

Discussion

Studies have shown that dragging and measuring features of DGS provides students opportunities to make and empirically verify conjectures and therefore construct new mathematical ideas (González and Herbst, 2009). However, the dragging and the measuring features of this environment also pose challenges for students to produce an abstract formal proof. Even though the teacher introduced two special cases to demonstrate why central angle theorem holds, a more general proof was missing in the whole-class discussion. The first special case has the very potential to be developed into a general proof had the teacher made it clear that why the sum of the two congruent bases angles of the isosceles triangle equals to the central angle. It's unclear in whether the teacher and students used the angles measures or a theorem (i.e. an exterior angle of a triangle is congruent to the sum of the two angles of the triangle that are not supplemental to the given angle) to conclude the sum of the two congruent bases angles of the isosceles triangle equals to the central angle (turn #13, #14, #15). If the conclusion was drawn based on the theorem, a general formal proof can be more easily developed from this special case. However, if the conclusion was drawn based on angle measures of the three angles, a deductive proof might be more difficulty to be obtained.

The data revealed even though central angle theorem was empirically constructed and verified, an abstract mathematical proof of the theorem was not collectively constructed by the teacher and students. In the process of verifying the theorem the teacher and students were mostly *recognizing* previously learned knowledge and partially *building-with* existing mathematical ideas. It seemed that the measuring and dragging functions prevented the teacher and students to construct an abstract formal proof. Further research is needed to explore how to move students to construct abstract proof in dynamic geometry environment.

CONTEXTUALIZING DIFFERENT PATHWAYS AT THE CROSSROADS OF CRITICAL MATHEMATICS IN URBAN CLASSROOMS

Sunghwan Byun
Michigan State University
byunsun3@msu.edu

A wide range of findings related to Critical Mathematics (CM) have been reported alongside descriptions of diverse sets of CM activities and challenges and successes that teachers have experienced. Little research, however, has considered how teaching contexts may influence the teaching outcomes of CM. The intent of this paper is to highlight the importance of teaching contexts through a comparison of three cases of CM. In the cross-case comparison, I examine how the three CM teachers take different pathways at the crossroads that I frame as the tension of teaching mathematics vs. teaching students (Gutiérrez, 2009). The comparison offers possible explanations of how the teaching context may have influenced such contrasting outcomes of CM, and this adds social and cultural contexts (e.g., teacher's status and power, students' academic goals, and school culture) as another dimension to CM theory.

Keywords: Equity and Diversity; Instructional Activities and Practices

In North America, rooted in Frankenstein's (1983) pioneering work, Critical Mathematics (CM) in K-12 settings has gained traction as a way to support marginalized students' identities and power. Although different terms are used for CM (e.g., Teaching Mathematics for Social Justice, Radical Mathematics), approaches to CM are commonly characterized by efforts to interweave two types of goals: mathematics and social justice, and by aims to synergize two areas of learning: mathematical and sociopolitical.

As an increasing number of CM educators have been examining cases of CM, they have reported a wide range of outcomes in secondary school settings. Often, the discussions focus on how the social justice tasks are created and implemented and what challenges the teachers faced within the classroom; yet the discussion on how the variety of teaching contexts may have influenced CM has been lacking. Without considering the contextual influence, we may unfairly attribute the success/failure of CM to the teachers and their teaching.

My intent of this paper is to highlight the importance of teaching contexts for successful CM teaching, and I will do so by comparing three cases of CM. Some scholars have used cases of CM (e.g., Gutstein, 2003) and comparisons of cases (e.g., Esmonde, 2014) to expand theoretical understanding of CM. To expand theories of CM to account for connections between CM teaching and contexts, I analyzed three existing cases of CM from the research literature using a framework for pivotal moments of teaching, and in particular, moments when tensions arise between teaching mathematics and teaching students (Gutiérrez, 2009).

A Theoretical Framework for Understanding Inherent Tension in Critical Mathematics

CM scholars maintain that teaching CM is not a straightforward task; it requires facing many sorts of tensions and negotiating them (Enyedy & Mukhopadhyay, 2007; Gregson, 2013; Gutstein, 2003). Because CM aims to synergize two areas of learning (mathematical and sociopolitical), negotiating the tensions is at the crux of its success. To frame the tensions that emerge while teaching CM, I borrow Gutiérrez's (2009) three types of tensions inherent in teaching mathematics from an equity stance. In her essay, Gutiérrez (2009) describes the different types of tensions her pre-service teachers experienced when they were interacting with marginalized students in urban school settings. She categorized those tensions into three types: "1) knowing your students and not knowing your students, 2) being in charge of the classroom and not being in charge of the classroom, 3) teaching mathematics and not teaching mathematics" (p. 12). Later in the essay, she rephrased "not teaching mathematics" into "teaching students" to highlight the focus of one side of tension: students. In this manner, I will call her third type of tension as "teaching mathematics versus teaching students."

In this paper, I will focus my discussion on the third: the tension between teaching mathematics and teaching students, because it reflects the complexity of teaching CM in a classroom context with a rigid curriculum while confronting the gatekeeping role of school mathematics. CM teachers need to teach the required curriculum (i.e., teaching mathematics) to help their students advance their education and careers, but they also need to engage with their students around issues beyond the required curriculum (i.e., teaching students) to support their identities and power.

Comparing Three Cases of Critical Mathematics Teaching

To make meaningful cross-case comparisons, I selected three cases of CM teachers within seemingly similar contexts (i.e., minimized variation of context) with varying degrees of reported tensions (i.e., maximized variation of tensions). The selected teachers were: (1) Mr. Rico (his classroom name) in his own study (Gutstein, 2016); (2) Mr. Brantlinger in his own study (Brantlinger, 2013); and (3) Ms. Myles in Gregson's (2013) study. They all taught in urban secondary school settings where they predominantly served students of color from low-income communities.

In each case, I looked for the descriptions of social and cultural characteristics of the teachers, the students, and the schools from the articles. In addition, I looked for incidents of the teaching mathematics versus teaching students tension, and how the teachers negotiated this tension. The summary of the findings is presented in Table 1.

Discussion and Implications for Expanding CM Theories

Due to the seemingly similar teaching contexts of the three cases, I was surprised by the contrasting outcomes. Mr. Rico performed a skillful "dance" (p. 469) between mathematics content and critical and community content. Gutstein (2016) presented powerful evidence that illustrated how his students were able to use mathematics to understand the unjust society and to advocate for changes. On the other end of the spectrum, Brantlinger (2013) presented his unsuccessful experience of teaching CM to the students from similar demographic groups as Mr. Rico's students. He initially blamed his lack of experience and skills for the failure of his CM activities, but toward the end of the paper, he questioned if CM is a good fit for his urban students and his geometry course. Considering these two ends of the spectrum of CM teaching, I ask "What could have made their outcomes so different?" For one possible answer to this question, I now turn to the contexts of their teaching and consider the role that subtle differences in context might have played in shaping the tensions teachers experienced.

Differences in Teacher's Status and Power

Table 1 shows the various statuses of the teachers. Mr. Rico is a university professor, which affords him a certain degree of power within society. In general, professors are seen as people with more knowledge and professionalism than secondary teachers. Moreover, Mr. Rico was involved in the founding process of the school, and the school had consulted him for its teacher development programs. Being such an important figure in the school may have come with certain privileges: Mr. Rico was allowed to design his own curriculum for his course and to select mathematical topics that would fit well with his CM projects and his students.

Table 1: Summary of Three Cases

	Mr. Rico	*Mr. Brantlinger*	*Ms. Myles*
Teacher	University professor who was involved in founding process of the school and teacher development activities	Graduate student with 9 years of teaching experience	Full-time teacher with 12 years of experience with teaching and community organizing
Students	12th-grade students who chose Mr. Rico's class over 2 other options; Mr. Rico met with them twice prior to the school year.	Generally, older (18-19 years olds) students who are motivated to pass the course but not necessarily to learn	8th-grade students
School	Social justice focused high school	Night school with a vocational focus. It mainly serves students who failed a course in the day school or who have disciplinary issues.	Social justice focused school (grade 6-12) Ms. Myles plays a critical role to meet the federal requirement for the standardized exam.
Standardized Exam	Not required	Unknown	High-stake
Tensions	Not apparent. Mr. Rico skillfully interweaves mathematics and social justice goals.	Geometry content is not relevant to social justice topics; Students bypassed mathematics during the social justice discussions.	Time demand for social justice activities conflicts with the time needed for preparing for the standardized exam.
Negotiation	Moved his emphasis between mathematics and social justice so that these two types of learning support each other.	Incorporated statistic concepts that are out of the scope of the required curriculum; Separated mathematics and social justice portions of the lesson.	Downsized social justice project into a small problem-based lesson; Focused more on the test as the test gets near.

Mr. Brantlinger (a graduate student) and Ms. Myles (a full-time teacher), on the other hand, did not appear to have the luxuries that Mr. Rico had. In contrast to Mr. Rico, Mr. Brantlinger had to design his CM activities around the required geometry concepts although he did not see them as a good fit for his social justice activities. A similar tension was present in Ms. Myles's case: If the social justice activity required mathematics that was not emphasized on the gatekeeping assessment, the time needed for a social justice activity could consume the time needed to prepare for the assessment. In these two cases, a meaningful negotiation between teaching mathematics and teaching students required teacher autonomy to select mathematics content often not included in the required curriculum and on high-stake exams.

Differences in Students' Academic Goals and School Culture

Although all teachers predominantly had students of color from low-income communities, I noticed differences in students' academic goals in the respective mathematics classes and different foci of students' schools. Mr. Brantlinger's students being "more concerned with getting through his course for accreditation than for learning mathematics" (p. 1057) suggested that his students did not willingly choose the geometry class but, instead, were required to take the course for high school graduation. Moreover, the focus of his school was not social justice but vocational training. Considering the school's focus and the students' desire to obtain their geometry credits to move on with their post-secondary lives, Mr. Brantlinger's social justice activities likely came as a surprise for his students. In this sense, it appears reasonable for some of his students to perceive his social activities task as a distraction from their academic goals.

In contrast, the schools of Mr. Rico and Ms. Myles have an explicit vision and mission for social justice. Hence their students had more likely experienced social justice related topics in their previous classes, were less likely to resist social justice activities. Moreover, Mr. Rico's students chose his class out of three options for their fourth-year mathematics courses. He also met with the students twice prior to the school year to discuss the topics; thus his students were well informed about political contexts of Mr. Rico's CM course, and his students' academic goals were more likely aligned with the CM activities compared to the students of Mr. Brantlinger. This illustrates how the particular school culture and students' academic goals may support CM teachers to negotiate the tension in a meaningful manner.

The above comparisons of the three cases of CM offer the possible explanations to how the teachers took different pathways at the crossroads of CM in relation to their teaching contexts. This paper adds one more dimension to the theory of CM: teaching context, in particular, differences in teacher status and power, students' academic goals for the course, and school culture, may heavily influence the success/failure of CM. Similar to Brantlinger (2013) blaming himself, we often attribute the instructional success/failure to the teachers' knowledge, experience, or actions; however, this comparison offers another way to look at how the teachers negotiate the tensions of CM. The context, which is sometimes out of the teacher's control, can funnel the teacher into decisions that are far from ideal. This suggests we need to work not only from the inside (teachers and teaching) but also from the outside (broader teaching context), so that innovative teaching methods, like CM, can evolve and flourish.

DEWEY ON EARLY CHILDHOOD TEACHERS' EXPERIENCES LEARNING AND TEACHING MATHEMATICS

Sue Ellen Richardson
Purdue University
Richa114@purdue.edu

Using initial and debriefing interviews around a photo visual narrative inquiry (Bach, 2007), this pilot study aimed to create space for 10 early childhood teachers to explore and make sense of their experiences learning and teaching mathematics, as well as to hear their voices sharing detailed and nuanced views of their strengths, needs, and areas for growth related to mathematics teaching and learning. Components of Dewey's (1938/1998) experience construct, including continuity, interaction, social control, and subject matter were used to understand nuances of the teachers' experiences learning and teaching mathematics. Initial findings indicate that these teachers had negative mathematics learning experiences, but are now enthusiastic early childhood mathematics teachers, indicating that their experiences should be valued and explored in training, and by those who determine their training.

Keywords: Early Childhood Education; Teacher Education – Inservice/Professional Development; Instructional Activities and Practices; and Policy Matters

Purpose

Early childhood teachers ask why they are required to take college algebra courses in which they struggle and whose content is not related to the work they do with young children. Their question implies that expectations for their training and professional development are not well-aligned with their experiences of mathematics preparation or teaching work. I argue the teachers' perspectives and voices are not included in the dialogue about their mathematics training and teaching work. I aim to create space for early childhood teachers to explore and make sense of their experiences with mathematics. Also, I aim to give early childhood teachers a voice and platform from which to share a more detailed, nuanced view of their mathematical learning and teaching strengths, needs, and areas for growth. I report initial findings from a pilot study in which I joined with a community of early childhood teachers to explore their experiences learning and teaching mathematics with young children.

Perspectives and Theoretical Framework

Standards for professional preparation and early mathematics are well-aligned with the mathematics teaching work that teachers do (NAEYC, 2009, 2016; NAEYC & NCTM, 2002; NAECTE, n.d.). However, goals put forth in the standards do not always reach preservice and in-service teachers (Sarama & DiBiase, 2004). Accounting for that gap is a set of policy, funding, and social viewpoint quagmires (Grunewald & Rolnick, 2010; Heckman, 2008, 2011). Early childhood education policy and funding hail from all levels of government and not-for-profit agencies (US Dept. of HHS, 2014; United Way Worldwide, 2016). Social viewpoints range from understanding early childhood education as a salve for educational and social strife to babysitting (Phillips & Shonkoff, 2000). Researchers make suggestions for early childhood teachers' mathematics practices based on their own research observations (e.g., Parks & Blom, 2013). Missing is the perspective of early childhood teachers' professional voices. This multi-faceted research puzzle considers gender and mathematics (Brooks, 2007; Fennema & Sherman, 1977; Hancock, 2001), early childhood education as "women's work" (Kim & Reifel, 2010) and the social situatedness of teaching and learning (Edwards, 2003), which creates a need for a multi-pronged investigation approach.

A framework for delving deeper into teachers' lived experiences with mathematics, in order to understand nuances of their experiences (Clandinin & Connelly, 2000) and empower participants as early childhood mathematics is used. Dewey's (1938/1998) *experience* construct, including components *continuity*, *interaction, social control,* and *subject matter,* is used to understand nuances of early childhood teachers' experiences learning and teaching mathematics.

Research Questions

What role, if any, do mathematical learning experiences play in early childhood teachers' mathematics teaching practice? In what ways do their voices contribute to the professional dialogue?

Methods

This study used visual narrative inquiry methods (Bach, 2007) to situate the participants' experiences learning and teaching mathematics within the three-dimensional inquiry space, situating it within the teachers' mathematical history, classroom context, and social milieu.

Participants

Ten teachers in an early childhood lab school at a Midwestern state university participated. Participants included seven lead teachers, two assistant teachers, and one student teacher. Teachers had been at the center from one to 22 years. One assistant teacher has a four-course early childhood certificate, seven teachers have bachelor degrees related to teaching young children, and two have master degrees. The children in the classrooms range in age from two to 5 years, with 14 to 20 children in each classroom depending on age.

Data Sources

This study included three data collection activities: (1) initial semi-structured interviews with classroom teaching teams, regarding their experiences learning and teaching mathematics; (2) teaching teams and researcher photographing mathematical activity and materials; and (3) debriefing interviews during which each classroom teaching team described the mathematics captured in photographs taken by themselves and the researcher.

Analysis

Several rounds of analysis were conducted to gain a sense of the underlying relations and tensions (Clandinin, Murphy, Huber, & Orr, 2009) that teachers experience as they learn and teach mathematics. Initial interview questions were answered from the transcripts for each teacher. Passages from all initial and debriefing interview transcripts were marked for the main principles of Dewey's (1938/1998) *experience* construct, *continuity* and *interaction*. Additional components of Dewey's experience construct, *social control*, and *subject matter* were marked in each transcript. Anecdotal snapshots of each classroom were developed, and short narratives of each teacher were created that included a timeline and dominant themes found in their individual transcripts. From these pieces, narratives were developed of the teachers as learners and teachers of mathematics with young children, along with their philosophies. Photos related to transcript passages accompany the narratives.

Preliminary Findings

Here, data are related to components of Dewey's (1938/1998) experience construct.

Initial Interview: Union of Continuity and Interactions

E1 and D2 did not like geometry as students and had trouble learning it (internal condition), but as early childhood teachers, they have learned about geometry with and from the children and since developed engaging geometry activities (objective condition) (see Figure 1).

Figure 1. Geometry Activities.

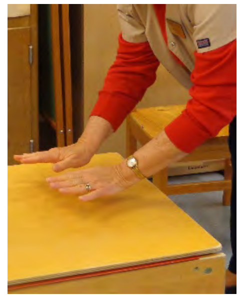

Figure 2. Table Rhythm.

Figure 3. Letters & Math

Photographing Mathematical Activity: Social Control

The researcher photographed S1 pounding rhythmically on the lid of the sensory table (see Figure 2). When asked about this photo, she explained that this is a routine used for multiple purposes: a signal to the children to clean up (which they do eagerly when they also get to pound), the children practice imitating and following, and they learn patterns and counting. S1 used her knowledge of the children's interests and subject matter in this routine that encourages social organization.

Initial and Debriefing Interviews: Subject Matter

D2 shared an activity that illustrates several facets of subject matter. She incorporates patterning into the lining up routine to both organize the children and connect an everyday occurrence to mathematics content. Children "keep track" (Dewey, 1938/1998, p. 110) of the pattern, reconstructing the experience daily, and self-correct as they line up or notify the teacher when they no longer have enough children to keep the pattern going as defined (i.e., more girls than boys mean a girl-boy pattern will end with a group of girls).

While examining photos, S1 and D2 were surprised as they noticed previously unrecognized instances of mathematics. Referring to the Table Rhythm photo (see Figure 2), S1 said, "Gosh, you know what? You don't think about these things. You do it so many times, you don't think about that. I guess I've never seen a picture of that before." D2 said (see Figure 3), "Look how many letters I have, and I was like, oh, my gosh. We've got math! So, I quickly found the camera and took that, and I guess this research project to me, more than anything, has made me more aware of math is in lots of places other than one plus one is two."

Discussion

Teacher interviews and photos analyzed using Dewey's (1938/1998) *experience* construct and components indicate that teachers' mathematical learning experiences influence their current practices, in their dispositions to learn mathematics from and with the children, and to make math "fun" so the children associate mathematics positively (Lenz Taguchi, 2005). The study afforded teachers an opportunity to uncover unforeseen mathematics practices, nurturing curiosity in their practices and understanding of children's mathematics. Teachers eagerly taught mathematics with young children, despite many having negative feelings from their own "mis-educative" (Dewey, 1938/1998, p. 13) experiences learning mathematics.

Early childhood teacher educators should respect the knowledge early childhood teachers bring to training, and help these teachers unpack meanings from their experiences. Also, this might indicate that grounding math methods or content in experiences *with* young children could more productively engage early childhood teachers who feel less competent in mathematics training settings (Philipp, 2008). A next step is for early childhood teachers to communicate their experiences to the funders and stakeholders who determine their training.

DO YOU SEE WHAT I SEE? CONNECTING MATHEMATICS TO THE REAL WORLD

Marcy B. Wood
University of Arizona
mbwood@email.arizona.edu

Kristin L. Gunckel
University of Arizona
kgunckel@email.arizona.edu

This study explored how three high school mathematics teachers thought about using real world connections to teach mathematics. Each of these teachers expressed beliefs about mathematical objects as entities that could be seen in the real world. This belief was connected to ideas about knowing mathematics as seeing these mathematical objects. This paper elaborates this epistemology of visibility and describes some of the implications.

Keywords: Learning Theory; High School Education; Affect, Emotion, Beliefs, and Attitudes

Most teachers, educational researchers, and policy makers agree that students learn best when mathematics problems are embedded in real world contexts. These real world connections support students by allowing them to use their prior knowledge and experiences to make sense of new mathematical ideas (e.g., NCTM, 2000). These connections can also prepare students for their careers and adult responsibilities.

In spite of widespread agreement about the benefits of real-world connections, there is limited research about teacher understandings of and uses of these connections in their classrooms. Gainsburg (2008) reported on *ways* in which teachers used real-world connections including the contexts they referenced, the format of problems, and the constraints they noted. Her detailed study provides an important overview of real-world contexts in secondary mathematics classrooms. Two other studies sought to make sense of *how* teachers understood and presented the real-world contexts in mathematics word problems. Chapman (2006) and Depaepe, De Corte, and Verschaffel (2010) examined the epistemological framings, or ways of knowing, teachers brought to the teaching of word problems. Both studies considered whether teachers focused on paradigmatic knowing, in which the key to knowing was to strip away the context and focus on minimal necessary information to reason to an answer, or on narrative knowing, in which the focus was on the social context of the word problem. The authors argued that students needed opportunities to consider word problems from both paradigmatic and narrative perspectives and that it was challenging for teachers to juggle these two different perspectives within a lesson.

These studies begin to paint a picture of teacher understandings of real-world contexts. However, they are necessarily only a small glimpse into what is an important component of mathematics education. In our study, we sought to add to this understanding of teachers' work with real world contexts. In particular, we wanted to better understand how teachers thought about mathematics in the real world and about what it would mean for students to come to know that mathematics.

Theoretical Framework

Earlier studies of epistemology and mathematics teachers' real-world connections focused specifically on paradigmatic and narrative framing of ways of knowing. While this provided interesting insights into teachers' perspectives, it was also a narrow lens on the nature of knowledge. In our study, we sought to add to this picture by considering how teachers' epistemological beliefs might be connected to their ontological beliefs.

Epistemology is the study of beliefs about knowledge and ways of knowing (Olafson & Schraw, 2010). For example, some people believe that knowledge is created or constructed by the mind and has no existence in the real world. Others believe that knowledge comes only from what one can

Galindo, E., & Newton, J., (Eds.). (2017). *Proceedings of the 39th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* Indianapolis, IN: Hoosier Association of Mathematics Teacher Educators.

sense. These beliefs are influenced by one's ontological beliefs, or beliefs about the nature of objects and of their existence (Kang, 2008; Packer & Goicoechea, 2010). For example, teachers may hold the ontological belief that mathematical ideas are entities that can be treated as though they were real-world objects. Ontological beliefs are connected to understandings of the nature of knowledge and of knowing so that some teachers might think that students need to interact with these mathematical objects in order to gain knowledge about them. These beliefs also influence teachers' instructional practices so that if teachers assume that mathematical ideas can be treated as real-world objects, they then design lessons in which students have opportunities to find real world examples of mathematical ideas.

In our study, we investigated the ontologies and epistemologies of mathematics teachers as they considered the role of real-world connections in teaching students.

Methods

This research was conducted in the context of a three-year master's degree program in mathematics and science education at a large research university in the Southwest. Three high school mathematics teachers from the master's program accepted our invitation to participate in the study. All teachers were within the first seven years of their teaching careers. They taught in suburban public, urban charter, or urban public schools. The student populations at the schools ranged from 28% to 59% receiving free or reduced-rate meals and were from 33% to 83% non-white. All teacher names are pseudonyms.

Data Collection

We conducted initial interviews with each teacher, asking about their goals and purposes for teaching mathematics, their ideas about what makes mathematics instruction relevant or authentic, and their perceptions of how real-world mathematics might relate to school instruction. We also observed and recorded field notes on a mathematics lesson in each teacher's classroom. We conducted pre- and post-observation interviews in order to learn more about each lesson. All interviews were recorded and transcribed.

Other data sources included selected written assignments from a graduate course taken the first summer of the program. Teachers wrote two short essays on prompts that asked them to reflect on (1) what curriculum is and what teachers should do to make connections among students, the disciplines of mathematics, and the real world; (2) a lesson that they had taught in the past that made connections between students, the school curriculum, and the "real world."

Analysis

For each teacher, we parsed their talk and writing into examples of real-world connections. We defined an example of a connection as a description of an activity, lesson, event, or student interaction in which the teacher attempted to involve students in learning mathematics or science by referring in some way to the real world. This process produced 18 examples.

We then open-coded (Esterberg, 2002) the data for each teacher, seeking themes in how the teachers talked about knowing mathematics in the real world. As we found patterns in these themes, we developed a set of categories and then recoded the data using those categories. The findings in this paper elaborate just one theme that emerged from the data.

Findings

Knowing is Seeing

When the teachers talked about students and mathematical ideas, they frequently used discourse that either literally or metaphorically referenced seeing as a way to know mathematical objects. This talk aligns with other expressions used to describe knowing or understanding. For example, we might exclaim, “I see” when we suddenly grasp an idea. This phrase suggests that we understand knowing, at least metaphorically, as a kind of seeing.

For example, one teacher, Brian, described the difference between teaching as giving and teaching as showing:

> I’ve gotta teach them the basic principles, I need them to *see* why that they can do what they’re doing, ya know. For instance, the quadratic formula, I could give that to them. I could say here is the quadratic formula, let’s divide the square root. But then if I tell them, let’s use it in this problem, they don’t know what it means. They don’t know where it comes from, and they just don’t *see* the use of it. Whereas if I go though it with them and actually *show*, here, here’s how you do a *y*, the actual quadratic formula, they *see* the purpose behind it. They *see* the understanding and so … they know how it works. [Italics added.]

Brian started this response by describing the problems with a transmission model of learning in which he would merely *give* the quadratic formula to students. In contrast, he felt it was important for students to *see* where the formula comes from. If they saw the purpose of the formula, they would then understand it and could use it to solve problems.

Another teacher, Rohit, said,

> I show them [students] one video where the parabolas can be used. For example, most of the antennas and antennae dish are parabolas and so we can *see* the focal point. Or the headlights of the car and porch lights; all these are to *see* the parabolic shape inside and built there. And then they connect the parabolas, what they learn in here, to the real life applications and it’s kind of a little bit fun…It makes a little bit [more] sense to them why they’re learning parabolas and all that stuff. [Italics added]

As students learned to see parabolas in a variety of real world objects, they would understand why parabolas were important to learn about.

These are just two examples of seeing. Of the 18 total examples of real world connections, seven contained instances of what we are calling an *epistemology of visibility*. In other words, these teachers seemed to think about knowledge as seeing mathematical objects. While this epistemology of visibility was not the only framing of knowing used by these teachers, it was striking that each of the teachers made numerous references to seeing as knowing.

Mathematical Ideas Exist

This framing of knowing as seeing seems to arise from the teachers’ thinking about the nature of mathematical knowledge. When teachers discussed their efforts to connect mathematics to real world perspectives, they consistently described mathematics in terms of real objects that could be found in the world. For example, in a lesson on congruent triangles, one teacher (Jessica) pointed out examples of congruent triangles in structures surrounding the school, including bus stops and high-rise cranes. In his quotation above, Rohit talked about parabolas as though they were real entities that could be visibly perceived.

The notion of a visual aspect to knowing mathematics is not new. However, studies of visualization in mathematics are typically focused on visual representations and contrast those to nonvisual representations such as algebraic equations (Rivera, 2011). In contrast, these teachers talked about equations as though they were objects that existed and could be known through seeing them.

Conclusion

In this study, we noted a novel epistemology, one that we are calling an *epistemology of visibility*. In this epistemology, teachers hold ontological beliefs that mathematical ideas are objects that are visible (either literally or metaphorically) in the real world and that knowledge of these objects is gained by seeing the objects in the world. In other words, the work of teaching is showing mathematical objects and processes to students so that they might come to know them.

This epistemology is an important variation on the commonly discussed epistemology of knowledge as received. Received knowledge epistemologies frame knowledge as something that can be conveyed or transferred from the teacher to the student. Knowledge is information like facts that can be organized into discrete bundles. Learning is about taking in these facts. In contrast, an epistemology of visibility is less about knowledge transfer and more about coming to see or notice objects. The knowledge is not contained within the mind of the student, but is instead present in the world and noticed by anyone who looks.

This finding offers important insights into teachers' attempts and frustrations in using real world examples to teach mathematical ideas. Teachers are sometimes puzzled when students, whose mathematical vision is not the same as the teachers, fail to see, or become enthusiastic about, mathematical objects that are so obvious to teachers. Teachers may also fail to understand how students cannot grasp a mathematical explanation that is so clearly illustrated in real world phenomenon.

Real world connections can be an important learning resource for students. However, if teachers are going to make the most of these connections, they may need to reflect upon their epistemological beliefs and consider how their teaching relies upon a way of seeing that may not yet be possible for their students.

Observing and responding meaningfully to students' thinking is a key component of effective teaching. In this regard professional noticing of students' mathematical thinking has become an important area of study in mathematics education. Researchers have examined the effect of teachers' experiences on their abilities to notice, however less work has been done examining the role of cognitive and psychological factors on what and how teachers notice. In this study, we sought to explore if and how these constructs, specifically teacher efficacy, emotions and mathematical knowledge for teaching, influenced how and what teachers were able to notice.

Keywords: Mathematical Knowledge for Teaching; Affect, Emotion, Beliefs, and Attitudes

Purpose of the Study

To teach effectively, teachers must attend to students' thinking during the act of teaching and make in-the-moment decisions about the best ways to respond to what they observe (Ball and Cohen, 1999). In efforts to better understand what teachers observe, how they respond to it and how it can be influenced, over the past few years a significant body of work (e.g. Sherin & van Es, 2009) has emerged documenting the role teacher noticing has played in teacher learning and subsequently improvement of instructional practices (Sherin, Jacobs & Philipp, 2010). Some of the work on teacher noticing has focused on the differences in what and how teachers' notice concluding that expert teachers tend to interpret and recall classroom events with greater detail and insight than novice teachers.

Although researchers have examined the effect of teachers' experiences and professional development on teachers' abilities to notice students' thinking, less work has been done examining the role of cognitive and psychological factors on what and how teachers notice. In particular, we were interested in the relationship between the teachers' mathematical knowledge for teaching (MKT) – specifically their common content knowledge (CCK) and their knowledge of content and students (KCS) -, emotions, efficacy, and their level of noticing. In this study, we explore if and how these constructs influenced how and what teachers were able to notice.

Theoretical Framework

We know from research that teachers' mental lives greatly influence their teaching experiences (Schutz, Hong, Cross & Osbon, 2006), commitment to the profession and overall wellbeing. However, absent from the literature are the ways in which specific cognitive and psychological constructs, such as MKT, TE and emotions, influence teachers' instructional activity, specifically noticing. A growing body of literature on emotion and cognition has shown that one way in which emotional valence influences an individuals judgment is by foregrounding and making accessible emotion-congruent information in memory (Forgas, 2001). So individuals experiencing positive emotions tend to identify and recall positive memories more easily than negative memories, and vice versa (Bower, 1981; Forgas, 2001;). Subsequently, individuals in a positive emotional state tend to evaluate people, places, and events more favorably than people in a negatively emotional state (Forgas, 2001). As such, the emotions teachers experience as they engage in noticing may influence what and how they notice. Teacher efficacy (TE) is defined as a teacher's belief about her capacity to affect how students learn and their overall performance (Tsachannen-Moran, Woolfolk-Hoy & Hoy, 1998) and has been shown to influence teachers' willingness to adopt and enact particular instructional practices. Knowledge efficacy related to mathematics describes a person's confidence in his/her understanding of mathematics content (Roberts & Henson, 2000). Personal efficacy describes a person's confidence in his/her ability support students' learning through their teaching. Teachers with a strong sense of efficacy tend to exhibit greater levels of planning and organization, are more open to new ideas and more willing to experiment.. Mathematical knowledge for teaching (MKT) encompasses deep knowledge of math concepts and the knowledge and skills to attend to students' thinking during the act of teaching and make in-the-moment decisions about the best ways to respond to what they observe (Ball and Cohen, 1999).

Methods

This study involved eight elementary teachers who were involved in a professional development program. The teachers were each involved in coaching with each coaching cycle consisting of a pre-meeting, post-meeting lesson planning, the coaching session and a post-coaching meeting. All meetings with the teachers were audiorecorded and the coaching session, in which the coach supported the teacher during the teaching of a lesson, was videorecorded. Data for this study was drawn from the videorecordings of the coaching sessions, and the audiorecordings from the post-coaching meetings. Teachers also stated the emotions they experienced prior to, during and after the coaching experience. They also completed the adapted SETAKIST (Self-Efficacy Teaching and Knowledge Instrument for Science Teachers) for Teachers of Mathematics. The 16-item, 5-point Likert scale survey was scored to determine a score for personal (8 items reversed scored with a score of 8 being high) and knowledge efficacy (8 items with a score of 40 being high). All teachers completed the MKT surveys. The raw scores were converted to IRT scaled scores then aligned with a percentile value. Scores above the 80^{th} percentile indicated high MKT, between 61^{st} and 79^{th} percentile medium MKT, and below 61^{st} indicated low MKT. To classify their noticing, we first watched the coaching video and selected clips that focused on students' thinking. We also asked the teachers to select three videoclips he/she wanted to discuss with the coach in the post-coaching meeting. Then we used Van Es (2011) noticing framework (Fig. 1) to analyze the clips the teachers selected to determine what and how teachers noticed and compared the emotions they stated, their efficacy related to mathematics teaching and their level of MKT.

Findings

For the purposes of this proposal, we present the results of two cases to show the relationship between teachers' emotions, TE, MKT and *what* and *how* they noticed.

Table 1: Results of Analyses of Teachers' Noticing, MKT, TE and Emotions

	Noticing		MKT		Emotions			Efficacy	
	What	How	KC	KCS	Before	During	After	KE	PE
Bill	Level 3	Level 3	High	High	Nervous/ Anxious	Nervous/ Uncomfortable	Nervous/ Uncomfortable	Mid	Low
Kathy	Level 3	Level 1	Low	Low	Indifferent/ Excited	Calm	Calm	High	High

We observed that the teachers were attending to students' mathematical thinking to some extent. In the cases of Bill and Kathy who both scored level 3, although they were attending to students' mathematical thinking, they were not consistent in making explicit connections between what they noticed and the teaching strategies they observed. In contrast to the score on *what* they noticed, there was variation in how they noticed. Bill identified significant events that showcased students' thinking, and explained why it was noteworthy drawing evidence from the videoclip. For example, one of the clips Bill selected to discuss was one where a student drew connections between the organization of base 10 blocks into recursive groupings of 10 to the way stickers, packets (10 stickers in a packet) and envelopes (10 packets in an envelope) were being used in a place value activity. Bill selected this clip because the student was able to recognize the similarities between the groupings of smaller units into larger units around the base of 10 showing his growing conception of place value. Although Kathy identified a clip that showed students' reasoning about number patterns as noteworthy, she did not discuss how her teaching strategies were linked to the students' ability to identify number patterns. She also made general comments about the difficulty grade one students experience in identifying number patterns, without any evidence, justification or suggestions of pedagogical approaches that would support their learning.

	Level 1	Level 2	Level 3	Level 4
What teachers notice	Attend to whole class environment, behavior and learning to the teacher pedagogy	Primarily attend to teacher pedagogy	Attend to particular students' mathematical thinking	Attend to the relationship between particular students' mathematical thinking and between teaching strategies and mathematical thinking
		Begin to attend to particular students' mathematical thinking and behaviors		
How teachers notice	Form general impressions of what occurred	Form general impressions and highlight noteworthy events	Highlight noteworthy events	Highlight noteworthy events
	Provide descriptive and evaluative comments	Provide primarily evaluative and some interpretive comments	Provide interpretive comments	Provide interpretive comments
	Provide little or no evidence to support analysis	Begin to refer to specific events and interaction as evidence	Refer to specific events and interactions as evidence	Refer to specific events and interactions as evidence
			Elaborate on events and interactions	Elaborate on events and interactions
				Make connections between events and principles of teaching and learning
				On the basis of interpretations, propose alternative pedagogical solutions

Figure 1. Noticing framework.

We observed that there was alignment between high MKT and strong noticing abilities. Bill, who had high MKT also scored on average at level 3 with respect to what and how he noticed. However, Kathy who scored low on MKT, was level 3 on what she noticed and level 1 how she noticed. These results would suggest that to be able to identify significant incidents of students' mathematical thinking and to attend to the relationship between such thinking and teaching strategies (key aspects of high level noticing) requires deep understanding of mathematical concepts and how students make sense of mathematical ideas (key aspects of MKT). On the other hand, low MKT may not be a significant in order to attend to particular students' thinking but essential to making connections to instructional practices.

The relationship between teachers' efficacy, their MKT and how they noticed was interesting. In particular, Bill had mid-low scores for both knowledge and personal efficacy, yet he had high levels of MKT and noticing. In contrast, Kathy had high scores for efficacy but demonstrated low levels of MKT and noticing. We also observed that unpleasant emotions, such as anxiety and nervousness was positively related to how teachers noticed, while more pleasant emotions aligned with lower scores on how they noticed. In this context, we believe teacher efficacy may have a significant influential factor, in that Bill had fairly low confidence in his knowledge of math and teaching which may have encouraged him to pay more attention to students' thinking in the class as well as how his teaching actions supported or hindered students' reasoning. It may also have contributed to his feelings of anxiety throughout the experience. On the other hand, Kathy was very confident about her knowledge of mathematics and teaching so she may have attributed any struggles students had to the individual student, or students in general, therefore not focusing attention on how her teaching actions may have influenced their thinking. Overall, low knowledge and high efficacy aligned with more pleasant emotions, while high knowledge and low efficacy aligned with unpleasant emotions (e.g., nervousness, anxiety).

Discussion

It's not surprising that a teacher with strong MKT is able to identify significant mathematical events, interpret them meaningfully and connect them with instructional practices. This finding aligns with existing research that suggests that high quality teachers are skilled at effectively utilizing students' thinking to drive instruction. Of note however is that a teacher with low MKT can also attend to students' thinking but may struggle to interpret the thinking or meaningfully connect it with pedagogical solutions. Our findings suggest there may be other factors at play or there are dimensions of MKT that may better support noticing. In this regard, the relationship between teacher efficacy and noticing provides some insight. Being overly confident about one's mathematical knowledge and teaching may negatively influence a teacher's response to observed students' thinking, in that the teacher may overlook the ways teacher moves influenced students' thinking (particularly in the case of errors or misconceptions) or may not have the knowledge needed to make connections to principles of teaching and learning or to propose alternative solutions. Further examination of the full corpus of data should provide greater insight into the nature and strength of the relationship among these constructs.

HOW STUDENT QUESTIONS IN MATHEMATICS CLASSROOMS ARE RELATED TO AUTHORITY DISTRIBUTION

Melissa Kemmerle
University of Michigan
mkemm@umich.edu

This paper analyzes the questions students ask in two very different middle school mathematics classrooms. Both classrooms were taught by experienced and respected mathematics teachers, but the instruction was very different between the two classrooms. Mr. Cordoba characterized his instruction as student-centered, project-based, and focused on understanding. Mr. Ezzo used a more traditional approach. Classroom instruction was videotaped, student questions were highlighted and categorized, and instructional moves were analyzed. Results show that authority distribution in the classroom is connected to the types of questions students ask in mathematics lessons.

Keywords: Classroom Discourse, Middle School Education, Equity and Diversity

Objectives and Framework

Studies show that teachers who distribute authority within their classrooms promote more productive discourse than teachers who maintain all the authority with themselves and with the textbook (Herbel-Eisenmann, 2007). An important component of classroom discourse is student question asking. This study seeks to build on Herbel-Eisenmann's work by showing that the types of questions students ask in mathematics lessons are linked with the way authority is distributed in the classroom.

Methods

Two middle school mathematics teachers, Mr. Cordoba and Mr. Ezzo, were selected for this study because their students frequently ask questions in whole-class lessons and their instructional styles are very different from one another. Mr. Cordoba engages in complex instruction (Cohen & Lotan, 2014) and asks students to collaborate (more than half of class time is spent in small group work). He presents his students with tasks that require high cognitive demand (Stein & Smith, 1998) and states that students should be "active participants in mathematical activity through generating and discussing mathematical ideas in class." Mr. Ezzo's approach is what some might call traditional: every day class begins with a scoring of the previous night's homework followed by a lecture on new material. Each night for homework, students in Mr. Ezzo's class solve mostly context-free problems in the precise way they were taught by their teacher.

Data for this study consisted of approximately 15 hours from each teacher of transcribed videotape of whole-class lessons (i.e. small group work was not transcribed). Extensive field notes, semi-structured interviews with each teacher, and student surveys were also used. All student questions were highlighted in the transcripts. These questions were then counted and coded using a categorization schema (Kemmerle, 2016) designed to highlight the different kinds of student questions asked during mathematics lessons. See Table 1 for a selection of the categories that showed up most frequently in the data.

During whole class lessons, students in Mr. Cordoba's classroom asked, on average, 11 questions per hour and these questions most often fell in the Mathematical Curiosity/Extension, Visual Representation (Conceptual), and Seeking Conceptual Information categories. Students in Mr. Ezzo's classroom asked, on average, 56 questions per hour and these questions most often fell in the Correct Answer, Form of Answer, and Meeting Teacher's Expectations categories.

Next, the video transcripts and interview transcripts were open-coded (Glaser, 1978) for instructional moves or instructional philosophies that might affect the questions students ask, and it was found that distribution of authority (Cobb, Gresalfi, & Hodge, 2009; Boaler, 2012) appeared to be related to the types of questions students asked during their mathematics lessons.

Table 1: Abbreviated Categorization of Student Questions in Mathematics Classrooms

Question Category	Examples from Transcripts
Form of Answer	-Do I have to show it as a repeating decimal, or can I round up? -I didn't simplify, is that okay?
Correct Answer	-I got 74%. Is that right? -But what is the answer?
Assessment/Grading	-Could I get extra credit for this? -Can we do any of these ways on the test? -How many points are on the quiz?
Meeting Teacher's Expectations	-Wait, do we copy down the percents bar model too? -Do you want us to draw it or label all the points?
Seeking Procedural Information	-How did you get 16? -What is your shortcut for filling in your t-table?
Seeking Conceptual Information	-Wait, how is it 3 out of 5? -Why did you have to cross out the 40 and the 10?
Visual Representation (Conceptual or Informational)	-If your x were to get bigger and then the trend line, would your points, can it ever cross the x line? -Where would it be on the graph?
Mathematical Curiosity/ Extension	-Can *k* be an odd number, like 27, and could you still have *x* and *y* be the same number? -If k were to be bigger and the k was negative, where would it be?

Findings and Conclusion

Mr. Cordoba and Mr. Ezzo handled authority very differently in their respective classrooms. During whole class discussions, Mr. Cordoba almost always stood in the back or at the side of the classroom and asked students to present ideas to each other. During one lesson, a group of four students gave a presentation to their classmates about indirect variation ($y=kx$). After their presentation, a few students in the audience asked fairly simple questions such as "Could you please repeat your summary statement because I couldn't hear?" and "What was your *k* because I don't see the point on the graph?" At this point, Mr. Cordoba instructed the class on what kind of questions he expected from them. He said,

> You guys have done a good job asking clarifying questions. Like I especially appreciate whoever asked Sophia to clarify her [ideas] because the first time I didn't know what she was talking about, but the second time I understood it much better. Now I'm wondering if you have questions that would, not just clarifying questions, but questions that would push them further. Let me say why I'm saying that. Three of you have really clear summary statements. Remember I am looking for the summary statements to include statements about the graph, t-tables, and reasons and I don't think any of you covered all three of those. So [to the audience] can you think about what you heard from each of them and ask them a question that pushes a little bit, so they can get full credit just like everybody else?

There are multiple norms depicted in this excerpt. First, Mr. Cordoba thanks the audience for being helpful. He also makes it clear that they are a community of learners, responsible for each other's success. The audience is expected to listen carefully and take their peers' explanation of mathematics seriously. Mr. Cordoba thus shares his authority with the four group members who are presenting; he expects them to explain their thinking using "graphs, t-tables, and reasons." His expectation that the presenters use mathematical representations and reasons requires the presenters to first understand the content and second to explain it in a convincing way. Mr. Cordoba requires them to be the experts who have real mathematical knowledge to present to the class. In addition, he expects the audience to also have knowledge and understanding and to share in the responsibility of pushing the community forward in their mathematical understanding and their ability to explain it to the class.

Immediately after Mr. Cordoba's statement, audience members proceeded to ask the presenting group questions that fell mostly into the Mathematical Curiosity/Extension and Visual Representation—Conceptual categories. Here is a partial excerpt from the transcript:

Student from Audience: Did you notice any patterns on your t-tables?
Student Presenter: I noticed that when x was smaller, it had a bigger y and when x was bigger it had a smaller y.
Student from Audience: Is there a way that your point could cross the x and y axes?
Student Presenter: No, it could not, because in order for it to cross, a number times zero would have to equal 16 and a number times zero is zero, so it couldn't cross.
Student from Audience: Are any of you guys, do you know what would happen if your k was negative?
Student Presenter: What would happen to what?
Student from Audience: If your k was negative, would you notice any patterns?
Student Presenter: My graph, if my k value was negative, then I would have to multiply a negative number by a positive number to get my negative k so it would be down here (points to graph), depending on if the x number is negative or the y number is negative.

The shift in authority is clear here. Students are the source of mathematical ideas for each other. Student questions from the audience guide and direct the discussion. Mr. Cordoba is not the source of all mathematical knowledge; instead, he encourages students to ask each other and answer meaningful questions, thus shifting expert authority away from himself. On other occasions, Mr. Cordoba said the following statements to students who were asking questions to the presenting group, "Can you try your question again because what you are asking is really important and here's why…" and "I'm really glad you asked that, Luis" and "That's a good question, Carlos, did you understand her answer?" These statements encourage students to ask meaningful and productive mathematical questions.

In Mr. Ezzo's classroom, in contrast, the teacher stood in the front of the classroom almost 100% of the time and was the only person in the classroom who wrote on the Smartboard. When a student Emily asked, "I didn't simplify, so is that okay?" Mr. Ezzo replied, "No, that's wrong. Sorry." This simple statement implies that Mr. Ezzo is the ultimate authority on whether or not an answer is correct or incorrect. During a daily homework check, the following dialogue occurred:

Monique: When you do 21 over 25, is that the fraction?
Mr. Ezzo: Yes, that's the fraction and you have to convert it to a decimal and a percent.
Emily: And you already have the fraction, but no, [the textbook] says to write a fraction and a percent, so the answer would actually be…
Mary: Do we have to draw it like that?
Emily: It says to write a fraction and a percent, so would the answer be 21 over 25 *and* 84%?

Mr. Ezzo: I'm going to answer Mary's question first, Emily, and then I'll come to you.
Emily: Sorry.
Mr. Ezzo: That's okay. So how did you do it, Mary?
Mary: I just wrote the steps…
Mr. Ezzo: Perhaps you did it like this…(writes on board). My friend Mary punched 21 divided by 25 into her calculator and the calculator said 84 hundredths, and she converted the 84 hundredths into 84%.
Emily: But wait, what's the answer then?
Mr. Ezzo: 84%
Emily: Yeah, but it says fraction *and* a percent, so would it be 21/25 *and* 84%?
Mr. Ezzo: Uh yes, so I'm looking for this (points to the two forms of the answer on the Smartboard).

In this excerpt we see that not only is Mr. Ezzo considered the authority on mathematics in the classroom, but also the textbook is revered as authority. Throughout his lessons, Mr. Ezzo encouraged students to participate and he was kind, but his statements such as "That would be wrong, dear" and "Yes, that is correct" indicate that students should look to him as the authority and rely on him to determine the mathematical validity of their work. Mr. Ezzo's students asked many more questions per hour than Mr. Cordoba's students, but this is, in part, because most questions in Mr. Ezzo's class can be answered in a quick and concise (sometimes yes or no) way.

The data above show that authority distribution in a mathematics classroom impacts the types of questions students ask. Through focusing on authority issues as well as reflecting on the types of questions we want students to ask, we can help teachers begin to see themselves and their students as mathematicians at work together. This does not mean that teachers need to relinquish authority completely, but rather to share authority in a community of inquisitiveness, respect (for each other and for mathematics), and productivity.

MASTERY-BASED GRADING: AN EXPLORATION OF ONE TEACHER'S IMPLEMENTATION OF REFORM GRADING PRACTICES

Michelle A. Morgan
University of Northern Colorado
Michelle.Morgan@unco.edu

The following paper is a brief report of a qualitative case study of a mathematics teacher as he planned for and implemented instruction in a mastery-based learning classroom. This study took place at a college preparatory high school in a large community in the Rocky Mountain region. Interviews, classroom observations, and lesson reflections were collected over the course of one week. The data were analyzed for common tensions that arose within the teacher's activity system. A rich description of the teacher's experiences includes a discussion of how timing and content coverage, lack of student preparation, and mastery-based grading impacted how the teacher planned for and implemented instruction.

Keywords: Teacher Beliefs, Instructional Activities and Practices, High School Education

Successful mathematics teaching involves navigating a complex series of decisions and consequences with respect to how teachers engage in classroom instruction (Schoenfeld, 2008). Schoenfeld (2008) argued that mathematics teachers mold classroom instruction by identifying goals and designing classroom activities to achieve those goals. Specifically, teachers are constantly making decisions, some obvious and other less so, which impact the flow of classroom activity. The purpose of this qualitative case study was to explore the planned and unplanned decisions made by a mathematics teacher, and how those decisions impacted instruction and student learning opportunities as classroom instruction continued from one day to the next. This paper will focus on the first of three research questions: *What do secondary mathematics teachers attend to during the lesson planning process?*

Methods

Mr. Jones is a secondary mathematics teacher who was working towards implementing reform teaching practices. During the time of the study, Mr. Jones was in his fourth year of teaching at a college preparatory high school in a large community in the Rocky Mountain region. This research study focused on Mr. Jones' planning and implementing instruction in an upper-level, college preparatory mathematics course, which covered topics studied in a traditional college algebra course. Students in the course included sophomores, juniors, and seniors of whom Mr. Jones described most as being of advanced ability level.

A semi-structured initial interview was conducted to understand Mr. Jones' initial plans for the observed lessons. In addition to instructional plans, the interview focused on better understanding the classroom norms, students, and typical lesson design for the class under consideration. That is, the initial interview was intended to gain an understanding of Mr. Jones' initial *activity system* (Engestrom, 2015). Data collection involved audio- and video-recording lessons during one week of the focus course. Additionally, Mr. Jones was asked to record a lesson plan summary prior to teaching each lesson his goals and plan for the upcoming lesson, his rationale for the flow of the mathematical concepts, and other lesson plan decisions. During the day following the last classroom observation, Mr. Jones participated in a stimulated-recall interview during which he was asked his perspective on the success of the observed lessons as well as to reflect on specific, video-recorded episodes of classroom instruction.

Cultural-historical activity theory (CHAT) is a perspective of human cognition which takes as its minimal unit an *activity system* consisting of six components: subject, object, instrument, community, division of labor, and rules (Engestrom, 2015). Activity systems transform when tensions or contradictions emerge between or within the components of an activity system. With respect to the mathematics classroom, these tensions or contradictions have a direct impact on what the teacher attends to when planning for and implementing instruction. In the present study, all interview and classroom observation data were transcribed and coded based on the CHAT coding scheme developed by Herbst and Chazan (2012). Specifically, coded data were analyzed for common themes in the form of tensions or contradictions within the transformation of Mr. Jones' classroom *activity system* over the course of the observed lessons.

Mastery-Based Learning

A significant characteristic of Mr. Jones' teaching philosophy and classroom policy is his use of something he called *competency-based grading*; this is commonly called *mastery-based grading* (Vatterott, 2015). Mastery-based learning differs from more traditional learning philosophies in that "instead of teach, test, and move on in one large group, learning is a series of masteries for individual students – teach, check for understanding, apply learning, get feedback, revise learning, and get more feedback until mastery is achieved" (Vatterott, 2015, p. 29). Students are given a list of learning targets on which they must demonstrate mastery by the end of a learning term (e.g., a semester). Over the course of that learning session, students will be given multiple opportunities to demonstrate mastery with only their best attempt being used as part of final grade calculation (Vatterott, 2015). Implementation of this learning model requires a fundamental shift in classroom activity from a teacher-centered classroom to a more individualized, student-centered classroom (Vatterott, 2015).

Summary of the Activity System

Analysis of data self-reported by Mr. Jones during his initial, semi-structured interview provided insights into his activity system (Engestrom, 2015). The following is a summary of the subject, object, instruments, community, division of labor, and rules.

Mr. Jones expressed enjoyment in learning mathematics. He believed that this stemmed from mathematical problem-solving and the tools mathematics provides for problem-solving in the real-world. He believed that it is important to make meaningful connections between the mathematical concepts being taught and the real-world applications of that content.

Mr. Jones expressed both short- and long-terms goals. These are the object of his activity system (Engestrom, 2015). For the short-term, he wanted to focus on two main goals: (1) review of previous content and (2) introduction of new content. Specifically, he wanted to give his students an opportunity to go back and review the mathematical concepts, or learning targets, that were missed on the most recent quiz as well as move forward with an exploration of functions with the ultimate goal of discussing inverse functions. As for long-term goals, Mr. Jones acknowledged that there was a set amount of curriculum that he was expected to cover during the semester. This was especially the case in the observed course as it was the first in a two-course sequence.

Mr. Jones noted several instruments that he utilized during lesson planning and instruction. These instruments, or tools, included a list of objectives for which students needed to demonstrate mastery, a school resource website, and the course curriculum. Based on prior courses, Mr. Jones had a complete map of the course over the entire academic year. This resource served as a pacing guide and as a list of objectives for achieving mastery. With the goal of being able to spend more time in class on exploration, Mr. Jones utilized an online course website where he posted class materials and links to videos for students to watch. In addition, this website included discussion boards that Mr. Jones used to identify student misconceptions and prior knowledge before class instruction. As a college-preparatory course, Mr. Jones was restricted by an official curriculum. However, he used this curriculum as a resource for identifying mathematical tasks and course activities. In addition, he used previous exams as a resource for developing new assessments as well as homework assignments.

Mr. Jones identified multiple members of the community which had either direct or secondary impact on his lesson planning process. In addition to himself, this community included his students, their parents, students in another section of the same course, the members of the mathematics department, and the administrators in the school district. His students consisted of multiple grade levels who, in Mr. Jones' estimation, had varying degrees of academic maturity, desire to learn, and mathematical understanding. Based on his philosophy of mastery-based grading, this was expected and encouraged. Mr. Jones believed that his students' parents were supportive of this new grading policy because many expressed a dislike for learning mathematics and, therefore, valued any attempts to teach it better than what was their experience. Mr. Jones perceived support for his implementation of mastery-based learning practices from both the other members of the mathematics department as well as administrators in the school district.

With respect to his classroom, Mr. Jones described the division of labor in terms of his role as the teacher and his students' role as a class or individual students. As the classroom teacher, it was his responsibility to present the content in such a way that makes mathematical connections clear as well as makes the mathematical concepts relevant to students. In contrast, Mr. Jones expected his students to be active participants during class instruction. Mr. Jones believed that it was important for students to ask questions. Mr. Jones encouraged his students to be reflective learners. Students were expected to work continually towards mastering the course content.

Mr. Jones focused primarily on how the philosophy of mastery-based learning influenced his classroom expectations. He argued that students shouldn't stop learning following a test and that students should be able to improve their grade. As a result, it was the expectation that students would continue to work towards mastering the learning targets covered by a specific test. Mr. Jones implemented a *soft deadline* when it came to collecting homework. That is, homework was never truly due and students had access to a complete answer key. In Mr. Jones' view, homework was a formative opportunity for students to measure their progress towards mastery.

Lesson Planning Tensions

Data analysis revealed three *lesson planning tensions* that were pervasive over the course of the week of instruction. These tensions involved timing vs. content coverage, lack of student preparation, and mastery-based grading.

Timing vs. Content Coverage

Mr. Jones expressed concerns about taking the time to explore concepts in depth while making sure that all important mathematical concepts were addressed. Adding to the complexity of this issue, the mastery-based learning model, adopted by Mr. Jones, emphasized that learning is individualized where students are given the opportunity to work at their own pace. This manifested itself as a tension among the object, instruments, and rules within Mr. Jones' activity system. Mr. Jones found himself having to make instructional decisions during lesson planning that took into consideration a balance of coverage, timing, and individual student needs. This resulted in a fewer application problems than he would have liked to have done.

Lack of Student Preparation

In order to help reduce the amount of content coverage needed during class, Mr. Jones implemented an online course website where he posted resources for students to learn basic skills prior to attending class with the hope that class time could be spent focusing on more advanced problems and topics. Students were expected to complete discussion board questions in order to help

Mr. Jones gauge student understanding. During the observed lessons, students were not completing these pre-class tasks. This tension among the object, division of labor, and rules within Mr. Jones' activity system forced Mr. Jones to modify his desired lesson plan. Instead of focusing on exploratory activities aimed at helping students grow their understanding as well as provide time for students to go back to prior concepts, he spent more class time engaging in direct instruction in order to cover all of the concepts necessary for class.

Mastery-Based Grading

A significant component of Mr. Jones' mastery-based learning model was the policy that students would only be graded when they were able to achieve mastery of a particular concept. When a student achieved the basic level of mastery, they were given an 80% in the gradebook, otherwise they were given a 0% in the gradebook. Students could improve their grade above an 80% by working beyond basic mastery. This policy caused a tension between the community and the rules within Mr. Jones' *activity system*. For many of his students, this was their first experience with this type of grading system. During the week of observations, the students were returned their first quiz. On this quiz, there were quite a few missing, or below mastery, scores. As a result, there was a significant amount of stress surrounding their grades. Mr. Jones spent time during every lesson reassuring students that their grades will improve as long as they put forth the effort to obtain content mastery. This caused Mr. Jones to reduce the amount of time spent on instruction than he had planned.

Discussion and Future Research

This case study focused on the experiences of a single mathematics teacher while planning for and implementing instruction in a mastery-based learning classroom. For Mr. Jones, timing and content coverage, lack of student preparation, and mastery-based grading impacted how he planned for and implemented instruction over the course of the week of observed instruction. His instructional issues were supported by general education literature focused on *mastery-based grading* (Vatterott, 2015). However, there is limited available literature focused on implementation of these models in mathematics classrooms. Future research is needed to explore how *mastery-based grading* models can be implemented in mathematics classrooms.

Lesson planning is a focal activity in elementary teachers' teacher preparation, however existing research suggests that teachers' lesson planning practices shift as they enter the profession. In this paper, we report results from a large-scale project that interviewed 99 early career teachers (ECTs) about their planning for mathematics lessons twice during the 2015-2016 academic year. We analyzed transcripts to determine factors related to lesson planning, including when they conducted their planning, who they planned with, and what resources they used when planning. Our findings also shed light on district-level influences on teachers' use of resources when planning.

Keywords: Elementary School Education, Instructional Activities and Practices, Policy Matters

Introduction

Following the widespread adoption of the Common Core State Standards (NGA & CCSSO, 2010) and the accompanying federal reforms such as Race to the Top, early career teachers (ECTs) have faced unprecedented pressure to fulfill expectations of "highly effective" teachers, such as producing strong results on standardized assessments with their students, early in their careers. The supports ECTs receive from their schools and districts, including mentoring offered through interactions with school-based colleagues, can help them face such pressures. As lesson planning is a common practice shared among novice and experienced teachers alike, albeit manifesting in different forms (Borko & Livingston, 1989), the broad focus of our inquiry is to understand the nature of ECTs' planning for mathematics instruction in this "high-stakes" era, including how planning practices shift as ECTs gain more experience and the role of institutional factors, such as mentoring from school-based colleagues, on ECTs' planning.

Researchers have long faced the challenge of understanding what teacher planning is and how teachers conduct it. The focus of existing research on planning has largely considered the time units that characterized teachers' planning (e.g., daily, weekly, unit) (Clark & Peterson, 1986) and concluded that unit planning was often unproductive because of the unpredictability of classroom life (e.g., McCutcheon, 1980). While most teachers do not produce written plans on a regular basis (McCutcheon, 1980; Morine-Dershimer, 1979), teachers' routine planning often involves practices such as envisioning connections within the academic content and determining activities students will engage with to learn the content (Morine-Dershimer, 1979; Mutton, Hagger, & Burn, 2011). However, ECTs may struggle with these planning practices, as they lack the experience to visualize how their mental plans are likely to play out (Norman, 2011) and their teacher preparation does not fully prepare them to plan capably given the pressures and time constraints of full-time classroom instruction. Thus, novice teachers are likely to need targeted assistance for planning (Mutton, Hagger, & Burn, 2011).

Given this conceptual foundation, the research questions guiding our work are: *What is the nature of elementary ECTs' mathematics lesson planning practices? What district-level influences do ECTs mention as influential on their lesson planning practices?*

Methods

This study was a part of a larger study investigating the mathematics instructional practices of elementary ECTs in the Common Core era and the relationship between instructional practices and factors such as collaboration with school-based colleagues and the instructional practices of those colleagues. We conducted a lesson planning interview with each participating ECT (n = 99) in conjunction with observations of their mathematics instruction over the course of two consecutive days in both fall 2015 and spring 2016. All participants were within the first four years of their careers, teaching grades K-5.

The research team members received training on interview techniques prior to conducting interviews, and shadowed an experienced team member for the first few observations before conducting observations and interviews on their own. Each team member was instructed to follow the interview protocol closely and only use follow-up questions to ensure that questions were answered clearly. The interview data was audio-recorded, and each interview was fully de-identified and transcribed prior to analysis. The results in this paper focus on participants' responses to the following set of questions, asked in this order: *How did you start? How did you decide what content to focus on? What resources did you use when you planned this lesson and why? How did you decide to use these resources? When did you do the planning of today's lesson? Did you talk with any other teachers or staff to help you prepare for this lesson?*

Analyses of responses began by having individual research team members review a sample of 5 responses to a single question. From their review, they generated a set of codes they felt captured the essence of the majority of responses to the question. Then, the entire research team analyzed additional responses to assess the utility of the initial coding frameworks for each question. The team met bi-weekly to discuss individuals' reflections on the emerging codebook and to suggest improvements. Then, in the final stage, individual team members were assigned to focus on all responses for a single question and review the codes assigned to make sure codes had been applied consistently and revise coding if necessary. This method allowed for collective input and review of the codebook for *all* questions by *all* research team members, rather than solely obtaining inter-rater reliability between two of the raters for analyses of each question.

Results

With Whom Are ECTs Planning Their Mathematics Lessons?

Overall, most ECTs in our sample engaged in some aspects of mathematics lesson planning with other school-based colleagues (n=73 in fall 2015) rather than planning solely on their own (n=26). The nature of these discussions, however, varied among the participants and could be described as one of four types: (1) informal collegial conversations; (2) formal collegial conversations; (3) informal planning and (4) formal planning. These four categories describe the level of engagement (collegial conversations tended to be more general compared with planning activities which focused specifically on what to do and what resources to use) and routine (informal interactions were not arranged in advance compared to formal interactions that happened as the result of meetings being set by teachers/teams/schools/districts).

Although many ECTs described interactions with others when planning, some answered "no" when asked specifically: *Did you talk with any other teachers or staff to help you plan this lesson?* For example, one ECT described talking with a grade-level peer regarding "if they typically find this is a more difficult lesson" for the purpose of gauging what to expect from her students during the lesson, yet she did not consider this conversation to be planning with a colleague. Overall, we found our participants did not consider discussing resources, struggling students, or the curriculum in general with others to be planning with a colleague.

When Do ECTs Plan for Mathematics Lessons?

We received three types of responses to the question *When did you do the planning of today's lesson?*, either (1) day-by-day; (2) weekly overview planning, with some modifications day-by-day; or (3) weekly, with little to no modification. One trend we noted was shifts in ECTs' responses from the fall interview to the spring interview. Notably, the majority of ECTs (fall, n=48; spring, n=63) indicated that they planned for their mathematics lessons on a weekly basis, usually with their fellow grade-level teachers in their building (as noted in the findings above). Approximately 30 ECTs indicated that, in either semester of observation, they also planned weekly but with modifications based on assessment of student understanding on a daily basis. Yet, in the fall, 24 of the 99 participants indicated that they planned primarily day-to-day, whereas, in spring, only 11 indicated that they planned day-by-day. While not surprising, the findings suggest that ECTs may start the school year planning day-by-day, but are likely to switch to either planning weekly, or weekly with some daily modifications as the school year continues.

What Resources Do ECTs Use When Planning Mathematics Lessons?

Participants mentioned a variety of resources they utilized for mathematics instructional planning in response to the question: *What resources did you use when you planned this lesson and why?* as well as questions such as *How did you start?* Overall, a total of eight coding categories arose from ECTs' responses to the interview prompts: (1) prior classroom experience; (2) professional development; (3) pacing guides or curriculum maps; (4) students' performance on in-class assessments; (5) students' standardized test performance or specific items from standardized tests; (6) learning standards (e.g. Common Core State Standards or the specific content objectives of a unit or lesson); (7) teachers' knowledge of students' understanding, based on students' work on non-assessment-oriented classroom tasks; and (8) supplemental materials from sources online such as Teachers Pay Teachers. Results show that the ECTs primarily draw from supplemental materials when planning (fall, n=64; spring, n=60), along with pacing guides or curriculum maps (fall, n=57; spring, n=54). In general, the number of ECTs using each type of resource decreased from fall to spring, except for the number of teachers using learning standards as a resource, which increased (fall, n=34; spring, n=40). Ongoing analysis will unpack the different types of resources coded into the category of supplemental materials.

What External Factors are Salient for ECTs' Mathematics Lesson Planning?

Throughout the interview, many (though not all) ECTs discussed how various external factors, particularly pertaining to the institutional context in which they work, influenced how, when, and with what resources they conducted their planning of mathematics lessons. We characterized their descriptions as aspects of fidelity, using a notion of fidelity that resonates with the definition "faithfulness to a person, cause, or belief" (Fidelity, 2017). Three codes related to fidelity to the curriculum emerged in ECTs responses, namely: (1) Fidelity to scope of curriculum, with option to modify sequence; (2) Fidelity to scope *and* sequence; (3) Fidelity to "script" of curriculum.

ECTs' responses were most frequently coded as fidelity to scope of curriculum, with option to modify sequence. For example, ECTs made statements such as: "I can't tell you specifically if we follow directly the, the pacing guide. We get to choose the order" (231.062, spring). To a lesser extent ECTs described fidelity to scope *and* sequence of curriculum, with statements such as: "So we did a scope and sequence, one for the first half of the year and one for the second half of the year and then we just kind of follow that to see. It goes weekly what we are suppose[d] to be doing this week, what are we suppose[d] to be covering" (121.053, spring). Finally, some ECTs (n=28) stated following the curriculum in a scripted fashion ("everything is all scripted. It's all laid out for you," 120.011, fall).

District directives pertaining to curriculum use appeared to influence ECTs' fidelity to the curriculum to a larger extent than the nature of the curriculum provided. For example, while District 230 provided the Go Math curriculum for teachers, a curriculum that provides step-by-step guidance for how teachers are to implement the lessons, the majority of participants from that district indicated that they closely followed the scope but took liberties to adapt the sequencing of the content. In contrast, teachers from District 210 all described that they followed the scope and sequence of the curriculum (Everyday Math) closely. Ongoing work involves investigating the fidelity of implementation during the video-recorded lesson observations to triangulate evidence of teachers' stated fidelity to the curriculum.

Conclusion

Taken together, the results present a snapshot of mathematics lesson planning practices for ECTs in an era of accountability. Some trends are promising; ECTs increasingly seek out school-based colleagues as resources when planning. However, other findings suggest that teachers may not modify plans on a daily basis in response to student progress. As we continue to develop this line of inquiry, we plan to analyze how these variables interact with other data that we have gathered from surveys and observations. Most importantly, this descriptive work can inform those working in instructional improvement through policy and professional development to consider ways to change institutional supports and constraints so as to create more effective mechanisms for ECTs to prepare to engage in high quality instruction for all students.

MATHEMATICS PEDAGOGY AS SOCIAL JUSTICE ACTIVISM: THE CASE OF MS. LARA

Manjula Peter Joseph
Fresno Pacific University
Manjula.joseph@fresno.edu

Jenna Tague
California State University at Fresno
jtague@csufresno.edu

This case study occurred in a culturally, ethnically, and linguistically diverse fifth grade classroom. Ms. Lara's (pseudonym) mathematics pedagogy exemplified equitable teaching practices. Data from video recordings of lessons and interviews were coded using equity and social justice pedagogy codes to identify nuances of social justice mathematics pedagogy. The findings present the teacher's activism for social justice, and have implications for teacher practice and teacher education.

Keywords: Equity and Diversity, Elementary School Education, Instructional Activities and Practices

Introduction

Teaching mathematics for social justice is understood in multiple ways - teaching about social justice issues using mathematics, teaching mathematics with a social justice lens, or teaching students to use mathematics to challenge social injustices (Gutstein, 2006). Rarely do we find a discussion about a teacher's pedagogy as work for social justice. Imagine a classroom where students are accepted for who they are and respected for what they bring, especially when, some of what they bring is pain and struggle. Not all students have such an opportunity and students thus marginalized continue to under-perform. Achieving equity involves creating opportunities for all students to access engaging mathematics including high quality teaching and pedagogy. Equity in mathematics education remains elusive for various reasons, such as teachers with fewer mathematics experiences and lower Mathematics Knowledge for Teaching (MKT) (Hill, Rowan, & Ball, 2005). This study identifies pedagogical practices, and argues that development of such pedagogy is the teacher's activism for social justice.

Theoretical Framework

Four key features of teaching for equity are commonly agreed upon by multicultural education theorists: 1) recognizing that racism exists at individual, institutional, and cultural levels, 2) racism is perpetuated in educational settings, both in curriculum and practice, 3) the purpose of education must go beyond content knowledge and passing standardized tests, and 4) building students' critical consciousness must be an expected outcome of education. Banks and Banks (1995) describe equity pedagogy as teaching that is dynamic, by being strongly student-centered and flexible in being able to cater to individual student needs. Ladson-Billings (1995) posits a *culturally relevant pedagogy*: "specifically committed to collective, not merely individual, empowerment" (p. 160); a pedagogy that places high expectations on all students, and helps them achieve academic excellence, cultural competence, and critical consciousness. Three dimensions of a teacher's pedagogy are considered critical to equitable mathematics instruction: focus on rigorous mathematics content, learner-responsive pedagogy, and application of real-world contexts (Erchick, Joseph, & Dornoo, 2014; Gutstein, 2006). Students also need the opportunity to understand the world critically and become agents of social change (Banks & Banks, 1995; Gutstein, 2006). Studies are needed to inform the "theoretical understanding of the issues as well as [our] practical efforts to reduce existing disparities" (Gutstein, 2006, p. 95). This study, which is part of a larger study (Joseph, 2013), fulfills such a need.

The Study

This interpretive ethnographic study took place in a fifth-grade classroom in a low performing urban school. Student-demographics showed 61.4% non-white, 89.9% on free/reduced lunch, and 20.5% limited English proficiency. The participant, Ms. Lara, provided a potential exemplar of teaching for equity and social justice. She has a certification in special education and Montessori training. She completed part of a doctoral program in Educational Philosophy, has 30+ years of teaching experience, and was invited to Liberty Elementary because of her commitment to students.

Data Sources and Analysis

Multiple sources of data informed the study (Joseph, 2013): audio-recordings of interviews, video-recordings of teaching sessions, student work samples, field notes, and participant reflective notes. Data was analyzed using a research-based codebook (shown in Table 1.)

Table 1: Equity and Social Justice Mathematics Pedagogy Codebook (Joseph, 2013)

Code	Concept		Research support (e.g.)

	EMR	**E**xplicit attention to **M**utual **R**espect	Bartolome (1994)
	ECT	**E**ncouraging **C**ritical **T**hinking	Gutstein (2006)

The research-based codebook consists of instructional practices in teaching mathematics for equity and social justice. They are grouped into four categories: *content objectives* (teacher's attention to mathematics), *pedagogical orientation* (purposeful support of students as learners), *contextual relevance* (awareness of instructional context), and *social justice objectives* (intentionality for student self-empowerment). Transcripts were chunked collaboratively coded, and reached inter-rater reliability of 85%.

Key Elements of Ms. Lara's Work

1. *Developing students' critical thinking as a personal* process – Ms. Lara's activism was seen in providing students opportunities to develop critical thinking skills. She required students to reflect on their realities, make choices, voice their decisions, and make a conscious decision to learn.
2. *Having informal and informative assessment strategies* – Assessments tend to be framed in ways that disadvantage students who are from cultural and linguistic backgrounds different from the school (Morgan, 1999). Ms. Lara's informal continuous assessment of her students helped her to 'keep her finger on the pulse' of her classroom and learners.
3. *Intentionality in getting to know her students* – Ms. Lara made deliberate choices in her commitment to her students – work in a high-need environment, understand, and connect with students. She communicated with her students to know them – their context, their hopes and aspirations, and made instructional decisions based on that knowledge.
4. *Helping students build mathematical and social identities* –Ms. Lara's practice characterized student identity building through collaboration. Her classroom represented a 'learning community' in which students from all ethnic, cultural, language and ability groups engaged in learning and legitimate participation (Lave & Wenger, 1991) to produce knowledge and benefit in positive ways both personally and as a community.
5. *Students as the locus of authority for both mathematics and instruction* - Having students as the locus of authority meant focusing on student thinking. Ms. Lara's students were invigorated to think deeply and take responsibility for their participation. From being often considered 'deficit' in their mathematical knowledge, her students became endowed with credibility and had their ideas valued.
6. *Paying explicit attention to "connected knowledge"* – Making connections is required in the process of helping students learn mathematics. Ms. Lara not only made connections through multiple representations of content and across content areas, but she also made connections with students' lived experiences.

Implications for Teacher Practice and Teacher Education

Providing equitable learning environments for students in mathematics classrooms is a challenging endeavor. Besides needing in-depth MKT, teachers need to facilitate 'bringing the world into the classroom' (Gutstein, 2006). Teachers often reject the idea based on the perception that attending to social justice means moving away from rigorous content (Erchick & Tyson, 2011). Another reason for rejecting the idea of teaching mathematics for social justice is that teachers believe that it requires curriculum and resource changes over which they have little control. This study provides a vision of social justice mathematics pedagogy where subtle actions can produce classrooms with no barriers to learning: classrooms where every child is provided the unique opportunity to explore, learn, know their voice is heard, and follow their dreams.

Challenges to Social Justice Pedagogy

Teachers like Ms. Lara face many challenges to their work, such as policies that call for strict adherence to a curriculum detailing step-by-step instructions, standardized testing, and programs that are not necessarily aligned with student needs. Standardized tests continue to show students from linguistically diverse and poverty backgrounds as academically unsuccessful. This has grievous impact on student confidence and leads to students accepting this as a sign of their inability and giving up. Students' lack of effort and teachers' acceptance of their lot may lead to a vicious cycle of a society that continues to marginalize underserved communities. In such a context, a teacher's role is critical. Ms. Lara found ways to negotiate these challenges by using her own means of assessing students through verbal communication and representations, and finding ways to help students regain confidence in themselves, their abilities, and even take pride in what they know.

In understanding the kinds of knowledge teachers bring to their work for equity that include mathematical and pedagogical knowledge, Gutierrez (2012) added political knowledge: "negotiating the world of high stakes testing and standardization, connecting with and explaining mathematics to community members and district officials, and buffering oneself, reinventing, or subverting the system in order to be an advocate for one's students." (Gutierrez, 2012) This aspect of a teacher's work for social justice is perhaps the most crucial.

MEASURING RECOGNITION OF THE PROFESSIONAL OBLIGATIONS OF MATHEMATICS TEACHING

Patricio Herbst
University of Michigan
pgherbst@umich.edu

Inah Ko
University of Michigan
inahko@umich.edu

We show validation data of surveys that estimate high school teachers' recognition of four obligations of the mathematics teaching profession. Measures of internal consistency show three instruments reliably measure three of the four obligations, while the fourth has lower internal consistency. Factor analyses support a 3-factor model for the disciplinary obligation and 2-factor models for each of the individual, institutional, and interpersonal obligations. We inspected correlations between recognition of obligations and teachers' beliefs: Low correlations found suggest recognition of obligations and beliefs are different constructs.

The Study of Mathematics Teaching: Background and Theoretical Framework

Our research contributes to theoretical and methodological progress understanding the work of mathematics teaching. Teaching has often been described as the expression of teacher characteristics or as the enactment of behaviors (Shulman, 1986). In mathematics education these have led to studies of teachers' beliefs and teacher knowledge (e.g., Even, 2009; Leatham, 2004), on the one hand, and studies of classroom discourse, norms, and patterns of interaction (e.g., Cobb, 1998) on the other hand. These two approaches have complemented each other, often drawing data from classroom observations, but seeing it alternatively as projection of an individual teacher goals, beliefs, and orientations (Schoenfeld, 2010) or as adaptations of the teacher to the context of his or her interactions with the students and the content (Voigt, 1985).

Less prominent has been attention to how the environments of instruction (Cohen, et al., 2003) frame both what it means to be a mathematics teacher and what a teacher is required to do in mathematics teaching. Yet these environments warrant the encounters among teacher, students, and content. How do those environments create expectations that frame the position of mathematics teacher? Herbst and Chazan (2012) proposed the notion of *professional obligations* to identify those expectations. The position of the mathematics teacher obligates mathematics teachers to stakeholders that look at mathematics teaching from four different perspectives, which Chazan, Herbst, & Clark (2016) call Knowledge, Client, Society, and Organization. From the Knowledge perspective, mathematics teachers are obligated to the discipline of mathematics--to engage students with mathematically correct knowledge and practice. From the Client perspective, mathematics teachers are obligated to the individual students--to tend to their cognitive, emotional, physical, and other needs. From the Society perspective, mathematics teachers are obligated to the interpersonal collective of their class--to promote social values such as fairness and respect. From the Organization perspective, mathematics teachers are obligated to institutional policies and practices of the system, district, school, and department.

These obligations are hypotheses; confirmation requires looking at how much mathematics teachers themselves recognize being under those obligations in contrast with other people that might not be so obligated. We developed the PROB surveys to measure the extent to which teachers recognize each of the four obligations and describe its properties below.

The PROB Surveys

There are four PROB surveys, PROB-MATH, PROB-INDV, PROB-INTP, and PROB-INST, designed to measure recognition of the obligations to the discipline, the individual student, the interpersonal collective of the class, and the institutions of schooling respectively (see also Herbst et al., 2014). Each of the items in all four surveys asks participants to consider a statements that avowedly describes mathematics teaching (e.g., "Mathematics teachers take time to discuss school policies") and then asks participants to “Rate the degree to which mathematics teachers are expected, as professional educators, to act in the manner that this statement describes” using a 4-point Likert-type of scale that ranges from (1 = Teachers are never expected to act in this manner to 4 = Teachers are always expected to act in this manner). We developed the survey through several iterations that included brainstorming, item writing, cognitive pretesting, internal and external vetting, piloting with teachers, and examining the collected pilot data using classical test theory (Crocker & Algina, 1986). The rating prompt, resulted from a design process informed by cognitive pretesting, oriented to elicit the participant’s sense of whether mathematics teachers were expected by others to act in the way described.

Method

We administered the PROB surveys to a national representative sample of U.S. high school mathematics teachers (497 teachers, 47 states), along with other questionnaires using the Lesson*Sketch* online platform. Participants were majority Caucasian (83%) and female (59%), which is consistent with nationally representative data obtained from the NCES database. On average, participants had been teaching mathematics for 14.1 years (SD = 8.7), and had taken 14 college-level mathematics courses (SD = 7.25). The analysis looked at the internal consistency of the surveys and dimensionality of the constructs we attempted to measure.

Analysis

Reliability as Internal Consistency

To document the reliability of the PROB surveys, we evaluated internal consistency of retained items using both Cronbach’s Alpha and the mean inter-item correlation (MIIC). Cronbach's Alpha values over .7 are usually seen as acceptable and over .8 as good, while acceptable mean inter-item correlation values range between 0.15 and 0.25 (Kline, 1995; Clark & Watson, 1995). As can be noted in Table 1, the disciplinary, interpersonal, and individual surveys had good internal consistency, but the institutional survey had acceptable Cronbach alpha and low MIIC.

Table 1: Internal Consistency of PROB Surveys

Obligation	Number of items	Mean inter-item correlation	Cronbach’s Alpha
Disciplinary	18	0.273	0.8711
Institutional	20	0.1117	0.7154
Interpersonal	29	0.2226	0.8925
Individual	18	0.3082	0.8891

Dimensionality Validation

Cronbach’s Alpha is a good measure of internal consistency if it is possible to assume that items are unidimensional, that they are all equally good to measure the construct, and that their errors are uncorrelated. Because the possibility existed that one or more of those assumptions was not met, we examined the factorial structure of disciplinary, individual, and interpersonal scales using factor analysis. The WLSMV estimator, which is optimal for categorical variables with a small sample size was used to test the factor model. To find the best model that is not only meaningful but also satisfies fit criteria, we considered the Root Mean Square Error of Approximation (RMSEA) looking for a value of RMSEA <0.6, the Tucker-Lewis index (TLI) and the Comparative Fit Index (CFI), in both of these looking for values greater than 0.95 (Hu & Bentler, 1999). Factor means were set to 0 and factor variances were set to 1. The specific factor models tested are described in detail below.A three-factor model, where 7 items have the same estimated loadings (discrimination) and two pairs of items are correlated due to the same wording, fits our PROB-DISC data well with all standardized factor loadings greater than 0.5. Three suggested factors are interpretable in regards to the item statements (see Figure 2).

F1: Obligation to the discipline insofar as member of a community contributing to increase and extend appreciation of knowledge outside of the classroom (9 items)
F2: Obligation to the discipline insofar as responsible for its correct representation in classroom interaction (5 items)
F3: Obligation to the discipline insofar as responsible for its correct representation in study resources (3 items)

Figure 2. Factors of the disciplinary obligation.

Using similar procedures we determined that the items in the PROB-INDV survey could inform a two-factor model of recognition of the individual obligation. The two individual factors we found are defined in Figure 3a. The items in the PROB-INTP survey were also best accounted for by a two-factor model which are defined in Figure 3b. Items in the PROB-INST also loaded in a hypothesized two factor model (Figure 3c). The results above show a mostly positive outcome of the PROB surveys. It is of interest to investigate how these measures relate to other constructs being used in research on teaching, particularly other measures of teacher characteristics. Years of experience teaching showed significant positive correlation with the all three PROB-DISC factors though no significant correlations with either of the others.

F1: Obligation to the academic needs of individual students (12 items)
F2: Obligation to the socio-emotional needs of individual students (6 items)

Figure 3a. Factors of the individual obligation.

F1: Obligation to support social interaction among small groups of students (16 items)
F2: Obligation to support social interaction in the whole class (8 items)

Figure 3b. Factors of the interpersonal obligation.

F1: Obligation to support policies for school-wide events and activities (4 items)
F2: Obligation to support school policies that concern classroom activities (9 items)

Figure 3c. Factors of the institutional obligation.

Our participants had also taken the survey by Stipek, et al. (2001), which measures 7 different aspects of teachers' beliefs. We were interested in correlations between factor scores in the obligations and mean scores in belief factors. Significant correlations were found, yet the most important finding is that those correlations are uniformly low. This suggests that recognition of obligations does not measure the same thing as this measure of beliefs.

Endnotes

The test-based accountability movement has had profound impact on classroom practice, particularly at the high school level where teachers' experiences may differ from elementary and middle schools where students are tested on a yearly basis. We use a multiple case study to examine how high school mathematics and science teachers use data and what challenges they face in the current accountability context. Our findings reveal unique aspects of data directly related to test-based accountability. Expectations for what mathematics looks like (subject area expertise) as well as testing schedules (state and federal policy) influence their data practices, along with district structures and norms. Individual teachers' beliefs about data and what it means to know a student also had a significant impact on their day-to-day work.

Keywords: Assessment and Evaluation, High School Education, Teacher Knowledge

Background

Data-driven decision-making (DDDM) has become a central focus for educational policy and practice at all levels as a strategy to support teachers in developing the skills and knowledge needed to engage in these key tasks of teaching (Gill, Borden, & Hallgren, 2014; Luo, 2008; Mandinach, 2012). DDDM is broadly defined as "the use of data analysis to inform choices involving policies and procedures" (Gill et al., 2014, p. 338). Educators must integrate assessment results with data from other sources, such as attendance and discipline data, to fully understand student development. Data-literate educators can be a driving force of student learning because of the emphasis on data-based evidence and decision-making (Orland, 2015).

Teachers' subject areas likely influence their data practices, especially for secondary teachers whose practices are based largely on their content-specific education (Daly, 2012). Within a building, high school teachers are most likely to meet with their subject area departments on regular bases, whereas elementary school teachers are more likely to meet with teachers who teach the same grade level. In addition, different content areas have criteria for student success, which translates to differences in assessing students, identifying relevant data, and measuring knowledge (Datnow, Park, & Kennedy-Lewis, 2012).

As mathematics has been at the forefront of the high-stakes accountability culture, data use practices of mathematics teachers are a viable subset to detail. They are expected to skillfully handle data such as scores from external, interim, and benchmark tests, district-level program assessments, classroom-level assessments, classroom behavioral, demographic, and attendance data (Schleppenbach, 2010). Additionally, science's heavy emphasis on scientific practices, hands-on inquiry activities, and scientific knowledge merits additional investigation into the specific data use practices of science teachers (Rangel, Monroy, & Bell, 2016). The existing literature, however has not focused on content-specific distinctions (Rangel et al., 2016). There is also little research on how high school teachers experience the current accountability context in ways that are similar to or different from elementary and middle schools, in which students are tested on a yearly basis. In this study, we address the research questions: *(1) How are high school mathematics and science teachers using data? (2) What challenges do high school mathematics and science teachers face in the current test-based accountability context*?

Framework

Systems theorists (Bronfenbrenner, 1994) argue that in order to understand learning and practice, we must attend to the influence of larger systems in which individuals are situated. Bronfenbrenner's model identifies a series of "nested structures" that situate individuals within multiple contexts. *Microsystems* refer to individuals and institutions that immediately impact the individual, which likely includes teachers' peers, building administrators, students and community, and their teacher preparation. The *mesosystem* highlights that all of the elements within the microsystem are in constant interaction with each other with the high school teacher at the center. The *exosystem* includes norms around district practice and policy related to data use, curriculum, and standards. The *macrosystem* involves dominant ideologies and beliefs around teaching and learning and state and federal policy. In considering teacher data practice, it is necessary to consider policies that mandate specific types of data use, different school and district practices and norms around data use, subject-specific practices and norms around data use, and individual teacher practices, beliefs, knowledge, and dispositions around data.

Methods

We address the research questions through a case study of data use amongst science and mathematics teachers at one high school conducted over two years. We conducted 30-50 minute interviews with the mathematics and science teachers and principals to gain an in-depth understanding of practices, beliefs, knowledge, and dispositions around assessment, accountability, and data use. We first coded the teacher interview transcripts using line-by-line coding (Charmaz, 2006) and then looked for pattern codes within each teacher's transcript. Examples of pattern codes include "online assessments," "role of intuition," and "school expectations." We then read the codes across transcripts to identify similarities and differences with teachers from the same district. Using these pattern codes, we next analyzed the transcripts of principals and developed case narratives (Stake, 2013). We also analyzed through the lens of systems-theory, using the systems identified as the nested structures in which teacher data use occurs. We inductively coded data within each system to develop a set of pattern codes, which we overlay to understand how the nested structures influenced data use.

Findings

The case study revealed that specific aspects of expectations for what mathematics looks like (subject area expertise) as well as the testing schedules (state and federal policy) in particular influence their data practices. District structures and norms also influence teacher data use, though individual teachers' beliefs about data and what it means to know a student also had a significant impact on their day-to-day work. We share a sample of findings here.

Showing My Work, Online: The Role of Computers in Test-Based Accountability Systems

To monitor students' progress and prepare them for on-line assessments, the district invested in various software programs for teachers and students. This presented a significant challenge for Patricia, an Algebra 1 teacher, who identified several reasons that online assessments were not a useful tool. Patricia shared that online assessments are "a little deceiving because you really don't know what's going on behind the scenes." Patricia uses the online assessment platform provided by the district "once a year," which she finds nice because the assessment platform scores the assessment. However, she finds this problematic because "I don't really know much about the score because I didn't physically grade it. I don't know what they really did when it says 72."

In addition to concerns about a numerical final score on an assessment, Patricia also found that using online platforms that were open-ended were tedious in the mathematics classroom:

> We just had a chapter on exponents. We did the whole chapter on paper by way of worksheets and the reason, I told the kids, "Here's the reason we're doing it. Because it's going to take you forever to type to the power of, to the power of." Like (4m^2)(y^3)(z). Well, that'll take forever, when they could write it so much faster.

For Patricia, it does not make sense to have students complete certain types of mathematics problems on the computer because of the inefficiency of having students type specific equations.

Alexa, however, also an Algebra 1 teacher, finds great value in an online program that creates reports showing "each student and what they're struggling with...That helps to see if everybody's struggling with this concept, maybe I need to re-teach it again." Alexa increased her use of online quizzes "to make sure the kids are all hitting these standards" that will most likely be tested. Alexa reported that she uses data from these assessments to determine who needs extra help and who to "keep an eye on." She also appreciated that online platforms give students "immediate feedback" if they get a problem right. However, she expressed concern, "because if [students] do keep getting [a problem] wrong and they don't write their work down, they're just trying to do it in their head, I can't see the steps."

Mary, a biology teacher, spoke about,

> A variety of ways you can structure tests and quizzes and assessments, where they are matched to other certain objectives or standards. Then you can get a report through [the online program]…so I utilize that a lot…I want the kids to know their own data, and I want them to know where they fall along with the rest of the class. Usually after a test, I'll ask them to assess whether they've mastered a certain standard…

Mary acknowledged that "for biology, everything I do is standard-based... because we have a state test tied to the biology, we push it a little more." This push includes more regular use of online assessments to monitor student mastery.

The test-based accountability context has led to an emphasis on online assessments that provide immediate, easy, and efficient data to teachers and students about their work; however, for teachers in the same school, these online assessments are used differently.

Intuition Versus Tests: How Teachers Determine Student Growth Objectives (SGO)

As part of the state's guidelines, all teachers were required to identify Student Growth Outcomes (SGOs) — rigorous learning goals aligned to standards-based, common assessments that are specific and measurable. To develop SGOs, teachers are to use previous standardized assessment data as a baseline. However, several teachers reported that their intuition led to the same conclusions about student mastery as students' prior performance on standardized exams. Kate, a biology teacher, said that the "[summative assessment data] does usually correlate when I'm looking at who are my low kids in a class." Patricia agreed, noting that she initially develops her SGOs based on the knowledge of students developed over the first two weeks of school, and then when she compares her informal assessments to the state standardized assessments scores later in the year, she shares, "It's the same list. I spend an hour fighting through the data when I already knew what the data was." Sean, a science teacher, had a similar attitude toward "data" and intuition, and wondered, “what could the data tell me that I don't already know?” He developed his SGOs in part based on students’ prior science and math grades, but he does not “place a lot of emphasis on the standardized tests.” He is more interested in how students perform in various settings, and would rather know about students’ learning styles, interests, and comfort levels with content than their prior performance. Overall, teachers’ beliefs about a teacher’s intuition and what it means to know a student lead them to question the usefulness of data in informing their practice, even within a context that requires certain data practices.

Discussion and Implications

Not surprisingly, mathematics and science teachers face unique challenges related to data use in the test-based accountability context. The heightened use of online platforms for regular assessments of student mastery, for example, is a challenge for teachers to know how students are thinking. The expectation to use specific assessments to evaluate student growth also is a place of challenge, particularly for science teachers who students have not taken a science assessment since 6th grade. Different mathematics and science subjects draw on different types of knowledge, and a student who did well in a prerequisite may not do well in the next course. It is unclear what valid prior standardized data can be used to help teachers to develop useful SGOs, and what prior data can be used as the comparison point at the end of the year.

This study highlights the need for greater research into how different subject areas are impacted by different mandates and policies related to test-based accountability. While all courses are aligned to state standards, teachers and the principal give that extra push to the tested subjects. The teachers in this study, with an average tenure of 22 years, shared how their assessment practices have changed over time and the specific impacts of the test-based accountability on their practice. It was clear that the macrosystems of federal and state policies were not totalizing forces that drove all of their decisions, but it was also clear that these policies influenced how they view data and its role in education. While some embraced the changes, they largely viewed “data” as something tedious and not as a meaningful way to improve practice.

STORIES OF AGENCY: DO GRADUATE STUDENTS PERCEIVE THEMSELVES AS PART OF THE MATHEMATICAL COMMUNITY?

Mollee Shultz
University of Michigan
mollee@umich.edu

Patricio Herbst
University of Michigan
pgherbst@umich.edu

Graduate student teaching assistants (GTAs) are responsible for the instruction of undergraduate students in critical introductory courses, but are not yet in the position of professors. Given their unique status, we ask if there are differences in how graduate students and professors express their agency when speaking about their responsibilities and how graduate students position themselves as members of the community of mathematicians. We use tools from systemic functional linguistics (Halliday, 1994) to analyze 16 interviews with graduate students and professors from research I universities. We found important differences in how graduate students and professors perceive their agency, and agency varies according to whether it concerns disciplinary or institutional responsibilities. Future research can investigate how to create more opportunities for developing the agency of GTAs in institutional decisions.

Keywords: Post-Secondary Education; Affect, Emotion, Beliefs, and Attitudes

Each year approximately 743,000 undergraduate students enroll in calculus courses and 834,000 enroll in introductory level courses (e.g., pre-calculus) taught in mathematics departments (Blair, Kirkman, & Maxwell, 2013). In some departments GTAs are only responsible for leading recitations and grading, but in other departments they teach over a third of all course offerings (Lewis & Tucker, 2009). Graduate students benefit from the experience because teaching is an aspect of being a mathematician, the community into which they are entering. As Lave and Wenger (1991) stressed, teaching and learning do not only occur in an individual's mind, but rather are mediated by social situations in a community of practice. Teaching positions, as part of the graduate education, assist in the socialization of graduate students into the faculty positions they may eventually take (Austin, 2002). However, GTAs have little to no experience and are given little training. Preparation programs range from a few hours' orientation to weeklong workshops (Ellis, Speer, & Bookman, 2016). How can we support the apprenticeship into teaching for graduate students while fostering quality instruction? This study seeks to understand differences between how professors and GTAs perceive and manage their roles as instructors. We compare their social positioning and *agency*.

Researchers have noted the significance of agency, or "who has control over the way mathematics is done and expressed" (Wagner, 2007, p. 36), for the doing of mathematics in the context of voice in textbooks (Herbel-Eisenmann, 2007; Herbel-Eisenmann & Wagner, 2007; Morgan, 1996) and in classroom discourse (Wagner, 2007). Previous research has addressed teacher and student agency in their interactions with each other and the discipline, but it has not addressed agency in two key areas: comparing agency of different groups of teachers and comparing agency in different aspects of teaching. We will compare graduate students and professors in two aspects provided by our theoretical framework.

Theoretical Framework

Herbst and Chazan (2012) proposed a framework of four *professional obligations* that mathematics teachers must respond to as professionals: towards representing the discipline of mathematics appropriately (disciplinary), treating individual students as persons with unique assets and needs (individual), creating a socially and culturally appropriate environment for students to share space and resources in a class (interpersonal), and respecting institutions such as the school, department, district, State, or unions in matters including curriculum, assessment, and policy (institutional). We use the institutional and disciplinary obligations as lenses for agency because they are most relevant to how a graduate student socializes into the mathematics community - the departmental community (institution) and the work of a researcher (the discipline). We explore the remaining obligations elsewhere.

Our study of agency uses tools from systemic functional linguistics (Halliday, 1994), which is a theory of language that enables us to explore how meaning is construed by the language people choose. In this study we draw from what Halliday refers to as *processes*, which are aspects of a clause that report about "the event or state that the participants are involved in" and are canonically realized by verbal groups (Thompson, 2013, p. 87). Processes are typically categorized as material, relational, mental, verbal, existential, or behavioral. We wanted to identify processes that revealed happenings with actors or doers, so we focused on *material* processes, which are processes of physical actions (e.g., I taught…, if you are writing..., students have to solve…), and *verbal* processes, processes of saying (e.g., I can talk about..., we have to tell our students that..., I asked them to...) (Thompson, 2013). We contend that analyzing the actors that instructors identify in material and verbal processes will reveal important insights to who feels agentive in different contexts, leading us to ask the following research questions:

1. Are there differences in how graduate students and professors express their agency when speaking on their responsibilities to represent the discipline of mathematics and to their institutions?
2. How do graduate students position themselves as members of the community of mathematicians and/or the departmental community?

Methods

The source of the text analyzed in this study was a set of sixteen hour-long interviews with eight doctoral graduate students and eight tenured or tenure-track faculty members from large midwestern research universities. We focused on responses to questions about the institutional and disciplinary obligations. Participants read and listened to a full definition of each obligation (taken from Chazan, Herbst, & Clark, 2016) and were asked to respond to the question, "Given this description, how does this obligation play a role in your own teaching practice?"

We analyzed the interviews by transcribing them and identifying material and verbal processes with their corresponding actors and sayers. In the following results, we have italicized actors and underlined material and verbal processes. We counted the actors of almost every material and verbal process and decided to count instances of *I*, *we*, *you*, *the institution*, and *students* because they were most frequent. Infrequent actors or processes with ambiguous actors were counted under "other" to create accurate percentages (see Table 1). Certain material and verbal processes were excluded or indicated a lack of agency. Details on the specific ways these were determined are available in a longer report.

Results

The largest distinction between graduate students and professors was in their use of 'we' in material (portraying physical action, e.g., "we break [problems] into simple pieces") and verbal processes (saying, e.g., "we talk about why it's wrong") when speaking about how the institutional obligation plays a role in their practice. Professors used the pronoun *we* in 24% of their clauses, compared with 3% from graduate students (see Table 1). The complement to this observation is that graduate students referred to the institution as an actor for 18% of their material processes, compared with 9% by the professors. For instance, student 2 explained, "There are certain due dates that are part of the, that are already designed and built in by the institution." These observations suggest that when GTAs enact the institutional obligation, they perceive the institution as an external actor while professors perceive themselves as part of the institution. Professor 7 elaborated,

> So in terms of institutional obligation…at least as far as the university is concerned, is to ourselves. *We* decide a policy, and *we* enforce them... And those things are our obligations to policy that *we* set ourselves and the policies are ones we deem reasonable.

Here, the professor has situated himself as a member of the departmental community.

A different story of community emerged in discussions around the obligation to the discipline (see Table 1). We did not find as large of a difference in how graduate students (7%) and professors (13%) used *we* to express agency. The following quote illustrates a graduate student speaking for mathematicians:

> Whatever *we* have done, say for centuries before, that subject is built on truth and truth only. At every step we had this choice, zero or one, and every time *we* choose one, and the whole *subject* is built upon it. So that I feel that *I* must impart to students.

He situated himself as one of the mathematicians who knew what was important to represent about the discipline.

Between the two obligations, the largest difference in agency is in the use of ‘I’. Both sets of instructors use ‘I’ to represent the agents of verbal and material processes more often in the disciplinary obligation (36% and 37%) than in the institutional obligation (19% and 15%). This signals that they have much more personal agency when acting on behalf of representing mathematics than when addressing institutional practices.

Discussion

To address our first research question, our findings suggest that there are important differences in how graduate students and professors perceive their agency, and agency varies according to which obligation is at stake. Both professors and graduate students had more individual agency speaking with ‘I’ in responses to the disciplinary obligation. Graduate students use ‘I’ as often as the professors, which may indicate that the students feel as agentic as the professors when representing the mathematical content at stake--this suggests that the issue is not reducible to developmental differences in the sense of agency, or, that agency varies depending on the obligation undergirding what instructors feel responsible to. One valued purpose of course policies is to create a uniform experience covering the same core material at least for the students that pass through a given institution (Rasmussen & Ellis, 2015). But we question whether this is achieved, and why graduate students are disproportionately assigned to these introductory courses that are critical for so many students.

In response to the second research question, we did find evidence that students position themselves as members of the mathematics community by their use of the pronoun *we*. Wagner (2007, p. 42) said that “student[s] who want to show that they are members in this collective of people who do things right have the *we* voice at their disposal.” Both students and professors were able to position themselves as members of the group that holds knowledge of mathematics. However, graduate students were much less able than professors to speak for the community of the department or institution. Professors may feel they can represent their institution due to the stability of their tenure or tenure-track positions and as a byproduct of other work they do to serve their institution. Although the graduate students did not seem oppressed by institutional constraints, they were not affiliating with the choices made by the institutions. Future research should investigate how to create more opportunities for developing the agency of GTAs in institutional decisions.

Table 1: The use of actors or sayers as indicators of agency

Obligation	Actors/Sayers	GTAs		Professors	
		Frequency	%	Frequency	%
Disciplinary	I	27	36	33	37
	Students	19	25	11	12
	We	5	7	12	13
	You	16	21	12	13
	Institution	0	0	0	0
Institutional	I	22	19	12	15
	Students	24	21	9	11
	We	3	3	20	24
	You	6	5	3	4
	Institution	19	17	5	6

This paper reports on the development of a national lexicon for describing what happens in middle school mathematics classrooms in the United States. Using primarily surveys and focus groups with mathematics teachers, 100 terms were widely agreed upon as familiar to the teachers. The terms varied on a number of features including whether they referred to particular classroom activities or broader instruction-related concepts, whether they focused on teacher or student actions, and the degree to which teachers reported using the terms. Challenges experienced by teachers in the process of reflecting on their own language use are discussed, and implications for research and classroom practice are addressed.

Keywords: Classroom Discourse, Instructional Activities and Practices, Middle School Education, Teacher Knowledge

Introduction

Over 30 years ago, Lortie (1975) lamented the absence of a "common technical vocabulary" (p. 73) for describing teaching. More recently, Grossman and McDonald (2008) continued to advocate for a "framework for teaching with well-defined common terms for describing and analyzing teaching" (p. 187). Despite these important claims and some recent work investigating teachers' adoption of new terms (e.g., Davis & Boerst, 2014; McDonald, Kazemi & Kavanagh, 2013), teaching in the U.S. still lacks a precise common language for describing what takes place in classrooms. The work we present here is a first step towards identifying a lexicon used by middle school mathematics teachers in the U.S. to describe mathematics teaching and learning.

Theoretical Framework

Gaining insight into the common language of U.S. middle school mathematics teachers is important for several reasons. In writing about social communication, Carroll (1980) discusses the difference between the linguistic forms of naming and describing. Carroll explains that names come to stand in for descriptions once items become "nameworthy," that is, once they become familiar enough to warrant a name for more efficient reference. As he explains, "Shorter name expressions are substituted for more lengthy descriptions when a social and referential familiarity is established" (p. 321); therefore, names provide a means of communicating socially shared ideas. In the same way, mathematics teachers' names for what happens in their classrooms indicate what they deem as communally important. Furthermore, research suggests that names can also help us to recognize and make sense of phenomenon of interest, such as teaching and learning in mathematics classrooms. Sapir (1958) wrote of the "language habits" of a community, claiming that "we see and hear… largely as we do because the language habits of our community predispose certain choices of interpretation" (p. 69). Thus, naming an object can help to make the object more salient to those familiar with the name. In the domain of secondary mathematics teaching, Milewski and Strickland (2016) worked with teachers to create a framework that defined and characterized the different ways that teachers responded to students in the moments of instruction. The researchers found that once teachers had names for particular "moves," the teachers were better able to shift their practices in ways that increased their responsiveness to students. Thus, names have the potential to shape both communication and practice. Here we explore this idea through the development of a teacher-generated lexicon representing terms that U.S. teachers currently use to describe and discuss their classrooms. To be clear, our goal is not to focus on a set of ideal instructional practices. Rather, we aim to be fairly comprehensive in the terms we include, as long as they are familiar to teachers.

Methods and Data: Three Phases

This research was conducted as part of an international study in which teams from nine countries sought to construct local lexicons of mathematics teaching and learning at the middle school level. This paper reports on the findings from the U.S. team.

Initial Generation of Terms

To begin, two middle school teachers and two researchers watched classroom videos from eight countries. The videos served as a stimulus for the teachers and researchers to note things that happened for which they had a name. This process generated approximately 70 terms that the researchers and teachers agreed were familiar terms used to describe what happens in a mathematics classroom in the United States. Next, approximately 20 former and current mathematics teachers known to the researchers were asked to brainstorm 5-10 terms that they would use to describe middle school mathematics teaching and learning. In all, 157 terms were identified. The initial team of teachers and researchers then wrote definitions for the 157 terms.

Local Validation

A process of local validation was conducted with three focus groups comprised of middle school mathematics teachers with a range of teaching experience. One group included three teachers from different schools (one suburban public, two urban private), a second group included four mathematics teachers from a suburban public school, and the third group involved four mathematics teachers at an urban religious-affiliated private school.

Teachers first completed a Q-sort task (Block, 2008) in which they separated lexical terms into familiar and unfamiliar. Familiar terms were subsequently sorted into somewhat familiar and very familiar. Teachers then provided feedback on the definitions of those terms with which they were very familiar. Teachers were also invited to propose new terms that they would use to describe what happens in a mathematics classroom but that had not been included in the lexicon.

Teacher ratings of familiarity were compiled and terms were ranked by the number of teachers who were very familiar with each. Any terms with which three or fewer teachers were very familiar were removed. Following this analysis, 103 terms remained in the lexicon. Definitions of those terms were then edited by the researchers based on teachers' suggestions.

National Validation

Finally, a survey was developed to gather national data regarding the lexicon. The survey asked teachers to review a subset of the lexicon and rate their familiarity with the terms, as well as how frequently they use each term in conversations with colleagues. Teachers also identified whether the written definitions matched their own understanding of the terms, recommended changes if needed, and proposed new terms that were familiar to them but did not appear in the survey. In total, the survey was completed by 241 teachers (131 female, 49 male, 53 did not respond) from 28 states across the U.S. Fifty-nine teachers reported teaching in urban schools, 67 in suburban schools, and 40 in rural schools. Of the 183 teachers who recorded their years of teaching experience, 31 reported 1-3 years of experience, 84 reported 4-14 years of experience, and 68 teachers reported 15 or more years of teaching experience.

To determine the final lexicon, we sorted terms by the percentage of teachers who rated each term as very or extremely familiar (1 or 2 on a 5-point scale). Three of the 103 terms did not meet the

Galindo, E., & Newton, J., (Eds.). (2017). *Proceedings of the 39th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* Indianapolis, IN: Hoosier Association of Mathematics Teacher Educators.

threshold of 75% of teachers rating the term as very or extremely familiar and thus were removed from the lexicon.

Findings

The resulting U.S. lexicon consists of 100 terms, a subset of which is listed in Table 1. Several key distinctions were noted. First, the terms represent different aspects of mathematics classrooms, including general classroom activities (*offer feedback, note taking*), more specific practices (*compare multiple strategies*, *pattern recognition*), participation structures (*partner work*, *student presentation*) and assessment-related terms (*remediation*, *differentiation*). Second, some terms refer to activities that occur during instruction (*homework check, warm up*), while others refer to broader educational concepts (*high expectations*, *student accountability*). Third, some terms refer to actions that are more typical of either the teacher (*assign seats*, *give directions*) or the students (*struggling*, *memorizing*). Fourth, terms represent actions and events that occur over different time scales (*aha moment*, *whole-class discussion*). This range of terms seems to highlight the complexity of teaching, which involves a wide array of activities, is multimodal, and requires attention to many things simultaneously (Sherin & Star, 2011).

Table 1: Sample of Terms in U.S. Lexicon

Asking Questions	Posing questions to either a teacher or student(s).
Justifying	Providing evidence to support one's explanation, idea, or solution in order to illustrate that the solution or explanation is reasonable.
Scaffolding	Teacher providing a series of supports, hints, or questions to move students forward on a problem, assignment, or concept.
Wait Time	Several second pause provided by the teacher to allow students time to respond to a question.
Warm Up	Brief activity used at the beginning of class, often for review.

Several challenges emerged for teachers as they worked to identify the terms they use to describe mathematics teaching and learning. First, questions arose about what it would mean to say that a term was familiar and should be included in a national lexicon, as many teachers had never before reflected on what terms they use to discuss their teaching. Teachers in the focus groups sometimes recognized terms as familiar but did not consider them to be part of their own practice, and thus questioned whether these terms belonged in the national lexicon. For example, Eliza acknowledged that *assign seats* was a familiar term, but she categorized it as outside of her lexicon and thus unfamiliar. This example illustrates a key challenge related to evaluating the familiarity of terms: How should teachers treat a term that they recognize and understand if it does not describe the teaching and learning that takes place in their own classrooms? Related, teachers were frequently familiar with multiple terms that describe the same action or idea. For example, when discussing what term reflects the idea of "a sudden discovery made by a student," the focus group teachers suggested both *aha moment* and *light bulb*. Some teachers then raised the issue that they might be more likely to use the term *light bulb* but that *aha moment* was, in fact, more familiar. While our lexicon includes only the most familiar term for each practice or idea, we acknowledge that many alternative terms exist that teachers use to describe those same practices.

Finally, differences emerged in teachers' familiarity with terms as compared to their usage of terms. While all of the 100 final terms were very or extremely familiar to at least 75% of the teachers, not all terms were used frequently. In fact, only 35 of the 100 terms were used daily or weekly in conversations with colleagues by at least 75% of teachers (e.g. *asking questions*, *clarifying, collaborating, differentiation, partner work, proving, reasoning, struggling, warm-up*).

While discussing differences in usage of the terms, some focus group teachers reported using different terms when speaking with different communities. For example, John mentioned that he uses the term *critical thinking* “a lot more with parents and… colleagues,” while he would talk to his students about “how you’re thinking.” Mike and Christina, in contrast, do use the term *critical thinking* with students. We suspect that some differences in usage might be related to teachers’ preparation and professional development experiences and thus plan to examine such connections in the future using existing data.

Discussion and Conclusion

We believe this lexicon has the potential to serve as both a window into teachers’ practices and a lever for change. On the one hand, we gain insight into how teachers describe mathematics teaching and learning today and how they define key components of their practice. Doing so at different points in time and with different populations of teachers might provide valuable information about the state of mathematics teaching in the U.S. In addition, interacting with this lexicon can prompt teachers to reflect on both their language use and teaching practices. Because naming a practice can promote the spreading of that practice, this lexicon can be an important resource for teacher education and professional development. Developing a shared language is a key component of that work, both because it enables teachers to communicate with each other about their teaching and because it can highlight for teachers gaps in their language – and perhaps even their practice. In future work, we plan to expand the national validation to a broader sample of U.S. teachers and compare the current teacher-generated lexicon with one developed by teacher educators. Once all international teams have completed their lexicon generation, we will also begin a phase of comparative work. These comparisons will help us to both identify gaps in the language that teachers use to describe teaching and learning in the U.S. and reflect on unique features of the U.S. lexicon.

Keywords: Equity and Diversity

Equity remains an enduring challenge for mathematics education. The experience of many students is one of marginalization such that school mathematics is disconnected from their lived experiences (Chazan, 2000). This is consequential because such disconnect, together with systemic factors of oppression, contribute to disparities in achievement (Ladson-Billings, 1994). Research has demonstrated the benefit of drawing on students' community-based knowledge and experiences in mathematics instruction and the importance of attending to both children's mathematical thinking (CMT) and their community knowledge (FOK) to support mathematics learning (Aguirre, et al., 2013). This poster examines how connecting to authentic student experiences supports students' opportunities to learn rigorous mathematics by studying the work of teachers and students around the following task: How many bottles of water does our class need for one day, based on recommended daily amounts of water for children (40 oz/day)? Students' FOK included their experiences of their community's ongoing water crisis, which required students to use only bottled water for washing, cooking, and drinking at home and at school. CMT included eliciting student thinking, use of discourse moves, etc. Data sources were videos of two classroom sessions. In multiple passes, we looked for evidence of attending to CMT and attending to FOK. In subsequent passes, subcodes were identified. We used Studio-code to identify every instance of each subcode, to indicate the duration of each instance of a subcode across the two classroom, and to see the back and forth across the two broad codes. Our analysis revealed that teachers attended to student thinking in a variety of ways, connected to students' funds of knowledge throughout the lesson, and effectively cycled between the two to provide a rich context for student learning. The teachers' decisions to connect mathematics learning to students' lived experience provides mathematics teachers and mathematics teacher educators with evidence of practices to do this work effectively. The lessons were mathematically rigorous and the deep connection to the lived experience provided a context for teachers and students to refer back to. The research reported in this article was supported with funding from the NSF (Award #1417672). Any findings, conclusions or recommendations expressed are those of the authors and do not necessarily reflect views of the NSF.

CHARACTERIZING TEACHERS' INFORMAL CONCEPTIONS OF LEARNING TRAJECTORIES IN MATHEMATICS

Alison Castro Superfine
University of Illinois at Chicago
amcastro@uic.edu

Wenjuan Li
University of Chicago
wenjuanli@uchicago.edu

Keywords: Teacher Knowledge, Learning Trajectories

While there has been a considerable increase in research related to learning trajectories (LT) in mathematics (e.g., Clements, Wilson & Sarama, 2004), more recently, researchers have begun to explore LT-based professional development (PD) programs (Wilson, 2014) and how teachers use LTs in their instruction. Little attention, however, has been paid to teachers' own conceptions of LTs, conceptions that are often (re-)formed from their instructional interactions with students over time. In this poster, we characterize teachers' informal conceptions of LTs in middle school math to better understand ways of supporting teachers to effectively navigate students' LTs during instruction.

Data from this study is taken from the BLINDED Project, a multi-year project focused on developing LT-based instructional resources and PD for middle school teachers. Ten participating teachers were interviewed at least 3 times across the first year of the project about their instructional and assessment practices. Our analysis focuses on how teachers think about LTs in the context of these interviews. We define LTs as an empirically-supported description of ordered experiences students progress through instruction, moving from informal to formal ideas with increasing sophistication over time (Confrey, 2008). We are particularly concerned with the landmarks and obstacles that define such a progression.

Results of our analysis raise several important issues. First, teachers' described *sequences* of student learning and *obstacles* students typically encounter as part of these sequences, which comports with definitions of LTs. However, teachers described these *sequences* and *obstacles* at different *grain sizes* of specificity. For example, three types of grain size emerged from the data: LTs at grade level, LTs at instructional unit level, LTs at math topic level. We found that teachers generally talk about LTs at a large grain size (e.g., students struggle with fractions), but seldom attend to finer grain size levels of LTs, especially levels of sophistication in students' thinking, which echoes those of Wilson (2014). Second, we identified the concept of *gap* in teachers' reflections about LTs, which we define as a lack of prior math knowledge that students should have become proficient in previously. While teachers help students tackle obstacles from newly-learned topics, they have to address the knowledge gaps relevant to the math concept understudy. We argue that it is important for LT research to not only on develop LTs, but also on the development of instructional resources that support teachers in managing obstacles and gaps.

CROSSROADS TO STEM CAREERS: MATH AS A BRIDGE NOT A GATEKEEPER

Robin Angotti
University of Washington Bothell
riderr@uw.edu

Rejoice Mudzimiri
University of Washington Bothell
rejoicem@uw.edu

Keywords: Post-Secondary Education, Curriculum, Equity and Diversity

At a four-year public university in the western United States with over 5,000 students and 40 degree programs, more than half of the population of students are students of color, 51% are first generation college students, and a large proportion of students come from low-income backgrounds or are non-traditional students. With this population, many students enter the university underprepared for the rigors of college level mathematics and are placed in courses below Calculus. As a STEM focused campus, a significant population of students enter the institution with the intention of majoring in disciplines for which Calculus is a prerequisite. Thus, many of these students find themselves at a crossroad of whether to stay straight on their path to a STEM career or to turn because of a lack of mathematics background. By the time students actually declare a major, the number of students choosing STEM disciplines has declined by over half. These proportions are even higher for women and students of color. Although there are many reasons for which students change their intended major, mathematics has been consistently cited as a contributing factor. In an effort to make STEM majors more accessible to all students, faculty are reforming mathematics curriculum of courses below Calculus using ambitious strategies outlined in recent research (Bressoud, Mesa, & Rasmussen, 2015) to include more active learning, group work, multiple representations, as well as metacognitive strategies.

The Study

The purpose of this research is to study the effects of these changes to add to the knowledge of effective practices for educating all students in mathematics for the 21st century. The full study seeks to begin to answer the question: *What effect does using active learning, group work, multiple representations, and metacognitive strategies have on students' beliefs about mathematics, their ability to do mathematics and their attrition from STEM fields*? The subset of the study featured in this poster specifically examined the effect of group interactions on students' understanding of graphical, tabular, symbolic and verbal representations of mathematical concepts and the connections between them.

The study uses a mixed-methods design with observation instruments, video analysis of group interactions and discourse patterns, and student work. The data provides insight into how groupwork contributes to students' understanding about different mathematical representations. Preliminary data suggests that student discourse during group interaction plays a significant role in students' sense-making of different representational forms. Although research on the relationship between multiple representations and student understanding is abundant, this study seeks to connect theory and practice by considering the impact of pedagogical practices and student discourse on students' sense-making of representations. Pedagogical practices are significant because, as first year courses are revised, consideration should be given to planning opportunities for student communication when learning concepts that are heavily loaded with multiple representations.

Introduction and Background: Horizontal, Vertical, and "Teacher-Facilitated" Discourse

Public policy, theory, and evidence suggest that mathematical learning is supported in U.S. elementary classrooms when students voice their understanding directly to each other, following *horizontal* discourse patterns. In contrast, in Chinese classrooms, where students have been reported to excel in mathematics, both Confucian tradition and cultural expectations dictate that teachers remain in control in guiding their students, thus following *vertical* discourse patterns. The question examined in this investigation was: To what extent do we find these two patterns and an additional, hybrid pattern—*teacher-facilitated horizontal* discourse—in U.S. and Chinese classrooms and what roles might they play in students' construction of mathematical knowledge?

Method

We videotaped one lesson on equivalent or adding fractions from each of 31 4th- and 5th-grade classrooms (14 from a mid-size city in the U.S. and 17 from Beijing, China). These topics were chosen because they are central to the mathematics curricula in both countries. Next, we transcribed all classroom talk and then coded each student statement to identify to whom the student was directing that statement. We identified three forms of discourse: vertical (the student statement was directed only towards the teacher), horizontal (the student statement was directed towards another student), or teacher-facilitated horizontal (the student statement was directed by the teacher to respond to another student). We also coded the mathematical terms mentioned by the student in each response statement.

Results

Using a generalized linear mixed model with log transformation, we did not find significant differences in vertical discourse between the U.S. lessons and the Chinese lessons, $F(1, 56) = 1.36$, $p = .74$. We did, however, find significantly more horizontal discourse responses in the U.S. lessons than in the Chinese lessons, $F(1, 56) = 8.53$, $p < .001$. We found significantly more teacher-facilitated horizontal discourse responses in the Chinese lessons than in the U.S. lessons, $F(1, 56) = 17.09$, $p < .001$. Moreover, Chinese students used more mathematical terms than U.S. students in both their vertical and teacher-facilitated horizontal discourse.

Discussion

The hybrid "teacher-facilitated horizontal" discourse—in which the teacher in control, but the students to address each others' ideas—may potentially be significant in helping to understand how Chinese teachers appear to engage their students to learn mathematics successfully, in ways theoretically supported, but at the same time maintaining control of classroom discourse, in concert with cultural expectations. This hybrid form may act like horizontal discourse, in that students must reckon with each other's ideas and, in this way, provoke cognitive discord that provides fertile ground for cognitive change.

STUDENTS' ENGAGEMENT WITH THE SCIENCE AND ENGINEERING INTEGRATED CALCULUS TASKS

Enes Akbuga
Texas State University

Calculus acts as a filter to the STEM pipeline, which blocks students' access to STEM careers (Steen, 1987). Therefore, a strong foundation and understanding of calculus concepts is an important requirement for all STEM degrees (Young et al., 2011). Students who are engaged during learning activities, achieve better grades and educational activities are positively related to academic performance (Kuh et al., 2008).

Schools should provide opportunities to learn about mathematics by working on problems arising in contexts outside of mathematics (NCTM, 2000). Literature shows tendency towards integrated science and mathematics education; however, more empirical research grounded in these theoretical models is clearly needed (Berlin & Lee, 2005). Therefore, this study aims to investigate the following question:

- How students engage with the Science and Engineering Integrated Calculus Tasks?

The Science and Engineering Integrated Calculus Tasks refers to the calculus tasks that includes ideas from science and engineering fields and requires students to use calculus tools to perform.

The Science and Engineering Integrated Calculus Tasks refers to the calculus tasks that are science and engineering related in nature. Since this study was a small-scale study for those tasks, physics and computer science tasks were selected and piloted. Participants were students who were enrolled to calculus courses at a Southwestern university in the U.S. Data come from task-based interviews involving the participants working on the tasks.

Strong evidence showed that the tasks supported the participants in connecting physics and science to calculus. One participant states that:

> It's to me it's coming up, its creating and designing a solution to something that could be a real-world problem and so I think that I think that adds more to the experience. It certainly gives a lot. Like I feel like I am doing something I feel like I am not just doing a bunch of math you know?

Evidence shows that the tasks were interesting and enjoyable for the participants and that they felt motivated through this experience. This finding suggests that interdisciplinary approaches might increase students' engagement and thus contribute to positive learning experiences with calculus.

A NARRATIVE INQUIRY ON THE EARLY TEACHING EXPERIENCES OF POSTSECONDARY MATHEMATICS TEACHERS: A PILOT STUDY

Sarah Mathieu-Soucy
Concordia University
sarah.msoucy@gmail.com

Keywords: Post-Secondary Education, Research Methods

In the context of a doctoral project, this poster presents a pilot study on the process of becoming a postsecondary mathematics teacher. More precisely, the context is set in cegep institutions (general and vocational colleges), the first step in postsecondary education in the province of Quebec, Canada. The program in those institutions covers about the same mathematics as the last year of high school and the first year of university in the United States. Our focus is on new cegep mathematics teachers and how they negotiate the transition from being a mathematics students (graduate or not) to teaching at postsecondary level, without any formal training in teaching or education. Little is known about the process of becoming a mathematics teacher at postsecondary level (e.g. Speer & Hald, 2008) and our work is meant to contribute to this issue. We also hope to contribute to the discussion on the mandatory (or appropriate) education to teach in those types of institutions.

Framed by Dewey's philosophy (1916, 1938), our goal with this work is to shed some light on their experience as new teachers, in order to know more about the process of becoming a teacher.

With a methodology based on narrative inquiry (Clandinin, 2013; Clandinin & Connelly, 2000), weekly meetings were arranged with two cegep teachers during a whole semester. The first one was staring his third year as a teacher, the other was starting his second. They shared stories of events they lived and identified as significant for their teaching, and of reflections they made about these events. An account was written of these stories as the interviewer heard them, and of their reflections about them. An analysis was then performed according to the three-dimensional framework designed by Clandinin & Connelly (2000), with a focus on the teachers' relationship with mathematics and education. This poster discusses what this pilot taught us about our choice of method and about our general topic. It also addresses possible changes in the method and what are the next steps to be taken to get closer to our goals.

SUPPORTING COLLABORATIVE TEACHER REFLECTION BY VISUALIZING PRACTICE WITH DATA

Ryan Seth Jones
Middle Tennessee State University
ryan.jones@mtsu.edu

Keywords: Classroom Discourse, Design Experiments, Teacher Education/Professional Development

Facilitating whole class discussions is highly valued in math classes because they can support deeper conceptual understanding by making the elements and connections within mathematical systems visible to students (e.g. Ball, 1993; Cobb, Wood, Yackel, & McNeal, 1992; Kazemi & Stipek 2001). In addition, discourse during whole class discussions can provide opportunities to develop new epistemic practices that more closely resemble the epistemologies in STEM professions (Ford & Forman, 2006, p. 3). However, the value of class discussions varies widely, and high-quality discussions require facilitation from a teacher skilled in "effectively guiding whole-class discussions of student-generated work toward important and worthwhile disciplinary ideas" (Stein et al, 2008, p. 319). Teachers need significant support to develop the practices necessary to do this challenging work. Because of this, their effectiveness can vary due to differences in teacher facilitation.

This poster describes an innovative approach to supporting teachers to continuously reflect on their facilitation of classroom discussion called Visualizing Practice with Data (VPD). The VPD approach systematically supports teachers to reflect on practice through exploring data visualizations that represent their whole class discussions. This new routine for teacher collaborative reflection is designed to orient teachers towards specific problems of practice, and to link these problems to conceptual framings that can support continual improvement (Horn & Little, 2010).

We will report on a pilot design study (Cobb, Confrey, diSessa, Lehrer, & Schauble, 2004) conducted with two 7th grade teachers over a three-week period. The author co-planned a three-week unit on probability, modeling, and inference with two teachers. The author created data representations of the discussions, and the teachers used the visualizations to collaboratively reflect on their lessons. VPD sessions provoked replays of classroom practice and rehearsals of future lessons with strategies for improvement, which we will share and elaborate on (Horn, 2010).

CONNECTING CONTEXTUAL AND MATHEMATICAL KNOWLEDGE FOR BUILDING THE COLLECTIVE MEMORY OF THE MATHEMATICS CLASS

Gloriana González
University of Illinois at Urbana-Champaign
ggonzlz@illinois.edu

Keywords: Classroom Discourse, Geometry and Geometrical and Spatial Thinking, Instructional Activities and Practices, Problem Solving

The main question of this study is: *what linguistic resources did a teacher use to bridge contextual elements of a problem and mathematical ideas during public discussions?* I analyze a teacher's choices for creating the collective memory using Systemic Functional Linguistics (Martin & Rose, 2007). I focus on choices for keeping track of people or things (i.e., participants) using options from the system of identification: *presenting*, *presuming*, *possessive, comparative,* and *text reference*. Madeline (a pseudonym) taught a problem-based lesson about the theorem stating that the set of points that are equidistant to two given points are on the perpendicular bisector of the segment connecting the two points. The problem was situated in the context of finding a fair location for an after-school center, considering two schools.

Madeline used more contextual participants during the launch than in the summary (Table 1). In contrast, the summary focused on mathematics. In addition, Madeline's references to the geometric diagram during the summary connected the problem's context and underlying mathematical ideas for solving the problem. The diagram illustrated the segment connecting the two schools, its midpoint, and the perpendicular bisector of the segment.

Table 1: Participants and Tracking

Activity	Contextual				
	Presenting	Presuming	Possessive	Comparative	Text Reference
Launch	7	35	0	0	1
Summary	0	2	0	0	0
	Mathematical				
Launch	1	0	0	0	0
Summary	8	37	0	2	1

The study shows a case of how a teacher created the collective memory of the mathematics class by shifting students' attention from the problem's contextual to mathematical ideas, using the context as a starting point to reach the mathematical goal of the lesson.

TEACHER BELIEFS: UNAWARENESS OF AND CONFLICTS WITH EQUITY

Jin Hee Lee
Michigan State University
leejin18@msu.edu

Keywords: Teacher Beliefs, Equity and Diversity, Elementary School Education

This study examines teacher beliefs about good mathematics teaching viewed through the lens of social justice teaching [SJT]. I define SJT as teaching that considers diversity for inclusive learning community and promotes equitable learning for all students, which is grounded in anti-oppressive teaching (Kumashiro, 2008). Teachers' beliefs serve as filters through which they view education; mediate knowledge; and work as a guide for teaching (Thompson, 1992). Given the powerful influence of teaching on learning, what a teacher believes results in equitable or inequitable learning; therefore, attending to teaching mediated by beliefs is important. Employing a case-study design, I investigate two Korean teachers' common sense of good mathematics teaching through espoused and enacted beliefs, using SJT perspective. Despite a Korean contextualized study, it could provide an opportunity for the dissemination of SJT to improve school mathematics because equity is a matter for everyone, regardless of countries.

In this study, the key notion is equity: *All* students should not receive identical instruction but access to meaningful mathematics through appropriate accommodations, along with uniformly high expectations (NCTM, 2000). For this, previous studies suggest that mathematics instruction considers all students' active participation in learning process; helps find out their mathematical strengths and hold positive identity as learners; and includes beyond classical knowledge and connects funds of knowledge. Also, mathematical authority should be shifted from teachers or textbook to learning community (e.g., Boaler, 2002; Moll et al., 1992). These all contribute to developing the conceptual framework to analyze espoused and enacted beliefs of teachers.

According to their interviews and teaching practices, the teachers could not well recognize the notion of equity and its importance and necessary in mathematics education, which is related to a general conception of mathematics (e.g., absolute, value-free) and a Korean educational context (e.g., excessive competition, emphasis on students' uniformity, rather than diversity). Also, the teachers felt tensions between efficient, effective, meaningful, and equitable instructions, and a priority presented in their teaching lacked consistency. Last, their teaching processes/goals were not often aligned with their students' learning processes/goals in terms of equity. Findings suggest that teachers need learning to teach for productive beliefs and knowledge against oppressiveness and inequity in teaching and learning mathematics.

DEVELOPING A PROTOCOL FOR DESCRIBING PROBLEM-SOLVING INSTRUCTION

Awsaf Alwarsh
University of Toledo
Awsaf.Alwarsh@rockets.utoledo.edu

Keywords: Problem solving, Instructional Activities and Practices, Elementary School Education

Schroeder and Lester (1989) distinguish between three approaches to problem solving instruction: teaching *about*, *for*, and *through* problem solving. Each approach has distinct tasks and emphases in students' learning. Teaching about problem solving (TAPS) focuses on learning of heuristics and/or processes of problem solving; teaching for problem solving (TFPS) helps students to understand concepts and procedures in problem solving first thin use the knowledge gained to solve problems; in teaching through problem solving (TTPS), students learn a concept or procedure through an experience as they engage in problem solving. As states and districts adopt new standards such as the Common Core State Standards for Mathematics (CCSSM) that focus more on reasoning and sense-making, teachers should align their instructions to meet these standards. Since TTPS contexts are feasible with CCSSM and demonstrate ways to align these standards with a problem-solving focus (Bostic, 2011), I used the following research method to develop a protocol to support teachers in implementing a problem solving approach based on TTPS. This protocol answered the research question: "What are descriptors of teaching for, about, and through problem solving in grades 4-6 mathematics teachers' instruction?". In this protocol, I provided detailed descriptions of strategies for each approach in problem-solving instruction and presented many examples of each strategy to elucidate the practices that would support a change to TTPS.

Participants in this study were teachers from fourth-, fifth-, and sixth-grade classrooms. These teachers participated in a PD program to improve their understanding of the CCSSM and thereby their pedagogy overall. Data were collected using two sources: teachers' lesson plans and video tapes of the lessons being taught after attending the PD program. I used the constant comparative method of qualitative analysis to compare newly-collected teacher data with previous findings elaborated in literature about TAPS, TFPS, and TTPS in order to develop an observation protocol to describe each of the approaches to problem solving.

This protocol can be used to determine which type of teaching a teacher uses and which practices he/she might change to move toward TTPS approach. This protocol can be useful for mathematics teachers who are looking to develop their classroom practice in relation to problem solving. It can also serve as a self-directed orientation for teachers' professional development. Finally, it can be useful to administrations and teacher educators who work for practicing teachers in professional development settings.

TEACHER NOTICING: A QUALITATIVE STUDY OF NOVICE AND EXPERIENCED SECONDARY MATHEMATICS TEACHERS

Melissa McAninch
Central College
mcaninchm@central.edu

Soonhye Park
North Carolina State University
spark26@ncsu.edu

Kyong Mi Choi
University of Iowa
kyongmi-choi@uiowa.edu

Keywords: Classroom Discourse, Instructional Activities and Practices, Teacher Noticing

Recent research has examined teacher attention, studying activities in the classroom that teachers notice (Jacobs et al., 2010; Russ & Luna, 2013), such as a pivotal teaching moment (PTM), defined as a student-generated disruption to the flow of discussion where a teacher can respond flexibly to extend or enhance student thinking (Ruiz-Primo & Furtak, 2007; Stockero & Van Zoest, 2013). Questioning is an important consideration within the context of noticing.

This multiple case study compared three novice and three experienced secondary mathematics teachers' noticing of PTMs and use of questions during PTMs. Six participants from five schools took part in two interviews and five lesson observations. The research question examined was: What similarities and differences exist in questions and responses to students during PTMs between novice and experienced teachers?

Analysis of lesson and interview transcripts and field notes revealed: 1) Both novice and experienced teachers emphasized proper procedures but reflected this emphasis differently; 2) One novice teacher and one experienced teacher placed emphasis on connections within and outside of mathematics; 3) One experienced teacher emphasized efficient problem solving.

The first finding showed participants emphasized mathematical procedures differently when using questions during PTMs. Tom's procedural focus was coupled with conceptual understanding, and Samantha emphasized correct procedures without emphasis on related concepts. Dana steered her students tightly toward correct procedures to avoid misconceptions.

The second finding showed one novice teacher and one experienced teacher emphasized connections within and outside of mathematics. Amy made connections to pop culture and other disciplines. Kathleen used questions to connect current topics with previously learned concepts.

A third finding relates to one experienced teacher's emphasis on efficient problem solving strategies. Amy used questions to prompt students in sharing their strategies with classmates and explain why a particular strategy was or was not useful for solving particular problems.

The topic of PTM noticing and response has many avenues for further research in mathematics education. The current literature in mathematics education could be enhanced with more study of teacher questioning in relation to the noticing and response to PTMs. Empirical studies on a larger scale can examine teacher noticing and PTMs with regards to how a teacher frames the questioning before, during, and after a PTM.

Despite the promise of differentiated instruction (DI) as a way to address cognitive diversity, it is least likely to be used in secondary mathematics classrooms (Gamoran & Weinstein, 1998), due in part to the many challenges of implementation. DI requires proactive planning to meet diverse needs of students while still maintaining a cohesive classroom community (Tomlinson, 2005). To follow through on the promise of DI it is vital to investigate the how secondary math teachers—starting with middle school—understand and implement it. This poster presents preliminary findings from a year-long Teacher Study Group (TSG) with 15 middle school math teachers from around the state of Indiana that, together with a university research team, investigated DI.

This research is drawn from the third year of a 5-year study of DI for middle school students and their teachers. The members of the TSG met for a 3-day workshop during July 2015, for 8 monthly meetings from August to April, and for 1 day of sharing and presentations during June 2016. Between monthly meetings, participants completed and shared assignments about DI, drawing on student thinking from their classrooms. The analysis for this poster was drawn from a comparison of questionnaires completed by teachers in July 2015 and June 2016.

Over the course of the TSG, we saw development in two domains: teachers' ideas about students' thinking and their ideas about DI implementation. At the beginning, their discussion about both reflected grand goals but somewhat superficial details. For example, their discussion about students was about innate ability or procedural accuracy rather than student reasoning about particular mathematical ideas. They discussed DI as a key to closing achievement gaps among students, and their ideas about implementation often involved giving students work that differed in appearance or quantity but not necessarily in depth or complexity of the mathematical thinking required. By the end of the year, teachers had made some changes in how they thought about the endeavor of differentiation. Teachers commented on the need to build on what students were thinking, which involved gathering careful evidence of that thinking, posing tasks that could allow students to make small steps, and focusing on mathematical meaning. With regard to their implementation of DI, they recognized more clearly what they were already doing in their classroom to differentiate, what was meaningful to them about differentiation, and focused on making small changes to better meet the needs of their students.

As researchers, our ideas about DI evolved alongside those of the teachers; we began to understand how important it is to focus on student thinking as a foundation. We began to understand how important it is to make small steps, tailored to the needs of both students and teachers.

TEACHERS' NUMBER CHOICES FOR EQUAL SHARING PROBLEMS

Gladys Krause
The University of Texas at Austin
gladyshrueda@utexas.edu

Susan Empson
University of Missouri
empsons@missouri.edu

Victoria Jacobs
University of North Carolina at Greensboro
vrjacobs@uncg.edu

Keywords: Teacher Knowledge, Rational Numbers, Elementary School Education

Equal Sharing story problems can be used to teach fractions when the context involves quantities that can be individually partitioned. For example, the Equal Sharing problem of 11 bars shared equally among 4 children results in a remainder of 3 bars that can be partitioned to exhaust the bars and give each sharer a fractional amount. The specific numbers in Equal Sharing problems can influence the accessibility of problems for a child, the knowledge a child might use to solve problems, and the mathematics that can be addressed. Teachers' choices for numbers used in Equal Sharing problems are therefore a potentially powerful component of planning for fraction instruction.

Studying teachers' number choices for whole-number story problems, Drake and Land (2014) identified the need to investigate how teachers select numbers for problems used during instruction. We answered their call by exploring teachers' reasoning for number choices in a fraction story problem by interviewing 43 teachers of grades 3-5 after a classroom observation where they posed an Equal Sharing fraction problem of their choice. These teachers had participated in 1, 2, or 3 years of professional development focused on children's fraction thinking. We asked: *How did you decide on this problem for these students? How did what you know about your students inform your number choice(s)?*

We found that teachers' number choices were informed by children's mathematical thinking in two main ways: (a) Sometimes teachers drew on general information about children's fraction thinking (e.g., children often draw to solve such problems); and (b) sometimes teachers drew on detailed information about specific children's fraction thinking (e.g., Rosie's repeated halving). In addition, teachers' number choices were informed by the mathematical content they wanted to address, also in two main ways: (a) Sometimes teachers described how their target content emerged in children's strategies (e.g., a strategy where each brownie was split into 8 parts and the parts combined for each share could be used to address addition of unit fractions); and (b) sometimes teachers described target content with minimal connections to children's thinking (e.g., "I chose 10 sharers because I wanted to work with decimals"). These findings highlight critical components in teachers' reasoning about number choices for fraction story problems and lay the groundwork for research on such choices in instructional planning.

EXPLORING TEACHERS' SCAFFOLDING OF STUDENTS' MATHEMATICAL EXPLANATIONS IN SECONDARY SCHOOLS

Joanna O. Masingila
Syracuse University
jomasing@syr.edu

Grace Njuguna
Syracuse University
gnnjugun@syr.edu

One way to communicate and clarify one's thinking is through giving mathematical explanations (Clark, Moore, & Carlson, 2008), which has been connected by researchers to students' understanding of mathematics (Goos, 1995). Yet, studies have shown that students struggle with giving mathematical explanations (e.g., Brunstrom & Fahlgren, 2015). To understand the genesis of this struggle, it is important to explore how teachers scaffold students' mathematical explanations. Through scaffolding, the anticipation is that the support offered will enable the learner to internalize the strategies required to complete a similar task independently (van de Pol, Volman, & Beishuizen, 2010). That said, if students are to demonstrate the competency in explaining their work, then studying how teachers foster such competency is worth considering.

In this study, we employed a case study design to explore what two high school mathematics teachers perceived as a sufficient mathematical explanation, what they thought are scaffolding methods that support students in giving mathematical explanations, and their methods of scaffolding students in giving mathematical explanations. The two participants from a suburban independent school and a suburban public school were selected following their practice of asking students to give mathematical explanations during their lessons. Data were collected using two semi-structured interviews and four lesson observations, each roughly one hour in length. A constant-comparative data analysis method was employed, where analysis involved three phases: (a) transcribing all recorded interviews and lessons observed; (b) through open-coding, identifying names, events, and actions that seemed to address the research questions; and (c) categorizing all codes and creating analytical memos. We identified three major themes: (1) teachers' perception of a sufficient mathematical explanation; (2) methods perceived to scaffold students' mathematical explanations; and (3) enacted methods of scaffolding mathematical explanations.

Our poster will present findings and their implications. In sum, teachers in this study perceived a sufficient mathematical explanation to reference the quantities of the problem in context (Clark et al., 2008). They also perceived diverse and common methods of scaffolding students' mathematical explanations, which some were observed during their lessons. Our poster will provide examples of these methods.

TEACHING NORMS FOR THE CONCEPT OF DERIVATIVE IN HIGH SCHOOL AND COLLEGE LEVEL CALCULUS COURSES

Anita N. Alexander
Kent State University
aalexa17@kent.edu

Keywords: Instructional Activities and Practices; High School Education; Post-Secondary Education

From its inception, Advanced Placement calculus was implemented to not only bridge the gap between high school and college level courses by providing a challenging curriculum, but to promote equity by providing opportunities for motivated students who excelled in mathematics in the public school system. Certain teaching norms may differ from one context to another (Herbst & Chazan, 2012), from an Advanced Placement calculus classroom environment to a college calculus course in a university setting with respect to practical rationality and instructional activity. The purpose of this study is to explore whether this has an impact on student learning with respect to the concept of derivatives, and whether certain teaching norms e.g. inquiry-based tasks, are either less prevalent in a university setting, in upper level mathematics courses, or possibly both.

This study is situated with the perspective that instructional strategies in the calculus classroom vary with regard to procedural and conceptual understanding of the content (Törner, Potari, & Zachariades, 2014). Educators' perceptions of effective practice with respect to teaching derivatives can impact the depth of student learning, which will be explored with the following research question through the lens of practical rationality to examine aspects of procedural and conceptual understanding: How do college and high school level calculus instructors describe teaching norms for the concept of derivative, and what justifications do they use for endorsing or departing from these norms?

Two high school AP calculus teachers and two college calculus instructors are participants in this study. Participants were interviewed with the objective of gaining insight into instructional methods, curricula, and perceptions of effective practice. This study could impact the way calculus is taught in both high school and college classrooms, and provide insight into the alignment between AP calculus and college calculus courses.

In each interview lasting approximately 45 minutes, four scenarios were developed using the platform LessonSketch.org to see how participants respond to two teacher focused scenarios and two student focused scenarios, designed to elicit certain responses regarding instructional practices. Preliminary analysis of interview responses revealed that college calculus instructors recognized more instructor-centric teaching as normative at the collegiate level, regardless of whether they endorsed these norms individually. AP calculus instructors were more likely to have higher expectations of their students, responding immediately with confidence that their students were able to describe the relationship between a function and its derivative.

FIRST GRADE WRITTEN MATHEMATICAL EXPLANATIONS

Nicole Venuto
Georgia State University

Lynn C. Hart
Georgia State University
lhart@gsu.edu

Keywords: Elementary Education, Classroom Discourse

Communicating about their thinking in mathematics is challenging for young children. The Common Core State Standards for Mathematics requires children, beginning in Kindergarten, to *construct viable arguments and critique the reasoning of others*. While the CCSSM (2010) does not specifically require children to construct their arguments in writing, children in grades three and up are asked to construct arguments on standardized assessments, requiring them to *write* about their mathematical reasoning. However, while writing in mathematics helps children consolidate their thinking (NCTM, 2000), undeveloped metacognitive awareness frequently limits their ability to put that thinking in writing. Since the early elementary grades are a foundation for future success, exploring ways to help young children develop writing about their mathematical thinking is warranted (Cohen et al., 2015).

The CCSSM (2010) specifically state that first grade students explain the reasoning used when adding and subtracting two-digit numbers and multiples of ten. To study the impact of writing on students' ability to explain their reasoning, two classes of first graders engaged in eight 45-minute lessons in which they solved simple word problems using a strategy of their choosing, such as direct modeling, counting or an invented algorithm (Carpenter et al., 2015). Students then shared their solution strategy with a partner. After sharing with a partner, students wrote about how they solved the problem. Finally, the whole class engaged in a conversation about the students' solution strategies and the mathematical goals of the lesson.

To determine change, the students participated in a pre/post assessment in which they explained in writing how they solved a Join Result Unknown problem. The written responses on the pre-assessment were vague and mainly limited to describing their drawings, such as *I drew ten blocks and one blocks.* The written responses on the post assessment included more mathematical vocabulary, including add, more, counted, tens and ones. Students demonstrated conceptual understanding of adding two-digit numbers and multiples of ten by writing statements such as " *I used 3 tens 6 ones and made 36. I used 4 tens 0 ones and made 40. I counted them and made 76.* Students also demonstrated mathematical reasoning by explaining that they knew to add because "*he went to the store and got more*." The student responses on the post assessment demonstrate that *very* young children are able to write about their mathematical thinking in deep, thoughtful ways.

MY CALCULUS, YOUR CALCULUS: TEACHING MATH THROUGH SOCIAL JUSTICE IN COLLEGE CALCULUS

L. Jeneva Clark
University of Tennessee
Dr.jenevaclark@utk.edu

Lynn Liao Hodge
University of Tennessee
Lhodge4@utk.edu

Michael Lawson
University of Tennessee
Mlawso13@vols.utk.eduKeywords: Instructional Activities and Practices, Post-Secondary Education

Teaching mathematics through social justice supports students' perceptions of relevance in mathematics (e.g., Gutstein, 2006). However, while some research reports tension between mathematics and social justice (e.g., Enyedy & Mukhopadhyay, 2007), Gutstein (2017) describes it, instead, as an interweaving dance, and this study investigates the choreography of teaching mathematics through social justice. How do tasks support students' development of critical dispositions toward social topics, or their views of mathematics?

A growing body of scholarship has informed our understanding of teaching mathematics through social justice and has emphasized the usefulness of real-world contexts in creating opportunities for math and sociopolitical learning. The data were collected in a semester-long Calculus course. This study contributes to literature by addressing the following questions:

1. What capabilities and constraints are observed when teaching and learning mathematics through social justice?
2. How can teachers and students "dance" between social justice pedagogy and mathematical content?

University calculus students (n=106) conducted social justice projects. Classes were audio-recorded, transcribed, and analyzed. In questionnaires, students tended to identify constraints in correlation with mathematical content ($p<.05$) and capabilities in correlation with cultural knowledge ($p<.05$). While these correlations inform the tensions between content and culture, the qualitative analysis reveals more about the dance between mathematical and sociocultural knowledge. For example, a thematic analysis reveals a humanization of mathematics. After analyzing homeless rates among psychiatric patients, one student reported, "It puts a face on the numbers." Other themes included access and action, encouraging critical dispositions.

By analyzing the instructor's perspective, practical implications include affordances in developing engaged dispositions toward Calculus and social justice-themed activities. Theoretical implications include refinement and extension of Gutstein's framework.

SIMULATING SPREADING IDEAS ACROSS MATHEMATICAL CLASSROOMS

Thomas E. Ricks
Louisiana State University
tomricks@lsu.edu

Keywords: Classroom Discourse, Teacher Education/Professional Development, Teacher Beliefs

This paper explores how students' mathematical ideas can spread across the mathematics classroom space during seatwork. Recent reform recommendations emphasize the importance of a well-designed challenging task forming the core of students' in-class mathematical experiences (e.g., NCTM, 2000). Maintaining each individual student's cognitive demand while solving this central task is a major part of teacher work during the implementation phase of a mathematics lesson. However, in a class where communication, collaboration, and joint cognition are expected, valued, and encouraged, students' own interactions can paradoxically and ironically undermine the teacher's attempts to maintain the cognitive load of a teacher-posed task for each individual student. As students listen to each other's thoughts, successful solutions to teacher-posed cognitive task can rapidly promulgate across the classroom space. When students adopt successful ideas of their peers, their cognitive demand (relative to the central task) is diminished.

To better understand this dilemma, this study explored ways in which students' mathematical ideas can spread across the mathematical classroom space. Using an idealized classroom space of 36 student desk locations (six desks across by six desks deep), 3,568 separate computer simulations were run on a computer program based on the initial parameters of (a) spread initiating from a single location and (b) propagating in eight possible directions (c) based on a pre-set percentage chance of idea spread from one student location to the next. 1,561 simulations allowed for (d) possible new student understanding to potentially and spontaneously crop up at other locations in the classroom (to simulate the possibility of unique student understanding developing that was unconnected to the original student's idea, as seatwork progressed). Results from these computer simulations include (1) empirical justification for the theory of placing more able students on the periphery of the classroom space slowed the spread of mathematical ideas (which allowed slower students the opportunity to experience longer the vital element of struggle so important to mathematics learning), (2) the distributions of the number of time iterations for full classroom understanding were not normally distributed, and (3)

This study contributes to the growing body of research on the development of authentic mathematical communities in mathematics classes, although this study is limited in scope. Better understanding how student ideas can spread across the mathematics classroom landscape will enable more robust theory generation for the dilemma of maximizing students' cognitive demand during seatwork of teacher-posed challenging tasks while simultaneously respecting the need for appropriate communication. More research utilizing more precise computer simulations that better model how student ideas spread across mathematics classroom spaces is needed to better understand how to maintain students' cognitive load during mathematics task activity.

UNPACKING SECONDARY MATHEMATICS TEACHERS' FORMATIVE ASSESSMENT PROCESSES SUPPORTED BY TECHNOLOGY

Amanda J. Roble
Centerville City Schools, OH
Amanda.Roble@centerville.k12.oh.us

Keywords: Assessment and Evaluation, Instructional Activities and Practices, Technology

Existing literature on formative assessment focuses on the characteristics, cyclic processes, and ongoing conceptualization of formative assessment (Black & Wiliam, 2009; Cowie & Bell, 1999; Heritage, 2010; Wiliam, 2014). The purpose of this qualitative case study research was to identify the formative assessment processes of three secondary mathematics teachers who used technology to gather feedback/answers from students during instruction. Data collection included audio-recorded non-participant classroom observations, audio-recorded semi-structured pre- and post-observation interviews, and when applicable, screen capture of student responses through technology. The conceptual framework of formative assessment by Black and Wiliam (2009) was used to analyze transcribed classroom observations to determine how each teacher utilized, implemented and sequenced the five key strategies (KS) of the framework during instruction.

Results indicated that all three teachers incorporated *eliciting evidence of student understanding and learning* (KS2), *providing feedback to move learning forward* (KS3), and *activating students as instructional resources for one another* (KS4) into instruction. All three teachers verbally shared learning objectives with students, but only one *clarified and shared learning intentions and criteria for success with students* (KS1). Two teachers *activated students as owners of their own learning* (KS5). Only one teacher implemented all five KS into their formative assessment process. In addition to identifying the KS that emerged during the formative assessment processes, the implementation and sequencing of strategies was also revealed. Each teacher demonstrated their own unique process of formative assessment. Diagrams depicting the sequence of KS implemented by each teacher during their formative assessment process will be shared.

Future implications include continuing to explore teachers' implementation and sequencing of KS of formative assessment using technology, how each teacher's mathematical disposition impacts their process of formative assessment, and the impact of each formative assessment process on student achievement. In the three cases presented, some instruction occurred prior to using technology to elicit evidence of student thinking. How did this implementation and sequencing of KS impact student understanding and achievement? How would varying the sequence of KS impact student understanding and achievement? Additional work is needed to learn more about how teachers use the key strategies of formative assessment in practice and the impact these formative assessment processes have on student understanding and achievement in mathematics.

DEVELOPING PRESERVICE TEACHERS' UNDERSTANDING OF FUNCTION USING A VENDING MACHINE METAPHOR APPLET

Allison McCulloch
NC State University
allison_mcculloch@ncsu.edu

Jennifer Lovett
Middle Tennessee State University
jennifer.lovett@mtsu.edu

Cyndi Edgington
NC State University
cpedging@ncsu.edu

The purpose of this study is to examine the use of a Vending Machine applet as a cognitive root for the development of preservice teachers understanding of function. The applet was designed to purposefully problematize common misconceptions associated with the algebraic nature of typical function machines. Findings indicated affordances and limitations of the applet as a cognitive root, motivating revisions to the applet for further study.

Keywords: Algebra and Algebraic Thinking, Instructional Activities and Practices, Technology

Functions are a critical base for mathematical understanding of STEM disciplines and are often regarded as the unifying element of much of secondary mathematics. This is recognized in the CCSSM where the study of functions is given its own domain, separate from Algebra, in grades 9–12 (National Governors Association Center for Best Practice & Council of Chief State School Officers, 2010). The conceptual obstacles with respect to putting function front and center have been well documented in the literature (e.g., Even, 1990, Tall et al., 2000) and have proven particularly hard to overcome. Rather than constructing their own definition of function based on tasks, students are often presented with a highly theoretical definition, resulting in a disconnect between their concept definition and their concept image (Even, 1990). The same is true for undergraduate students (Carlson, 1998), including preservice mathematics teachers (PSTs). Thus it is important that PSTs have an opportunity to develop a deep conceptual understanding of functions that remedies any existing misconceptions and understand how to engage students in tasks to develop and test their own definitions.

Theoretical Framework

There is evidence that PSTs often have a view of function that is limited to algebraic expressions and their associated graphs (e.g., Carlson 1998; Even 1990). Such understandings typically result in a "vertical line test" related definition of function (e.g., Carlson, 1998). Furthermore, those working with a vertical line test definition of function or an equation view of function often have the misconception that constant functions (horizontal lines) are not functions (Bakar & Tall, 1991). One suggested strategy for mitigating these common misunderstandings is the use of a function machine as a cognitive root.

The idea of a *cognitive root* was introduced by Tall as an "anchoring concept which the learner finds easy to comprehend, yet forms a basis on which a theory may be built" as he was developing a cognitive approach to calculus (Tall et al., 2000, p.497). One common example is the use of a *function machine* (sometimes referred to as a function box) as a cognitive root for the development of a definition for function as well as for building understanding of independent/ dependent variables and domain/range. The machine metaphor suggested by Tall and colleagues was typically a "guess my rule" activity. In such activities the inputs and associated outputs are provided, and students are challenged to determine what happened in the function machine (i.e., determine the function rule). While students are presented with a machine to embody the function concept, the rules used by the machine are algebraic in nature. Using such machines proved quite promising, yet some students still struggled with connecting representations and determining what is and is not a function (McGowan et al., 2000).

Given the potential of the machine metaphor as a cognitive root for function, in our work designing learning experiences for PSTs that incorporate technology, we originally followed Tall and colleagues' recommendations and created a function machine using GeoGebra to engage PSTs in "guess my rule" activities, including designing their own function machines. Our PSTs demonstrated misconceptions that were similar to those in the literature, namely, that all functions needed to be represented by a formula, difficulty differentiating between the terms unique and exactly one output, and identifying constant functions as non-functions.

As a result, we set forth to design a set of machines that would not only be a familiar anchoring concept, but would hopefully also push and probe PSTs current understandings about functions in ways to intentionally problematize these misconceptions. To do this we considered Carlson's (1998) key aspects of function as they related to the function machine metaphor: interpreting and characterizing independent and dependent variables, ability to identify and describe the domain and range, using one representation of function to make sense of another, and distinguishing between functions and non-functions. The function machine as a cognitive root and these aspects of function as they related to common misconceptions framed both the design of our applet and our analysis of PSTs' work with the applet.

Design of the Applet

Unlike previous machine metaphors PSTs had experience with, the function machine applet we designed contains no numerical or algebraic expressions, rather the applet was built on the metaphor of a vending machine. The Vending Machine applet (https://ggbm.at/LdtLR0ex) is a GeoGebra file that contains five vending machines each with buttons for: Red Cola, Diet Blue, Silver Mist, and Green Dew. The directions state to explore the five machines and determine which are functions (Figure 1; McCulloch et al., 2015). When the user presses a button (input), one or more cans appear in the bottom of the machine (output). To remove the can(s) from the machine, the user clicks a reset button. The functionality of each machine was designed to address misconceptions from the literature on distinguishing functions and non-functions that our PSTs had previously demonstrated. Machine A is the identity function; each button produces a can of the corresponding color.

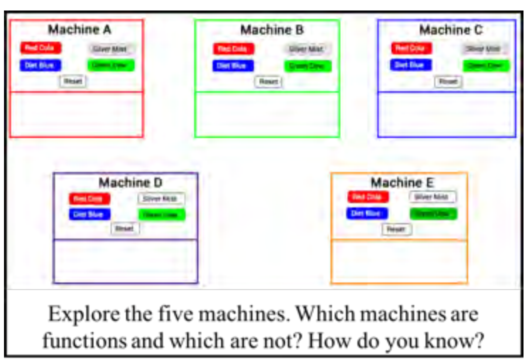

Figure 1. Screenshot of function machine applet.

Machine B is the same as A except when Silver Mist is selected, it produces two silver cans. This machine requires students to wrestle with the notion of what represents an element in the range. For Machine C, every button results in a single green can. The purpose of which is to present PSTs with a constant function to consider (i.e., the same number of cans of the same color for each button). For each button on Machine D a single can is produced, but the color is different from the color of the button pressed. This machine was designed to problematize their occasional use of the term "unique" when thinking about outputs. Finally, Machine E is similar to D, except the Silver Mist button randomly produces cans of different colors each time it is pressed. The purpose of Machine E is to provide a context in which testing the buttons on the machine once is not sufficient for determining whether or not the object is a function. Thus machines B, C, and E explicitly address the misconceptions we found when using function machines with associated algebraic expressions or graphs.

The purpose of this study was to examine the effectiveness of the Vending Machine applet as a cognitive root for function. In this paper we specifically address the following research question: What understandings of function do PSTs develop from engaging in a task using a vending machine metaphor applet?

Methods

To answer our research question, we engaged PSTs enrolled in a content-focused methods course in a task exploring the Vending Machine applet. Nine PSTs (referred to as S1-S9) engaged in the task; of the nine, seven were undergraduate secondary mathematics education majors (three of the seven were also dual mathematics majors), and two were enrolled in the Master of Arts in Teaching (initial licensure) program.

Data Collection and Analysis

The study began by asking PSTs to individually write a definition of a function, including examples and non-examples. After doing this independently, a whole class discussion was facilitated using their definitions through which the class agreed upon the following definition: *A function is a mathematical relationship such that each input has exactly one output.* Then, they were asked to engage in the Vending Machine applet task as a homework assignment; they were to explore the machines to determine which were functions and which were non-functions. Each PST captured a screencast of their work as they followed a "think aloud" protocol while working on the task. Simultaneously, they completed a worksheet to provide written documentation of their thinking. Following the task, PSTs completed a written reflection where they were asked to revise the agreed upon definition of function based on their experience with the task, to reflect on the different representations of functions presented in the task, and to discuss aspects of function highlighted by different machines with which they engaged (including possible uses with students). The PSTs uploaded their screencasts to a shared, secure online folder and submitted their written work during the following class session.

We began by examining the data to develop a code book based on four key aspects of function (Carlson, 1998) we previously identified that informed our theoretical framework. We chose two students' data (screencast, written worksheet, and reflection) and used open coding to identify themes related to each key aspect. We used a constant comparison method (Strauss & Corbin, 1998), which allowed for emerging categories within each key aspect and the refinement of these categories as they were contrasted with new data. Since we were particularly interested in how PSTs made sense of the applet, we also looked for evidence of the affordances and limitations of the applet, as well as misconceptions/errors, and an "other" category to capture any unanticipated themes. Then, to check for reliability, each author individually coded the two original students' data, plus an additional student's data, using the code book.

For the screencasts, we recorded the code and machine the PST referenced. For example, when working on Machine E, one PST commented "Machine E is a non-function because the silver button points to different colored cans" This was coded as "Distinguishing between functions and non-functions" and "Machine E" since the PST was justifying why that particular machine was a non-function. For the written artifacts, we coded their written explanations and drawings. For example, on the worksheet, several PSTs drew mappings that described each vending machine. These drawings were coded as “Interpret and characterize independent and dependent variables” and labeled with the letter of the corresponding machine that the drawing was in reference to. The researchers met to discuss the codebook and emerging themes and to clarify the codebook.

Once the codebook was finalized and reliability achieved, we coded all of the remaining data. We then looked within each code to understand the ways in which the PSTs engaged with the function machines to make sense of each key aspect. Finally, we examined the data by each function machine (for example, we looked at all codes associated with Machine A) to understand how each particular machine supported (or conflated) PSTs understanding of function, in particular the key aspects, as well as the affordances and limitations of the applet.

Results

Of the nine PSTs that completed the function machine task, five of them provided correct responses for all five machines. The other four PSTs’ errors were related to Machine B and/or Machine E (see Table 1). Their interpretations and characterizations of the independent and dependent variables (referred to as “inputs” and “outputs” by most PSTs) were central to their determination of whether or not each machine was a function. Here we focus on the ways in which the PSTs made sense of two specific machines, B and E. These machines are the only two for which PSTs provided incorrect answers and as such they provide insight to the aspects of function that the machines were designed to elicit. For the purposes of this paper we discuss two specific code categories, *distinguishing between functions and non-functions* and *interpreting and characterizing independent and dependent variables*, and the ways they provide insight to student sense making.

Table 1: PSTs’ Worksheet Responses: Function or Non-Function

Machine	S1	S2	S3	S4	S5	S6	S7	S8	S9
A	F	F	F	F	F	F	F	F	F
B	F	N	F	N	N	N	F	F	F
C	F	F	F	F	F	F	F	F	F
D	F	F	F	F	F	F	F	F	F
E	N	N	N	F	F	F	N	N	N

The Case of Machine B

As a reminder, pressing the Silver Mist button on Machine B results in the production of two cans of Silver Mist. The other three buttons act as the PSTs expected, producing one can of the soda noted on the button. Noting that Machine B is not a function was the most commonly made error in this task (n=4). The characterizations of the independent and dependent variables were quite different for those students that determined B was a function and those that determined it was not.

When examining the machines, the PSTs that described the independent and dependent variables (called inputs and outputs from here on out) only attending to how many elements there were in the output for each input determined that the machine was not a function. For example, S4 explained, “Red cola has one output, diet blue has one output, silver mist has two outputs, and green dew has one output...since silver mist has two outputs, I would say that is not a function.” Similarly, S5 noted “So you put in an input and you get two outputs, in a function you are not supposed to get two outputs.” Notice that both PSTs were focused on the number of outputs for each input.

In contrast, other PSTs were attending to not only the number of elements in the output, but also what they were and if the mapping from input to output was “predictable”. S3 stated, “Exactly one output for each input, 2 silver mist cans is the output for silver mist.” S9 went further and explained the importance of the output being “predictable” when he said, “Even though silver mist comes out with two cans versus one can but it always comes out with two silver cans, instead of three silver cans one time and two silver cans another time.” While the idea of two cans being the output was not problematic for some students, there were a few that grappled with it as they made sense of the situation. For example, S1 noted

> So silver mist comes out with two sodas...hmmm...[keeps pressing]...that's interesting...cuz it depends on what you consider the output. The output could be how many different kinds of sodas there are...so it could be like you're putting in red you're getting out one, you're putting in blue you're getting out one, you're putting in silver you're getting out two, it doesn't necessarily mean it's not a function...it's just a different value.

The difference between these responses and those from the PSTs that focused on only the number of elements was that these students identified a mapping.

The Case of Machine E

Like we saw for Machine B, attending to only how many elements in each output was also problematic when trying to determine whether or not Machine E represented a function. As a reminder, Machine E included a button for Silver Mist for which the output was random, so it was not a function. S4 explained, "Red cola has an output, diet blue has an output, silver mist has an output, and green dew has one output...again [presses buttons]...they each have one output, silver mist has one output but it is a blue soda as well...each choice has one output...so it is a function." Even though she clearly identified that the Silver Mist button did not always produce the same output, she determined it was a function because it always produces one output. S5 only tried each button once, so he did not see that the Silver Mist button was unpredictable. He said, "For Red Cola you get a Red Cola, for Diet Blue you get you a Diet Blue, for Silver Mist you get a Green Dew, for Green Dew you get a Green Dew. I still think it's a function...you can get two of the same outputs because you are still getting one output for each input." While he did not have the opportunity to see the different outputs, the fact that he only tested the button once suggests that he does not understand what it means for an input to map to exactly one output.

The PSTs that interpreted outputs to have characteristics beyond just "how many" elements, correctly identified Machine E as a non-function. We have taken to describing this coordination between inputs and attending to multiple characteristics of the outputs as "mapping thinking". The following explanations are examples of what we are referring to as mapping thinking:

- "Silver mist can give you any soda. Yeah this one is not going to be a function because the silver mist button can give you all kinds of sodas. Machine E is not a function because it has different outputs for the same input." (S9)
- "Every input is supposed to have one output. It's not supposed to change all the time...The assignment of inputs to outputs can't change all the time. It has to be a unique prescription. It looks like it varies all the time." (S8)
- 
(S7)

These explanations not only include an interpretation of independent and dependent variables beyond simply how many elements in an output are associated with a given input, but also show evidence of a deeper understanding of the definition of function. This understanding goes beyond "one input gives one output" and is not attached to an equation or graph.

Revising Definitions Based on Machines B and E

In a reflection assignment the PSTs were asked if they would suggest any changes to the agreed upon definition: *A function is a mathematical relationship such that each input has exactly one output*. The PSTs that misidentified both B and E did not suggest any changes to the definition. S1, who misidentified only B, wrote, "I think that to be a function, it had to map colas to one other cola, not change the colas it was giving out or producing more. So, I think that our definition is still a good one." Notice that he is still focused on the number of elements in the output. In contrast, all of the PSTs that correctly identified all 5 machines suggested some changes to the definition to address the misconceptions that might be associated with working in the context of vending machines. For example, S3 suggests,

> I would like to change it to a "function is a mathematical relationship such that each input produces the same output at all times." [...] I noticed that in Machine B, each input produced one can except Silver Mist, which produced two cans, and this made me initially say it wasn't a function. However, I know that you can have a function that is not uniform, so producing two cans each time is an appropriate thing for Silver Mist to do without violating the function rules. Thus, the "exactly one" language is misleading… Then, Machine E threw me off because each input produces exactly one output, but Silver Mist produces a different output each time...Because of that discovery, I realized that the language "exactly one output" could be very confusing to students and does not exactly explain what is going on in a function, which is that no matter when you place an input into the function, you will always get the exact same output that you got the last time you put that particular input into a function. That is what we mean by "exactly one output," but the language restricts students from really understanding what the function is doing with that input.

It is clear from these suggested revisions that the context of a vending machine was not only a powerful cognitive root for the PSTs' own understanding, but it also resulted in an understanding of ways to mitigate their future students' possible misunderstandings.

Discussion

As this was our first use of the Vending Machine applet as a cognitive root for function with PSTs, it is important to note affordances and limitations of its design. Machines B and E, the two most commonly misidentified machines, are nice examples of how these PSTs make sense of the definition of function within the context of the Vending Machine applet being used as a cognitive root and provide insight to the ways that they interpret independent/dependent variables and apply them to their existing definition of function. Results showed that through these experiences, PSTs recognized that the use of the commonly used phrase "exactly one output" in the definition of function can be problematic. Furthermore, the fact that the applet used non-expression objects seems to have been a helpful context for this realization.

The need to press the reset button to remove the output was first seen as a limitation as PSTs often forgot to do so and ended up with multiple outputs showing at once. However, this feature was also an affordance in that it offered insight to their thinking and, for those that did it intentionally, provided a representation of the range. Another limitation was the number of machines that were included in the applet. There were not enough examples of non-functions or functions with more than one element as an output. In more than one instance PSTs got to the final machine and assumed it was a non-function simply because "at least one of these must be". Finally, it is possible that agreeing upon a class definition of function prior to engaging with the task might have changed the way that PSTs interacted with the applet. It was not clear if all PSTs were actually in agreement with the adopted definition. If one did not understand the agreed upon definition, it would be difficult to apply it to an analysis of the machines.

From our research on the PSTs' engagement with the applet and the affordances and limitations identified, a revision to the applet has been made. The new version has been created to address PSTs' interpretations of Machine B and Machine E and the limitations noted above. It consists of four pages (Figure 2). The first two pages contain two vending machines, on each page one machine is labeled as a function and the other is labeled as not a function. The two non-function machines each have at least one button that produces a random can when pressed. The new applet provides the opportunity for PSTs to make a conjecture, after page two, on why Machines 1 and 3 are functions and Machines 2 and 4 are non-functions. They then test their conjecture on the pages three and four, that each contain five machines. The five original machines are included, along with five new machines. These new machines provide additional opportunities to examine machines that are not one-to-one, produce random pairs of cans as an output, and have random outputs for all four inputs.

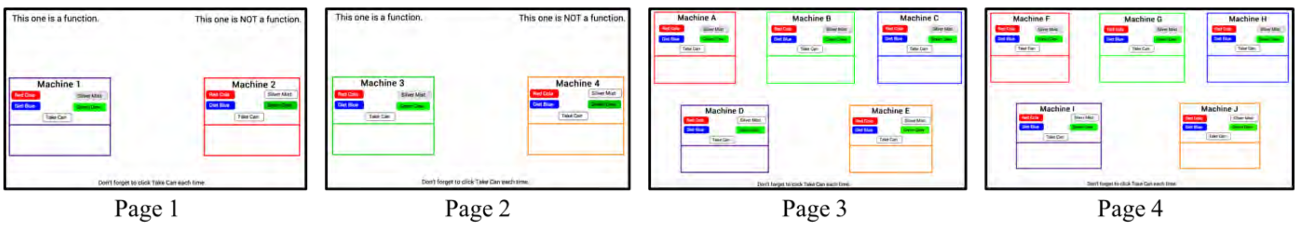

Figure 2. New version of the applet (https://ggbm.at/MAEdhkH6).

Conclusion

Our findings suggest that the Vending Machine applet might be a powerful tool (cognitive root) for building understanding of key aspects of function as identified by Carlson (1998). In thinking about the theme of this conference, this work suggests a potential change in route in the ways we might consider engaging PSTs with concept of function. However, to determine whether or not these findings are generalizable the use of the applet needs to be studied on a larger scale. We are currently conducting a larger study using the new version of the applet with approximately 40 PSTs from five universities across the country. Our hope is that through further study and revision, this work results in a solid cognitive root that remedies existing misconceptions and on which deep conceptual understanding of function can be built.

Acknowledgments

The work in this project was partially supported by the Preparing to Teach Mathematics with Technology (PTMT) project, funded by the National Science Foundation with grants to NC State (DUE 04-42139, DUE 08017253, and DUE 1123001). This research report presents the final year results of a three-year research project on computational thinking (CT). The project, funded by the National Science Foundation, involved training teachers in grades four through six to implement Scalable Game Design and LEGO® EV3 robotics during afterschool clubs. Thirty teachers and 531 students took part in the Year-3 study that blended game design and robotics. Eight of these teachers and 98 students participated in a large urban city in Pennsylvania, while the remaining 22 teachers and 433 students participated in rural Wyoming. This paper reports on the results as it pertained to teacher outcomes, specifically, teachers' development of CT beliefs and engineering practices.

Keywords: Technology

Computer science is a rapidly growing field (Bureau of Labor Statistics, U.S. Department of Labor, 2016) that when coupled with engineering offers youth a broad, multidisciplinary pathway to occupations that provide both intrinsic and extrinsic rewards and benefits. Computing is integral to science, technology, engineering, and mathematics (STEM) in general and roughly 67% of computing jobs will be in non-STEM industries (Israel et al., 2015). Underrepresented minority students have limited opportunities to engage in high-quality STEM education. As access to school-based technology increases, opportunity expands to out-of-school time (OST) programs. Given the data-rich context in which we live, this expansion fills a critical need to identify the tools, pedagogy, and practices deemed essential for promoting STEM learning.

This report describes our Year-3 study, which blended game design and robotics to provide elementary school teachers with a robust curriculum that would allow them to engage students in computational thinking (CT) at high levels. While several teachers were familiar with robotics, few had previously worked with game design. Because competency in computer science and engineering demands an understanding of mathematical and scientific processes and problem solving, we believe our pedagogical approach—to couple game design and robotics within the context of culture—is both necessary and innovative. Culture is defined as "a group's individual and collective w ays of thinking, believing, and knowing, which includes their shared experiences, consciousness, skills, values, forms of expression, social institutions, and behaviors" (Tillman, 2002, p. 4) and can be used to motivate students to learn difficult concepts. Game design and robotics were used to promote CT as students engaged in abstraction, logical thinking, and debugging to create game conditions using simple commands and to make the robot perform a task. Specifically, we were interested in how teachers' beliefs and practices changed as a result of their work in STEM with rural or urban elementary students during OST.

The research questions that guided the study reported here were as follows:

How did teachers' beliefs about computational thinking change as a result of the study?

How did teachers' engineering beliefs and practices change as a result of the study?

How did teachers' instruction change in comparison to baseline observations?

How did focal teachers describe their teaching practices during OST?

Theoretical Framework

The theoretical framework is grounded in theories of cognitive development that emphasize a developmental and constructivist view of the relationship between cognition and culture. The Saxe (1999) model is grounded in developmental and constructivist theories of learning and emphasizes the relationship between cognition and culture. Saxe argued that individuals create new knowledge while participating in culturally influenced goal-structured activities that occur in social settings. The model focuses on three areas: (a) goals for learning structured by common cultural practices, (b) particular cognitive forms and functions created to reach goals, and (c) identifiable characteristics involved in the interplay across learning in different cultural contexts.

First, the goal structure of cultural practice consists of the tasks or activities that must be carried out. "Games are inherently artifacts of culture through which cultural roles, values, and knowledge bases are transmitted" (Nasir, 2005, p. 6). In African American communities, for example, goal structures may be communal as success of the group is valued over individual success (Coleman et al., 2016). Intricate roles of help-seeking and help-offering strategies occur during game design, revealing the intertwining characteristics of individual and sociocultural systems of cognitive processing (Nasir, 2005). These roles may also be evident in game design and robotics, particularly if teams of students work together. In game design, goal structures are associated with creating unique agents and developing functional games to maximize points; in robotics, goals are associated with movement and carrying out specific tasks.

Second, according to the Saxe model, sign forms—such as counting systems and cultural artifacts — are needed to execute and influence goals that emerge in cultural practice. "Practice-linked goals are influenced by many dynamics of activity, including social interaction between those engaged in a practice, the organizational structure of a practice, individuals' prior goals and understandings, and artifacts, norms, and conventions of the practice" (Nasir, 2002, p. 216). There are shifting cognitive processes in game design to adapt the game to meet gamers' needs and goals (Nasir, 2005). These cognitive processes may be noticeable in game design and robotics as students developed CT strategies via learning progressions. The role of the teacher as a facilitator is critical to students' development of these skills.

Literature Review

While STEM encompasses a wide range of disciplines, the literature review focuses on digital game design, robotics, and computational thinking as teachers used CT strategies and engineering practices to broaden equitable participation in STEM.

Digital Game Design

K-12 students are part of a digital and gaming culture. Game design and simulation have been used to address elementary and middle school students' motivation and interest in computer science courses and careers (Webb et al., 2012). Software tools like Scratch (Mouza et al., 2016; Israel et al. 2015) and Scalable Game Design (SGD) (Repenning et al., 2015) have been used successfully to help children design digital games. SGD uses instructional units to support game design and simulations through the use of AgentSheets and AgentCubes, allowing students to engage in higher-level thinking skills as they use code to move the agent through obstacles in a game (Repenning et al., 2015). Scratch, AgentSheets, and AgentCubes were used in this study to provide teachers with robust curriculum.

Robotics

Sullivan and Heffernan (2016) conducted a review of research on robotics construction kits (RCKs) as computational manipulatives in P-12 settings. They define computational manipulatives as those that have internal computing capabilities, programming, or microcomputers embedded in the hardware. Grounded in the LOGO (i.e., logic oriented graphic oriented) programming language, computational manipulatives allow children to engage in analytical and embodied cognition (Papert, 1993). Sullivan and Heffernan assert that RCKs have a dual function as students engage in both cognitive and physical aspects of learning. For example, during LEGO® robotics, students may mimic the physical motions of the robot as it travels along a path while also engaging in reasoning, reflection, discussion, and problem solving to complete a robotics task. Most importantly, students may follow a learning progression, such as sequencing, causal inference, conditional reasoning, and systems thinking, as they interact with RCKs (Sullivan & Heffernan, 2016).

Computational Thinking

CT is an evolving field that also emerged from the work of Papert (1993), who was the first to use the term. Wing (2006) defines CT as a human endeavor that "involves solving problems, designing systems, and understanding human behavior by drawing on the concepts fundamental to computer science" (p. 33). CT is a cognitive skill that all students are expected to use across disciplines and in multiple contexts (Mouza et al., 2016; Weintrop et al., 2016; Yadav et al., 2014). Weintrop et al. (2016) developed a taxonomy to incorporate the computational nature of mathematics and science into more recent educational endeavors. Their taxonomy for CT in mathematics and science includes the following practices: using data, modeling and simulation, computational problem solving, and systematic thinking. We use this definition of CT because it aligns well with both the computer science and engineering aspects of our study.

Methodology

Participants and Setting

Thirty teachers participated in most aspects of the Year-3 study. However, we limit this report to 19 teachers new to the project and 4 teachers, who chose to continue from the Year-2 study; these 23 teachers fully participated in the Year-3 study.

All of the teachers received the same training, which consisted of two logistics meetings and an eight-week course on game design and robotics. Game design was taught by a computer scientist, who was a member of the research team. Lesson plans focused primarily on creating mazes, Frogger, and PacMan games using SGD. Robotics was taught by a science educator, who was also a member of the research team. Lesson plans focused on using LEGO® EV3 robotics kits to make the basic car, gyro boy, and sumo bot. MINDSTORMS® programming controlled the robot's movements and use of ultrasonic, color, and touch sensors.

Data Analyses and Data Sources

Mixed methods were used to analyze data in the Year-3 study. Quantitative data were used to examine changes in teachers' CT beliefs (Yadav et al., 2014) and engineering practices (i.e., Engineering Education Beliefs and Expectations Instrument for Teachers (EEBEI-T) (Nathan et al., 2010). Internal reliability of the survey instruments revealed Cronbach alphas were in the acceptable range (Black, 1999): CT survey ($\alpha = 0.76$); EEBEI-T ($\alpha \geq 0.70$). The CT survey consists of 21 items related to understanding CT (i.e., definition), dispositions (i.e., comfort, interest, and classroom practices), and future careers. Examples of these items included: "*Computational thinking involves thinking logically to solve problems; Knowledge of computing will allow me to get a better job.* Using a 4-point Likert scale, scores ranged from 1 (strongly disagree) to 4 (strongly agree). Two constructs on the EEBEI-T were analyzed for this report: STEM Integration of Content and Applied Knowledge (13 items) and Engineering Cycle (5 items) to query teachers about the use of curriculum and engineering practices. Since these two constructs were specifically developed for use with teachers in Project Lead the Way (PLTW), reliability parameters are not available. However, the EEBEI-T survey in its entirety and inclusive of these two constructs does possess established content validity (Nathan et al., 2011). An example of these items included: "*I use curriculum activities that rely on application and design activities as a way to introduce students to basic laws in math and science.*" Using a 5-point Likert scale, scores ranged from (0-never; 1-almost never; 2-sometimes; 3-often; and 4-almost always). The *T*-statistic was used to analyze pre-post scores on each of these surveys. We set the confidence interval at 0.90 since the sample size was small (Quinn & Keough, 2002).

Qualitative data included using the Dimensions of Success (DoS) instrument to collect field notes and rate teachers' practices (Noam et al., 2014). Factor analysis revealed the 12 DoS dimensions can be aggregated into two groups: student learning and learning environment (Gitomer, 2014). Student learning may be further divided into three domains: (a) Activity Engagement; (b) STEM & Knowledge Practices; and (c) Youth Development. A score of 3 constitutes what researchers document as reasonable evidence while a score of 4 constitutes compelling evidence. Ratings were shared with teachers at the end of the study year as member checks. Additionally, three teachers agreed to serve as focal participants to share their experiences and reflections on the project.

Results

Computational Thinking (CT) and EEBEI-T Surveys

Twenty-three teachers completed pre-post CT surveys. The data (see Table 1) reveal significant differences on the CT survey from pre-post: (t = -2.173; p = 0.041; Cohen's d = 0.34). Cohen's d shows a small effect size for this increase. Two teachers who completed the CT did not complete the EEBEI-T. Table 1 also reveals significant differences from pre-post on the modified EEBEI-T (t = -2.882; p = 0.009; Cohen's d = 0.78). Cohen's d shows a large effect size for this increase. Interpretation of the data reveal teachers ranged from 'almost never' to 'sometimes' on the STEM Integration of Content and Applied Knowledge and Engineering Cycle constructs on the pre-survey but tended toward 'sometimes' on these constructs on the post-survey. Thus, teachers made progress on use of engineering practices in the Year-3 study.

Table 1: Results of Teachers' Survey

Construct	Pre-Survey Mean	Standard Deviation	Post-Survey	Standard Deviation
CT Survey (n=23)	3.34	0.30	3.45*	0.30
EEBEI (n=21)	1.88	0.57	2.40*	0.77

* $p < 0.05$

Dimensions of Success

We observed 23 teachers during the Year-3 study using the DoS instrument. However, three teachers were observed only once and, therefore, removed from the sample. Mean ratings (M_1) of the first observation were used as a baseline, and mean ratings (M_2) of the last observation were used to show growth. The interval between teaching episodes was typically four to six weeks unless the teacher participated in multiple years. Four teachers engaged in co-teaching and 12 taught lessons individually. Thus, 16 total observations were analyzed by lesson type to show trends on the three domains of interest (see Table 2). Teachers' ratings were slightly higher on robotics than game design at the baseline. Teachers' ratings showed compelling evidence ($M_2 = 4.0$) for Purposeful Activities, STEM Engagement, STEM Content Learning, and Relationships on final observations in the game design context. Scores increased from $M_1 = 2.9$ to $M_2 = 3.6$ for game design. However, the lowest rating was on the Relevance dimension ($M_2 = 2.8$). DoS scores dropped from $M_1 = 3.3$ to $M_2 =$ 3.2 in the robotics context, with the most substantial drop on STEM & Knowledge Practices. Overall, teachers' practice improved from $M_1 = 3.1$ to $M_2 = 3.3$ regardless of context. The strongest domain at the end of the study was Activity Engagement, which was followed by Youth Development and STEM & Knowledge Practices. Relevance ($M_2 = 2.4$) was the weakest dimension in Year 3 as well as in prior years (Leonard et al., under review).

Table 2: Analysis of DoS Observation

Observation	ACTIVITY ENGAGEMENT			STEM & KNOWLEDGE PRACTICES			YOUTH DEVELOPMENT			Mean
	Student Participation	Purposeful Activities	STEM Engagement	STEM Content Learning	Inquiry	Reflection	Relationship	Relevance	Student Voice	
Baseline – Gaming (n=9)	2.9	3.2	3.6	2.8	2.9	2.4	3.8	1.8	3.0	2.9
Final – Gaming (*n* =6)	**3.7**	**4.0**	**4.0**	**4.0**	**3.2**	**3.2**	**4.0**	**2.8**	**3.3**	**3.6**
Baseline – Robotics (*n*=7)	3.1	3.7	3.9	3.4	3.3	3.0	3.9	2.4	3.1	3.3
Final – Robotics (*n*= 10)	**3.3**	**3.4**	**3.7**	**3.0**	**3.1**	**2.8**	**3.8**	**2.2**	**3.1**	**3.2**
Total Baseline (*n*=16)	3.0	3.4	3.7	3.1	3.1	2.7	3.8	2.1	3.1	3.1
Total Final (n=16)	**3.4**	**3.6**	**3.8**	**3.4**	**3.1**	**2.9**	**3.9**	**2.4**	**3.2**	**3.3**

Case Narratives

The cases of three focal teachers allowed us to examine the complexity of enabling CT and engineering practices during OST. Each of the teachers worked with students during before- or afterschool clubs teaching game design and robotics for 20 hours in each context for a total of 40 hours or more. These teachers — one White female (rural), one African American female (urban), and one White male (urban) — wrote extensive narratives about their teaching experiences during this project. Pseudonyms were used for anonymity.

Annette. A technology specialist in rural Wyoming, Annette worked with nine White fourth- and fifth-grade students for two hours per day, four days per week, before and after school. Class sizes in rural Wyoming are typically 10-14 students. As a facilitator, Annette allowed her students to develop agency by having "deeper experiences, more meaningful conversations with peers, and ownership of the project" while "working towards a common goal." During game design, her students faced a challenge creating PacMan games. "The students understood that the chasers needed to chase their main character, but were not quite sure how to accomplish this. Now, I was able to teach them about hill climbing and diffusion because it was finally relevant. The main character had to emit something that would attract the chaser…[like] 'stinky feet.' Tracking the scent, is called a hill climb, and the scent being detected [is] diffusion, not to be confused with osmosis, which requires water. The video game needed to be programmed to take the main character's scent and diffuse it throughout the game. The chaser needed to be able to 'sniff' in all four directions and start to move in the direction

Galindo, E., & Newton, J., (Eds.). (2017). *Proceedings of the 39th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* Indianapolis, IN: Hoosier Association of Mathematics Teacher Educators.

that the scent was strongest. I got lots of nods, and 'Oh, that makes sense.'" Thus, Annette provided students with opportunities to use more advanced CT strategies (Repenning et al., 2015) within a constructivist paradigm, which aligned with Saxe's (1999) cognitive theory and supported the finding for high Activity Engagement and STEM & Knowledge Practices on the DoS. Her ratings across the three DoS domains were stable M_1 = 3.6 (game design) to M_2 = 3.6 (game design).

Charles. As a teacher-leader in science and technology at an urban elementary school in Pennsylvania, Charles worked with 20 predominantly African American students for 90 minutes two times per week. None of his students had participated in robotics or game design before. He described how he laid the foundation for learning: "…I explained that computers are machines that are programmed to perform computations or actions based on the input they receive. We discussed the inputs that the human body might receive through senses, as well as the concept of involuntary reflexes." Then he distributed cards with conditional statements to help students understand how commands are implemented. "For example, if they heard someone say 'thank you,' someone else would respond, 'you're welcome.' I explained that computer programming was binary 'if/then' or 'yes/no' language that we needed to understand before creating a program." This activity revealed that cognitive and physical activity may be intertwined in computer science as well as robotics (Sullivan & Heffernan, 2016). However, Charles found that challenges to programming "involved rudimentary debugging. Having learned from their own mistakes, students became more effective in identifying problems in their classmates' games. Students were able to create increasingly intricate programs. Some chose to create multiple levels, multiple games, or multiple rules on a single worksheet." These activities showed how cognitive processes shifted as students engaged in social interactions (Nasir, 2005) and communal practices (Coleman et al., 2016). It also supported reasonable evidence of STEM Knowledge & Practices and Youth Development. Charles' ratings across the three DoS domains increased from M_1 = 3.0 (game design) to M_2 = 3.4 (game design).

L'wanda. As the school librarian, L'wanda was able to work with 20 students for 90 minutes a week at two different urban schools in Pennsylvania. None of the 40 predominantly African American students had participated in robotics before, and only one had previously experienced game design. L'Wanda was able to use "iPads to reinforce the skills students needed to develop CT skills. There were 10 robotics kits so students were able to work in groups of two. However, some students preferred to work in groups of three or four. Students used iPads to access templates on the LEGO website that helped them learn to build the robots. Students developed their research skills as they searched for information to improve their designs. Students used the scientific method to develop programs that would allow their robots to go longer distances and avoid obstacles. As they raced their robots against other teams, they constantly revised their designs and made changes to the programs to build better bots that would help them achieve their goals. Participation in the club was a turning point that changed attitudes toward learning. My students were able to see themselves as capable, intelligent leaders, who were able to be producers and not just consumers. Students used iPads to create videos that explained the steps they took to create their robots. These videos demonstrated the depth of their understanding of the material and showed that they had a real sense of purpose." Thus, L'Wanda's students engaged in learning progressions as they used RCKs to develop CT. L'Wanda's ratings across the three DoS domains increased from M_1 = 3.0 (robotics) to M_2 = 3.2 (robotics).

Discussion

The findings of our Year-3 study are promising. Teachers' pre-post surveys on computational thinking beliefs and engineering practices improved significantly, and overall, teachers' ability to implement STEM during OST showed improvement when baseline data were compared to final observations. Trends in terms of the overall DoS show teachers met the threshold of 3 on all domains during the last observation. The narratives were rich and provided examples of the learning that occurred during OST. Teachers were facilitators that provided guided inquiry when necessary to help students engage in independent learning. Both game design and robotics provided students with opportunities to engage in highly cognitive tasks without sacrificing cultural norms (Nasir, 2005). For example, students engaged in communal learning in urban settings (Coleman et al., 2016). Teachers encouraged student collaboration, and some children became peer coaches at times. Children were successful in designing digital games and performing robotics challenges (Leonard et al., 2016; Repenning et al., 2015; Sullivan & Heffernan, 2016). Nevertheless, some teachers did not promote cultural relevance or career awareness during their lessons. Although we encouraged culturally relevant pedagogy (CRP) (Ladson-Billings, 2009), some teachers paid cursory attention to students' culture and were less likely to link computer science and engineering tasks to STEM careers. We will address the issue of CRP in future studies through teacher reflection, case studies, and co-generative dialogue.

Significance

In this study, robotics and game design were used to broaden STEM participation in rural and urban communities. We learned that game design facilitated co-generative dialogue that allowed learners to take familiar concepts and apply them to a range of complex tasks including the creation of representations and models. We strongly believed that the research design not only facilitated CT applicable to STEM but also promoted the kinds of social engagement and collaboration that will build 21st century skills and normative habits that allow students to develop computer science and ICT skills.

Limitations

The results of this study are limited to the participants and settings where the study took place and should not be generalized to teachers in other contexts. One limitation was the smaller number of robotics clubs for baseline observations, which may have skewed the DoS tabulations. Another limitation associated with the quantitative data is the absence of reliability parameters for the two EEBEI-T constructs used in this study.

Acknowledgments

INTEGRATING INTERACTIVE SIMULATIONS INTO THE MATHEMATICS CLASSROOM: SUPPLEMENTING, ENHANCING, OR DRIVING?

Kelly Findley	Ian Whitacre	Karina Hensberry

kfindley@fsu.edu	iwhitacre@fsu.edu	khensberry@mail.usf.edu

High-tech tools can be integrated to serve a number of purposes in the mathematics classroom, with different purposes being appropriate for different learning goals. We focus specifically on the various purposes for interactive simulations (sims). This study followed three experienced middle-school mathematics teachers integrating PhET sims into their classrooms for the first time. Using both our data and literature about high-tech tool integration, we offer a framework defining three categories of purpose for sims in the classroom and describe how the teacher positioned the sim to meet that purpose. We also touch on each teachers' beliefs about high-tech tools in the classroom and the link between their pedagogical beliefs and sim integration practices. We believe this framework contributes to the field by defining varying categories of integration for a tool with growing utilization in the mathematics classroom.

Keywords: Teacher Beliefs, Technology, Modeling

The last two decades have seen an upsurge in the number of high-tech tools being introduced in classrooms. However, effective instruction is not guaranteed by mere inclusion of such tools (U.S. Department of Education, 2010). Despite easy accessibility to computers, teachers often integrate them to complement teacher-centered practices, rather than to transform the classroom environment to one that is more student-centered (Cuban, Kirkpatrick, & Peck, 2001). Even when a teacher holds positive views towards the advantages of technology, their teaching practices may be hindered by various classroom constraints (e.g., high-stakes testing, packed curriculum, limited planning time) (Ertmer, 1999; Hew & Brush, 2007).

We focus on one particular high-tech tool in mathematics: interactive simulations. We define interactive simulations (sims) for mathematics as dynamic environments that model a mathematical concept, relationship, system, or phenomenon and allow users to interact with the model within that environment. Sims may facilitate the use of multiple representations, support students' efforts to construct their own knowledge, focus student attention on conceptual ideas, and allow immediate feedback (D'Angelo et al., 2014; Hensberry, Moore, & Perkins, 2015).

Though sims offer great potential to benefit mathematics classrooms, it is how the teacher integrates this tool that will determine its effectiveness. In this article, we define a framework categorizing three different purposes sims serve and describing how the teacher may position the sim to meet those purposes. We also investigate how teachers' pedagogical beliefs influence how they position sims in their instruction. Specifically, we examine how teachers' views on whether sims offered affordances or created constraints to their teaching affected the sim's purpose and positioning in the lesson. We find this research pivotal as we consider a path for technology integration beyond mere tool inclusion, but rather a path where such tools offer opportunities to drive the lesson in new, transformative ways. Our research questions are as follows: (1) What purposes do sims serve in mathematics lessons, and how do teachers position sims to meet those purposes? (2) How do teachers' positioning of sims relate to their pedagogical beliefs about integrating high-tech tools and meeting content standards?

Conceptual Framework

High-Tech Tool Integration

In lessons involving high-tech tools, teachers assign various roles to such tools. We define this assignment of roles as *positioning*. Harré and Van Langenhove (1998) discuss positioning as the dynamic roles between members of a group. These positions hold varying levels of authority (e.g., leader, follower) that determine who is driving any particular activity in the classroom. Wagner and Herbel-Eisenmann (2009) note that positioning is “immanent,” meaning that actors do not hold a permanent role, but instead hold roles that vary depending on the other actors surrounding them. They also describe positioning as “reciprocal,” meaning that when one actor takes a leader role, other actors are positioned as followers. In applying positioning theory to sims, the sim’s role is dependent on the tasks the teacher has set up for the students. The same sim could be positioned to drive the lesson in one task or to supplement lecture-style instruction in another. Student positioning will be reciprocated by the sim’s positioning.

With these two aspects of positioning in mind, we examined integration frameworks from the literature with an eye for how high-tech tools like sims may be positioned in multiple ways and how other actors’ positioning is affected. Such frameworks are beneficial in understanding what characterizes expert use of a high-tech tool, as well as the pedagogical beliefs associated with such use. Three frameworks, each outlining multiple categories of integration, guide our understanding of the purposes sims may serve in a lesson and how teachers position sims in the classroom to meet those purposes. The Technology Integration and Curriculum framework focuses on the relationship between high-tech tools and lesson content (Ertmer et al., 1999). The SAMR Model is concerned with the influence of high-tech tools on lesson tasks and instruction (Puentedura, 2010). And a tool-specific framework (featuring interactive whiteboards (IAWs)) provides an example of how specific, high-tech tool features can be considered when describing sophistication in integration practices (Miller, Glover, & Averis, 2005). We have built our framework with each of these three lenses in mind.

Pedagogical Beliefs

Teachers’ beliefs about how students learn are manifested alongside their beliefs about how various classroom constraints (e.g., time, resources, testing, student behavior) are appropriately managed (Skott, 2001). These constraints often have both an intrinsic and extrinsic component; the teacher cannot influence their existence, but she can decide how they should best be managed (Philipp, 2007). For the purposes of this paper, we define *pedagogical beliefs* as comprising teachers’ beliefs both about how students learn and beliefs about the balancing and resolution of these classroom constraints.

Research on successful technology integration finds successful teachers are confident in their ability to use high-tech tools (Ertmer, Ottenbreit-Leftwich, Sadik, Sendurur, & Sendurur, 2012). These teachers overcome internal barriers by having a well-defined classroom vision that focuses on the affordances such tools offer (Ottenbreit-Leftwich, 2007). Teachers must be motivated for change by taking “positive approaches”—actively and autonomously *choosing* change in their classrooms with high-tech tools (Kershaw, 2016).

Research Methods

Setting

This study took place at a large, public charter school with a diverse student population reflecting state demographics. We focus on three middle-school mathematics teachers new to using PhET sims in their instruction who agreed to integrate PhET sims centrally in some of their lessons. All teachers were female and had at least seven years' experience teaching mathematics. Two members of the PhET research team introduced the teachers to the project through two introductory workshops. The three teachers taught a total of 11 lessons involving sims, each of which spanned one or two class sessions. Nine of the 11 lessons were observed and recorded by the researchers. Ten out of 11 lessons were authored by the teachers (with feedback provided from the researchers) and one was authored by one of the researchers.

Data Sources

Data sources consist of videos from end-of-year reflective interviews with the teachers, group meetings involving the three teachers and the researchers, nine lessons involving PhET sims, and six "business-as-usual" lessons in which the teachers did not use sims. We also collected the worksheets and lesson plans from the sim lessons. Finally, email correspondence was collected as supplemental data that enabled us to capture the interaction between the teachers and researchers concerning the teachers' lesson planning progress.

Methods of Analysis

To answer Research Question 1, we first took a grounded approach to define different categories of sim positioning. We began by investigating the recorded sim-based and business-as-usual lessons through a process of open coding in which we charted the lesson structure and noted various teacher instructional methods within each lesson (Savin-Baden & Major, 2013). We also inspected the worksheets teachers provided to students during each lesson and discussed how the various questions and directions contained on the worksheets positioned the sim in the tasks students completed. Through this preliminary descriptive analysis of the lesson videos and worksheets, we were able to define an initial set of sim positioning categories based on the kinds of tasks the students were asked to complete and the instructional methods implemented.

After this grounded analysis, we then took a more theory-driven approach by drawing on extant high-tech tool integration frameworks (Ertmer et al., 1999; Miller et al., 2005; Puentedura, 2010) to situate our framework in the current literature. We used this combination of data-centered and theory-driven analysis to iteratively revise our sim positioning categories. This process resulted in a three-tiered framework that defines three general purposes sims serve in mathematics lessons and describes how the teacher positions the sim to meet those purposes.

To answer Research Question 2, we used multiple-case study analysis (Yin, 2009) to create a profile for each teacher that described the affordances and constraints teachers faced in relation to integrating sims. These profiles were grounded in the interview data and email correspondence and were informed by themes and barriers highlighted in the literature. We completed a cross-case synthesis by identifying similar themes and concerns in the teachers' remarks about sims in the classroom. We also used pattern matching and explanation building to unpack each teacher's pedagogical beliefs and relate those beliefs to her sim positioning tendencies. The first author presented the teacher profiles to the second and third authors for evaluation and further revision. We noted distinct characteristics about each teacher's beliefs and categorized them under cross-cutting themes that seemed consistent across all three (see Table 1). Finally, the researchers mapped the teacher profiles to the framework categories, giving careful attention to how the profiles connected to kinds of sim positioning enacted in the classroom. The results are thus grounded in the available data and represent the consensus of the authors.

Table 1: Cross-Cutting Themes

Vision	Alignment	Barriers
Teacher's description of ideal classroom environment and the role that high-tech tools/sims should fill in this environment	Remarks about success or difficulty in adapting a sim to meet certain content standards and whether sim integration competed with meeting content standards	Remarks about other difficulties involving sim lessons, such lack of adequate planning time, low self-efficacy, and other concerns about high-tech tools

Results

Supplement, Enhance, Drive (SED) Sim Positioning Framework

Based on our analysis, we created a framework to define different categories of purpose for sims and the respective roles sims are assigned in these categories. Those categories are as follows: Sims positioned to supplement the lesson, enhance the lesson, or drive the lesson. We unpack each category by providing a general description and an example from our data.

Supplement. In this category, the sim aids the teacher in implementing a lesson with no critical differences from the lesson that the teacher might otherwise administer. The sim supplements the learning goals by making the lesson more precise or time-efficient, but the content is unchanged in terms of both depth and scope, and the tasks students complete are fundamentally the same. Sims in this role may act as a direct tool substitute or lesson add-on.

As an example of this category, Arlene used the "Graphing Lines" sim to supplement her lesson. Graphing Lines allows users to create lines on a Cartesian coordinate plane by moving points to define the line and seeing the slope equation adjust automatically. Arlene's two-day lesson had students first complete several rate problems and graph the ratio pairs on a Cartesian coordinate plane. After completing several rate problems on paper, students plugged in the values from the tables into the sim by creating a line with points matching the coordinate pairs they had recorded by hand. Students then recorded the slope values resulting from these lines.

While the sim afforded more precise graphs and verifications of slope calculations, Arlene did not position the sim to expand the range of content addressed or to enrich the presentation of the mathematics beyond what a paper or whiteboard drawing could accomplish. Students' attention was not drawn to the sim's dynamic features; rather, they focused on the static result after having inputted the numbers on their worksheet. The task that students completed with the sim was an extension of the task completed by hand to verify answers. For these reasons, we conclude the sim was positioned to supplement this lesson.

Enhance. In this category, the teacher integrates exclusive sim features to enhance lesson tasks beyond saving time or increasing precision. Opportunities for pattern-noticing and sense-making are made available through the sim's dynamic, interactive environment to enrich the content. Learning goals are influenced by this enrichment but are ultimately accomplished afterwards with the sim serving as a launching vehicle to meeting learning goals. Unique sim features are integrated but do not reinvent the tasks students complete. The content addressed is enriched without being expanded or reoriented to a new perspective.

Becky's sim lesson using "Equation Grapher" fit the enhance description. Equation Grapher allows students to observe dynamic changes in the graph of a linear or quadratic equation as the coefficient sliders are adjusted. Becky's learning goal focused on having students explain how changes to the parameters of a linear equation are reflected in its graph. Becky used this learning goal as an opportunity to emphasize the use of correct vocabulary when describing shifts in the graph. The lesson alternated between timed episodes of worksheet-directed sim use and episodes in which selected students responded to closed-ended prompts from Becky.

Even though Becky's lesson incorporated unique sim features (e.g., sliding coefficient scales resulting in dynamic changes to graph), these features served as a vehicle to enhance the lesson's procedural learning goal. The learning goal was addressed during the teacher-centered dialogue between Becky and the students and involved the sim as a common reference point. This task of applying vocabulary was certainly influenced by students' interaction with the sim, but this lesson was not set up for students to accomplish the learning goal solely through their interaction with the sim.

Drive. For this category, the sim serves as an impetus for lesson transformation as learning goals are accomplished in students' meaningful exploration and interaction with the sim. The range of content is expanded and/or an innovative perspective is achieved.

In Carmen's lesson involving the "Graphing Lines" sim, students were instructed to create various systems examples and comment on them. For example, "Do you think these lines will ever cross again? Why do you think that?" At one point, students were asked to create two lines they thought would never intersect. Carmen positioned the sim as a setting for exploration and discovery. As students moved through the worksheet, they collaborated with their neighbors and tried to identify patterns and generalize results. Carmen circulated around the room, challenging students to use precise language and supporting students who were struggling. During a summary discussion, Carmen had students share their answers and pushed for explanations.

Carmen did not position herself to introduce mathematical ideas; she instead created opportunities for students to share sense-making moments they had experienced while working with the sim. Carmen took a facilitating role that encouraged students to articulate their own connections more clearly. This contrasts with an enhance positioning in which the learning goals are accomplished away from the sim and depend on heavy teacher guidance.

Table 2 presents the SED Framework, which builds on the foundational lenses discussed in the Conceptual Framework to elaborate on each category as it applies to sim use.

Table 2: SED Framework

	Supplement	**Enhance**	**Drive**
Curriculum	Sim supplements presentation of mathematics by making the lesson more precise or time-efficient.	Sim enhances and enriches presentation of mathematics through engaging graphics and interactive features.	Sim drives presentation of mathematics by facilitating innovative perspectives and/or making new content accessible.
Nature of the Lesson Tasks	Students use sim to check and verify work completed by hand or to complete an unrelated, non-critical task.	Students complete a task that is influenced by their engagement with unique sim features. Sim is common reference point	Students complete task directly with the sim that directly addresses learning goals. Post-sim discussion is student-centered.
Unique Features	Interactive, dynamic features are largely absent from the lesson.	Interactive, dynamic features are present and tangentially influence the completion of the learning goals.	Interactive, dynamic features are present in the lesson and are used by students to directly accomplish the learning goals.

Sim Positioning and Pedagogical Beliefs

The teachers in our study demonstrated a range of approaches to positioning PhET sims into their instruction. Our findings indicated that sim purposes and positioning were influenced by each teacher's beliefs about whether the sim would bring affordances or create constraints for her teaching. We captured each teacher's perspective regarding sim affordances and constraints by coding her interviews for three emergent, cross-cutting themes: Classroom vision with sim, alignment between sim and content standards, and barriers to implementation. We next present each teacher's profile and connect their profiles to their sim positioning tendencies.

Arlene's profile: Sims as a tradeoff. Arlene's sim lessons consistently positioned sims in a supplementary role. Her vision for high-tech tools was constrained, most notably, by her concern that having students behind screens would detract from teacher–student interaction. She viewed these tools as creating hindrances within her vision of a normal classroom environment. Arlene stated that sims often worked best toward the end of the unit after students are familiar with the content; otherwise students might be confused and fail to engage with the sim productively.

Arlene's views regarding alignment between the sims and the content standards were partly demonstrated in her selectivity with choosing sims. She frequently mentioned that there were not a lot of options on the PhET website for sims that could be used in 6th grade math. She struggled to find PhET sims that she saw as aligned with the content standards or to find a way to adapt the available sims to her needs. Arlene described sim lesson planning as an "awaking moment" where "things just pop up," suggesting that she perceived creating a sim lesson as being more like waiting for a stroke of brilliance rather than systematic planning that she could control.

In summary, Arlene viewed sims as something to accommodate into her lesson. While she frequently talked about being excited to learn more about using high-tech tools and about liking sims, that optimism did not translate into a smooth, sophisticated integration. Arlene's lack of an established vision for how sim lessons could enhance or drive her lessons left her to dwell on concerns about what she might lose by integrating sims. We believe this lack of vision explains her frequent positioning of sims as an extension to traditional, business-as-usual tasks.

Becky's profile: Sims as a visual aid. Becky's classroom vision had sims positioned to enhance the lesson, allowing students to visualize the mathematics they were working on. She remarked that student understanding was facilitated by "seeing" rather than "memorizing." She was excited during the interview as she recounted how students would commonly reference the sim as they motioned and verbally described the shapes and shifts of various graphs. She viewed sims as a means to launch the class into various mathematical tasks later on.

Becky initially struggled to balance PhET recommendations of facilitating student discovery with her perceived need to move quickly through the "packed" Algebra I curriculum. In response to that tension, she felt the need to cut discovery time short and fall back on more traditional, teacher-centered instruction, even though she saw value in letting students discover.

Becky demonstrated a compromise positioning in both of her sim lessons that included opportunities for sim-driven student exploration, but ultimately sidelined the sim as a reference tool during teacher-led discussions. She used students' experience with the sim as a reference point from which to draw from as she directed the class' pivotal discussion times.

Carmen's profile: Sims as an advantage. Carmen, who positioned the sim to drive the lesson in 2 of her 4 recorded sim lessons, articulated a vision that focused predominately on what sims could afford. She described high-tech tools as a central focus of her lessons. She cited the necessity of sims and similar tools for fostering increased student engagement, facilitating opportunity to do mathematics as students might in a real job, and creating space for discovery. She also had strong opinions on sims being best incorporated at the beginning of a unit: “I mean it’s not discovery learning if you’ve already told them all the rules.”

Carmen valued student discovery while also acknowledging students’ tendency to get off track if left to work unsupervised for too long. She referred to the moments where she brought the entire class together as “checkpoints” to ensure that they were still heading in the right direction and to better understand what they were gathering from their activities with the sim.

Like Arlene, Carmen mentioned limitations to the PhET math sims available at the time; however, she was able find science sims that could be linked to relevant mathematics. Carmen believed that her sim lessons appropriately prepared students for standardized testing. She saw making connections between the standards and available sims as an intriguing challenge. Rather than feel constrained by the lack of sims clearly linked to 7th grade mathematics, Carmen seemed to approach sims with an open mind and found creative ways to relate them to the standards.

While Arlene and Becky both focused on external barriers or constraints related to integrating sims, Carmen primarily focused on the affordances. Barriers were things to be overcome. Her classroom vision for high-tech tools clearly articulated the many affordances of sims and provided motivation for sim-centered lessons. Like Becky, Carmen valued the importance of creating space for student discoveries, but for Carmen, the importance of discovery was not diminished by the need to meet standards. She avoided that tension through her flexible integration of both mathematics and science sims and her ability to facilitate student discussion toward learning goals. Carmen’s comprehensive technology vision combined with her flexible sim integration practices explain how she positioned sims to drive her lessons.

Discussion and Conclusion

The SED framework identifies three distinct roles in which sims may be positioned in math lessons and describes the purposes of each role—supplementing, enhancing, or driving. We see this framework serving the research community by applying knowledge of high-tech tool positioning to a growing collection of sims with great potential to drive classroom learning environments.

Although the SED framework consists of defined categories, we do not see the categories as describing a hierarchy of less to more effective. We believe that all three sim roles can be appropriate in different situations. For example, Carmen administered two sim lessons at the driving level, but toward the end of the year, she decided to position the “Graphing Lines” sim as a demonstration tool to introduce the Pythagorean Theorem. That does not mean that Carmen’s pedagogical beliefs changed or that she had a fluke lesson; she simply saw an opportunity where one particular sim supplemented her lesson by saving time and aiding in the teaching of a mathematical idea.

In classifying these three teachers as consistently embodying one of our categories, we have chosen to highlight certain moments that we believe will help readers understand each category. But we also recognize that each teacher is complex and aggregately reflects characteristics of all three categories. No teacher fits a perfect pedagogical stereotype, but instead exemplifies both traditional and reform-based teaching practices (Crespo, 2016). Similarly, we believe teachers may articulate pedagogical beliefs from multiple categories of our positioning framework.

There were fundamental differences in how each teacher chose to position sims and in their related pedagogical beliefs. Constraining views about what sims could and could not do narrowed what Arlene and Becky considered to be in the realm of possibility. Enabling a teacher to envision a purpose for sims across the spectrum—from supplementing to driving the lesson—and likewise position the sim to accomplish that purpose seems inextricably linked to whether she sees sims as tools to be administered under constraints or tools that unleash possibilities.

We report on the development and evaluation of MathVision, a mobile-application designed to develop Virtual Professional Learning Communities through asynchronous discussion about 2nd, 3rd, 4th, and 5th grade students' mathematical thinking. MathVision allows teachers to upload videos of problems solving sessions using Cognition Based Assessment tasks and foster discussion aligning those strategies to research-based learning progressions for Length and Measurement. Our findings indicate that while it was possible to develop such an interface, sparking productive online discussion was difficult. The application served as a tool for enhancing physical teacher meetings and drawing attention to student thinking consistent with conducting task-based interviews, rather than actually facilitating this talk entirely.

Keywords: Learning Progressions, Technology, Elementary School Education, Geometry and Geometrical and Spatial Thinking

MathVision is a mobile application learning technology designed to help 2nd, 3rd, 4th, and 5th-grade elementary teachers develop a virtual professional mathematics community in their schools around noticing student's mathematical thinking. Specifically, teachers use MathVision as an all-inclusive tool to capture short video of their students solving validated mathematical tasks and then engage in chat room-like asynchronous, online discussions about what they notice in these videos. We built MathVision upon the extensive research on mathematics teacher noticing (Jacobs, Lamb, & Philipp, 2010; Sherin, Jacobs, & Philipp, 2010), teacher video clubs (Van Es & Sherin, 2008, 2010), learning progressions (Battista, 2011, 2012), and professional learning communities (DuFour, 2004).

In building and piloting MathVision in an elementary school, we explored the following research questions: 1) How should a Virtual Professional Learning Community (VPLC) environment be created that enables elementary mathematics teachers to base their teaching on research-based mathematical Learning Progressions, without requiring timely and resource-heavy physical interactions between teachers thus making teacher learning more accessible? 2) What affordances of MathVision will teachers utilize (i.e. commenting on each other's videos, noting each other's learning progressions ratings, a database of mathematical tasks) within their classroom practice? 3) How might using these features affect their teaching practice? 4) How will physical team-meetings be altered or augmented through the use of this technology, which allows teachers to view each other's videos before these meetings? And 5) How will teachers interact and talk to each other in reference to the technology?

Background and Rationale

Mathematics Teacher Noticing

Emphasizing how a teacher specifically listens to and responds to what a student says or does is one of the core tenants of modern mathematics education reform, often referred to a "professional noticing" (Jacobs et al., 2010). The very act of listening itself opens up space for a student to share his or her mathematical strategy, thereby positively impacting a student's mathematical growth (Empson & Jacobs, 2008). However, learning how to listen to and respond to student's mathematical thinking is a complex process that takes years to develop (Jacobs et al., 2010). There has been some evidence that video clubs, in which teachers watch video of each other's classroom teaching, can help teachers in the same school develop these crucial noticing skills (Van Es & Sherin, 2010). However, video clubs require busy teachers to find a common space and time to meet. Yet, when teachers watch and analyze student's mathematical thinking on their personal devices (e.g. smartphones, tablets), they can more better focus on the nuances of a student's thinking in much more detailed ways than video clubs (Author).

Virtual Professional Learning Communities

One research-based solution for supporting teacher learning without requiring high demands of support and time involves using Professional Learning Communities (PLC), which revolve around learning, collaboration, and instructional action (DuFour, 2004). Teachers working within PLC structures often have better instructional approaches, are more satisfied with their careers, and are more likely to remain in teaching long enough to become accomplished educators (Fulton & Britton, 2011). Yet because of a lack of shared spaces, meeting times, and the small number of teachers with common mathematics grade-levels in the same building, elementary school culture in the U.S. often prevents effective PLC organization. To solve this problem, we developed a learning technology environment that fosters the creation of a Virtual Professional Learning Community (VPLC) that can go beyond school boundaries so that elementary mathematics teachers can connect with each other without having to find a common meeting time and space (McConnell, Parker, Eberhardt, Koehler, & Lundeberg, 2012).

Research-Based Learning Progressions to Understand Students' Mathematical Thinking

Often missing from most mathematics teacher support models is assessment practices utilizing research-based Learning Progressions (LP), which help teachers understand the complexities involved in students' evolving mathematical thinking. The Cognition Based Assessment series provides research-based assessment tasks for teachers to identify students' Learning Progressions and then follow-up with relevant instructional tasks. However, the successful implementation of CBA-based mathematics instruction requires teachers to regularly meet to watch video from each other's classroom and discuss how they would interpret individual student's thinking on the learning progressions. As stated earlier, however, modern elementary school culture in the U.S. makes it difficult for regular teacher meetings to come together to focus on mathematical thinking or pedagogy (Horn, Garner, Kane, & Brasel, 2017).

Building upon these various literatures on mathematics teaching, we built a mobile application, MathVision, to see what would happen if teachers could capture and upload videos of students working on CBA tasks and then use the same application to discuss these students' strategies and how those strategies aligned to the established learning progressions. Key to this research was building technology that met teachers where they are: the technology had to work on multiple devices (e.g., laptops, phones, tablets), had to be intuitive to use for capturing and commenting on video, and had to contain all necessary supports and materials (i.e., the CBA tasks, the learning progressions framework, etc.).

Methods

Research Design and Measurement/Instruments

Since the main purpose of this study involved building and piloting a new learning technology, the research design followed a case study methodology of teachers using the actual technology, videos and discussion captured from within the MathVision application, observations from teacher team meetings after they had used MathVision in their teaching, and interviews with teachers. Teachers used MathVision as a grade-based team, meaning that all the 4th-grade teachers viewed and commented on each other’s videos.

During this 4-week intervention, teachers regularly used this learning technology to assign CBA research-based mathematics tasks about Length and Measurement to their students (Battista, 2012). Teachers then selectively captured video of their students’ strategies as they solved these tasks, focusing on particular on strategies that might elicit conversation among their professional learning teams. Within each team, teachers uploaded, commented and categorize on each other’s videos according to the CBA-framework and selected where on the Learning Progression scale they feel the student was in their mathematical thinking (Figure 1 & Figure 2). Teachers then engaged in chatting with each other about the specific videos through these online discussions. In particular we were interested in how teachers came to consensus with respect to student comments on particular corresponding CBA levels and the means by which they recommend instructional support to scaffold students through their thinking.

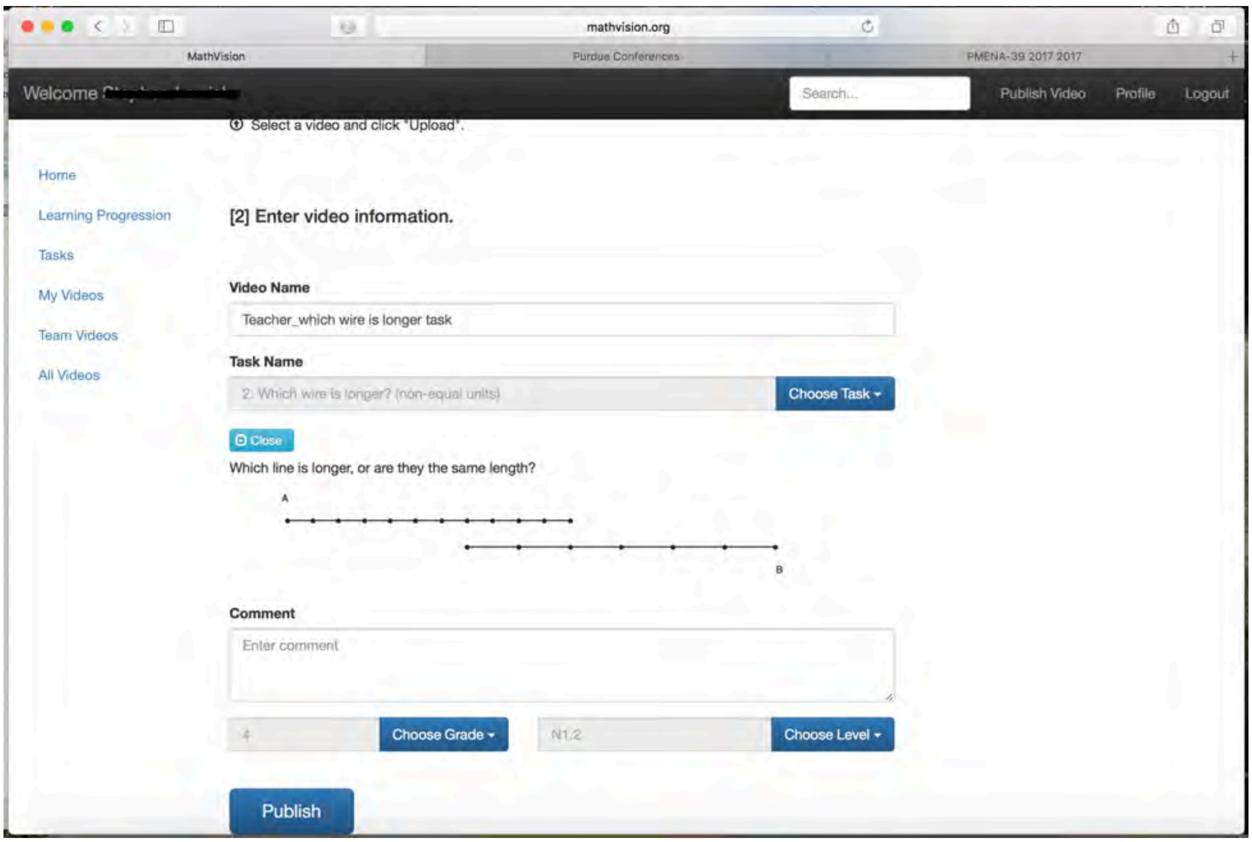

Figure 1. Video upload page where teachers enter metadata for video files including grade level, initial alignment to CBA level, corresponding task and initial thoughts or comments on problem solving strategies.

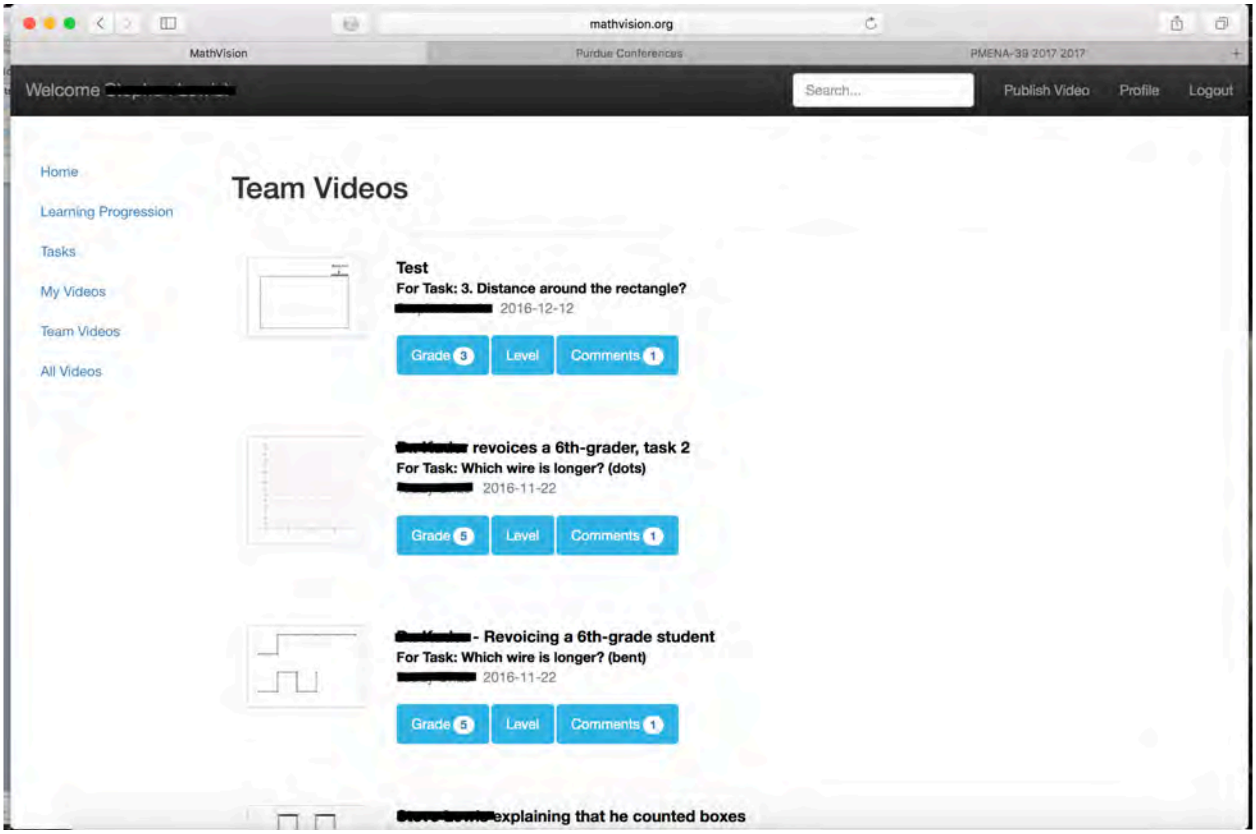

Figure 2. Repository of team videos designating grade, Learning Progression level, and comments where teachers can organize videos by team, individual videos or all videos.

Classroom Observation and Teacher Generated Video

During this 4-week intervention, our first point of data involved visiting the partnering classrooms to observe and capture video of how teachers and students used and interacted with the technology. This involved a research team member capturing video of the mathematics classroom, following the teacher as he or she used the MathVision technology with students.

Additionally, while the teachers used MathVision, they continually generated video and text data through uploading videos of their students and commenting on their own and other teachers' videos (Figure 3). Our second point of data involved our research team monitored this data collection as it unfolded, noting the progression of the teacher discussion and sophistication of the students' mathematical strategies.

Finally, at the end of the 4-week intervention, our research team met up with all the teachers, the mathematics instructional team, and the administrators who used MathVision for a reflective debrief. For our third point of data, our research team conducted follow-up focus group interviews with the teachers, instructional leaders, and administrators about their experience with the technology and how they used it. The focus of these interviews was to learn how the MathVision application helped in their professional practice, what particular changes or features might be beneficial to add, and how MathVision might fit into their school culture.

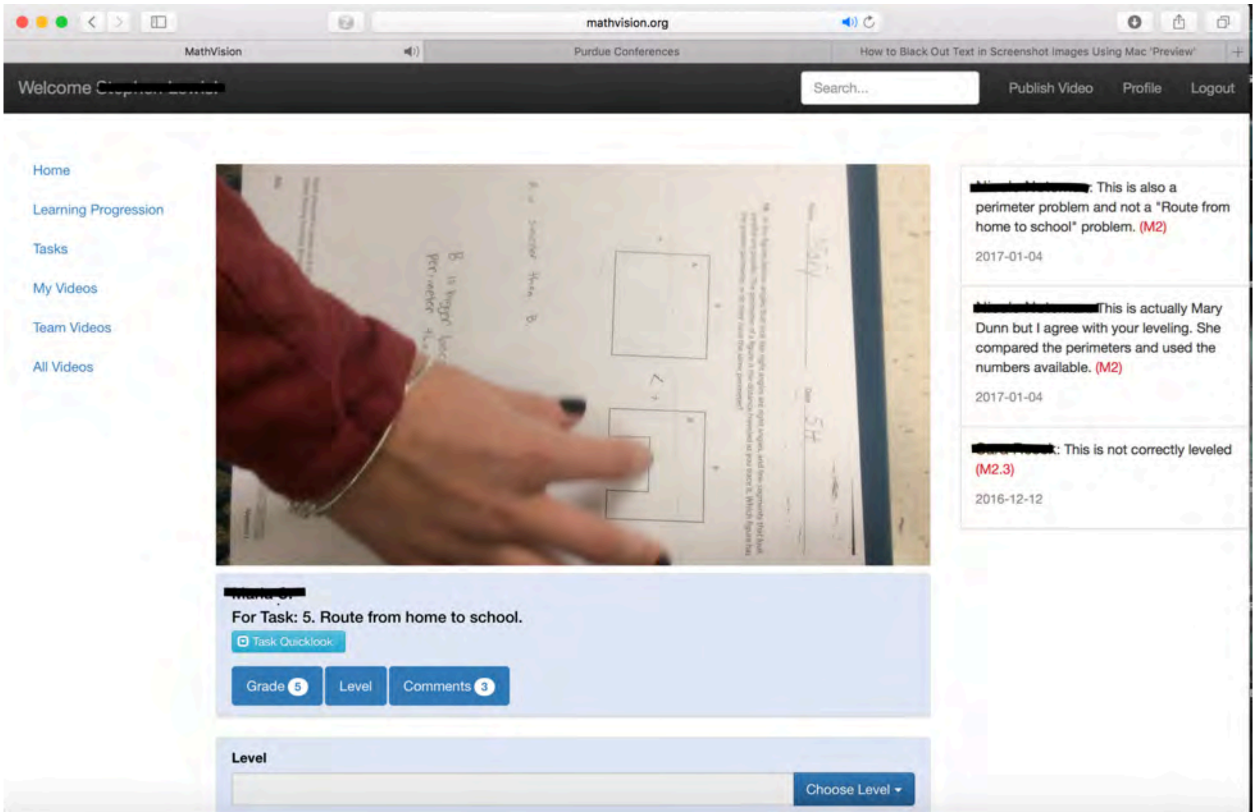

Figure 3. Video watching and commenting page allowing teachers to look at student strategies and engage in asynchronous chatting with other team members on aligning those strategies to CBA levels. Each comment (on the right) is tagged with a CBA level as a means for calling attention to particular aspects of the learning progression.

Sample

The Sample for this study consisted of the 2nd, 3rd, 4th, and 5th-grade teacher teams, the mathematics instructional team, and the administrators of a public elementary school in a high-socioeconomic neighborhood in a mid-sized city in Midwestern United States. Each math team consisted of 3 teachers and their 20 to 25 students. The mathematics instructional team consisted of the schools permanent mathematics instructional coach who also taught enrichment mathematics classes, and the administration group consisted of the head principal and the instructional leader for the school.

Internal Validity

While this research study utilized a case study methodology based around observation of participants using the technology, we also focused on the building and usability of the technology along with observing its use by teachers. Study bias was mitigated by not utilizing the developers of the technology to be involved in the data collection or the observation. Additionally, we began continual conversation with the research participants and presented our analysis to them for a form of "member checking" to ensure that our conclusions mirrored their own experiences with the technology.

Data Analysis

The primary data used for this study were the uploaded videos and comments generated from participants within the MathVision application. These were analyzed by the research team to understand the evolution of the professional knowledge that teachers exhibited through and with the application. This analysis involved continual watching and reading of this data, research team meetings to discuss our interpretations, and member-checks back to the teachers in the final interview. The secondary data involved video observations from the classroom. This data was analyzed through a grounded theory methodology (Corbin & Strauss, 2008) in order to notice any emergent themes that inform us as to how teachers and students utilized (or did not utilize) the technology.

Results

Our analysis uncovered the following results to our research questions. First, to answer how a VPLC environment might be created that enables elementary mathematics teachers to base their teaching on research-based mathematical Learning Progressions, without requiring timely and resource-heavy physical interactions between teachers, we found that this was possible through mobile technology. However, a larger finding was that teachers did not actually use this technology to house their discussions. For instance, teachers primarily focused on the novel ideas associated with doing individual task-based interviews with their students rather than having collective discussions about their respective strategies and aligning them to the learning progressions. The discussions themselves that emerged as a result of these task-based interviews were primarily done physically rather than through the web-based application. The technology itself was mainly used as a place to sore and retrieve the videos in an easily accessible way.

Second, to answer the question of what affordances of MathVision teachers utilized and how these features affected their teaching practice, we found that teachers did not actually engage in watching each others videos prior to their physical meetings, but rather used the meeting time to watch and discuss each others videos. It seemed that the physical meeting space afforded teachers the ability to meet, think about and discuss the video data itself. We ponder as to whether that had teachers a specific timeframe to upload and view/comment on each others videos might have been beneficial in accomplishing prior commenting.

Finally, in asking how will physical team-meetings be altered or augmented through the use of this technology, which allows teachers to view each other's videos before these meetings as well as how will teachers interact and talk to each other in reference to the technology, we found that teachers collaborated within this VPLC environment, teachers seemed to support each other through the process, but that seemed to be primarily due to the collaborative infrastructure that previously existed in the school. However, teachers indicated that the videos unveiled a level of depth into each student's individual thinking that they had previously not seen.

A number of results also emerged with respect to enhancing student learning. In particular we found that the instructional decisions and discussion that teachers had with each other about supporting the needs of their students, based on the strategies they saw, were important as they uncovered student conceptions related to solving particular length and measurement problems. In response, the teachers hoped that more instructional tasks could come about from this experience to support learning in this area.

As a result of this study we also observed that the teachers did engage in significant conversations about student learning process and their alignment to the research based learning progressions. This is one area that we feel may be appropriate for future inquiry.

Discussion

Overall in looking across these findings we offer the following overarching results. First in consideration of the proof of concept of this study we observed that it was possible to build a functional interface for teachers to have meaningful discussions about student strategies and align them to the CBA framework. However, with respect to this mobile application, we found it still very difficult for teachers to utilize for a number of reasons. First, the selection of length and measurement as a focus caused some difficulty, as this was not aligned to the current content they were teaching and treated more as an "add-on" to their already busy schedule. Additionally because the technology platform was still in a "beta" phase of development, the platform did not always perform as it was envisioned, particularly as teachers access to it over the school's WiFi wavered during the course of the study.

Additionally, the small-group meetings where the learning progression alignment was discussed were not consistent across teachers. When teachers were in the same physical space, there was seemingly less motivation to challenge each other's lines of reasoning and agree on a particular level after only a short explanation. With the drive of the interface as being to produce a space for disagreement and reconciliation of those disagreements through productive chat, this is something that we had hoped would arise through the use of the application. Furthermore there was a considerable number of interviews conducted by a relatively small number of teachers with one teacher in particular conducting a much larger number than others due to the busy schedule of the participating teachers. We question how our observed interviews would have been different with additional teacher voices conducting the interviews.

One other result was that the teacher who was presenting her own students' strategy often felt a sense of pride and ownership in the student's mathematical thinking. Teachers reflected that when their peers critiqued or commented on their students' thinking, their first reaction was often to take it as a personal critique and not a learning opportunity. Perhaps the immediacy of watching video on one's own mobile device or tablet instills a sense of ownership or connection to the student.

While teachers were excited and motivated to pilot this web-based application, we wonder as to the extent that which VPLC's were actually established, as there was initially little dialogue that occurred online. Rather simply participating in the study and having a home for the relevant video data sparked physical discussion on students' levels of reasoning and actually was able to bring out instances where students who were deemed as being high performing fell apart on tasks due to the nature of the CBA tasks. In one particular example, a young male student "Dylan", a pseudonym, responded incorrectly on a measurement task with an incorrect line of reasoning. Initially the teachers had wanted to dismiss this as a poor interview, but later realized that they were uncovering quite a bit of detail on the students' line of mathematical reasoning.

We did uncover some positive results with respect to using this interface during the course of our study. Teachers reported that this experience was helpful to their teaching practice, in particular in being able to watch and talk about each other's recorded videos. Teachers also felt this project connected strongly to the existing practices they see in other educational roles, in particular with their Reading Recovery program, in which they present student reading and work to the team of teachers for discussion. Further, through conducting these interviews, teachers were able to get a better understand of their students' lines of thinking as well as increasing familiarity with other teachers' students. Finally, and arguably most important finding, the teachers felt they gained significant knowledge in mathematical interviews and learned much about the learning progressions. As a result of this, our teachers reported that they had to question their own assumptions of mathematics learning and achievement and would be better equipped to use the learning progressions in their own teaching.

OPPORTUNITIES TO POSE PROBLEMS USING DIGITAL TECHNOLOGY IN PROBLEM SOLVING ENVIRONMENTS

Daniel Aurelio Aguilar-Magallón
CINVESTAV-IPN
aguilarm@cinvestav.mx

Willliam Enrique Poveda Fernández
CINVESTAV-IPN
wpoveda@cinvestav.mx

This article reports and analyzes different types of problems that nine students in a Master's Program in Mathematics Education posed during a course on problem solving. What opportunities (affordances) can a dynamic geometry system (GeoGebra) offer to allow in-service and in-training teachers to formulate and solve problems, and what type of heuristics and strategies do they exhibit during this process? Results show that combining semi-structured problems with the use of GeoGebra can be useful in motivating and involving teachers in various episodes of problem formulation. In this context, important strategies included analyses of the variation in the attributes of figures using dynamic points and loci.

Keywords: Problem Solving, Technology, Geometry and Geometrical Spatial Thinking, Teacher Education-Preservice, Teacher Education-Inservice/Professional Development

1 Introduction

It is widely recognized today that formulating, or posing, problems is a central activity in the practice of professional mathematics and a fundamental component of mathematical thinking (Cai et al., 2013). In this regard, in the past two decades problem formulation and problem solving have been identified as central topics in mathematics education (Rosli et al., 2015). On this theme, Osana and Pelczer (2015, p. 470) commented that:

> A growing movement in mathematics education that placed problema solving at the center of school mathematics further contributed to researchers' focus on problem posing, particulary its role in teaching and learning. (p. 470).

In this perspective, and in educational contexts, mathematical activity is conceived as a form of thinking in which a community (teacher and students) formulates questions and new problems to give meaning to, and resolve, problematic situations. In this scenario, the community recognizes the importance of seeking different means of supporting their responses. Santos-Trigo, Reyes-Martínez and Ortega-Moreno (2015) observe that one objective of mathematical activity is to identify and contrast diverse approaches to representing, exploring, conjecturing, resolving and formulating new problems. In communities of this kind, the role of teachers is determinant for students' learning because they are responsible for choosing and presenting the tasks that will allow learners to develop their ability to formulate and resolve problems. However, some researchers recognize that, in general, in-service and in-training teachers experience serious difficulties when confronting the tasks involved in preparing and posing problems (Rosli et al., 2015; Lavy, 2015).

What role does the use of digital technologies play in learning communities that promote and value problem posing and problem solving? In mathematics education digital technologies can provide an effective way of developing mathematical knowledge and transforming teaching scenarios by orienting them towards the formulation and resolution of problems (Aguilar-Magallón & Reyes-Martínez, 2016). To date, however, little research has been conducted on the role of technology in designing and implementing tasks whose goal is to enhance the ability to formulate and resolve problems (Abramovich & Cho, 2015).

In light of the foregoing, the principal objective of this study consisted in analyzing how the systematic use of a Dynamic Geometry System (DGS) by in-service and in-training teachers can contribute to the processes of problem formulation and problem solving. Thus, our research is oriented by the following questions: what opportunities (affordances) can the *GeoGebra* Dynamic Geometry System offer current and future math teachers in relation to problem formulation and problem solving, and what kinds of heuristic resources and strategies are exhibited in this process?

2 Conceptual Framework

Posing Problems and the Use of Digital Technologies

The literature sustains that the process of posing problems centers on two fundamental activities: formulation and reformulation. The formulation consists in generating new problems based on certain information, situations or contexts, while the latter entails elaborating new problems by modifying the conditions and/or objectives of an earlier, given problem (Silver, 1994). Reformulation activity also occurs when a problem that is in the process of resolution is transformed or re-posed in order to simplify it (Silver, Mamona-Downs, Leung & Kenney, 1996). According to this characterization, formulation and reformulation activities may take place before (the formulation or understanding of a statement), during, or after (reformulation) the resolving problems (Silver, 1994).

Following these ideas, Stoyanova and Ellerton (1996) presented a typology of problems that specifies the following three categories: open, semi-structured, and structured, as a function of the formulation or reformulation activities they involve. In open problems, individuals must posit problems based on information presented in the form of figures, tables, numbers, etc. The statement of problems of this kind do not include any specific requirements or objectives. In semi-structured problems, individuals are required to generate and/or add conditions in order to reach a solution; that is, the statement of this type of problem contains only partial information or conditions. Structured problems, finally, stipulate both the objective and all the information and conditions necessary to resolve them. Thus, open problems entail primarily formulation activities, while structured problems involve reformulation activities. Semi-structured problems can propitiate both formulation and reformulation activities. Silver (1997) holds that open or semi-structured problems can be useful in propitiating episodes of problem formulation.

Santos-Trigo, Reyes-Martínez and Aguilar-Magallón (2015) underscores the importance of the systematic utilization of various digital tools in environments of problem formulation and problem solving. Here, the goal is to have individuals constantly identify and examine distinct types of relations, posit conjectures, determine and analyze patterns, employ different systems of representation, establish connections, apply distinct arguments, generalize and extend initial problems, communicate their results, and posit their own problems. Some research has focused on examining the processes involved in posing problems using specific digital tools, such as DGS (Leikin, 2015; Lavy, 2015). According to Lavy (2015), a DGS constitutes a cognitive visual support based on immediate interactions between the tool and its user that can facilitate the processes involved in posing problems. Imaoka, Shimomura and Kanno (2015) recommend that the design of problem formulation activities utilizing a DGS entail exploring variable attributes of such figures as areas, perimeters, lengths, and angles, among others. They further advise designing problems that can be represented and solved in distinct ways; that is, they underline the importance of posing problems that are not made trivial once a DGS is applied. Leikin (2015), finally, argues that an important strategy for designing activities related to posing problems consists in transforming structured problems into open or semi-structured ones; *i.e.*, eliminating the specific conditions or objectives of structured problems to encourage exploration and research with the aid of a DGS.

3 Methodology

Participants

The participants in this study were nine students enrolled in a Master's Program in Mathematics Education. The study design consisted of fourteen weekly sessions, each with duration of three and a half hours. The group included six in-service and three in-training math teachers, all of whom had formal academic training in the field of mathematics.

Design of Activities

A total of five activities were implemented during the study, taking into account the ideas proposed by Imaoka et al. (2015) and Leikin (2015); that is, we began with a series of structured problems related to the area of figures that were then transformed into semi-structured research topics. In this report, we analyze the results of one of those problems. That problem emerged when the structured problem used by Schoenfeld (1985) was transforming by modifying its conditions (Table 1).

Table 1: Transformation of a Structured Problem Into a Semi-Structured One

Structured Problem	***Semi-Structured Problem***
You are given a fixed triangle T with base B. Show that it is always possible to construct, whit straightedge and compass, a straight line that is parallel to B and divides triangle T into two parts with equal area. Can you similarly divide the triangle into five parts of equal area? Schoenfeld (1985, p. 16).	***P.1.*** *Given any triangle, divide it into two regions with the same area.*

Implementation of the Activity and Data Collection

The development of the activity can be characterized as including three phases: 1) individual or pair work; 2) plenary discussions; and, 3) on-line discussions. The first phase consisted in three (weekly) in person sessions of three hours each. They took place in a computer laboratory so that each student had access to a personal computer with internet. During the plenary discussions, participants presented their ideas or advances in resolving the activity to the whole group. The on-line discussions utilized a digital wall (*Padlet*) that allowed participants to continue the discussion outside and beyond the in-person sessions. Study data were collected by video taping the in person sessions, recording the participations in the digital wall, *GeoGebra* worksheets, individual written reports, and interviews.

4 Results

In this section, we discuss the resources, heuristics and strategies that were presented in participants' efforts to solve the problem (P.1). Special emphasis is placed on the episodes involving problem formulation propitiated by the use of *GeoGebra*.

Initial Solutions

In a first instance, participants solved the problem using two basic ideas: 1) bisecting the area of the triangle by means of a median (*i.e.*, dividing the base in two equal parts while maintaining the height); and, 2) bisecting the area by dividing the height into two equal parts but conserving the initial base. Thus, participants used both static and dynamic solution strategies. Some of the initial dynamic solutions are shown in Table 2. One essential aspect of these approaches was the search for diverse ways to identify regions with the same area.

Table 2: Some Initial Dynamic Solutions to the Problem

Solution	Resources and Strategies
	*Resources*: circumference to transfer measurements, mobile point on the segment, mid-point, triangle. *Dynamic strategy:* point F on AB. Construct a dynamic triangle, FGD, with the same height as triangle ABD, but a movable base, FG, of constant length equal to AE where $AE = \frac{1}{2}AB$ (infinite solutions).
	*Resources*: Median, regular polygon, mobile point on the segment. *Dynamic strategy*: use a slider, "m", to draw a regular polygon of "m" sides and reflect it by means of the median; add and subtract dynamic polygons of the same area on both sides of the median (infinite solutions).
	*Resources*: parallel mean, mid-point, triangle, mobile point on the segment, Euclidean proposition 37. *Dynamic strategy*: divide the height in two parts by the parallel mean, ED, and construct two triangles with the same base (equal to half of side AC) and mobile vertices, G and H, on the parallel mean (infinite solutions). The area of the green region is equal to that of the blue region.

Problems Posed by Participants

After presenting their initial solutions in a plenary discussion, participants proposed new ways to find regions with the same area as the given triangle, motivated by the dynamic exploration of elements inside the configuration (Table 3). For example, one participant suggested using a circular sector to divide the triangle in two sections of the same area. Another focused attention on a construction that involved a quadrilateral. All approaches were based on a graphic representation of the variation of the area of the figures involved (Table 3).

Table 3: Problems Posed with Exploration and Solution Strategies

Problem Posed	*Resources and Solution Strategies*
1.1. Divide the triangle with a quadrilateral whose sides are perpendicular to two sides of the triangle (variation of a point D on side AC).	***Exploration***. Constructing a family of quadrilaterals based on mobile point D and with sides perpendicular to those of the triangle.

	***Important question***: where should point D be placed on side AC so that quadrilateral EDFB has the same area as the sum of the areas of triangles AED and DFC? ***Solution***. Construct the dynamic points *P = (x(D), areaDEBF) and* *Q = (x(D), areaABC - areaDEBF).* The intersections T and S of the loci described by P and Q upon moving D determine solutions U and V.
1.2. Use a circular sector to divide the triangle (variation of a point E on side AB). 	***Exploration***. Constructing a family of circular sectors of variable area "*e*" from mobile point E. ***Important question***: where to place point E on side AB so that circular sector BEF has the same area as section AEFD? ***Solution***. Create the points *H = (x(E), e)* and *G = (x(E), areaABD – e).* The intersection N of the loci described by H and G upon moving E determines solution P.
1.3. Division by means of a straight line parallel to one of the sides (variation of a point D on the side). 	***Exploration***. Constructing a family of triangles DBE with D mobile on AB and side DE parallel to side AC of the initial triangle ABC. ***Important question***: where to place point D on side AB so that quadrilateral EDAC and triangle DEB have the same area? ***Solution***. Create the points *P = (x(D), areaADEC)* and *Q = (x(D), areaDBE).* The intersection R of the loci described by P and Q upon moving D determines solution
1.4. Division by means of a straight line perpendicular to one of the sides (variation of a mobile point D on the side).	***Exploration***. </table>

The exploration strategy applied in these problems consisted in constructing dynamic sections (quadrilaterals, circular sectors, triangles) inside the initial triangle and then visualizing the change in the area of those sections by dragging points until the section had half of the initial area. Visualization of the change in area was performed using dynamic points and their respective loci. Solutions were determined in terms of intersection points between those loci (Table 3).

New Problems Posed After Solving the Original Problem

The solutions reached by participants were reviewed in a plenary discussion. Those solutions involved using such loci as parabolas and hyperbolas. New problems emerged as a product of this discussion, and participants then attempted to resolve them by: i) determining the important elements geometrically (focus, directrix, axis of symmetry, vertex, etc.) of the conic sections utilized to resolve the problem; and, ii) finding the equations of those conic sections and obtaining a general algebraic solution of the problem. To find the important elements of the conics sections, participants had to review their geometric properties (in different on-line resources); for example, to find the focus of parabolas they used their reflexive property, while to find the equations, they generally used parametrization of the attributes of the triangle and extreme cases (Figure 1). Finally, participants pondered extending the initial problem by considering how to divide a triangle in three and more sections of the same area.

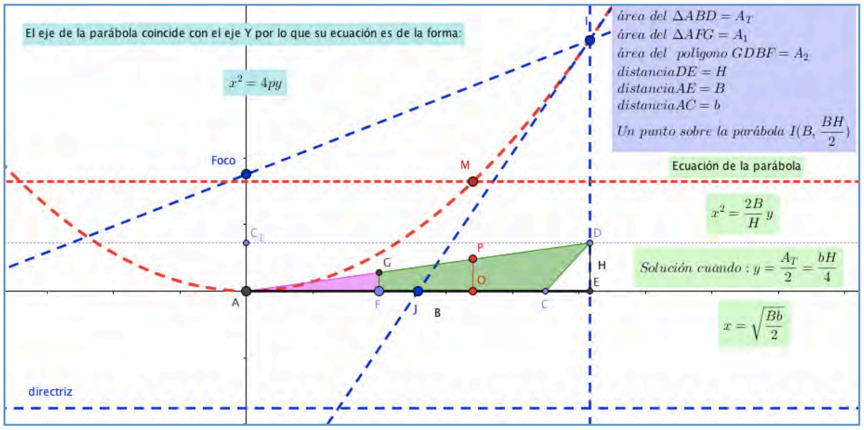

Figure 1. Parametrization and use of extreme cases to find the equation of the parabola used to resolve problem 1.4.

5 Discussion of Results

The results shown suggest that using the Dynamic Geometry System (*GeoGebra*) makes it possible to generate processes for posing problems by transforming a traditional (structured) problem into a semi-structured research problem. This transformation is achieved by *not making* certain objectives or conditions explicit. In the initial problem, *not making* the condition of dividing the triangle by means of a straight line parallel to one of the sides explicit proved to be determinant in leading the participants to formulate and resolve diverse problems.

Thanks to the ability to drag objects inside the dynamic configurations, participants were able to resolve the problem by applying dynamic approaches. These approaches allowed them to find infinite solutions that would be very difficult to visualize using traditional static tools like pencil and paper. Moreover, the dynamic exploration of the task motivated participants to pose a series of problems whose solution required analyzing variations in the areas of the figures. The use of dynamic points and their respective loci was crucial in this analysis. Later, another phase of posing problems emerged as participants explored the loci (conic sections) obtained to determine their important elements (focus, directrix, vertex, etcetera), their equations and, finally, algebraic solutions to the problems.

6 Conclusions

Any attempt to include the posing and resolution of problems in teaching and learning contexts in mathematics education depends, first and foremost, on the teacher(s) involved. In this regard, posing or formulating problems is important for teachers both in terms of their own training in the discipline and for their teaching practice. On the one hand, formulating problems allows both in-service and in-training teachers to develop their creativity and construct or strengthen their knowledge of mathematics. On the other, formulating problems is a fundamental pedagogical ability, because it is always necessary to formulate or reformulate problems as a function of students' needs, resources, ideas or errors. In this sense, it is necessary to address two key issues: 1) teacher training; and, 2) designing tasks that require formulating problems.

This study presented an example of the design and implementation of such a problem-formulation task. The use of a DGS was fundamental because it made it possible to transform a traditional problem in an activity that required exploration and research. We can conclude that the DGS can motivate processes of exploration and research that will eventually lead to the formulation and resolution of distinct problems. This idea could well become an essential element in the design of teacher training programs based on posing and resolving problems with the aid of digital technologies.

THE EFFECTS OF TWO SIMULATIONS ON CONCEPTIONS OF RATE OF CHANGE

Jenna Tague

pzhang@winona.edu

The focus of the current proposal is to examine the effect of two dynamic simulations on the participants' conceptions of rate of change. Conceptions of rate of change were measured according to Carlson et al.'s (2002) Mental Actions framework and how the participants related the physical simulations to the graphical representations (Heid, et al., 2006). Results indicate that the simulations increased participants' covariational understanding, but did not help the students create a more accurate understanding of rate of change.

Keywords: Technology, Algebra and Algebraic Thinking

Students who do not understand the concept of rate of change are unlikely to develop a conceptual understanding of algebra (Roschelle, Kaput, & Stroup, 2000) or calculus (Thompson, 2008). It has been suggested that dynamic simulations could help students, particularly in the middle grades, develop a better understanding of rate of change (Rochelle, et al., 2007). However, new simulations are created continuously, and it is unclear how these simulations affect the cognition of the individuals who interact with them. Thus, the focus of the current paper is the following question: How did two dynamic simulations affect middle school, high school, and undergraduate students' understandings of rate of change?

Significance

Past research has shown that visualizations are important in: developing an understanding of rate of change (Roschelle et al, 2007), and the historical mathematical development of rate of change (Struik, 1969). Roschelle, Kaput, and Stroup (2000) propose the inclusion of technology as a necessary aspect of introducing rate of change to students before algebra or calculus.

However, visualizations and simulations change the way that students interact with and develop an understanding of various concepts (Hegadus, 2005). Even when educational experts have designed visualizations, novices notice different features or interpret the features differently than the experts intended (Roschelle, 1991). Further, the introduction of dynamic simulations may result in the *development* of different or undocumented cognitive obstacles. For instance, in a study of preservice teachers' understanding of the definition of limit in interactive geometry environments, Cory and Garofalo (2011) found that their participants became unsure of which variable is dependent on which (amongst N, epsilon, and delta). Because of the structure of the technology, some of the well documented cognitive obstacles disappeared (i.e. what N, epsilon, and delta represent physically), but the misunderstanding of dependence appeared as a new cognitive obstacle.

Other work provides evidence of what tasks or teaching practices would be important in using dynamic simulations as part of rate of change instruction (i.e. Roschelle et al, 2007). However, it does not address how, separate from instruction, simulations may impact an individual's cognition. It is essential to examine how simulations affect the students' conceptions of rate of change. This information will allow for informed implementation of dynamic simulations centered on rate of change into a learning environment and into future research on rate of change.

Background

Development of an understanding of covariation has been linked to an improved understanding of rate of change (Thompson & Thompson, 1996; Confrey & Smith, 1994). An understanding of covariation refers to the understanding that as one variable changes continuously, the other dependent variable changes simultaneously. Thompson and Thompson (1996), in documenting a teaching experiment with one 6th grade student, indicated that students tend to initially conceptualize speed as a compound unit called *speed-lengths*: the time it takes to travel a given distance. That is, the participant was only able to understand discrete parts of the variation, rather than describe how continuous variation in time affects the continuous variation in distance. The authors reasoned that school learners first understand “speed as a distance and time as a ratio (total length/speed-length)” (Thompson & Thompson, 1996, p. 3).

In a study of secondary teachers’ creation of a graph of a bottle that is similar to the boiling flask shown in Figure 4, the researchers used two lenses to examine the participants’ work: “use and coordination of macro-perspective and micro-perspective; and coordination of mathematical entities and their features” (Heid, et al., 2006, p. 4). The study postulated that a central theme in students’ reasoning about the bottle problem was the “macro-perspective” (examining the overall view) and the “micro-perspective” (examining a smaller part such as small changes in the height to consider what change in the volume that would cause) (p. 5). A key factor in how successful their participants were was whether or not the participants were conscious of both perspectives and whether or not they could shift between them to overcome obstacles. The second key factor in the participants’ success was how the individuals related the mathematical entities (the graph) and the physical entities (the bottle). For example, sometimes participants would be unable to coordinate the mathematical and the physical entities or other times the participants would fixate on a particular connection and use only that connection to generalize.

Thus, the current literature indicates that students will likely have difficulty thinking about how the variables in rate of change tasks are related. In addition to this, participants will struggle to understand when gestalt views of the objects/graphs or piece-wise views of the objects/graphs will be helpful to their reasoning.

Research Design

The current qualitative study included two tasks that were part of a larger effort to document students’ conceptions of rate of change (Tague, 2015). Each participant took part in a task-based based interview (Goldin, 2010) lasting, on average, 70 minutes. The goal of the interviews was not to design instruction nor to teach the participants, but instead, to document the participants’ conceptions of rate of change before and after use of a dynamic visualization. As such, the interviewer did not push the participants toward a correct solution; however, follow-up questions were asked to clarify the participants’ conceptions.

Each interview was video recorded, and transcribed verbatim. The video recordings captured the participants written work, their hand movements, and their interactions with the visualizations. The transcripts included gestures where the participants did not possess the vocabulary to articulate their full understanding of rate of change (Roorda, Vos, & Goedhart, 2009). For example, one of the participants showed, using her hands, that when the bottle narrowed, the graph would increase in slope, by tilting her hands in and then out because she could not articulate the vocabulary for narrow/widen.

The transcripts were then analyzed according to the Mental Action Framework (Carlson, et al., 2002) shown in Figure 1 to determine the level of the participants’ understanding of covariation. The framework was developed through studying second year calculus students’ understanding of average rate. The authors argued that determining level of understanding of covariation involved examining many mental actions that might be elicited by a task, and that an individual should not attain higher levels of mental actions without mastering the lower levels. We also examined what other features or conceptions were important in completing the task (Heid et al., 2006), in interacting with the simulations, and in completing the task a second time. For example, if a participant matched bottles to graphs in the Water Filling task by iconic translation (how closely the shape of the graph matched the physical shape of the bottle) (Monk, 1992), that individual was not actually using any kind of covariation to complete the task.

Mental Action	Description of mental action	Behaviors
Mental Action 1 (MA1)	Coordinating the value of one variable with changes in the other	• Labeling the axes with verbal indications of coordinating the two variables (e.g. y changes with changes in x)
Mental Action 2 (MA2)	Coordinating the direction of change of one variable with changes in the other variable	• Constructing an increasing straight line • Verbalizing an awareness of the direction of change of the output while considering changes in the input
Mental Action 3 (MA3)	Coordinating the amount of change of one variable with changes in the other variable	• Plotting points/constructing secant lines • Verbalizing an awareness of the rate of change of the output while considering changes in the input
Mental Action 4 (MA4)	Coordinating the average rate-of-change of the function with uniform increments of change in the input variable.	• Construction contiguous secant lines for the domain • Verbalizing an awareness of the rate of change of the output (with respect to the input) while considering uniform increments of the input
Mental Action 5 (MA5)	Coordinating the instantaneous rate of change of the function with continuous changes in the independent variable for the entire domain of the function	• Constructing a smooth curve with clear indications of concavity changes • Verbalizing an awareness of the instantaneous changes in the rate of change for the entire domain of the function (direction of concavities and inflection points are correct)

Figure 1. Mental actions and indicators of the covariation framework (Carlson, et al., 2002, p. 357).

Participants

The participants (Table 1) were chosen purposefully to represent students at specific educational levels - before algebra (middle school students), after algebra (high school students and students taking calculus courses), and after calculus (students enrolled in differential equations courses). Algebra (Saldanha & Thompson, 1998) and calculus (Thompson, 2008) have been shown to be key places where a robust understanding of rate of change is necessary.

Middle school and high school participants were recruited through letters sent to parents from teachers in a large professional development program. In the case of the undergraduate students, participants were recruited through Calculus and Differential Equations courses at a large Midwestern University. Participants were chosen from the volunteers to maximize variation amongst the participants. When possible, the participants were chosen from different parts of two Midwestern states, or different courses.

Table 1: Participants and Pseudonyms

Participant Grade Level	Pseudonym
Middle School – 6th grade	Forrest
Middle School – 8th grade	Amy
High School – Precalculus	Sarah
High School – Precalculus	Kristi
Undergraduate - Calculus	Kyle
Undergraduate - Calculus	Angela
Undergraduate - Calculus	Brian
Undergraduate - Calculus	Amanda

Task Design and Choice of Simulation

Two simulations were used, and in both cases, the participants were asked to complete a task before the simulation, to interact with the simulation, and then to complete the same task again. During the second time through the task, the participants' original work was put away, and they had the option of continuing to use and test options in the simulations while working.

The first dynamic simulation was a Java applet called "The Moving Man" shown in Figure 1 (PhET). The applet has the image of a man that begins in the middle of a horizontal axis. The man can be dragged using the mouse or he can be programed to move in a particular way by choosing an initial position, velocity, and acceleration. If the user moves the man manually, the position, velocity, and acceleration change simultaneously.

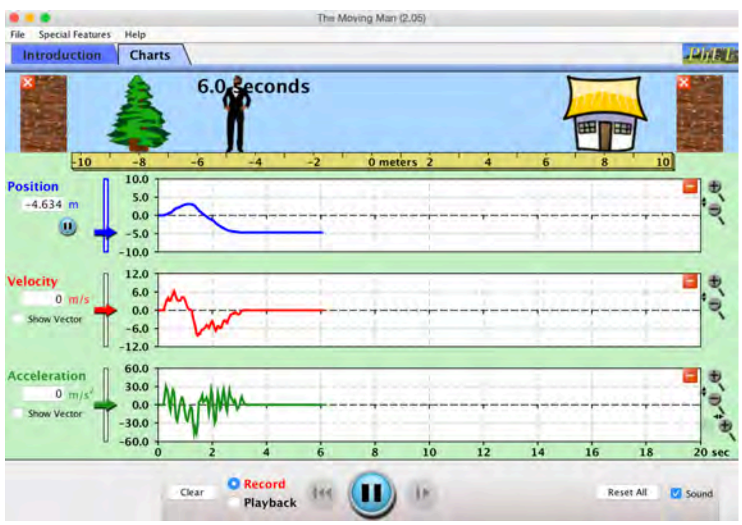

Figure 2. Screenshot of The Moving Man (applet by PhET).

The task associated with this dynamic simulation is the following: *Draw a picture of what you think the position, velocity, and acceleration graphs will look like if the man starts at the tree, realizes he is hungry, and then goes home to eat*. The task was deliberately left vague in order to allow participants to connect with their intuitive knowledge of how people move and how that motion affects their velocity and acceleration. Participants were also asked if they understood the terms position, velocity, and acceleration, and were given explanations if necessary.

The second dynamic simulation was a screenshot video of an individual playing with Wolfram Alpha's Bottle Filling simulation shown in Figure 3. In the online environment, the user can drag the outside points of the bottle, and then drag the fluid height level up. As the bottle is filled on the left side, a simultaneous graph of volume versus height is created on the right side. The participants could pause the video at any time, drag the action backwards or forwards, and watch as many times as they wanted to while they completed the task for the second time.

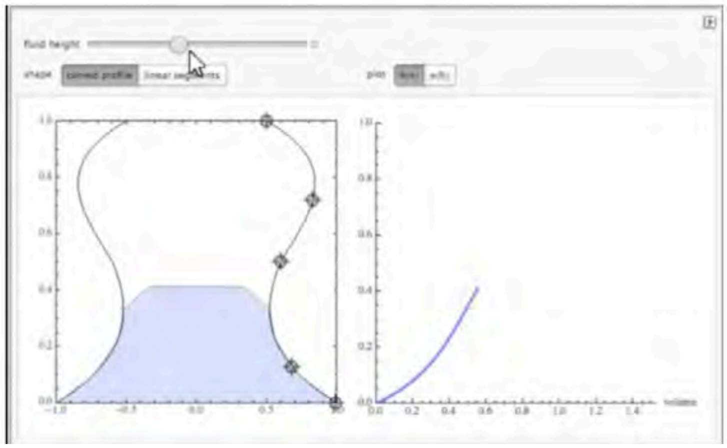

Figure 3. Screenshot of water filling simulation applet (Wolfram Alpha).

The task associated with the water filling simulation stated, "*Imagine filling each of the six bottles below (Figure 4), pouring water in at a constant rate. For each bottle, choose the correct graph, relating the height of the water to the volume of water that's been poured in*" (Annenberg Learner). Note that the graphs of C, G, and H do not match with any of the bottles, but their bottles would look like those shown in Figure 5. After the participants matched the bottles to graphs, we asked them to choose any graph they had leftover and sketch what the associated bottle would be.

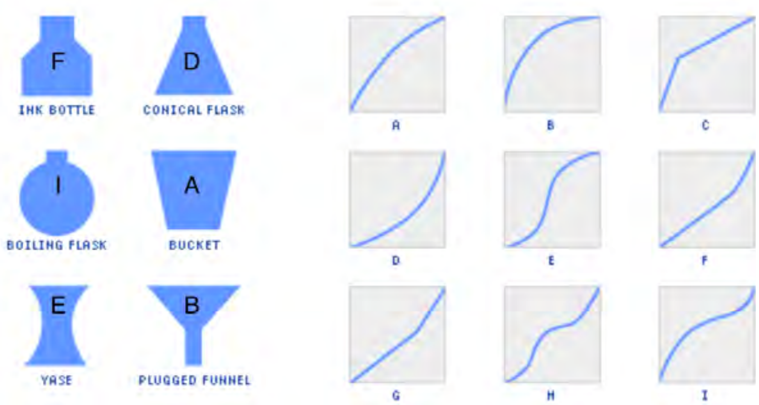

Figure 4. Task associated with the bottle filling simulation with the intended matches marked. (Annenberg Learner).

Figure 5. Bottles matching graphs C, G, and H from Figure 4 (Annenberg Learner).

The two dynamic simulations were chosen purposefully to be accessible, yet challenging to all participants from middle school through differential equations students. Both simulations were also chosen because they represent physical activities that the participants were likely to have experienced. The Moving Man represents a graphing of position, velocity, and acceleration, which is a paradigmatic type of rate of change problem that many individuals come to equate with their

Galindo, E., & Newton, J., (Eds.). (2017). *Proceedings of the 39th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* Indianapolis, IN: Hoosier Association of Mathematics Teacher Educators.

definition of rate of change (Zandieh, 1997). The bottle filling task is one that has been used by many researchers examining rate of change, and so would allow for comparisons with previous literature (Carlson, et al., 2002; Heid, et al., 2006).

Results and Discussion

Table 2 illustrates the mental actions of the participants associated with covariation before and after interacting with the simulations. As the tables illustrate, the participants generally moved toward a more covariational view of rate of change or maintained their current level. However, more covariational mental actions did not always coordinate with a more accurate physical understanding, as explained further.

Table 2: Mental Actions Before and After the Dynamic Simulations

	Water Filling		Moving Man	
	Before	After	Before	After
Forrest	None	None	MA1	None
Amy	None	None	None	None
Sarah	MA5	MA5	MA5	MA5
Kristi	MA3	MA5	MA1	MA3
Kyle	MA2	MA3	MA3	MA4
Angela	MA4	MA5	MA4	MA5
Amanda	MA5	MA5	MA4	MA5
Brian	MA5	MA5	MA5	MA5

The middle school participants, Forrest and Amy, matched bottles both before and after the simulation, using Monk's (1992) description of *iconic translation*. Monk (1992) described how students sometimes create graphs that replicated the physical features of a problem. For example, when asked to create a rate graph of someone biking across a flat surface and then biking up a hill, students are likely to create a horizontal line attached to a positive sloping line. Forrest and Amy matched the bottles with the graphs based on the physical features of the bottle that matched the physical features of the graphs. For example, they both matched graph D with the vase, and Amy explained, "because I think I was just trying to match the shape of it and not the actual amount of liquid it can be filled with." Further, Amy's explanation indicated that she was not even considering either of the variables involved in the task, and rather looked at the overall shapes to match. Neither one attempted to draw a bottle from one of their leftover graphs.

The rest of the participants were either at the highest covariational understanding of rate of change (for the water filling problem), or moved towards a better understanding (Table 2). Still, as before, improvement in understanding of covariation did not necessarily indicate a more accurate response. For example, Kyle's matches were based on a generalization of one physical feature of the bottles – corners. His reasoning was similar to that of the participants in Heid and colleagues' (2006) study, in that, although he was considering different uniform changes in volume and how that would correlate to height, he based those changes around relating the physical features of corners to physical corners in the graphs. However, he was ranked at MA3 afterwards because he could describe that wider parts of the bottle would results in more volume, but less height whereas before the simulation he could only describe as more water was added, the height would increase.

The Moving Man interaction seemed to have none or a negative effect on the rate of change conceptions of the middle school participants. Forrest actually moved from creating graphs where he considered the change with respect to time to creating graphs with iconic translation (Monk, 1992), or using the physical motion of the man to create the shape of the graph. Note, from Figure 6 that all of his graphs were horizontal and the man's movement can only be horizontal. Forrest had no cognitive dissonance about the fact that his graphs differed from those on the simulation. He was insistent that the graphs must look "just like the man moved." In Amy's case, she persisted in creating three discrete points for the graphs: one at (18,8) on the position, one at (18,8) on the velocity, and one at (8,6) for the acceleration. Like Forrest, she was undisturbed by the difference between her graph and the simulation. For the rest of the participants, the simulation moved them towards a more covariational understanding of rate of change. However, all of the other participants also copied what the simulation created, whether or not they understood it. For example, Kristi originally created a linear position function, and after interacting with the simulation, she changed it to curved. When she was asked why, she was unable to provide reasoning until the interviewer asked her what would happen if the acceleration were set to 0.

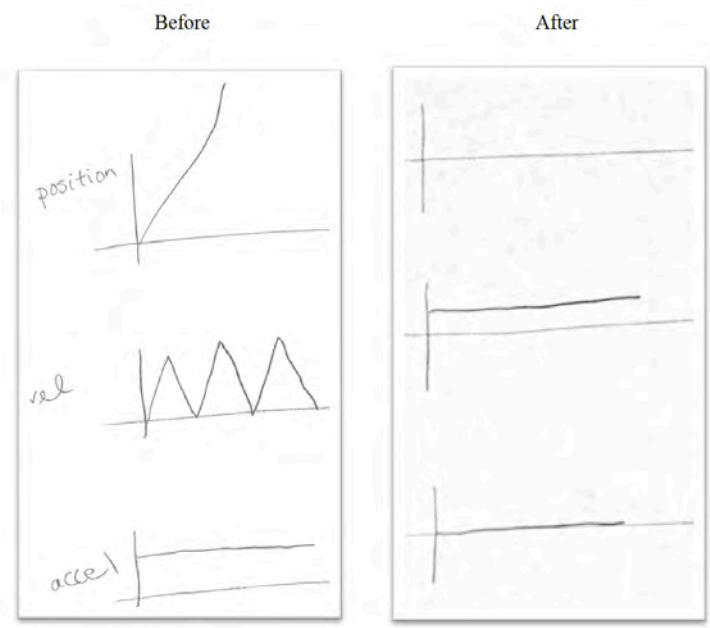

Figure 6. Forrest's graphs before and after the Moving Man simulation.

Conclusion

In summary, the dynamic simulations moved the participants' conceptions of rate of change towards a move covariational understanding. However, a better covariational understanding did not directly mean that they produced a more accurate graph/bottle/etc. It's possible that in addition to developing an understanding of how the variables co-vary, individuals also have prior experiences that cause them to focus only on one aspect of the physical situation or to use iconic translation. A better understanding of the relationship between the prior experiences and how they relate to covariational understanding is necessary to be able to describe fully individuals' understandings of rate of change.

It is clear from the current study, that questioning is essential because exposure to the simulations, in some cases, caused new misconceptions, led to less use of covariational reasoning, or did not address underlying misconceptions. Furthermore, technology is essential in studying understanding of rate of change, but it also transforms understandings, and as such, requires attention to changes caused by the technology, and further study on what kinds of questions and tasks would help students maximize their understandings.

In this study, we investigated how Grade 3 and 4 students' organizational structure for volume units develops through repeated experiences with a virtual manipulative for building prisms. Our data consist of taped clinical interviews within a micro-genetic experiment. We report on student strategy development using a virtual manipulative for counting cubes as a measure of prism volume. A descriptive case of one student, Jim, is included as an example of how students developed increasingly efficient counting strategies built on understanding of structuring, composite units, multiplicative thinking and an understanding of the number of cubes along an edge. We found students were able to develop structure for volume and advance their level of thinking along a learning trajectory for volume measure.

Keywords: Geometry and Geometrical and Spatial Thinking, Learning Trajectories, Measurement, Technology.

Introduction and Theoretical Framework

Volume measurement is an important component of elementary school mathematics; however, geometric and spatial structuring is a topic that presents students with significant challenge (Barrett, Clements, & Sarama, 2017). Unlike length or area measurement, students must coordinate the measurements from three dimensions to measure volume. Spatial thinking is related to enumeration strategies as children measure volume (Battista & Clements, 1996). Thus, it is important to characterize the development of enumeration strategies. We have established hypothetical learning trajectories to characterize such development and to support the development of curriculum and enhance teacher knowledge (Barrett et al., 2017). A trajectory includes the mathematical learning goal, the thinking and learning in which students might engage and the pertinent learning activities to support growth from one level to the next (Simon, 1995). We employed a trajectory to classify student growth patterns and to design and test a learning activity. In this study, we designed and tested a virtual manipulative intended to support organizational structuring of volume units.

Students initially attempt to organize and structure volume units by working without coordinating the set of cube faces on the prism. We now describe this level of thinking as *volume unit repeater relater* (VURR), a fourth of seven hypothetical levels in that trajectory (Barrett et al., 2017). As children gain capability for coordinating spatial components, they see the array as space filling (i.e., a child may rightly predict an entire collection of rows to fill a layer given only one visible row). This level of thinking is described as *volume initial composite 3D structurer* (VICS), the fifth level. Once children completely integrate a set of locally coordinated structures within a global structure, they use layering strategies to enumerate the volume of a prism. This level is called *volume 3D row and* *column structure*r (VRCS), the sixth level of the trajectory. There is still a need to expand our knowledge of effective instructional interventions for any given level in this trajectory. We developed an intervention intended to bring students up to the VRCS level. Battista and Clements (1998) found that most grade five students, but only 20% of grade three students, characterized a rectangular prism as a series of layers of rows and columns of cubes. Thus, we focused on grades three and four.

We developed and used a computer manipulative, our intervention, to help students recognize that edge lengths can be used to predict the number of cubes along an edge, and develop their use of composite units or units of units. We hypothesized that the manipulative would highlight the efficiency of enumerating composite units by constraining how students interact with increasingly complex units: first single cubes, then row collections of cubes, then layered collections of rows of cubes. Further, we expected to prompt for a correspondence between an edge length and the number of an appropriate unit along that edge. The following research questions guided our investigation:

- How does a student's organizational structure of volume units change through repeated experiences with a virtual manipulative for building prisms?
- What are the critical features of the treatment that supported student development?

Methodology

In this study we investigated the thinking of 31 participants in Grade 3 (14 students) and Grade 4 (17 students) at a private school in the Midwest. We used a microgenetic method to focus on growth. Three aspects of this provide insight on growth: (a) observations that span the whole period of rapidly changing competence, (b) the density of observation within this period is high, relative to the rate of change; and (c) observations of changing performance are analyzed intensively to indicate the processes that give rise to them (Siegler & Sventina, 2006, p. 1000). All 31 students participated in five interviews with one or two researchers. During each interview (taking approximately 15 minutes), the students completed three trials. A trial included first a paper version of a prism to measure, and then a virtual manipulative of the same prism.

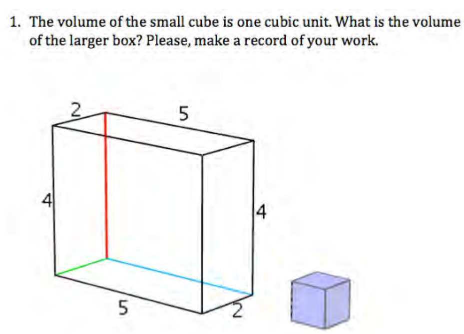

Figure 1. Paper portion of trial**.**

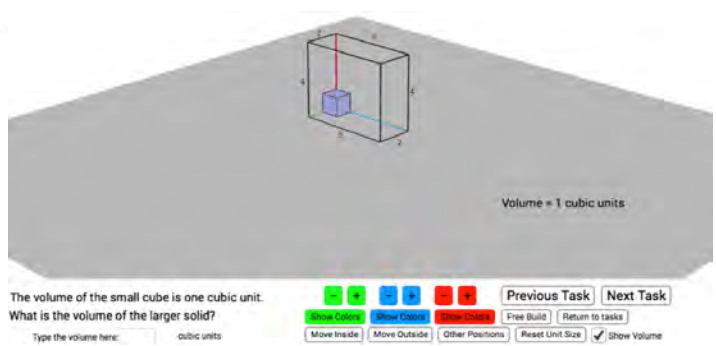

Figure 2. Virtual manipulative of trial**.**

For each trial, students had to find the volume of a rectangular prism (see Figure 1) using a pencil and a paper showing a prism with some edges labeled for length (in cm). The interviewer asked, "The volume of the small cube is one cubic unit. What is the volume of the larger solid?" After the student completed the paper task, they were asked to predict the volume of the same rectangular prism using a virtual manipulative. Each student was prompted to predict the next outcome of a button sequence, first for width, then length and finally altitude. They were asked, "How many cubes will you have when you are done pressing the green button [the first button sequence, width of prism]?" The green button sequence produced one complete row. Likewise, we asked students to predict for the second button sequence (the blue button; forming one layer of rows, now width and length), and for the third button sequence (red button; the total volume) (see Figure 2) if they continued making correct predictions about the accumulation of cubes and groups of cubes. If not, the interviewer directed them to press the relevant button so they would accumulate the cubes along that current dimension; this produced a report of the number of cubes associated with the button sequence they had been predicting. Our approach merely hinted that the prediction had been incorrect. Working thus, in three stages, students gradually filled the rectangular prism shown on a computer screen (see Table 1). (The virtual manipulative can be found at: https://www.geogebra.org/m/FgQVdDTb).

Results and Discussion

Our research question focuses on changes in students' organizational structure of volume units, so we categorized our participants into three categories to select participants who had changed their structuring. Of the 31 participants, eight (two Grade 3 and six Grade 4) showed prior, adequate knowledge of the structuring of volume and thus were not positioned to benefit during the study. Of the remaining 23 participants, eight (five Grade 3 and three Grade 4) did not display any meaningful changes in their ability to leverage the structure of 3D arrays to find volume. This left us with 15 (seven Grade 3 and eight Grade 4) participants out of a possible 23 (65%) who demonstrated changes in their organizational structuring of volume. The fact that 65% of the participants who could have benefited from this study suggests the virtual manipulative helped them measure prism volume by emphasizing and portraying structured sequences of units. To find the nature of the changes and relate them to their experiences, we describe a case study of one student. We anticipated finding a correspondence between changes in structuring the groups of units and the salient features of the virtual manipulative.

Case Study: Jim

Jim, a fourth-grade student, demonstrated the VICS and VRCS levels across the eleven trials. We trace his development of increasingly sophisticated use of units and understanding of length labels. We begin the case study by sketching our own model of his strategic interaction with the interviewer and the tasks and the given tools: initially, Jim's structuring included rows as units but the number of units in a row was not connected to the labels. Trial 4 was the first time he incorporated the length labels to guide his structuring of units. Next, he extended his structuring to include rows as units guided by the length labels, and then he extended his structuring to include layers as units. Finally, Jim's skip counting evolved into multiplication as a scheme for finding volume of rectangular prisms. Next, we offer a detailed interpretation across four trials. Lastly, we interweave observations and interpretations to present an ongoing model of Jim's thinking in keeping with our theoretical perspective drawn from the learning trajectory of volume measurement.

On the paper portion of Trial 1 (2 by 5 by 4 rectangular prism; see Figure 1), Jim referred to the unit cube as one, pointing to it. Next, he mentioned five, "it was five long, right?" dragging his finger across the bottom front edge (edge labeled 5). Jim then dragged his finger up the image of the prism skip counting, "five, ten, fifteen, twenty, twenty-five." He then said, "twenty-five of those" pointing back to the unit cube. We note that on the first trial Jim was already skip counting, an indication that he was treating a collection of five as a repeatable unit. However, he counted five sets of five, which was inconsistent with the length labels of 5 and 4. Additionally, he appears to have only dealt with two of the dimensions to arrive at his final answer of 25.

On the computer portion of Trial 1 Jim moved the unit cube inside the prism. He pointed with the cursor to the cube and said, "one". He then pointed to the next place he expected a cube would fit and said "two". He paused and continued in a regular pattern: "3, 4,…, 5, 6, …, 7, 8, …, 9, 10". Each pause included a motion to the next position on the base of the prism. We take this pattern in his counting and motion as an indication that although he was still counting single units. He was also attending to groups of two units to fill the bottom layer of the prism.

Still, prior to pushing any buttons (i.e., he could see just one cube inside the prism corner), he moved the cursor along the bottom front edge and the bottom back edge (edge labeled 5) saying, "so five, five". Then he took the cursor as he had moved his finger earlier on the paper portion and moved up successively on the front face. This time he skip counted by tens instead of fives and said, "So it would be 50 not 25. Ah, that is 25 times 2." His actions and statements indicate to us his attention to five countable entities during this trial: a unit cube, a row of two cubes, and a row of 5 cubes, horizontal layers of 10 cubes and vertical layers of 25 cubes. Although he exhibited an understanding of composite units, he did not mention or make use of the three distinct length labels. He treated the height as if it were five units high, even though that edge was labeled "4". We believe he was counting by visual estimation and repeated pointing gestures to find the height. This seems to indicate the VICS level because he attended to unit cubes as parts of rows, and rows as parts of layers, yet he was not using all three dimension labels to structure his groups (as he would if he operated at the VRCS level).

Continuing with the computer portion of Trial 1, the researcher asked Jim to predict how many cubes he would have when he finished with the first button sequence (colored green). He answered correctly, "two". Next the researcher asked him to predict the number of cubes after pressing the second button sequence (blue). Note that the second button was designed to add additional rows along the second dimension of the prism. Jim's response did not match that of the computer environment, "There will be five (motioning along the blue line) plus one is six. There is going to be six blocks." Because he used the cursor to touch five points along the back edge, and then one in the front left corner, he counted six cubes that included a row plus one cube next to that row. Next, Jim clicked through the first button sequence (green), and stopped with two cubes (to form a row). Thus, his prediction of two matched the number of cubes displayed. At this moment, Jim said, "wait no it adds two times five. The blue is going to add four more." We believe he meant four more groups of two cubes each. The interviewer asks him how many he would have when he finished using the blue button (which is the second button sequence) to add cubes. He said, "ten" (the correct number of cubes following the blue button sequence). We infer that he was creating a more sophisticated approach to counting composite collections of units that incorporated multiplicative operations. He was counting not only single cubes, but by coordinating the two dimension labels, of 2 and 5 along the base edges, he was able to use multiplication to group 10 cubes as five sets of two.

The researcher then asked him how many cubes he thought he would have when he finished with the red button (the third button sequence that builds vertically). Jim said he thought that it would take 30 for the whole box to be full. If he was thinking he would have to add 30 more, he was correct, but 30 cubes was not the total. Now the researcher asked him to use the blue button (the second sequence). While clicking along the blue line, Jim stated that he was wrong because it only added two and he thought he would click it once to add eight. We believe Jim was making sense of the program and the structuring of volume. Once he finished pressing the blue buttons (the second sequence), Jim was asked to predict how many cubes there would be when he was finished with the red button (the third button sequence). Jim said there would be fifty, which is incorrect. Nevertheless, after one click of the red button with 20 cubes showing, Jim said, "no, it only adds the ten more." Jim then went on to say, "now I get it, each one adds one more, like times two." We think this statement influenced his later work and solution on the paper portion of Trial 3. Once Jim filled the box, he said that the answer was forty but said he did not know for sure. Recall his work on the paper portion and his first two predictions on this computer trial were 25, and 50 cubes, rather than 40. To sum up, we think Jim relied on visual estimates to find the number of cubes in the rows during trial 1. Alternatively, he may have reported the number of square faces on the front of the prism.

Moving on to trial 2, we expected improved performance from Jim, particularly on the computer portion, as he had now practiced using the sequence of three buttons. Also, we anticipated that Jim would build on his use of composite units evidenced by his skip counting and multiplication strategy for counting row groups in Trial 1. On the paper portion of Trial 2 (5 by 4 by 3 rectangular prism), Jim drew a cube inside the rectangular prism, mimicking the virtual manipulative. He then said that it was four across, three up, consistent with the length labels. He counted four across and then said twenty; we take this as evidence that he was treating a row of five as a composite unit, and four of these rows would be consistent with the bottom layer of the rectangular prism. Next, he said "twenty times three, twenty times two, forty. I think it is forty." We notice a shift in his use of units, as he is now counting groups of twenty. The researcher then told Jim that if he needed help with calculations he could help. Jim responded, "Then you go one, two, three, four, five, that is four times five that is twenty. Then you already have one floor done, then you times two, that is forty. That fills the full box." Here we take his counting, one, two, three, four, five as another instance of his counting composites, five sets of fours, which gives him twenty; we also interpret his actions as a way of unitizing the twenty as "one floor".

On the computer portion of Trial 2, Jim correctly predicted the first button sequence and the second button sequence (he finds 20 on the floor layer), but not the third (for the whole prism). He said, "There will be thirty [in the whole prism]." Next, Jim used the virtual manipulative to fill the rectangular prism (the computer screen showed: *volume = 60 cubic units*). When he finished, he said, "No, 60…. I know why I am wrong." The interviewer asked Jim what he thought the actual volume was. After a pause, Jim said, "I don't know. I am thinking 60 cubic units and I did 40 cubic units on the last one (he refers to his answer on paper). I am thinking 60 but I don't know. It might be, hum… I think it is 60." We believe Jim is still operating at the VICS level because he has now begun coordinating spatial components more widely, but has not yet completely integrated the set of local structures into a global structure. His ability to identify a layer without finishing the structure to find 60 cubes indicates a transitional state of thinking.

Next, on the paper portion of Trial 3 (3 by 3 by 4 rectangular prism), Jim said, “4, 3, 3… now I get it.” While he said that he pointed to the length labels of each number. Next, he said, “that would be nine on the bottom… nine, nine plus nine is 18… 18 plus 9 is …” The researcher told him that was 27. Then Jim said, “I have to add 27 more. Twenty-seven plus 27.” He said, “44, …, no, 54.” Then he said, “I am going with 54. I hope I get this right.” The correct answer was 36. During, this portion of Trial 3, we believe Jim showed a development in composite units; he found the bottom layer of nine and then used that number of cubes to accumulate another unit of nine, perhaps another layer. He appeared to skip count, adding 9’s, but when he reached the third layer he doubled that quantity of 27, reaching 54. Why did he do this? We believe he followed a pattern he had set in his work on the virtual manipulative for Trial 1 when he had explained moving from one layer to two as a doubling. Because it had been the first layer, a doubling process was equivalent to adding one layer. But he did not try this doubling approach with higher levels until this instance, and here he doubles the third layer sum of 27 to get 54. He appears to intend this 54 as the accumulation of the fourth and final layer.

For the computer portion of Trial 3, Jim correctly predicted the first button sequence and the second button sequence, giving a correct prediction for the number of cubes in the bottom layer, similar to his paper task work. Next, Jim was asked how many cubes there would be when he was finished with the red button (third button sequence). He said, “it goes up 9, 18, wait… 27, 27 plus 9… I know it is 54.” As Jim filled the rectangular prism with the red button sequence, he skip counted by nine. After the prism was completely filled with cubes, Jim explained, “I went too many high because for 54. I added 18 more at 27 because 27 plus 9 is 36 … I know why I keep screwing it up.” Next, he said that he thought the box (pointing to the unit cube) was smaller and he “did tiny ones”.

We believe this experience with trial 3 was transitional for Jim and this is where he made a connection between the length label for the height of the rectangular prism and the number of layers. When Jim was asked what the actual volume was, he said it was 36 cubic units without hesitation as before. We believe Jim was transitioning toward VRCS in Trial 3, but still operating at the VICS level. Next we describe trial 4 which took place at the beginning of the second interview.

On the paper portion of Trial 4 (3 by 5 by 4 rectangular prism), Jim paused his work on paper to comment how he thought the virtual manipulative (computer task) worked. He said (pointing to the left bottom of his paper prism), “There are three here” and he made three marks with his pen (see Figure 3). While pointing to the computer, he said, “You hit the green, you would get one more, no wait, you would get two more.” Next, he wrote down 3 units along the green line. Following he said, “The blue, you would get three more” and he wrote that down on the page along the blue line. Next, he said, “The red goes up one more but adds three” and wrote that on his page along the red line. Then he said, “So you get three (pointing along the green line) and then three more and three more, no that is six, six more and then you will have twelve.” The researcher asked him if he thought 12 was the total volume and Jim responded, “No, no, you have twelve altogether right there in that little square” pointing to the 3x4 vertical face. The researcher asked, “What happens after that?” Jim responded, “You go, 3 and 5 (pointing to the base of the prism) that is 15, 15 + 15 is 30, wait no… 15 so, 15 (drawing one mark under the prism), 30,… two (drawing another mark below his prior), um 45 is three (drawing another mark), and then 50, no, 60 is four, yeah. So there is going to [be] 60 blocks in all.” On this trial, Jim integrated a set of locally coordinated structures within a global structure, and used a layering strategy to enumerate the volume of a prism. We interpret this incident to mean Jim is operating at the VRCS level for measuring volume. He coordinates sets of cubes as rows and groups of rows as layers.

Galindo, E., & Newton, J., (Eds.). (2017). *Proceedings of the 39th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* Indianapolis, IN: Hoosier Association of Mathematics Teacher Educators.

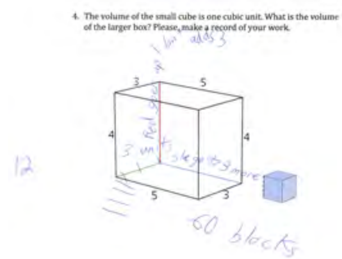

Figure 3. Jim's paper portion of Trial 4.

On the computer portion of Trial 4, Jim correctly predicted the number of cubes for each button sequence. After he filled the prism, Jim appeared very excited, "Got that one right!" Jim is demonstrating thinking consistent with the VRCS level. On the rest of the Trials (5-11), Jim completed the paper and computer predictions correctly. As he worked on the paper portions, he talked about how the computer program would work. At the end of Trial 5, Jim said he could use multiplication. He explained that you just do the six times the five, times the two. Jim showed another advancement of thinking. He shifted from skip counting to multiplying to predict the number of cubes. However, on the Trial 6 Jim used repeated addition again to find the answer. He said he was surprised he had the right answer because, "threes and sixes are hard for multiplication." Beyond Trial 6, Jim mostly used multiplication to multiply three edge lengths.

Conclusions and Implications

Measuring volume is a challenge for students (Barrett et al., 2017). We found that only six of the 31 participants in the study exhibited prior knowledge of spatial structuring for measuring the volume of rectangular prisms. Fifteen of the 23 participants who could have benefited from the experiences in this study developed more effective strategies and answered with increasingly correct measures. We take this as evidence that the treatment in this study was effective in guiding students to build a more structured understanding of volume.

We have used Jim's case to represent many students who did not initially use the length labels to predict the number of units fitting an edge. It was not until Trial 4 that Jim first used length labels to predict the number of units along an edge. Specifically, students developed more efficient enumeration strategies as well as a meaningful interpretation of the length labels as a way to predict the number of volume units fitting along an edge. The effectiveness of this treatment suggests an intervention to complement the volume learning trajectory we used to design the treatment (Barrett et al., 2017). The features of the treatment that supported student growth were those that prompted students to associate length measure labels on the prism edges with 3D arrays and those that promoted the flexible use of unit groups. Thus, the repeated pairing of length measurements (length labels) with the corresponding number of volume units was an important feature in helping students discover the predictive power of the length labels. We emphasized the pairings of labels to edge length by the continual, predict-and-check questions about accumulating quantity, through various unit groups (i.e., "How many will there be when you are done with the blue button?"). Second, students operated the three sequences of buttons independently, to meet goals of filling along three different but related dimensions of the prism. Their actions resulted in predictable but different numbers of additional cubes filling out various prism cases. We believe this was an important feature in guiding students to develop more efficient enumeration strategies. Students were expected to cope with a single button press resulting in three possibilities: the addition of a single cube, a row of cubes, or a layer of cubes, depending on the sequence. The pairing of a single action (a button press) with the appearance of either a 1D, 2D or 3D array of units suggested to students the value and utility of grouping units, and of the global coordination of those units.

In summary, we claim that changes in students' organizational structure of volume units followed from their experience with particular aspects of the virtual manipulative we employed. Secondly, we found students learned organizational structure of volume units through developing a flexibility of single units and composite units (i.e., single unit cubes, rows as units, and layers as units). Lastly, students enhanced their strategies for calculating volume by transitioning from repeated addition to multiplicative thinking.

A PRELIMINARY ANALYSIS OF USERS' INTERACTIONS WITH AN ARTIFACT: STUDYING LINEAR RELATIONSHIPS WITH TECHNOLOGY

S. Asli Özgün-Koca
Wayne State University
aokoca@wayne.edu

Technology as a cognitive tool helps students to externalize their internal representations and take actions on them in dynamic, interactive environments. In this study, the instrumental approach provided a conceptual lens to analyze the students' introductory interactions with an artifact in a technological environment. The results highlighted various aspects of the instrumental approach such as various instrumentation and instrumentalization instances via different utilization and instrumented action schemes.

Keywords: Technology, Middle School Education, Algebra and Algebraic Thinking

In *Principles to Actions*, the National Council of Teachers of Mathematics (NCTM, 2014) promotes the effective use of mathematical action technologies: "the ability to shift between different representations of a problem…can help students develop a deeper understanding of mathematical concepts" (p. 84). Changes in individuals' mathematical thinking as a result of an experience in an environment supported with technology is a main theme Heid and Blume (2008) synthesized as emerging from the research. Mathematical action technologies allow "students [to] learn mathematics by taking mathematical actions…on mathematical objects… observing the mathematical consequences of those actions, and reflecting on their meanings" (Dick, 2008, p. 334). This study aims to understand how students interact with these technologies and how their understanding shapes and is shaped these experiences as they decide what actions to take on different mathematical objects and reflect on the consequences of their actions. Once we learn more about individual students' ways of using the technology, we then are better equipped to enhance the teaching and learning environment when technology is used consistently in a classroom setting (Özgün-Koca, 2016).

Theoretical Framework

The instrumental approach provides a lens to analyze "the learning process in technological environments of increasing complexity" (Drijvers & Trouche, 2008, p. 366). An artifact is the bare tool available to the user with some constraints and possibilities. The instrumental approach argues that an artifact (which contains external representations) mediates the activity and influences the mental processes. Only after the user becomes aware of how the artifact can extend one's cognitive processes, it becomes an instrument; so instrument=artifact + scheme. The bidirectional relationship and interaction exists between the artifact and the user. Possibilities and constraints of the artifact shape the conceptual understanding. This process is called *instrumentation*. "The conceptions and preferences of the user change the ways in which he or she uses the artifact" (Drijvers & Trouche, 2008, p. 369) and even allow him or her to shape the artifact, "loading it progressively with potentialities, and eventually transforming it for specific uses" (Artigue, 2002, p. 250). This process is called *instrumentalization*.

Trouche and Drijvers (2010) also distinguish techniques and schemes. Since we cannot directly observe students' mental schemes, we are restricted to observing their actions, what they describe as instrumented techniques which are "more or less stable sequences of interactions between the user and the artifact with a particular goal" (p. 673). Instrumented techniques are results of utilization and instrumented action schemes. Utilization schemes are elementary schemes directly linked to the artifact. Instrumented action schemes are global schemes built up from utilization schemes. Both utilization and instrumented action schemes are mental schemes involving both technical and conceptual aspects of an activity (Drijvers & Trouche, 2008, Trouche & Drijvers, 2010).

Data Collection Methods

The participants were eighth grade students (*n*=44) from three middle schools enrolled either in pre-algebra, remedial algebra, or algebra classes and were chosen by convenience sampling. Students participated in 30-45 minute clinical interviews during which they did a mathematics activity using the computer software version of TI-Nspire. The interviews were digitally recorded to save the computer screen, the students' interactions with it, and surrounding audio. This way the main visual and audio cues were recorded for further detailed analysis of participants' instrumented actions as they interacted with an artifact. This kind of recording is defined as "observational recording" by Penn-Edwards (2004) where "a researcher follows subjects engaged in an activity" (p. 268). During the clinical interviews, students were encouraged to think-a-loud when working with the program.

The activity using TI-Nspire was designed to help students to explore the effects of dynamically-linked representations when completing tasks on linear relationships. The software was a novel instrument for most of them, and most had previously studied linear functions. The larger design of this study had the main goal of studying the effects of multiple linked dynamic representations. Therefore, there were different representations available to different users and two of four tasks in the activity were different for different users. This was a purposeful design decision to see how and when the utilization of various capabilities (potentialities) of an artifact would allow students to make connections between different representations of a linear relationship. Hence, we can observe students' utilization and instrumented action schemes.

Ratcliff's (2003) variation of Erickson's microanalysis approach was adapted and followed when analyzing the digital recordings. Following a five-step approach (Ratcliff, 2003), each digital recording was viewed in its entirety without pausing or rewinding while taking notes. Next, playing and replaying the video identified major events/segments. Linkages between major events/segments were sought. Vital statements and nonverbal behaviors from the major events/segments were transcribed. Finally, the analysis of major events/segments was compared to the remainder of the video data. Member checks, thick descriptions, and considering rival explanations were used to ensure trustworthiness of this study (Guba & Lincoln, 1989).

Results

A preliminary analysis of all interviews highlighted various aspects of the instrumental approach such as various instrumentation and instrumentalization instances. In this paper, detailed evidence for only chosen results will be shared: Deciding the algebraic form from a line graph—(i) as students enter the y-intercept and slope at the same time versus enter the slope and y-intercept separately with many attempts and (ii) as students use informed versus uninformed guess and check.

A part of the activity called Match Game asked participants to decide on the algebraic form of a line graph. The user's task was to match a bold red graph on the screen by making changes to the algebraic form $f_2(x) = x$. Four algebraic forms were used: $4x$, x-3, $2x$+4, and -$3x$-3. Schematic aspects of the techniques for deciding the algebraic form from graphical and/or tabular representations included both utilization and instrumented action schemes:

- How to change the algebraic form, the label notation, entry line, or the notation cell in the table (if the table representation was accessible)
- How to enter the slope and y-intercept into the algebraic form

    - Some students entered signs of the slope and y-intercept such as $4x$+-3 which was accepted by the software. But when +$4x$+-3 was entered, the software did not produce a graph due to its syntax rules.
- Noticing, relating, and using the algebraic, graphical, and tabular representations during the decision making.
- Recognizing the effects of changes in the algebraic, graphical, or tabular representations.
- Using feedback from previous changes effectively in subsequent rounds of changes.

While the first two schemes are utilization schemes, the last three are instrumented action schemes built on a combination of the first two utilization schemes and mental schemes. Table 1 shows one user's interaction with the software during the last task of the match game.

Table 1: Match Game With Informed Guesses

User's Comments	Screenshots
All right, this one's negative (see the figure to the right). So, the slope is going to be a negative number. So, it is going to be negative 2. *Int:* How did you decide that number? Well, you figure that if the number is too high, then it is going to be too steep. But if it is not high enough, it is going to be too horizontal. So, I am just going to pick a number and if it's wrong, then the reference it to be steeper or…And then, with the y-intercept, it'll probably be negative 2…A negative 3… *Enters -2x-3.* Probably the slope is going to be negative 3. *Enters -3x-3.*	
He recognized that he needed to change both the slope and y-intercept and he could think about the changes to the slope and y-intercept simultaneously. He could immediately differentiate the negative slope and determine the y-intercept. Although he was not able to determine the slope in one step, he had a strategy that depended on feedback from the software. So, this affected how he used the artifact according to his needs or wants; hence influencing the instrumentalization process. Finally, he was able recognize the effect of his changes in the algebraic representation and use the feedback from his previous change to inform his next moves. Knowing how to interpret the graphical representation and how to make changes to the algebraic form while using this software positively affected the whole process.

Some users were more dependent on the feedback from the software. Trying to match the red line (y=2x+4), a student's first choice for the y-intercept was -2. Immediately, she recognized that a negative y-intercept was not what she wanted. Even though she made multiple rounds of entries to match the y-intercept, she could recognize the effect of her changes and used the feedback from her changes effectively in her next rounds of changes. Although she could not show the y-intercept of the red line on the graph initially, she knew when she had matched them at the end. Her thinking was shaped by the artifact; the instrumentation process was influenced.

Both students noticed and used the algebraic and graphical representations in the artifact during the decision making. While the first student was immediately able to detect the type of slope or the exact y-intercept from a graphical representation, the second student tried negative slope and y-intercept to match 2x+4. Both students were able to recognize the effects of changes in the graphical representation as they make changes to the algebraic representation. How they used the feedback from previous changes in subsequent rounds of changes differed. Then the question becomes: how can we structure the task accompanying this artifact or the artifact itself to benefit (these) different students?

Discussion and Implications

We hear of more and more schools adapting technologies (with multiple linked dynamic representations) to their mathematics curriculum daily. Making changes in one representation and observing the results in another representation is complex work. Via more structured tasks we can ask users to record the effects of their changes in one representation on all other visible representations. We can also direct users' attention to the specific representation(s) by arranging what representations are visible. Another instructional move would be asking users to write down their next entry and explain why in order to help them use the feedback from previous changes to guide the next round of change. As Trouche and Drijvers (2010) state no tool is "'ready to do' computing, graphing, investigation, problem solving, learning or teaching. Doing requires appropriating a given tool" (p. 680). The accompanying task is a crucial part of the process of appropriating the tool for effective use and to foster the instrumentation and instrumentalization processes. Therefore, the task itself (e.g. sequence of the sub-tasks and available representations in each sub-task) is one of the important constructs that influences and completes the whole experience and the interaction between the user and the tool.

CREATING A SOCIAL ECOLOGICAL MODEL FOR ELEMENTARY MATHEMATICS HOMEWORK

Stephanie A. Sadownik
University of Toronto
stephanie.sadownik@mail.utoronto.ca

Research suggests that it is not simply time spent on task, independently completing mathematics homework, but rather purposefully designed, engaging homework activities, completed in specific social contexts, that helps students to achieve academic gains. In this study, two urban teachers share their use of blogs and discussion forums to communicate with parents and to help facilitate mathematics discourse with their students. The teachers highlight challenges with the age group ten to twelve and their access or use of technology in the home, or with the support of their parents.

Keywords: Middle School Education

Introduction

Homework is utilized by many professionals to communicate with parents, to increase student time on task and is believed to improve student achievement (Trautwein, 2007); despite a lack of consistent empirical evidence (Rønning, 2011). The National Council of Teachers of Mathematics (NCTM, 1980) suggests the sole purpose of mathematics homework is to productively extend student engagement (Landers, 2013); therefore, educators and administrators must plan homework tasks carefully to ensure students are actively engaged. Although the completion of homework has been shown to increase understanding and retention of academic material (Zimmerman, & Kitsantas, 2005) and a relationship exists between time on task and academic achievement (Trautwein, Köller, Schmitz, & Baumert, 2002), there is still a lack of strong empirical support. Considerations regarding instructional design (Epstein & Van Voorhis, 2001; Marzano, & Pickering, 2007; Van Voorhis, 2010), in addition to the social context in which students complete their homework (Landers, 2013), provide insight towards a homework-achievement relation and provide a rationale for contradictory results in homework gains. If research can suggest that it is not simply time spent on task, independently completely mathematics homework, but rather purposefully designed, engaging homework activities, completed in specific social contexts, results may prove to be more consistent.

The purpose of this study is to investigate the potential impact computer- supported collaborative learning (CSCL) environments have in developing mathematical discourse. The present study is guided by the following questions: (1) How do teachers' of students (aged 10-12 years) use online asynchronous communication tools in mathematics to facilitate discourse? (2) What evidence exists to support the argument online asynchronous communication tools in mathematics increase students' (aged 10-12 years) engagement in mathematical processes?

Theoretical Framework

Research on homework interventions in mathematics have considered multiple variables regarding the homework achievement equation such as: using selected homework strategies (i.e. real life contexts, homework planners) (Bryan, & Burstein, 1998); frequency of homework assignments (Trautwein, Köller, Schmitz, & Baumert, 2002); student perception of the purpose of homework (i.e. practice, preparation and extension) (Rosário, Núñez, Vallejo, Cunha, Nunes, Mourão, & Pinto, 2015); mother's level of self-efficacy in mathematics (Hyde, Else-Quest, Alibali, Knuth, & Romberg, 2006); student self-regulation (Zimmerman, & Kitsantas, 2005); family involvement (Van Voorhis, 2010) and parental monitoring (Sirvani, 2007).

Galindo, E., & Newton, J., (Eds.). (2017). *Proceedings of the 39th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* Indianapolis, IN: Hoosier Association of Mathematics Teacher Educators.

School-family partnership programs are one approach for educators to address inequalities amongst their mathematics students (Hyde, Else-Quest, Alibali, Knuth, & Romberg, 2006; Patall, Cooper, & Robinson, 2008; Sirvani, 2007; Van Voorhis, 2010). Based on earlier beliefs regarding the utility of homework, homework frequency and time on task, it is generally accepted that homework begins in elementary school and grows in difficulty, based on a student's ability to work independently and regulate their time (Zimmerman & Kitsantas, 2005). Younger students are less likely to be efficient or successful when working independently (Rønning, 2011). Whereas middle school students perform better on homework tasks when they perceive a sense of control and autonomy, away from the scrutiny of their parents (Núñez, Suárez, Rosário, Vallejo, Valle, & Epstein, 2015). Therefore, a small window of opportunity exists in the elementary grades for a school-family partnership to yield positive results related to homework and academic gains.

When students perceive a purpose for their homework they are more inclined to become engaged. Research suggests, a purposeful design of engaging homework is more effective than simply increasing time on task (Van Voorhis, 2010; Epstein & Van Voorhis, 2001). In a recent study of 638 grade 6 students, Rosário et. al., (2015) examined the effect of homework purposes on mathematics achievement. Of the three homework purposes, extension was found to have a positive impact on achievement, while practice and preparation did not. Purposeful design of homework, that ensures student engagement and extension in mathematics, is of great importance for teachers and school administrators (Rosário et. al., 2015).

It is of the utmost importance that schools approach families in a targeted attempt to improve "children's exposure to math-relevant experiences" (Galindo & Sonnenschein, 2015, p. 25). Without this intervention, children from low SES families are unlikely to "develop sufficient math skills to be competitive in today's technological world" (Galindo & Sonnenschein, 2015, p. 25). Furthermore, Jorgensen, Gates, & Roper, (2014) strenuously point out that it is important to understand the "wider set of social practices" (p. 221) in mathematics education by considering cultural backgrounds, dispositions of learners and learning environments. In many aspects, a child's ability in mathematics, sometimes evident as early as kindergarten, is not under the control of the teacher or the school (Jorgensen, Gates, & Roper, 2014), but rather, is shaped by their social background (Jorgensen, Gates, & Roper, 2014).

Background Information

As the primary investigator, and in my role as a Grade 7 teacher, I had daily contact with 75 grade 7 students for a period of 4 months between March 2016-June 2016. The students participated in a daily math journaling activity over the course of 8 weeks between April 2016- June 2016, along with 6 other teachers in the school who were also engaged in a math journaling activity with their respective classes. The purpose of the journaling activity was to increase mathematics discourse and time devoted to developing the mathematical processes. At the start of the 8-week period, the students were invited to participate in a goal setting activity related to mathematics and academic gains. Of the 75 participants, 26 completed the goal setting activity (0.347) and together submitted 66 goals for the 8-week period. Content analysis of the goals identified by the participants provided evidence that 14 of the 26 students (0.538) specifically referenced the word "homework" in their goal setting and perceived mathematics achievement gains to the timely completion and utilization of mathematics homework. Although other goals were cited (staying on task and asking more questions during class), homework is identified as the only activity related to academic gains in mathematics outside of the classroom.

Discussion

The idea to consider the relevance of homework within the parameters of the study, using online asynchronous communication tools to communicate with parents and students regarding homework (problems of the week, discussion topics) emerged as a promising focal point for the second year. At the close of the first year of study, and after analyzing the results of the previous mathematics journaling activity, five discoveries were made that impacted the direction of the study:

- Grade 7 students believed utilization of homework was related to academic gains in mathematics
- Grade 7 students believed improving their homework habits would produce academic gains in mathematics
- Grade 7 students believed they were in control of their academic gains in mathematics
- Grade 7 students believed academic gains in mathematics were directly related to their ability to self-regulate their time and attention
- Grade 7 students believed their home environment was not a barrier to their academic gains in mathematics

In the fall semester of 2016, semi-structured interviews were used to investigate six urban mathematics teachers who used technology to engage their mathematics students in discourse. The initial interviews lasted 60 minutes in length and provided a baseline to understand the teacher's background, familiarity with the technology and the teacher's motivation and intent for using CSCL to communicate with parents in the home and facilitate mathematics discourse with their students outside of the classroom. Of those six interviewed, two were selected based on their use of technology with their students, the age of their students and their motivation for participating in the study.

Veronica was chosen to participate in the second year of the study because she teaches mathematics to grades 3 and 4 with a heavy emphasis on asynchronous technology to communicate with parents and uses parent involvement to productively extend and engage her students in homework. Although Veronica is still struggling to think outside of the box for questions about mathematics and how to generate discussions about concepts students are learning, her acknowledgement and willingness to develop literacy or understanding in in Mathematics makes her an ideal candidate. Veronica has pre-established routines and a solid parent-school relationship that was developed before her participation in the study. The addition of a mathematics focus will be challenging for her but beneficial. Jeff is an ideal candidate because he teaches grade 6 students, who are preparing for a provincial assessment test in June. The additional pressure of performing well on an achievement test will increase his students' motivation and the motivation of their parents to be involved in additional practice and homework in mathematics. At my suggestion, Jeff has included a discussion focus for the PATs where students share concerns about the upcoming test, questions they have, and as a general resource for websites or materials other students have found helpful.

Follow up interviews are ongoing throughout the current school year to discuss challenges faced this year. It is hoped in the second year of the doctoral study, specific findings will be made related to the use of online asynchronous communication tools for engaging both parents and students in mathematics discourse, by identifying challenges related to:

- Engaging students in mathematics
- Communicating with parents about mathematics learning
- Assigning mathematics homework at the elementary level

EXTENSION OF INTERACTIONS BASED ON TECHNOLOGY: BRIDGING ELEMENTARY MATHEMATICS CLASSROOMS IN KOREA

Sheunghyun Yeo
University of Missouri
syhw6@mail.missouri.edu

Corey Webel
University of Missouri
webelcm@missouri.edu

This paper describes how communicative technology between two Korean classrooms located in different sociocultural contexts was used to support mathematics instruction. We analyzed what interactions emerged using the technology, how sociocultural differences were leveraged to construct mathematical knowledge, and how students built this knowledge together across urban and rural area classrooms. The results show that reciprocal interactions emerged. Teachers co-designed lesson plans and tasks with consideration of the different classrooms' social contexts. Through teacher's interaction, students justified their ideas and prepared answers before the connected discussions, and various ideas were synthesized as collaborative knowledge. These findings suggest that communicative technology has the potential to enhance learning opportunities for students across different social contexts.

Keywords: Technology, Elementary School Education, Equity and Diversity

According to the theory of social constructivism, learning can be seen as taking place in the social interactions between different contexts (Vygotsky, 1978). The interactions are mutual adjustments among teachers, students and content in environments (Cohen, Raudenbush, & Ball, 2003; Herbst & Chazan, 2012; Lampert, 2001). Interactive relationships can be used to support what has been called *knowledge building* (Scardamalia & Bereiter, 2006), a process that involves creative and sustained work with ideas. In knowledge building, students work collaboratively to improve shared ideas and to extend the frontiers of public knowledge. Network technology can play a significant role in providing an environment for students to engage in knowledge creation and collaborative idea improvement (Moss & Beatty, 2006).

The goal of the present study is to explore the interaction in mathematical instruction made possible when knowledge-building strategies are supported by Bridging Mathematics Classrooms via Skype [BMCS], a widely used computer-mediated communication technology. In particular, this study sought to examine the following questions: (a) What interactions emerged by using communication technology in mathematics classrooms? (b) How might sociocultural differences between schools be leveraged in BMCS to enhance learning opportunities?; (c) How do students build knowledge across classrooms through communication technology? Through this paper, we bring attention to a process in which students draw on their different social contexts to build mathematical knowledge via communication technology.

Theoretical Framework

Lampert (2001) described a teacher, students, and content as three key components in the mathematics classroom, and analyzed the complexity of teaching mathematics by characterizing the relationship between these elements. She defined teaching as an interactive process of managing the connections between students and content. Cohen et al. (2003) modified this model to include the situated environments in which teaching occurs, proposing a new view of mathematics instructional effects and resources. The instructional triangle diagram (see Figure 1. left) conceives instruction as a stream affected by environments such as teachers, students, and a local district. One question we sought to address in this study is how this framing of instruction might look different with the inclusion of multiple classes connected through networking technologies.

In particular, connected classes might have potential to impact the nature of student-student interactions, by supporting opportunities for students to engage in "knowledge building. Knowledge building, introduced and studied primarily in the domain of science education, is a process by which people not only create knowledge through social interactions, but also utilize knowledge collaboratively (Scardamalia & Bereiter, 2006). A key principle of knowledge building is 'epistemic agency,' which describes the power students have to set forth ideas and negotiate a fit between their ideas and the ideas of their peers. In mathematics classroom, this agency is related to students' own ideas and strategies of problem-solving. Students and groups need to justify their own mathematical conclusions with evidence, and, finally, a classroom negotiates its own generalized and consented conclusion through discussion (Moss & Beatty, 2006). Knowledge building discourse - refined and transformed knowledge through the discursive practices of communities - includes constructive and collaborative argument (Bereiter, 2002). Another core principle in knowledge building is "improvable ideas" (Scardamalia, 2002). Individuals' ideas are refined through collaborative interactions, which could employ network technology, which can lead to sustained improvement of these ideas (Scardamalia, 2002).

Methodology

In this exploratory case study, we used a methodological approach called *netnography*, a form of participant-observational research situated in online fieldwork (Kozinets, 2010). The case in this study was a cooperation between Mr. YH and Mr. KJ (pseudonyms), who are both 6th-grade teachers in Korea. In particular, Mr. YH worked in an urban area (CS school) and Mr. KJ did in a rural area (YG school). To conduct the netnography, we collected three types of data: elicited, archival, and field notes (Kozinets, 2010). As a first step, eight lesson episodes, already recorded and preserved on Mr. YH's YouTube channel, were selected and documented through field notes. Second, elicited data, co-created through personal and communal interactions, included three interviews with Mr. YH (overall, pre and post about Episode 3). Third, archival data, directly copied from pre-existing online material, consisted of students' activity results, lesson plans, and Mr. YH's reflection reports.

The procedures of data analysis are consistent with Charmaz's (2014) grounded theory approach. Based on literature review, we gained three framing codes: instructional triangle, knowledge-building, and context. We created line-by-line initial codes from the oldest episode, and added additional codes as needed in subsequent episodes. Then, we converged focused codes from initial codes. To confirm the categories, the teacher's reflection reports were compared and contrasted after implementing the lesson plans. We utilized the focused codes between interview data and filed notes back and forth and compared the teacher's planning with implementing.

Findings

To explore the interactions and knowledge building in Mr. YH's classroom, we concentrated on emerging patterns and how interactions were constituted through the incorporation of the communication technology. On account of the limitation of length in this paper, we are only reporting on the analysis of Episode 3. The episode was the last day of the 9-day project in which students planned, promoted and surveyed about which sport was appropriate to be selected for an after school sports club shared between CS and YG schools. In the episode, students were tasked with using survey data from different population sizes (CS: 327 students, YG: 73 students). They transformed the raw data into percentage graphs, such as pie chart or bar chart with proportions for each item, and then discussed their findings with the other classroom via Skype to make a final decision regarding the selection of common sports club. The following section presents the findings related to co-planning lessons and tasks to show how the interaction was adapted by applying communication technology and related to how social agreements worked to support knowledge building practices across classrooms.

Teacher-Teacher Interaction within Environments

Mathematical task. To make an interactive task suited to the context of each classroom, the two teachers co-designed the mathematics task. First, they justified why different populations were necessary. Mr. YH described how the teachers devised the mathematical task to consider the different sociocultural contexts with such instance in pre-interview:

> For example, students could compare the proportion between who like spring (50%) and summer (25%). In one class, this comparison could be not much different from using the bar graph. On the other hand, the comparison of the same favorite season, such as spring, should utilize the concept of proportion in the context of two different classes. In other words, the reason why the proportion of students who like spring in A school is different from the proportion in B school is connected to the relationship between the part and the whole, and I do want to teach this kind of lesson to my students on that day.

The two teachers devised the task for students to experience comparing and analyzing percentage graphs with the different populations by using actual survey data. When students dealt with the small population (rural school) and big population (urban school) simultaneously, the teachers reasoned that it would be possible to develop more sophisticated proportional thinking, because the total number of students was different. For example, a variation in the small sample can change the proportion more significantly than the same variation in the larger sample, and the teachers wanted a task that would make this apparent to students. They believed the sports club task would accomplish this because the different population sizes could provide an opportunity to deal with the discrepancy mathematically.

Students-Students Interaction within Environments

Social agreement. Part of the rationale behind BMCS is that when students in one classroom reach consensus with another demographic group, their ideas could be more meaningful to a greater number of people. In the field note, the following example emerged from the final connection via Skype:

> To share the comprehensive conclusion, Sujin (CS school) says, "We have the conclusion to choose dodgeball. Dodgeball is the largest in school YG and second largest in our school. The gap is only 7%. Therefore, we will select dodgeball." Dongju (YG school) also answers, "The sum of each percentage is highest in dodgeball. Therefore, we want to choose dodgeball, too." Finally, teacher YH comments, "Our conclusion is same. As a result, dodgeball is tentatively selected as the sports club."

In the first connection, they exchanged information between the two schools. After the activities and discussions about the percentage graph, they debated with each other using the data and providing a rationale for their ideas. This provided opportunities to learn not only the application of a percentage graph, but also how to solve an everyday-life problem using mathematic knowledge of statistical surveys and graphs. Each class' students approached the task using a percentage operation, not the raw numerical values. CS School used subtraction ("the gap is only 7%") and YG used addition ("the sum of each percentage") to make a reasonable decision. Both schools' students consistently had the opportunity to think about how the students in the other schools' idea beyond their classroom were related to their own idea. Consequently, individual students' ideas created a foundation for group discussion, and this discussion extended across both classrooms involved in BCMS. This example suggests that mathematical knowledge could be collaboratively synthesized through the same learning content with communicative technology.

Discussion

The findings of this study demonstrate that what interactions among teacher, students, and content in environments could be arisen and how communicative technology could support knowledge building in mathematics instruction. Based on our analysis, we propose a revised interaction framework for BMCS (see Figure 1. right). In the case reported here, utilizing Skype provided opportunities to result in the emergence of extended interactions among components and to connect student's interactions with teaching practices. Such opportunities included preparing a discussion that bridged classrooms and helped students consider the sociocultural context of another school that had different opinions. In addition, BMCS provided opportunities for students to focus on social contexts, particularly those that differed across schools, as well as mathematical meaning. For knowledge building, students engaged in mathematical tasks to construct and improve collaborative knowledge with networking technology rather than to transmit unchangeable mathematical truth. Consequently, the result of this exploratory study suggests that the efficiency of technology can support bridges between classrooms for extended mathematics learning experiences. BMCS is still in the beginning phase and needs further development with following studies.

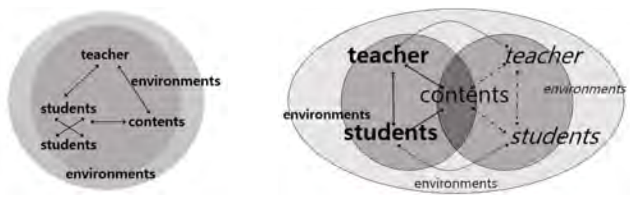

Figure 1. Revised interactional framework for BMCS environments (left: Cohen et al., 2003 (p. 124), right: revised).

FRACTIONS, MENTAL OPERATIONS, AND A UNIQUE DIGITAL CONTEXT

Caro Williams-Pierce
University at Albany, SUNY
cwilliamspierce@albany.edu

Following the PME-NA 2017 metaphor of crossroads, and acting with(in) the intersection point between digital media and mathematics education, I present the mental operations that middle school students engaged in while playing my fractions console game, Rolly's Adventure*. I found that participants engaged in iterating, partitioning, and re-unitizing quantitative representations of fractions with varying levels of units, and that these individual mental actions composed six distinct complex mental operations: splitting; iterating with units; iterating with pre-partitions; iterating with mental partitions (that is, not pre-partitioned by the game); reverse iterating with pre-partitions; and reverse iterating with mental partitions.*

Keywords: Technology, Cognition, Informal Education, Instructional Activities and Practices

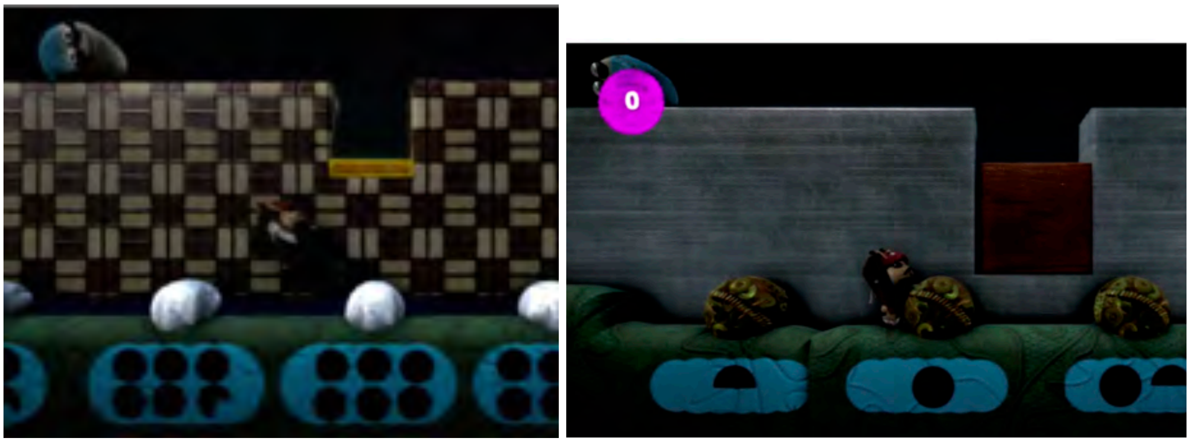
Digital media such as videogames provide the opportunity to investigate how new representations and interactions can contribute to and push back against current research on learning mathematics (Williams-Pierce, 2016a), and provide a useful and intriguing platform for engaging people in mathematical learning and play (e.g., Gresalfi & Barnes, 2016; Steffe & Wiegel, 1994; Williams-Pierce, 2016c). Following the PME-NA 2017 metaphor of *crossroads*, and acting with(in) this *intersection point* between digital media and mathematics education, I designed *Rolly's Adventure* (*RA*; Williams, 2015; Williams-Pierce, 2016a, 2016b) to take full advantage of the learning affordances of videogames (e.g., Salen & Zimmerman, 2004) and the ways that students best learn particular mathematics concepts (in this case, fractions), as identified by education researchers (e.g., Brousseau, 1997; Hackenberg 2007; Steffe & Olive, 2010).

In the following manuscript, I examine how players of *RA* engage in fractions reasoning with a particular focus on how individual mental operations (such as *partitioning*) compose more complex mental operations (such as *iterating with partitions*). In particular, structures within the game supported certain mental operations, and participants experienced and used those game structures differently within their mathematical activity. I found that participants engaged in iterating, partitioning, and re-unitizing quantitative representations of fractions with varying levels of units, and that these individual mental actions composed six distinct complex mental operations: splitting; iterating with units; iterating with pre-partitions; iterating with mental partitions (that is, not pre-partitioned by the game); reverse iterating with pre-partitions; and reverse iterating with mental partitions.

Theoretical Framework

I subscribe to the constructivist view of learning (von Glasersfeld, 1995), developed in detail within the field of fractions by scholars such as Steffe and Olive (2010) and Hackenberg (2007). I follow Thompson's (1995) view of quantity as a person's conception of measurable attributes of objects prior to any actual measuring, and rely upon my intentional design of *RA* to present fractions as quantities that support players in constructing their own understanding of the game and the underlying mathematical patterns directing the game's behavior. Although I generally follow Steffe and Olive's (2010) and Hackenberg's (2007) definitions of iterating, partitioning, and disembedding, I split from them (pun intended) with Confrey's (1994) characterization of splitting as an instantaneous and intuitive act of duplication.

Important notes: First, the game provides puzzles that each have a hole that the player must fill perfectly by operating upon blocks that have been preset in the hole (see Figure 1; see also Williams-Pierce, 2016a). Second, since I have insufficient evidence to hypothesize about interiorization with this data, I focus on *coordinating* levels of units, and my *levels of units* codes universally refer to coordinating and not interiorization.



(a) (b)

Figure 7: (a) Puzzle 7, which introduces the countability textures; and (b) Puzzle 4.

In Figure 1a above, the provided block in gold is exactly the height of the square texturing on the left of the hole. Since this texturing supports counting the numbers of squares, and concluding that is how many blocks fit in the hole, I termed this *countability textures*. In Figure 1b above, there are no countability textures provided, and unlike the gold block in 1a, duplication of the brown block will not perfectly fill the hole. Rather, the brown block and one-half of itself is the quantity that will fill the hole, so participants must compare the empty space to the brown block, and determine that one-half of the block will fill it. When participants disembedded one half of the brown block and iterated it to fill the hole, I termed that *mentally partitioning and iterating*, despite the fact that all iterating and partitioning is inherently mental (Steffe & Olive, 2010; Hackenberg, 2007). In short, when I use the word *mentally* in front of a word or phrase that already refers to a mental operation, it indicates my way of operationalizing the distinction between that mental operation with game supports, and that mental operation without.

Data Collection Methodology

Sixteen middle school students were recruited in dyads and solos, resulting in 11 males and 5 females from eleven to fourteen years who lived in a small Midwestern city. Each session included a playthrough of *RA*. The playthroughs were captured through video upon the participants' bodies and screen capture of their gameplay. Participants were asked to play the game as they would play any game at home, and told that I would likely not answer any questions they had while playing. Participants were asked to talk to me or each other as they played, and stopped them occasionally and ask questions. It is important to note that I never indicated that the game was about fractions – or indeed, mathematics of any sort – and during gameplay, never gave mathematical advice.

I used MaxQDA, a qualitative data analysis software, and iteratively open-coded gameplay transcripts. I then re-organized and finalized the coding scheme through the process of constant-comparison. The final coding scheme included two umbrella codes that will be examined in this paper: Individual Mental Operations, and Complex Mental Operations.

Results

The subcodes of Individual Mental Operations (Table 1) served to identify what mental operations were occurring. The goal to provide a reasonably smooth and natural game playing experience precluded me from asking the types of questions that can lead to more rigorous second-order models of thinking. The subcodes of Complex Mental Operations are presented in Table 2 with brief definitions.

Table 1: Individual Mental Operations Subcodes and Definitions

Subcode	Nested Subcode	Definition
Levels of Units	Two Levels of Units	When participants perceive the preset block(s) and the hole as units.
	Three Levels of Units	When participants perceive the preset block(s), a partition of those preset block(s) (mental or pre-partitioned), and the hole as units.
	Four Levels of Units	When participants perceive the preset block(s), a partitions of those preset block(s) (mental or pre-partitioned), a mental grouping of those preset blocks, and the hole as units.
Re-Unitizing		When participants re-unitize from perceiving one unit as the primary unit that all other units stand in reference to, to another unit as the primary unit.
Partitioning	Mentally Partitioning Blocks	When participants mentally create a partitioned block that is not offered by the game. The new partitioned block must be considered as maintaining a relationship to the original block or the hole.
	Mentally Partitioning Hole: Instant	When participants mentally partition the hole into block-sized partitions instantly, without counting or using countability textures provided by the game.
Mentally Iterating (Countability or Perfect Presets)		When participants are iterating the block in the hole, but the game is overtly supporting that mental operation, such as through countability textures.

Table 2: Complex Mental Operations Subcodes and Definitions

Subcode	Definition
Splitting	When participants instantaneously visually perceive the preset block(s) as a unit that can be duplicated to fill the hole, and manipulates their mental images of the block(s) to do so.
Iterating with Units	When participants mentally iterate preset block(s) as a unit to fill the hole. This mental iteration is not instantaneous, as with *Splitting*.
Iterating with Pre-Partitions	When participants disembed and iterate a single partition of preset pre-partitioned blocks to fill the hole. May be co-coded with *Iterating with Units*, if the participants view the disembedded partition as a unit.
Iterating with Mental Partitions	When participants mentally partition the preset block(s), then disembed and iterate that mental partition to fill the hole.
Reverse Iterating with Pre-Partitions	When participants disembed and reverse iterate a single partition of preset pre-partitioned blocks to fill the hole.
Reverse Iterating with Mental Partitions	When participants mentally partition the preset block(s), then disembed and reverse iterate that mental partition to fill the hole.

I considered the individual mental operations to *compose* the complex mental operations based upon co-occurrence rates, which also depended upon the game structures available for each puzzle. Due to space constraints, I cannot present those composition relationships here.

Discussion and Conclusion

The goal of this paper was to illustrate the mathematical reasoning that emerged when participants played *RA*, and to situate those findings within the field of fractions learning. Different patterns of Individual Mental Operations codes appear to compose different Complex Mental Operations, depending in large part upon which game structures were available for each puzzle. During my presentation, I will share more detailed accounts of the individual and complex mental operations described above, and how *RA* provokes fractions learning and reasoning differently from other digital contexts.

INVESTIGATING SECONDARY MATHEMATICS PRE-SERVICE TEACHERS' TECHNOLOGY INTEGRATED LESSON PLANS

Erol Uzan
Indiana University Bloomington
eroluzan@indiana.edu

The purpose of the study is to investigate secondary mathematics PSTs' technology selection and the intended way of utilizing technology in their lesson plans. In this multi-case study, six PSTs in their senior year were interviewed and their lesson plans were collected. What types of technology PSTs select and in what purposes the selected technologies have been used to support students' mathematical thinking were explored. The findings show that some PSTs selected cognitive technologies due to their dynamic features, ease of use, and providing different visual representations. On the other hand, some of them did not integrate these types of technologies because of their lack of technology knowledge, availability of technology in context, students' familiarity with technology and time considerations. Their way of integrating technologies vary and while some PSTs integrated as reorganizer, others planned to use technologies as amplifier.

Keywords: Technology, Teacher Education-Preservice

In the last decade, teacher education programs have more emphasized preparing teachers with the necessary knowledge and skills to teach with technologies to meet the needs of 21st century learners. Researchers argued that courses in teacher education programs and schools in which pre-service teachers (PSTs) complete field experiences and student teaching, significantly impact their learning (Peressini, Borko, Romagnano, Knuth, & Willis-Yorker, 2004). Therefore, teacher education programs offer technology-specific content and methods courses for PSTs to learn about available technologies and experience integrating these into mathematics teaching and learning. For instance, Niess (2005) required PSTs not only to integrate technologies into their mathematics teaching but also to think deeply about how they would use it and why they considered it critical in teaching the target mathematics concept.

Developing technology-integrated lesson plans help PSTs not only to demonstrate their competencies in technology integration but also to reflect on the process of selecting appropriate technologies to enhance teaching and learning. Although PSTs are required to develop technology-integrated lesson plans during their teacher education programs, little is yet known about their practice. Therefore, the purpose of this study is to investigate secondary mathematics PSTs' technology selection and the intended way of utilizing technology to support students' mathematical thinking in their lesson plans.

Conceptual Framework

In the literature, there are many categorizations of technology used in mathematics teaching and learning. However, this study employs Dick and Hollebrands's (2011) categorization of technologies, "conveyance technologies" and "mathematical action tools" and Pea's (1985, 1987) earlier categorization of cognitive uses of technologies as amplifiers or reorganizers (see Figure 1). This framework was considered as a useful one for discussing the uses of digital technologies in instruction to support and promote students' learning and mathematical thinking.

Digital Technologies as Conveyance Tools

Conveyance technologies are used to convey information and include tools for presentation, communication, sharing/collaboration, and assessment/monitoring/ distribution (Dick & Hollebrands, 2011). This type of technology has been the most commonly used in classrooms. For instance, presentation tools enable the display of documents, videos, or computer screens on a board for group viewing of the same information. Jonassen (1995) emphasized that such technologies as "conveyors of information… [are used] to 'teach' students by presenting prescribed information to them which they are obligated to 'learn' (p. 1). When conveyance technology is in use, the role of learners is to perceive the information as presented by the tool rather than interact with the tool to construct their own knowledge.

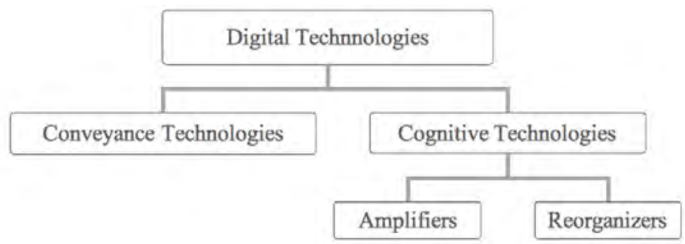

Figure 1. The categorization of digital technologies.

Digital Technologies as Cognitive Tools

Pea (1987) defined "cognitive technologies" as those which help users "transcend the limitations of the mind…in thinking, learning, and problem-solving activities" (p. 91). In this environment, the role of users is not passive receivers but active agents. Cognitive technologies can stimulate or amplify cognitive processes (Kozma, 1987). Learners actively interact with cognitive tools, which activate their strategic and critical thinking (Jonassen, 1995). Under this broad categorization, Pea (1985) stated that cognitive technologies in mathematics could be any tool to make students' thinking visible in order to promote analyzing, reflecting and discussing. The interest in this study is limited to digital cognitive technologies that may create environments for mathematical activity to support students' mathematical thinking.

Researchers have used the terms "cognitive technologies" and "cognitive tools" are used interchangeably. Peressini and Knuth (2005) identified technology as a cognitive tool that allows students "to represent and explore a variety of mathematics procedures and concepts so that they can be examined from a conceptual perspective" (p. 280). A cognitive tool allows students to investigate many cases of similar situations in a short time while directing their attention to their own actions and enabling them to make and test their own conjectures. Using cognitive technologies in mathematics education facilitates "technical or conceptual dimensions of mathematical activity" (Zbiek, Heid, Blume, & Dick, 2007, p. 1171). In terms of technical dimensions of mathematical activity, a cognitive tool must allow the user the means to act on mathematical objects or representations of those objects. To facilitate the conceptual dimension of mathematical activity, a cognitive tool must react in response to the user's actions by providing clearly observable evidence of their consequences. Similarly, Dick and Hollebrands (2011) defined mathematical action tools as those that enable users to interact and receive feedback during the performance of mathematical tasks. Thus, the term of "mathematical action tools" can be considered synonymous with cognitive tools that allow students to perform actions, receive immediate feedback, and so investigate mathematical ideas.

Cognitive Technologies as Amplifiers or Reorganizers

Pea (1985) explained cognitive technologies with the metaphors of amplifier and reorganizer of mental activity. Many researchers have adopted his notion to describe technology use in mathematics teaching and learning (Ben-Zvi, 2000; Goos, Galbraith, Renshaw, & Geiger, 2003; Lee & Hollebrands, 2008; Zbiek, Heid, Blume, & Dick, 2007). In this study, his metaphors of using technology as amplifier and reorganizer is employed when exploring PSTs intended way of using technology in their lesson plans.

When technology is served as an amplifier, it enables users to accomplish a task more efficiently and accurately with significantly less time. As Lee and Hollebrands (2008) stated, as an amplifier, a tool "expedites a process that could be completed *without* its use" (p. 329). Use of technologies as an amplifier increase what students can do without converting their actions but does not change the nature of what they think (Barrera-Mora & Reyers-Rodriguez, 2013; Sherman, 2014). For instance, performing arithmetic computations with a calculator can be considered using technology as an amplifier. With that, students can complete the task more efficiently and more accurately without any arithmetic errors. Their cognitive focus is on performing computations, and it does not change their actions and thinking (Sherman, 2014).

When technology is served as a reorganizer, technology transforms users' actions and enables changes in their thinking that otherwise would be difficult or impossible (Sherman & Cayton, 2015). For instance, with the use of dynamic geometry software, students can construct a triangle and its medians in order to make and test conjectures about the relationships between the medians of a triangle. Through their actions in this environment, students' mathematical thinking and behaviors might change. While the technology performs calculations, stores, and retrieve information, students are responsible for recognizing and judging patterns of information, and organizing it accordingly. This environment provides opportunities for students to interact with tool and so they may develop their own understanding as a result of their interactions.

Method

The following research questions are addressed in this study; (1) What types of technologies do secondary mathematics PSTs select in their lesson plans? and (2) In what ways do secondary mathematics PSTs plan to use technology in their lessons?

In this study, a qualitative multi-case study (Merriam, 2009) approach is employed. The participants of the study are six secondary mathematics PSTs who were enrolled in a method course in the Mathematics Education department in a large Midwestern state university and have completed all required content and methods courses. The site is selected intentionally because the objectives of the course is for students to develop knowledge of appropriate uses of technology and gain experience of using technology for mathematics learning and teaching. These PSTs created technology-integrated lesson plans during a semester.

The data sources of the study include these PSTs' lesson plans and semi-structured interviews. Their lesson plans provide what technologies these PSTs selected and how they plan to integrate those to support students' mathematical thinking. On the other hand, one-to-one interviews with each PST helps to clarify in what purposes they intended to use selected technologies. Interview transcriptions and lesson plans were analyzed by coding based on the conceptual framework to identify and categorize the technologies. Then, two researchers performed check-coding on each lesson plan by independently coding and then comparing the codes. Then, they discussed their analysis and came to consensus. Finally, these PSTs' intended way of technology use were identified based on Pea's metaphor of amplifier and reorganizer.

Preliminary Findings

The results of analyzing lesson plans of these PSTs revealed that each lesson plan consists of at least a task with utilizing a technology. These PSTs mostly intended to use cognitive technologies including dynamic geometry software (GSP and GeoGebra), and online or hand-held graphing calculator (Desmos and TI-Nspire). Their reasons of selecting cognitive technologies include dynamic features of the tool, ease of use, and providing different visual representations. The most frequently selected cognitive technology used in these lesson plans is GSP. In addition to cognitive technologies, some of PSTs preferred to use conveyance technologies including iPad and interactive whiteboard in their lesson plans. It was recognized that their lack of technology knowledge, availability of technology in context, students' familiarity with technology and time considerations were their main reasons to not use cognitive technologies. The intended way of technology use varied. While some PSTs integrated as reorganizer, others planned to use technologies as amplifier. In the presentation, detailed description for each case will be provided and evidence will be shared with the audience.

ONE TEACHER'S IMPLEMENTATION OF PROFESSIONAL DEVELOPMENT AROUND THE USE OF TECHNOLOGY

Anna F. DeJarnette
University of Cincinnati
anna.dejarnette@uc.edu

There is an opportunity at the crossroads of research, policy, and practice to translate calls for the use of technology into professional development (PD) that is relevant to teachers. In this study, I examine how one teacher translated a sequence of PD meetings into the design and implementation of two lessons using GeoGebra. Three overarching themes emerged from the teacher's work: bidirectional decision making in the selection of technology and mathematics content; adapting existing lessons to accommodate a new technology; and allowing "productive struggle" among students with the technology. This study suggests that the use of technology tools may help teachers conceive of new ways in which students may experience mathematics, but this new perspective can sometimes be at odds with efforts to adapt existing resources.

Keywords: Technology, Middle School Education, Teacher Education-Inservice/Professional

Discrepancies between policy recommendations for the purposeful use of technology in mathematics classes (NCTM, 2000; NGAC, 2010) and rates of implementation among teachers (Banilower et al., 2013), there is an opportunity at the crossroads of research, policy, and practice to support teachers to implement calls for the use of technology in mathematics teaching. This study addresses the issue of how professional development (PD) that is conceptually framed around the use of technology to support students' reasoning and sense making translated into practice for one eighth-grade mathematics teacher. I pose the question: *How does a mathematics teacher apply professional development in the use of mathematics technologies to design and implement technology-based lessons?* Through a six-month partnership in which I introduced the teacher to two technology tools and collaborated with her in planning two lessons, I investigated how the theoretical components of the PD translated into instructional decisions that supported the teacher's goals for her students and her content.

Conceptual Framework

The PD discussed in this study was framed through the intersection of teacher learning and student use of technology for mathematical reasoning. This paper addresses specifically the component of teacher learning, with regards to how a teacher applied PD in the design and implementation of technology-based lessons. The PURIA (play, use, recommend, incorporate, assess) model has been introduced by Beaudin and Bowers (1997), and elaborated by Zbiek and Hollebrands (2008), to describe different modes of technology integration by teachers. In the first two modes, teachers become familiar with the use of a technology, first in a non-directed way and then to engage with some specific mathematics problem or idea. In the recommend mode, teachers begin to work within small groups to suggest uses of a technology. In the incorporate mode, teachers integrate the technology into their classroom instruction; and in the assess mode they examine students' use of the technology in terms of their mathematical learning. The PURIA model provides an outline for the implementation and analysis of PD around the use of a mathematics technology.

Data and Methods

The PD program was implemented in a large suburban middle school in the Midwest with a strong technology initiative and a 1:1 ratio of students to laptop computers. I proposed the PD opportunity to a teacher whom I refer to as Ms. S as an opportunity to learn about new mathematics technologies, and then to select the technology she saw as most relevant to her content and to design two lessons incorporating it. Ms. S had three full years of middle school mathematics teaching experience at the start of the project. Upon agreeing to participate in the project, she chose to use her 8^{th}-grade honors-track mathematics class as the focal class for which she would design and plan two lessons.

Our work began in the fall, during which time Ms. S and I met approximately on a weekly basis for 1.5 hours after school. I first introduced her to two technologies that were new to her. The first, SageMath, is an open-source computing software that allows users to program through a Python-based language. The second, GeoGebra, is an open-source dynamic geometry environment that is more typically used in middle and secondary mathematics classrooms for representing geometric figures and relationships. The purpose of introducing two different technologies was for Ms. S to have the opportunity to *play* and *use* (Beaudin & Bowers, 1997) the technologies and to compare which may be more relevant to the content she would teach in the following quarters. For each technology, I designed two prototype lessons that Ms. S completed before she ultimately selected GeoGebra as the environment she would incorporate with her students. In collaboration, we designed one lesson on the topic of geometric transformations, and one on the properties of the perpendicular and angle bisectors of a triangle.

Data for this study come from video recordings of the PD sessions, as well as video recordings of the classroom implementation of the two lessons. The purpose of the study was to characterize some of the ways that Ms. S translated her work during the PD sessions into the design and implementation of lessons for her students. As such, I used a constant comparative method (Strauss & Corbin, 1998) to identify categories of phenomena that emerged from passes through transcripts from both the PD sessions and in-class implementation. Specifically, I looked for evidence in the transcripts of our after-school meetings of how Ms. S implemented the ideas that surfaced during her use of the technology, which could be corroborated or disputed by Ms. S's actions in the classroom.

Findings

Three overarching themes emerged that characterize Ms. S's work of designing technology-based lessons: bidirectional decision-making, adapting new lessons, and productive struggle.

Bidirectional Decision Making in the Selection of Technology and Content

In conceptualizing the PD program, the purpose of introducing two alternative technology tools was so that Ms. S could determine which technology would be most relevant to her content. In practice, however, the process of alignment between the technology tool and the content to be taught was bi-directional. Ms. S's comments about her goals for the project, which I asked her about during our initial meeting together, encapsulate this tension:

> *Ms S:* My goal would be to learn something new and to see if I can integrate it…There's five of us that teach 8^{th}-grade math, and we work very closely together and plan together, and feel like over the years we've developed some really good things and I'm now kind of like, I want to get to keep using this I like it. So I don't do as much as I did in my first two years just looking around and seeing what other tools or activities are out there.

With her comments above, Ms. S indicated two sentiments. First, she saw her participation in the project as an opportunity to learn something new that she could integrate into her mathematics teaching. Throughout her experience with the two new technology tools, Ms. S often noted discoveries of novel mathematical ideas that she proposed as interesting areas of exploration for her students. For example, working on a lesson about triangle constructions using GeoGebra, Ms. S recognized that the intersection of angle bisectors of a triangle is the center of that triangle's inscribed circle. This was not a topic that was currently embedded within the course she taught, but Ms. S was inspired by the ways in which the use of GeoGebra might open up new a new area of discovery during students' study of triangles.

In contrast to the excitement over identifying new mathematical ideas that could be explored through the use of technology, Ms. S also expressed a desire to find a tool that would align with her current curriculum. As she noted, the group of 8th-grade mathematics teachers had been working together for multiple years to develop a stable set of lessons and resources that were aligned with the state and district learning standards for the course. Ultimately, Ms. S selected the use of GeoGebra to incorporate into her class because she felt it better aligned with the existing content of the course.

Adapting Existing Lessons to Accommodate New Technology

A common theme during the "play" and "use" segments of the PD sessions was for Ms. S to recall a lesson she had taught in the past and to consider how it might be adapted or modified through the use of GeoGebra:

> *Ms. S:* Just last year we started doing constructions with them…And we, we did it by hand; we agreed that they could do it by hand. But, doing it on something like this would be pretty nice. Because it, then, because the measurements are already there, so it takes out that sort of error. Just measuring lines for them, sometimes, you know?

When Ms. S worked on the prototype lessons, she recalled materials she had used in the past and how they could be improved or adapted with the technology tool. In these cases, the use of technology did not open doors to novel mathematical ideas as much as it served to streamline existing activities.

Allowing "Productive Struggle" Among Students with the Technology

The use of the term "productive struggle" in Ms. S's conversations was of note especially because of how her use of the term in relation to technology compared to the way it is typically used in mathematics education research. Productive struggle in mathematics education most typically refers to extending "effort to make sense of mathematics, to figure something out that is not immediately apparent" (Hiebert & Grouws, 2007, p. 387). Ms. S indicated that the concept of productive struggle had surfaced frequently during the math department meetings at her school, as a goal for the type of activity students would engage in. When working on an early lesson using GeoGebra, Ms. S was struggling with the menu options to construct an angle of a given measure. When I noted that the software could sometimes be fickle, Ms. S noted with regards to her students, "I guess it's okay to allow that productive struggle." Although the struggle Ms. S was having would more typically be considered troubleshooting with the technology, she identified it as an opportunity for productive struggle for her students.

Following Ms. S's introduction of the term productive struggle, we regularly discussed the lessons and students' use of GeoGebra with respect to this idea. Towards the end of our lesson planning, I asked Ms. S to describe how she defined productive struggle for her students. In her response, she specifically addressed the role of technology:

> *Ms. S*: That's where I think GeoGebra is, again, I think it will be more straightforward for

them, um, a productive mathematical struggle rather than a logistical, you know, 'what did I type in that's wrong?' type of struggle.

Ms. S's ideas of productive struggle with regards to technology evolved throughout our time working together. Initially, she seemed to use this phrase interchangeably to discuss students' mathematical work and the learning curve associated with a new technology tool. Throughout the planning and implementation process, Ms. S developed a more nuanced way of discussing struggle, making a clear distinction about how the technology could promote "productive mathematical struggle" without creating undue burden for students trying to learn the tool.

Discussion and Conclusion

When experiencing two new technology tools, and then deciding about how to incorporate one of these tools into her teaching, Ms. S articulated a clear tension: There was opportunity to use new technology to foster mathematical discoveries that had not previously been part of the curriculum. At the same time, Ms. S saw opportunity to modify, and marginally improve, existing lessons by using GeoGebra in place of other materials. There is support from research to justify either position, and ultimately a teacher must determine which is the most appropriate for a given class. In the context of this study, Ms. S. aligned her use of GeoGebra to the content of existing lessons, but she leveraged the tools of GeoGebra to create more opportunities for reasoning and proof than had previously been a part of students' work.

This study also suggests how the discourse of mathematics teaching and learning translates to the introduction of a technology tool. Ms. S, although she spoke fluently about productive struggle in the context of her students' mathematical learning, initially applied this term to the use of GeoGebra in ways that referenced fairly superficial challenges with the tool. Throughout her work on the project, Ms. S became increasingly sophisticated in how she distinguished between different types of struggle, and this was reflected through the types of support she gave students during their work on the lessons. In sum, Ms. S's practical experience using and teaching with GeoGebra informed her understanding of the theory and research around struggle in mathematics, which in turn helped her to refine her practice of teaching with GeoGebra.

RESOLUCIÓN DE PROBLEMAS Y USO DE TECNOLOGÍAS DIGITALES EN UNA PLATAFORMA EN LÍNEA
MATHEMATICAL PROBLEM SOLVING AND DIGITAL TECHNOLOGIES IN A MASSIVE ONLINE COURSE

William Enrique Poveda Fernández
CINVESTAV-IPN
wpoveda@cinvestav.mx

Daniel Aurelio Aguilar-Magallón
CINVESTAV-IPN
daguilar@cinvestav.mx

La conectividad y potencial que ofrece la tecnología digital está generando nuevas oportunidades para aprender y compartir conocimiento matemático. ¿Cómo diseñar e implementar un ambiente de resolución de problemas y uso de tecnologías digitales en un escenario de aprendizaje masivo (MOOC) que promueva en los participantes una discusión matemática hacia el entendimiento de conceptos y resolución de problemas? Los resultados del estudio indican que el diseño de las actividades y el uso coordinado de GeoGebra, Wikipedia, KhanAcademy, WolframAlpha, Open edX y foros virtuales, permiten y favorecen la creación de un ambiente de colaboración en la resolución de problemas. Los participantes trabajaron colaborativamente y transitaron desde soluciones visuales y empíricas hasta la presentación de argumentos geométricos y algebraicos en la validación de las conjeturas formuladas.

Palabras clave: Resolución de Problemas, Tecnología, Actividades y Prácticas de Enseñanza

Introducción

Las tecnologías digitales abren nuevas rutas en el proceso de aprendizaje, no solo para obtener o compartir información, sino también son un medio para que los estudiantes compartan ideas, discutan, critiquen y se involucren en actividades matemáticas (Santos-Trigo, Moreno-Armella & Camacho-Machín, 2016). La disponibilidad de diversas tecnologías digitales abre nuevas interrogantes sobre qué transformaciones son necesarias en el sistema educativo y cómo incorporarlas en los ambientes de aprendizaje. Los cambios tecnológicos demandan una transformación en la práctica educacional, se requieren cambios en el proceso de enseñanza donde los estudiantes sean el centro de toda actividad y el profesor un apoyo para el desarrollo de habilidades y destrezas en la resolución de problemas (Churchill, King, & Fox, 2016).

Un MOOC (por sus siglas en inglés), es un Curso Masivo Abierto en Línea diseñado e implementado por una institución educativa a través de un equipo de expertos en el tema. En éste, se puede inscribir un gran número de participantes sin importar su nivel de estudios, edad o lugar geográfico en que encuentren. En este estudio interesa analizar y documentar el diseño y los resultados de implementar un MOOC basado en el modelo de diseño de ambientes aprendizaje de Churchill et al. (2016); donde las tareas matemáticas, basadas en resolución de problemas, promuevan la exploración de atributos y relaciones entre los objetos matemáticos dentro de una representación dinámica del problema creada en el Sistema de Geometría Dinámica (SGD) GeoGebra. El movimiento de objetos, la medición y los lugares geométricos son estrategias que fomentan la formulación de conjeturas y promueven la búsqueda de argumentos que las sustenten.

Marco Conceptual

Churchill et al. (2016) proponen un marco para el diseño de ambientes de aprendizaje en línea llamado RASE (Resources-Activities-Support-Evaluation), basado en la premisa de que todo ambiente de aprendizaje debe incluir e integrar esos cuatro componentes. Los *Recursos,* se refieren a los materiales disponibles a los estudiantes: videos, imágenes, documentos digitales, calculadoras, software, etc. Las *Actividades* tienen como objetivo involucrar a los estudiantes en el proceso de aprendizaje a través del uso de Recursos en tareas tales como experimentos y resolución de problemas. El *Soporte* indica que es necesario contemplar medios para proporcionar ayuda a los estudiantes en el momento en se presente alguna interrogante relacionada con la tarea que están realizando. La *Evaluación* enfatiza que los estudiantes deben recibir retroalimentación que les permita reflexionar sobre su aprendizaje.

Santos-Trigo (2014) afirma que la resolución de problemas es una actividad esencial en el aprendizaje de las matemáticas ya que es un medio que permite identificar, explorar, probar y comunicar los procesos de solución. Cuando se incorpora el uso coordinado de tecnologías digitales en los procesos que intervienen en la resolución de problemas, se ofrece a los estudiantes oportunidades para representar, explorar, compartir y discutir los conceptos y la resolución de problemas. GeoGebra favorece la exploración de situaciones matemáticas desde distintas perspectivas permitiendo a los estudiantes tener nuevas formas de visualización de los conceptos y objetos de estudio y analizar, de una forma más precisa, los elementos matemáticos que cuando se utiliza solo papel y lápiz (Santos-Trigo & Camacho-Machín, 2016; Aguilar-Magallón & Reyes-Martínez, 2015).

Metodología

El curso se diseñó como parte de la plataforma digital MéxicoX que utiliza *Open edX*. Se enfocó en la construcción del conocimiento matemático a partir de la resolución de problemas y el uso de tecnologías digitales, es decir, no se abordó de manera puntual una serie de contenidos específicos como generalmente se presentan en un ambiente tradicional de enseñanza.

Las tareas o problemas matemáticos incluyen diversos *Recursos*: representaciones dinámicas del problema elaboradas en GeoGebra, videos de KhanAcademy y vínculos a fuentes de información: Wikipedia, KhanAcademy y WolframAlpha.

Un aspecto fundamental en el diseño de las *Actividades* fue la idea de darle movimiento a figuras simples como triángulos, rectángulos, etc., por medio de representaciones dinámicas. Las tareas o problemas matemáticos guiaron al participante en su trabajo y fomentaron sus procesos de construcción o desarrollo del pensamiento matemático, mediante un método inquisitivo. El objetivo fue que los participantes al observar el comportamiento o variación de algunos objetos o atributos (medida de ángulos, áreas, perímetros, etc.) propusieran algunas conjeturas que den cuenta de su comportamiento y las sustentaran con argumentos. Este proceso les permitió explorar y buscar varios caminos de solución y extender y generalizar los resultados.

Se utilizaron diversas herramientas digitales para dar *Soporte* a los participantes: Wikipedia, KhanAcademy y WolframAlpha permitieron a los participantes consultar en línea conceptos o relaciones matemáticas y, los foros fueron un medio de comunicación para que los integrantes del curso exhibieran sus ideas, formularan interrogantes, conocieran otros puntos de vista y recibieran retroalimentación como una ruta para comprender ideas matemáticas.

La *Evaluación* estuvo presente durante todo el curso. A través del Foro de cada *Actividad*, los participantes desarrollaron y produjeron evidencias de su aprendizaje mediante la exploración de las propiedades de los objetos representados en un modelo dinámico y reflexionaron sobre éstas como producto de la retroalimentación que recibieron por parte de otros integrantes del curso.

La investigación es de carácter cualitativo. La unidad de análisis fueron las conversaciones desarrolladas por los participantes en cada Actividad. Estas permitieron obtener información sobre los comportamientos de los participantes, formas de razonamiento que exhiben durante el proceso de resolución de un problema y cómo éstas pueden ser modificadas a partir de la interacción con otros participantes. En el MOOC se inscribieron 2491 personas. Debido a los contenidos abordados en las tareas matemáticas, el único requisito solicitado a los interesados fue poseer estudios correspondientes al grado 12. Los datos se recolectaron a través de las conversaciones que se desarrollaron en el Foro de cada Actividad. En total hubo 35 foros que incluyeron 7573 comentarios de los participantes.

Presentación y Discusión de Resultados

Se discute una de las *Actividades* del MOOC referente al uso de lugar geométrico como estrategia en la resolución de problemas. En la primera sesión de trabajo se presentó a los participantes un modelo dinámico que incluía un segmento AB, su recta mediatriz n y un punto móvil C sobre $n,$ esto fue la base para que ellos construyeran triángulos isósceles y encontraran alguna posición de C donde también el triángulo fuera equilátero. En la segunda sesión, se proporcionó a los participantes una familia de triángulos isósceles FGC, cuyo lado FG estaba sobre AB y sus lados congruentes tenían una longitud dada r. También se incluyó, la gráfica que modela la variación del área de la familia de triángulos isósceles como resultado de mover el punto C. El punto R, relaciona la longitud de la altura con el área del triángulo (Figura 1).

En las conversaciones, un participante mencionó que el lugar geométrico que describe el punto R cuando C se mueve correspondía a una parábola, otros le indicaron que tal afirmación era falsa argumentando que su ecuación era $A(h) = h\sqrt{r^2 - h^2}$. Los participantes aseguraron que al mover el punto C, el valor aproximado del ángulo β debía ser 90°. Ante esto, algunos preguntaron en el Foro: "*¿Cómo justificar que el área máxima se obtiene cuando $\beta = 90°$?*". Los participantes argumentaron la existencia de un triángulo de área máxima a partir de la observación de la gráfica, ya que el valor del área aumentaba desde cero y después disminuía para volver a ser cero. También, indicaron la existencia de dos posiciones, una sobre y la otra bajo el eje X, para el punto C donde era posible obtener un triángulo de área máxima. Posteriormente, se proporcionó a los participantes un nuevo modelo dinámico en donde el triángulo FGC fue colocado de tal manera que el punto C coincidiera con el origen del plano cartesiano y el lado CG estuviera sobre el eje X; además, se construyó la altura h_1 sobre CG (Figura 2).

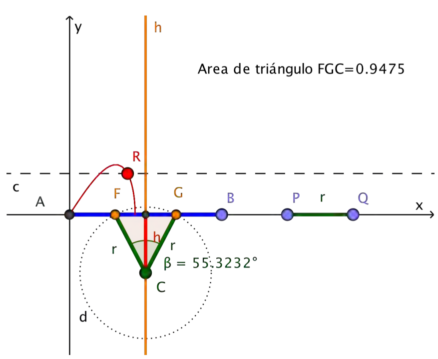

Figura 1. Representación dinámica de una familia de triángulos isósceles.

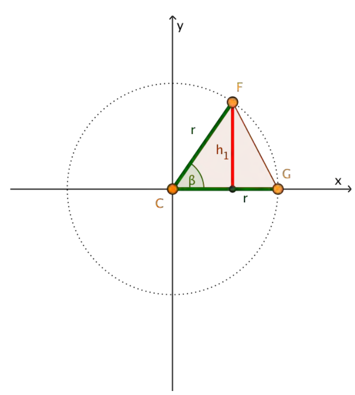

Figura 2. Otra vista del Triángulo $\boldsymbol{FGC}$.

En las conversaciones los participantes coincidieron en que la nueva representación del triángulo FGC les permitió observar la relación que existe entre el punto máximo del lugar geométrico que describe el punto R cuando C y el ángulo β y, así, concluir que de todos los triángulos isósceles de lados congruentes r, el de área máxima es también triángulo rectángulo. Observaron que h_1 maximiza el área del triángulo FGC, pues la base CG permanece constante, y h_1 es máxima cuando mide lo mismo que el radio de la circunferencia, es decir, cuando está sobre el eje Y. Después de la solución geométrica, dos participantes plantearon dos justificaciones adicionales utilizando desigualdades y trigonometría.

Las diversas representaciones que ofrece GeoGebra para visualizar de manera instantánea la variación en los atributos (longitudes, ángulos, áreas, etc.) de objetos geométricos ayudaron a los participantes a establecer conjeturas que posteriormente justificaron. Una estrategia visual y empírica importante fue el uso de un lugar geométrico para modelar la variación del área de una familia de triángulos como un recurso adicional para resolver el problema.

El diseño de las actividades permitió a los participantes, mediante el uso de los foros de discusión, comunicar y contrastar sus ideas en una comunidad virtual, lo cual favoreció la construcción o refinamiento de conceptos e ideas matemáticas ampliando sus recursos matemáticos y estrategias en la resolución de problemas. En los foros, la moderación que realizó el equipo de diseño del MOOC en las conversaciones, orientó la discusión de los participantes en la resolución del problema y, en conjunto con el rol que asumieron varios participantes de proporcionar retroalimentación a otros, promovieron la comprensión de conceptos e ideas matemáticas.

Conclusiones

El uso coordinado de diversas herramientas digitales ofreció los medios para crear un ambiente de aprendizaje MOOC en una plataforma en línea. En este escenario, los participantes trabajaron en un ambiente de colaboración que les permitió compartir sus ideas, a través del Foro de discusión, durante el proceso de resolución de problemas. Todos los participantes tuvieron la oportunidad de explorar representaciones dinámicas que les permitieron identificar conceptos, buscar conjeturas y diversas maneras o argumentos para sustentarlas. En este proceso, los participantes mostraron heurísticas asociadas con el uso de las herramientas como movimiento ordenado de objetos dentro de la configuración dinámica, la cuantificación de atributos (longitudes, ángulos, áreas) y la generación de lugares geométricos.

En el Foro de la *Actividad* varios participantes respondían dudas y daban seguimiento puntual a sus propios comentarios, lo cual favoreció el refinamiento de las ideas matemáticas propuestas inicialmente. Es importante reconocer que el diseño e implementación del MOOC representa un gran reto relacionado con los niveles de compromiso y responsabilidad de los participantes para que ellos mismos monitoreen sus avances en la comprensión y uso de las ideas matemáticas en la resolución de problemas.

The connectivity and potential offered by the use of digital technologies opens up novel opportunities for learners to construct and share mathematical knowledge. How could we design and implement an online learning scenario (MOOC) that fosters the use of digital technologies to engage the participants in a continuous mathematical discussion to understand concepts and to solve problems? The results showed that the design of interactive activities and the coordinated use of digital technologies (GeoGebra, Wikipedia, KhanAcademy, WolframAlpha, Open edx and virtual forums) became important for the participants to formulate conjectures, to look for different ways to validate them and to communicate results. To this end, the participants work collaboratively and transited from the use of visual and empirical arguments to the presentation of geometric and algebraic validation.

Keywords: Problem Solving, Technology, Instructional Activities and Practices

Introduction

Digital technologies are opening new pathways in learning processes, not only in terms of obtaining or sharing information, but also as means for students to share, discuss and criticize ideas while becoming more involved in mathematics activities (Santos-Trigo, Moreno-Armella &

Camacho-Machín, 2016). The availability of diverse digital technologies raises new questions as to what transformations of educational systems are necessary, and how to incorporate them into learning environments. Technological changes demand a transformation of educational practices and require modifying teaching processes to make students the center of all activity while teachers act as supports for developing abilities and skills related to problem-solving (Churchill, King & Fox, 2016).

A Massive Open On-line Course (MOOC) is designed and implemented by educational institutions through the efforts of a team of experts in the field. Large numbers of participants can be enrolled, regardless of their level of schooling, age, or place of residence. The present study is concerned with analyzing and documenting the design and results of the implementation of a MOOC based on the design model of learning environments presented by Churchill et al. (2016), in which mathematics tasks, based in problem-solving, promote exploring the attributes of, and relations among, mathematics objects in a dynamic representation of a problem created in the GeoGebra Dynamic Geometry System (DGS). Object movement, measuring, and locus are three strategies that foster the formulation of conjectures while also promoting the search for arguments to sustain them.

Conceptual Framework

Churchill et al. (2016) proposed a framework for designing on-line learning environments called RASE (Resources-Activities-Support-Evaluation). Their system is based on the premise that all learning environments should include and integrate these four components. Resources refer to the materials available to students, including videos, images, digital documents, calculators and software, etc. The objective of the Activities is to involve students in the learning process by applying Resources to tasks like experiments and problem-solving. Support indicates the need to contemplate the means that will provide students with the help they require when a question or doubt arises in relation to the task they are asked to perform. Evaluation, finally, emphasizes that students need to receive feedback that will allow them to reflect on their learning.

Santos-Trigo (2014) sustains that problem-solving is an essential activity in learning math because it is a medium that leads students to identify, explore, test and communicate solution processes. When the coordinated use of digital technologies is incorporated into the processes that intervene in problem-solving, students are provided with opportunities to represent, explore, share and discuss both concepts and the process of problem-solving itself. GeoGebra fosters the exploration of math situations from distinct perspectives and offers students new ways of visualizing concepts and objects of study while also analyzing elements of mathematics with greater precision than is possible using only pencil and paper (Santos-Trigo & Camacho-Machín, 2016; Aguilar-Magallón & Reyes-Martínez, 2015).

Methodology

This course was designed as part of the MéxicoX[i] digital platform that utilizes Open edX[ii]. It does not address a series of specific contents as is usually the case in traditional learning environments. Instead, it focuses on constructing mathematical knowledge through the process of problem-solving supported by using digital technologies. The math tasks or problems presented include diverse resources: dynamic representations of the problem elaborated in GeoGebra, videos from KhanAcademy and links to sources of information such as Wikipedia, KhanAcademy and WolframAlpha.

One fundamental aspect in the design of the Activities was the idea of endowing simple figures – such as triangles and rectangles, among others– with movement using dynamic models. The math tasks or problems guided participants in their work and fostered their processes of constructing or developing mathematical thinking through an inquisitive method. The objective was for participants to observe the behavior or variation of certain objects or attributes (measuring angles, areas, perimeters, etc.), propose conjectures that might account for their behavior, and then sustain or refute those conjectures through argumentation. This process allowed students to explore and search for various means of solution while extending and generalizing results.

Several digital tools were used to provide Support to participants: Wikipedia, KhanAcademy and WolframAlpha allowed them to consult mathematics concepts or relations on-line; while forums provided a means of communication where they could present their ideas, formulate questions, and give or receive feedback to improve their understanding of mathematics ideas.

Evaluation was conducted throughout the course in the Forums associated with each Activity. Participants developed and produced evidence of their learning by exploring the properties of the objects represented in a dynamic model and reflecting on them as products of the feedback they received from other students enrolled in the course.

A total of 2,491 people registered in this MOOC. Given the contents of the math tasks involved, the only requirement for registration was that interested individuals had a minimum schooling level equivalent to grade 12.

The research involved was qualitative in nature. The units of analysis were the conversations developed by the participants themselves in each Activity, which allowed researchers to gather information on participants' behaviors, the forms of reasoning they exhibited during the problem-solving process, and how these could be modified through interaction with other participants. Data were collected from the conversations held in the Forum for each Activity, and included a total of 7,573 comments by participants in 35 forums.

Presentation and Discussion of Results

Only one of this MOOC's Activities is discussed. It refers to the use of locus as a problem-solving strategy. In the first work session, participants were presented with a dynamic model that included a segment, AB, its straight perpendicular, n, and a movable point, C, on n. From this base, they were told to construct isosceles and equilateral triangles. The next Activity involved a family of isosceles triangles, FGC, whose side FG was on AB and whose congruent sides had a given length of r. This task included a graph that modeled variations in the area of this family of isosceles triangles that resulted from moving point C. Point R related the length of the height to the area of the triangle (Figure 1).

In the conversations, one participant mentioned that the locus of point R when point C moves along the n, corresponded to a parabola, but another replied that this was false, arguing that the corresponding equation was $A(h) = h\sqrt{r^2 - h^2}$. The participants affirmed that upon moving point C, the approximate value of angle β should be 90°. At that moment, some students in the Forum asked: "How can we justify that the maximum area is obtained when $\beta = 90°$?". Participants argued for the existence of a triangle with maximum area based on observing the graph, since the value of the area increased from zero and then decreased to return to zero. Moreover, they sustained that there were two positions for point C –one on, the other under, the X-axis– that indicated where it was possible to obtain a triangle with maximum area.

Later, students were given a new dynamic model in which the triangle FGC was positioned in such a way that point C coincided with the origin of the Cartesian plane, side CG was on the X-axis, and the height, h_1, was constructed on CG (Figure 2).

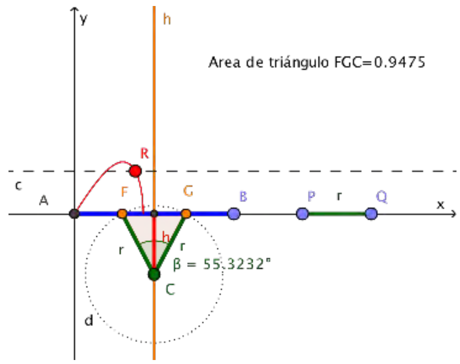

Figure 1. A family of isosceles triangles Dynamic representation.

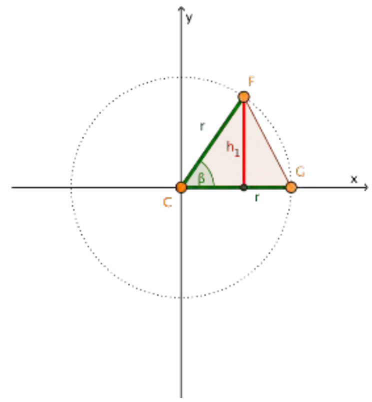

Figure 2. Another view of triangle $\boldsymbol{FGC}$.

In their forums, participants coincided in that the new representation of triangle FGC allowed them to observe the relation that existed between the maximum point of the locus of point C when point E moves along n, and angle β and, therefore, reach the conclusion that of all the isosceles triangles with congruent sides, r, the one with the maximum area is also a right-angle triangle. They observed that h_1 maximizes the area of triangle FGC, since the base, CG, remains constant, and h_1 is maximal when it measures the same as the radius of the circumference; that is, when it is on the Y-axis. After arriving at this geometric solution, two participants presented two additional justifications utilizing inequalities and trigonometry.

The diverse representations that GeoGebra offers for instantaneously visualizing variations in the attributes (lengths, angles, areas, etc.) of geometric objects helped participants establish conjectures that were justified later in the problem. One important visual and empirical strategy was the use of locus to model variations in the area of a family of isosceles triangles as an additional resource for resolving the problem.

The design of the activities allowed the participants, through the use of discussion forums, to communicate and contrast their ideas in a virtual community. This fostered the construction or refinement of mathematics concepts and ideas by broadening access to mathematical resources and strategies for resolving problems. The moderating of the forums performed by the team that designed the MOOC oriented participants' discussions towards a search for responses. Various participants took on the role of providing feedback to others through comments offered in the forums.

Conclusions

The coordinated use of several digital tools provided the means for creating a MOOC learning scenario in an on-line platform. In this scenario, participants worked in a collaborative environment that allowed them to share their ideas through discussion forums during the problem-solving process. All participants had the opportunity to explore the dynamic models and conceptualize them as a starting point for identifying concepts and looking for relations, and then devising diverse means or arguments to sustain them. During this process, participants showed heuristics associated with the use of such tools as the ordered movement of objects inside the configuration, the quantification of attributes (lengths, angles, areas), and loci.

Through the Activities of this MOOC, a participative environment was generated in the forums as participants adopted different roles, including some who responded to questions, others who resolved doubts, and individuals who offered timely follow-up to comments. All of this propitiated the refinement of the mathematics ideas proposed initially. It is important to recognize that the design and implementation of MOOC represents a great challenge in terms of the levels of commitment and responsibility required of participants so that they can monitor their advances in the understanding and use of mathematics ideas in problem-solving.

VARIATIONS IN TEACHING PRESENCE: FACTORS CONTRIBUTING TO SOCIAL PRESENCE AND EFFECTIVE ONLINE DISCUSSION

Erica L. Demler
University at Buffalo
ericadem@buffalo.edu

Deborah Moore-Russo
University at Buffalo
dam29@buffalo.edu

The purpose of this study is to identify factors that impact discussion in asynchronous online learning environments. Various facets of teaching presence related to the design and facilitation of online discussion activities are considered in conjunction with common indices from social network analysis. Levels of in-degree and out-degree centrality and betweenness speak to the social presence within a given forum while average degree, density, and connectedness are representative of the volume and diversity of connections comprised within that forum. Findings indicate that having students initiate their own thread within a forum leads to a more balanced discussion, while required forums tend to have both a higher volume of communication and a greater diversity of connections than optional forums. The information gained from this study will inform practices of online, discussion-based courses offered at the post-secondary level.

Keywords: Technology, Post-Secondary Education, Instructional Activities and Practices

Introduction

Programs in higher education across the country are at a crossroads as traditionally seated courses are being transitioned to online alternatives. A common feature of most online courses is the use of asynchronous discussion forums as a means for students to interact with the instructor, each other, and the course content. Indeed, research has shown that online discussion forums have the potential to promote skills like knowledge construction, critical thinking, and problem solving in students (An, Shin, & Lim, 2009) but only do so when the activities are properly designed and facilitated by the instructor in such a way as to incite high student engagement (Jo, Park, & Lee, 2017). While general consideration has been given to the role of the instructor in online settings, An et al. (2009) recognized that little attention is often devoted to specific strategies that can increase the effectiveness of online discussion. Therefore, our research focuses on those facets of design and facilitation that impact student interaction in online discussion.

According to Garrison, Anderson, and Archer (1999), students and teachers in online courses must form a community of inquiry (COI) in order to generate worthwhile educational experiences. Teaching presence, social presence, and cognitive presence are the three core elements in a COI, and learning is said to occur as a result of the interaction between these three elements. We focus specifically on the interaction between teaching presence and social presence and its impact on asynchronous online discussion.

Teaching presence is "the design, facilitation, and direction of cognitive and social processes for the purpose of realizing personally meaningful and educationally worthwhile learning outcomes" (Anderson, Rourke, Garrison, & Archer, 2001, p. 5). Akyol and Garrison (2008) identify three categories of teaching presence in a COI: (a) design and organization; (b) facilitating discourse; and (c) direct instruction. We consider the first two categories. For an online discussion forum, design and organization refers to the structure of the forum, the topic of discussion, and the nature of the prompt used to generate discussion. Facilitation of discourse is related to the instructor's level of involvement in the forum, which should decrease over time as students become able to sustain discussion on their own (An, Shin, & Lim, 2009).

Social presence, the second element in a COI, refers to "the ability of participants to identify with the group or course of study, communicate purposefully in a trusting environment, and develop personal and affective relationships progressively by way of projecting their individual personalities" (Garrison & Akyol, 2013). The categories of social presence as listed by Joksimović et al. (2015) include interpersonal communication, open communication, and cohesive communication. Social presence is fostered through teaching presence (Joksimović et al., 2015; Rogers & Lea, 2005); so, the choices an instructor makes regarding the design and facilitation of online discussion can directly influence the levels of interpersonal, open, and cohesive communication that are evident in a discussion forum.

The purpose of this study is to explore variations in teaching presence within and across two virtual COIs to determine if and how those variations influence the students' social presence and quality of generated discussion. The following research questions guided the study: (1) How does teaching presence (as evidenced by the design and facilitation of discussion board activities) impact students' social presence (as measured by interpersonal, open, and cohesive communication) in online discussion forums? (2) How does teaching presence impact the quality of asynchronous online discussions?

Methodology

The data were collected from two sections (Section 1 and Section 2) of an online, asynchronous course that served as an introduction to doctoral studies in a department focused on preK-16 education at a public research university in the northeast U.S. Students' grades in the course were determined by the number of points they compiled on required and optional assignments. Assignments required posting to discussion forums that related to the weekly reading assignments. At the beginning of the course, students were given a general directive to contemplate, extend, explore and/or push back on ideas raised by peers or in the readings to mimic a conversation that would occur in a face-to-face learning environment. Each reading also had a specific prompt. Readings from the textbook tended to have short instructional prompts for discussion, since this was already built into the text's readings. Other readings tended to have slightly more explicit directions on how to start the discussion but were rather vague.

The course instructors for the two sections had co-planned the course and implemented almost identical instructional interaction on the forums. Each section instructor responded to every participant and on every thread at least once in the first discussion forum, to about a third of the threads for the second forum, about a fourth of the threads for the third forum, and then only to a few (zero to three) posts on all subsequent forums. For each forum, both instructors would summarize the discussion and provide additional resources via an email sent to the students after the discussion forum closed. The instructors purposefully refrained from always responding to posts and would share information as needed via a separate e-mail communication. To conclude, by design each instructor was a heavy poster at the beginning of the course as students introduced themselves but quickly weaned away from participating in the discussion forums intentionally to ensure that student-student relationships were being built.

Social network analysis (Borgatti, Everett, & Johnson, 2013; Scott, 2000) via UCINET was used to examine person-to-person interactions in each forum at both the individual and group levels. The following common indices from social network analysis were used to measure social presence at the individual level: *in-degree centrality* or IDC (the number of responses a participant receives), *out-degree centrality* or ODC (the number of responses a participant sends), and *betweeness* or BTW (a measure of the degree to which a participant serves as a bridge connecting others in discussion). Each index correlates to one of the three categories of social presence identified above. IDC relates to interpersonal communication and is an indicator of a participant's prominence in the forum. ODC represents open communication and speaks to the influence a participant has on the discussion. BTW is indicative of cohesive communication and signifies the control a participant holds over others and their connections (Scott, 2000).

Three additional indices were used to explore interactions at the group level: *average degree* (mean number of connections, both IDC and ODC, per participant per forum), *density* (extent to which all possible connections between each participant are present), and *connectedness* (percentage of pairs of participants who were linked in some way across the network of possible connections). These help to assess the quality of online discussions (Jo, Park, & He, 2017), as they speak to the volume of communication and the diversity of connections within a forum.

Results & Discussion

Teaching presence is evident in the structure of discussion board activities, which varied across the 13 forums. First, some forums were required and some were optional. Next, for many of the forums (six optional and two required) it was not mandated that each participant initiate a thread. On those forums, a student could opt to forgo drafting an initial post and instead make all posts as responses to others. On other forums students were expected to initiate a thread as well as craft varying amounts of response posts to their peers.

The distribution of prominence (IDC), influence (ODC), and control (BTW) within a forum tends to be determined by whether or not initiating a thread is required for that forum. In Figures 1a and 1b below, the sociograms for two forums from section one are shown. Forum 11 was a forum in which students did not have to initiate a thread. The discussion centered on a single student participant, as was the trend for forums in this category; one or two participants held most of the power. In contrast, the sociogram of Forum 10 depicts a discussion in which power was dispersed across four participants. The distribution of power in Forum 10 is representative of others where initiating a thread was mandatory. This implies that discussions are more balanced in forums in which all participants devote at least one of their posts to initiating a thread; otherwise, the discussion tends to be dominated by one or two participants.

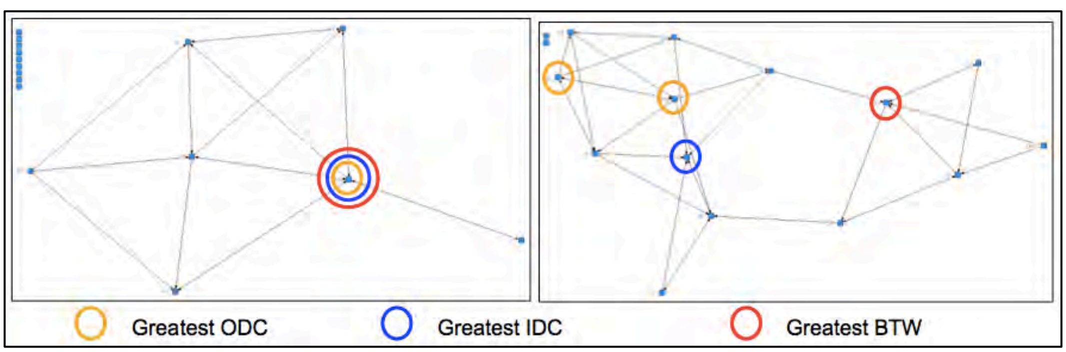

Figure 1a: Sociogram of Forum 11. **Figure 1b:** Sociogram of Forum 10.

Average degree, density, and connectedness are indices concerned with a network as a whole (Jo, Park, & He, 2017). Values for these indices were calculated for each forum and compared based on variations in teaching presence. Whether participation in a forum was required or optional was the first consideration. Independent *t*-tests found that the mean for the 14 required forums was significantly higher than the mean for the 12 optional forums across all three indices (average degree: $t_{13.7} = 2.338, p = 0.035$; density: $t_{13.0} = 2.510, p = 0.026$; connectedness: $t_{16.4} = 2.161, p = 0.046$). Therefore, required forums generated more posts and were more complete than optional forums and participants in required forums were more connected to each other than in optional forums. This is not surprising.

Variations in the minimum number of posts required for a forum did not impact social presence or the quality of discussion. The forums depicted in Figures 1a and 1b above each required participants to make at least four posts, but the distribution of prominence, influence, and control varied greatly. There were forums with fewer required posts that matched both types of distributions. Consider two forums from section 2: Forum 8 had a higher volume of communication and a greater diversity of connections than Forum 9 (average degree: 4.45 vs. 2.25; density: 0.234 vs. 0.118; connectedness: 0.671 vs. 0.289), although Forum 8 only required three posts per participant as opposed to the four required for Forum 9. This shows that, in terms of teaching presence, factors beyond a required minimum amount of posts lend to the development of social presence and quality of discussion.

Conclusions and Future Research

Our work has revealed that variations in teaching presence can impact both social presence and the overall effectiveness of asynchronous online discussions within a COI. When the design of a discussion forum requires participants to initiate their own thread, the discussion tends to be more balanced and is not dominated by one particular student. This helps create a more collaborative environment in which social presence can develop. In settings in which both required and optional forums are present, required forums have both higher volumes of communication and a greater diversity of connections. Requiring a minimum number of posts per participant, another facet of teaching presence, did not have an impact on social presence.

Moving forward, it will be useful to examine the impact other facets of teaching presence (i.e., topic and timing of posts) have on asynchronous online discussion. An examination of individual participants' habits in online discussion forums could also help to explain variations in social presence. This information will be crucial for practitioners in every field of higher education who want to ensure knowledge construction, critical thinking, and problem solving in their students as they transition into online learning spaces.

Design engineering is potentially a very useful way of developing visual-spatial reasoning. In this research, seventh grade students designed and constructed cube puzzles and then printed these models using a 3D printer. The task provided for many opportunities for students to both develop and use their visual-spatial reasoning. Most challenging for the students was using the technology to visualize mental rotations and, in this respect, the physical model was essential to the task. Also essential to the task was the inclusion of the 3D printer which inspired significant engagement and also further learning. Recommendations for future directions for research are provided.

Keywords: Geometry and Geometrical and Spatial Thinking, Elementary School Education

Introduction

Visual-spatial reasoning has been identified as being essential to many STEM-careers (Wai, Lubinski, & Benbow, 2009). Moreover, there are numerous studies that report both a link between visual-spatial reasoning to overall mathematical performance and the predictive capacity of it to future mathematical achievement (Frick, Möhring, & Newcombe, 2015). In this paper, we explore pedagogy aimed at providing opportunities to support the development of visual-spatial reasoning through a design engineering task that involved 3D printing.

Design engineering, as used in this context, refers to "any engagement in a systematic practice of design to achieve solutions" (National Research Council, 2012, p. 11). Design engineering tasks that make use of 3D printing have been found to increase STEM engagement (Buehler, Comrie, Hofmann, McDonald, & Hurst, 2016; Wendt & Wendt, 2015). In this research, students were challenged to design a three-dimensional interlocking cube puzzle (see Figure 1). The cube puzzle was to include at least five different interlocking puzzle segments. Students first produced a physical model and then developed the renderings (digital plans) using Tinkercad (https://www.tinkercad.com/) to execute the 3D print (see Figure 2). The mathematical strands explored were geometry and spatial sense and measurement.

Figure 1. Cube puzzle.

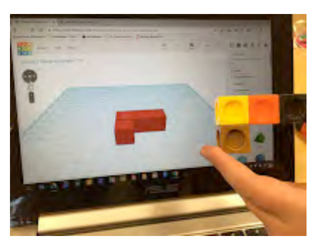

Figure 2. Tinkercad.

The overarching aim of integrating 3D printing in this classroom stems from a commitment to provide design-based opportunities for students to develop their visual-spatial reasoning whilst exploring the pedagogical affordances of virtual 3D learning environments. This approach encourages "a more visual endeavour and connects with what 'real' mathematicians do when they are exploring patterns in the world and making discoveries"(Ontario Ministry of Education, 2014, p. 3). We sought to answer the following question: What are the challenges and benefits associated with attempting to develop visual-spatial reasoning through a design engineering task which also uses 3D printing? There is a dearth of research on the affordances of 3D printing in mathematics learning; this is a contribution of this research.

Theoretical Framework

This research draws on the framework for visual-spatial reasoning proposed by (Uttal et al., 2013). According to Uttal and colleagues, there are four dimensions to visual-spatial reasoning and these are intrinsic (object specific), extrinsic (relation of an object to a frame of reference), static (object is stationary), and dynamic (object is moving). Building 3D models involves both mental rotations and the relation of objects to a frame of reference (or other aspects of the model). The interlocking 3D puzzle inspiring this project is an example of both intrinsic-dynamic and both extrinsic-static visual-spatial reasoning. Mental rotation is involved in the construction but then to rebuild the puzzle, pieces are rotated in reference to one stationary component of the puzzle. Mental rotation is proposed to be an important indicator of visual-spatial ability, with males tending to outperform females (Jordan, Wüstenberg, Heinze, Peters, & Jäncke, 2002; Thompson, Nuerk, Moeller, & Cohen Kadosh, 2013).

Block and puzzle play are good examples of both intrinsic-dynamic and extrinsic-static visual-spatial reasoning. The majority of the available research on block and puzzle play considers young children. Block play and talk about blocks, particularly in young children, have been identified as an important visual-spatial activity leading to more advanced visual-spatial ability (Dearing et al., 2012; Kersh, Casey, & Young, 2008). Puzzle play has also been found to be very important in building visual-spatial ability (Cannon, Levine, & Huttenlocher, 2007; Levine, Ratliff, Huttenlocher, & Cannon, 2012).

Methods

Participants

This research took place in an interdisciplinary seventh grade class in a large urban setting. Participants included the classroom teacher (lead author) and 22 students (14 females, 8 males). The 3D printer was purchased for the classroom (by the second author) and was present in the classroom from the onset of the school year. The students and the classroom teacher did not have any direct prior exposure to 3D printing. The research was part of a broader study exploring the development of visual-spatial reasoning in children.

Data Sources and Procedures

The first six weeks of school centered on learning how to use the 3D printer and the related software. To construct the cube puzzle, first students individually created a physical model using interlocking 2 cm by 2 cm by 2 cm linking cubes (see Figure 2). Then, working in small groups, students selected one of the models created by one of the group members to print a scaled down version of that model. To increase the cognitive challenge of the task, the side lengths of the individual cubes in the scaled version could either be 1 cm or 1.5 cm. In pairs, students within the group developed the renderings to build their segment of the model. The final step involved joining all the segments to recreate a scaled version of the physical cube model. Data sources included teacher generated reflections as well as reflections captured in student blogs.

Results and Discussion

All the groups were successful in printing their scaled model although some of the models did not fit perfectly together. There were four main findings. First, developing the renderings proved to be the most challenging for students, particularly engaging in visual rotations to make the pieces fit correctly. An understanding of geometry was central to the process, as also reported by others using

3D printing (Buehler et al., 2016). This is reflected in this student blog:

> Our piece we had to design was one that had 5 cubes on the bottom and 1 cube on top. It was very easy to construct the bottom but it took a little more trial and error to do the one piece on the top because we had to figure out how to put the cube in the air and make sure it wasn't floating.

Students had challenges visualizing how cubes could be stacked and then in the stacking of the cubes recognized the need for precision. Students problem-solved by duplicating cubes and by making better use of the visualization capabilities of the software which occurred as a result of questions emerging from manipulations with the physical model. For example, students would rotate their cube segments 90° in their hands and explore the tools necessary to make the same rotation on the screen so that the image and the model matched (see Figure 2).

Consequently, and second, the physical model played a very important role in developing the renderings and assisting with the visualization. Building models has been found to be helpful in supporting learning (Lazarowitz & Naim, 2013), and this was true in our study too. The model was a true partner to the software and allowed the students to calibrate the rotations that were occurring with the models in their hands with the software. Knowledge of transformational geometry also proved to be very instrumental in that students relied on concepts such as flips, rotations, and translations to position the virtual blocks of their cube segments.

Third, the affordances of the 3D printer posed additional visual-spatial challenges in that mental rotations were again required by students from those used in the renderings and in the model for a more efficient print (e.g., laying the piece flat rather than standing as it may have been in the actual puzzle). Finally, scaling proved to be equally challenging. Measurements needed to be precise and this was made abundantly evident through the rendering process – particularly for those students that opted to maximize the volume of their object versus those that chose a more efficient unit of measurement (i.e., side lengths of 1 cm in length). We see in this quote from a student's blogs that the tensions associated with choosing the best measurements was present but the optimal options were not perhaps initially:

> Decided on creating a rather small puzzle cube (10 mm by 10 mm by 10 mm) unlike some other groups who did 15 mm by 15 mm by 15 mm and I am excited to see if it works and if not then to see what went wrong. Also I wonder which measurement is more appropriate and whether the larger one will be much easier to use.

Conclusions

This design engineering task provided students with opportunities to develop visual-spatial reasoning – particularly around mental rotations. The need for physical models was an important component of the task as was the 3D printing. The geometry and the measurement required for the task was a challenge in that a fair amount of geometric knowledge was necessary to do the task but this can be learned while engaged in the design process. The possible affordances associated with the use of 3D printers and visual-spatial learning cannot be under estimated. This field of inquiry is truly at its infancy – particularly studies where students are responsible for the printing rather than teachers (cf. Wendt & Wendt, 2015). In our own jurisdiction and likely across others, teachers can be found who are using 3D printers in their classes to inspire learning and numerous blogs are available from teachers using this technology; however, very little systematic research exists and more understanding about effective pedagogy is needed to expand use to the potentially more reluctant or novice teacher. The 3D printing component and the required rendering was crucial for the design engineering process in this project. It allowed for a robust exploration of different types of visual-spatial reasoning, as defined by Uttal et al. (2013). Like others have reported, the entire design engineering process was made more impactful because of the 3D printing (Murray, 2013). Our view is that this project would not have inspired as many opportunities for visual-spatial reasoning if the end-game did not include 3D printing. Knowing how teachers can include design engineering with 3D printing in their classrooms will be an important future direction for research. Understanding the cognitive affordances of this approach for visual spatial reasoning is also a necessary future direction for research.

Acknowledgments

This research was funded by a Natural Sciences and Engineering Research Council (NSERC) to the second author.

CAN I MEASURE THAT WITH MY PHONE? MOBILE MEASUREMENT APPS FOR LONG LENGTHS

Hochieh Lin

lin.2532@osu.edu

Theodore Chao
The Ohio State University
chao.160@osu.edu

This study investigates how three 4th-grade children apply their prior knowledge of measurement when using mobile measurement apps to measure real objects that are difficult to estimate. We show mobile measurement apps as a potential learning tool to explore concepts of length and measurement and further improve children's estimation of length measurement.

Traditional mathematics instruction in measurement usually emphasizes "the procedures of measuring rather than the concepts underlying them" (Stephan & Clement, p.3, 2003). This procedural focus does little to help children conceptualize length and measurement, since numerous studies have found that focusing on concepts rather than procedure connects much better with the way children think about measurement (e.g., Clements & Sarama, 2009). Yet, despite this research, the teaching and learning of length measurement and estimation continues to be problematic and procedural (Joram, Subrahmanyam, and Gelman, 1998). Therefore, we explored innovative ways for children to conceptualize length measurement and estimation beyond learning measurement procedures, utilizing mobile app technology as a tool for interacting with and measuring the real world.

The four sessions in this study involved three 4th-graders exploring mobile apps in a teaching experiment facilitated by the first author, a 10-year veteran elementary mathematics and science teacher. The three participants were enrolled in a gifted program in their elementary school and historically performed well in mathematics. This mathematical background meant they had prior knowledge or at least exposure to concepts involving length and measurement. In the first two sessions, the children explored length and measurement without the use of mobile technology. In the last two sessions, the children explored more challenging length and measurement tasks with access to three mobile measurement apps. While the first three sessions lasted 30 minutes, the fourth session which focused heavily on children's individual exploration, lasted an hour.

Our results show that the mobile apps allowed children to measure objects they previously had difficulty estimating. The children also exhibited their conceptual knowledge and misunderstandings of length and measurement during the tasks. This exploratory study leads us towards larger research investigating the specific use of mobile apps in teaching and learning measurement.

EXAMINING HOW GRADUATE STUDENTS WITH DIFFERENT SCHOOL MATH EXPERIENCES INTERACT WITH *ROLLY'S ADVENTURE*

Yan Tian
University at Albany-SUNY
ytian3@albany.edu

Keywords: Technology, Number Concepts and Operations, Cognition

In the most recent National Educational Technology Plan, the U.S. Department of Education (2017) encourages incorporating games in education and more educational research with digital games. In this preliminary study, I investigated how graduate students with different views of math and school math learning experiences interacted with *Rolly's Adventure*, a videogame designed to support fractional knowledge and reversible multiplicative reasoning (Williams-Pierce, 2016). The study adopts von Glaserfeld's (1995) constructivist view that learning is the process of constructing and adapting one's mental models or schemes while interacting with one's environment. Thus, knowledge is situated in the activity and the context in which learning takes place (Brown, Collins & Duguid, 1989). Meanwhile, learning involves grasping specific subject matter as well as developing attitudes, dispositions and understanding of cultural practices (Greeno, 2006).

As a multiple-case study, there were three graduate student participants. Data sources included pre- and post-game interviews and game playing (audio and screen recordings). First I open-coded data with content analysis (Hsieh & Shannon, 2005). After organizing these codes based on constructs from previous literature, I coordinated and refined codes across three cases to make clearer comparisons.

This study's main findings are as follows. First, each participant's view of math and school math experiences corresponded to his/her gameplay patterns (e.g., performance- vs. understanding-oriented). Second, participants with advanced fractional understanding and adequate reversible multiplicative reasoning (RMR, Hackenberg, 2010) developed more sophisticated ideas about the fractional problems in *Rolly's Adventure*. More interestingly, Jamie, a low math performer at school, demonstrated insufficient RMR when solving a word problem but successfully made sense of and solved the problems in the videogame. The findings imply that *Rolly's Adventure* has potential in supporting learners to reason about reversible multiplicative relationships and to demonstrate RMR in action.

Introduction

The proposed poster presentation is situated within a larger project, a four-year NSF/DRK-12 research grant focused on developing middle-school mathematics teachers' formative assessment strategies. A central component of the project involves design and delivery of a multi-year professional development (PD) program for participating teachers. In Year 3 of the project, an online platform was developed to provide a flexible, accessible environment for delivery of synchronous PD and formative assessment resources. Improvement Science was adopted as a framework to guide implementation, testing, and revision of the platform to address the emerging needs of participating teachers as well as the broader research goals of the project. This poster presents a summary key design and implementation issues addressed.

Design Framework

Improvement Science (IS) produces knowledge that informs the use of practice in real, practical, and varied settings (Bryk et. al., 2016). It utilizes tools of disciplined inquiry that are user- and implementation- focused. Most importantly, it provides a nimble cycle of design-implement-test-revise that privileges the realities of education settings. Several main principles drive IS: the first set focuses on problem definition, analysis, and specification; the next set focuses on iterative prototyping and testing; the last principle focuses on organizing networks to drive sustainability.

Results

Challenges associated with implementation of the platform design included teacher responsiveness and attrition, logistical issues, and interface interactions in the online environment. Specifically, Table 1 presents a few of the curricular, pedagogical, and technological problems we will unpack along with the specific prototypes developed, evidence collected, and revisions implemented to address them. We also discuss lessons learned using an IS approach to design and the overall impact of the approach on outcomes related to teachers' formative assessment practices.

Table 1: Problems, Data, and Adjustments of the Online PD

Issue	Evidence	Revision
Reflection fatigue	Contribution patterns	Reduce session length
Reflection takes longer than anticipated	Unable to complete full cycle in time allotted	Assign as homework; re-tool as multi-year cycles of PD
Responsive and concurrent display of teacher comments	Teacher feedback; Facilitator feedback	Streamlining the submission and display process
Inequitable participation and communication	Teacher feedback	Scaffold online interactions with in-person opportunities

Keywords: Learning Theory, Technology, Instructional Activities and Practices, Elementary School Education

Theoretical Perspective

While existing research has identified different approaches to the development of digital educational games for mathematics teaching and learning, still unexplored are the ways in which design teams' priorities and views of learning influence the design process. As with the development of curricula, digital games involve constructing opportunities to learn based on the views of mathematics learning of the designers. Biddlecomb (1994) described the central importance of views of mathematics learning and game operations as influenced by existing models of children's mathematics. In our research, we draw from Biddlecomb's view that children's ways of operating must inform the operations allowed in the game environment to argue that design teams should begin by identifying views of learning and development.

Research Questions and Design

Using grounded theory (Strauss & Corbin, 1994) to investigate archived data from the project, we asked: How does a multidisciplinary research team with different epistemologies work together to design a digital educational game/program to support children's mathematics learning? Specifically, how do team-members' ways of knowing and views of mathematics emerge in their work and affect the final product?

Data Collection Techniques and Analysis

We used constant comparative analysis (Strauss & Corbin, 1994) to analyze team meeting notes with initial categories of aesthetic, children's mathematical thinking, and technology. Our disciplines included technology, programming, graphic design, special education, mathematics education, early childhood education, and English education.

Summary of Findings

Preliminary findings indicate that, although members of the team seldom made their models of how children learn mathematics explicit, team members did operate with explicit models (Biddlecomb, 1994). As we complete further analysis, we will generate theory on how these explicit models influenced the development of the digital educational game/program.

MATHEMATICS COMPUTER-ASSISTED INSTRUCTIONS FOR STUDENTS WITH LEARNING DIFFICULTIES: A SYSTEMIC REVIEW

Soo Jung Kim
Purdue University
kim2358@purdue.edu

Yan Ping Xin
Purdue University
yxin@purdue.edu

Students with or at risk for learning disabilities in mathematics (LDM) experience considerable difficulties learning mathematics. According to Author et al. (2016), the gap between students with disabilities and their same-age peers in mathematics seems becoming wider, rather than closing. To close this gap, computer-assisted instruction (CAI) has been widely used in practice providing additional supports for students with LDM. However, the latest meta-study of Seo and Bryant (2009) demonstrated that CAI did not show conclusive effectiveness on improving the mathematic achievement of students with LDM. Therefore, further investigation into the effects on CAI is necessary. The purpose of this study is to conduct a systemic review and analysis of empirical research where CAI is used to facilitate mathematics learning of elementary and secondary students with LDM.

Method

Research articles published between 2008 and 2016 were identified from electronic databases, major journals, and ancestral searches. We set the inclusion criteria as follows: 1) studies involved students with LDM in elementary or secondary schools, 2) studies focused on CAI as their independent variable, 3) studies considered the mathematics achievement as their dependent variable, 4) studies applied group comparison or single-case design, 5) peer-reviewed studies conducted in the US. Giving above selection criteria, we identified 13 articles. Following variables were coded: 1) participants, 2) research design, 3) setting and duration, 4) intervention agent, 5) the nature of the CAI program, 6) the nature of tasks, 7) instructional strategies, 8) software developer, 9) targeted math concept/skills, 9) dependent measure used, 10) social validity.

Results and Discussion

In the 12 studies, CAIs were implemented for an average 16.9 sessions with a total of 698 of students. The majority (67%) of the participants were at risk for learning disability. Five studies implemented the researcher-developed CAI and seven studies used commercial software. Six of the CAIs were designed on the basis of learning theories. The majority of the studies targeted basic operation and problem-solving skill. The results of these studies indicated that CAI was effective with varying degree in promoting mathematics performance for students with LDM. In addition, the results from group comparison studies indicate that there was no statistically significant difference between outcomes of CAI and teacher-delivered instruction. Overall findings from this systemic review suggest that CAI is promising in improving the mathematics performance of students with LDM. For future research and practice, it is important to design and implement CAI programs that taking into consideration of the characteristics of students with LDM.

Representations often refer to the information in material form on paper or the computer screen such as written text, graphical displays, tables, equations, diagrams, maps, and charts. Representation can also refer to a learner's internal thought. In our work, we use the term *inscription* as "a potential change in route" where meanings of external representations of thinking are developed in social settings. Research shows that student capacities to represent knowledge and make sense of their thinking is efficiently developed in social settings where meanings are publicly shared and negotiated among students (e.g. Medina & Suthers, 2013).

As part of a four-year project we are developing and studying digital inscriptional resources that will allow students new ways to work collaboratively to develop mathematical thinking. Building on the intersection of the literature in mathematics educational technology (e.g. calculators, dynamic geometry software, computer algebra systems) and information communication technology (e.g. collaborative whiteboards, real-time editing and sharing), the digital inscriptional resources support students to collaboratively create representations of their mathematics thinking, incorporate ideas from other students, and share their work with the class.

Our research is guided by the following questions: (1) What features of the digital learning environment help students to produce and refine inscriptions of their thinking as they explore mathematics problems? and (2) How does the construction, manipulation, and interpretation of inscriptions change over time? An iterative design research process incorporates multiple phases of development, testing and revision, to study student use of the digital learning space and related inscriptional resources. Data includes classroom observations and artifacts, student and teacher interviews and surveys, student assessment data, and analytics from the digital resources. The project team embraces a goal of working at the crossroads of research and practice, progressively testing and refining theories over multiple phases of design and enactment.

Our findings will inform the work in collaborative mathematics education technology by connecting design principles, classroom enactment of the developed resources, and student outcomes. The project will report on how evidence of student thinking is made visible through the use of digital inscriptional resources and the ways student inscriptions are documented, discussed, and manipulated in collaborative settings.

USING ELECTRONIC JOURNALS WITH PRESERVICE TEACHERS TO INFORM MATHEMATICS TEACHER EDUCATOR INSTRUCTIONAL DECISIONS

Heather Gallivan
University of Northern Iowa
heather.gallivan@uni.edu

Keywords: Teacher Education-Preservice, Technology, Instructional Activities and Practices

The benefits of using journal writing to both teachers and students in mathematics class are numerous. For teachers, they can use journals to assess their students' progress in a course. They can also allow teachers to reflect upon and improve their teaching as well as provide better individualized instruction for their students (Borasi & Rose, 1989). However, providing feedback on journals can be a very time consuming process for teachers (Baxter et al., 2005). Thus, teachers need to carefully determine how often to collect the journals and how quickly they can feasibly provide helpful feedback. New technology is emerging that has the potential to address these issues with journal writing in mathematics. In particular, electronic journals where students can write by hand and upload their journal pages to the cloud (e.g. Google Drive) are making their way to the marketplace.

Purpose and Methods

While there have been many studies on the impact of journal writing in mathematics classrooms, there are few, if any, studies that explore the use of electronic journals with preservice teachers. The goal of this exploratory project is to determine the impact on a mathematics teacher educator's ability to adjust her instruction to fit the needs of her students as a result of better and more consistent access to her students' journals. Each student enrolled in a mathematical problem solving course for elementary preservice teachers received an electronic journal. They were required to use this journal every class day throughout one semester to record their mathematical thinking as they worked on high-level mathematics tasks. At the end of the semester, the preservice teachers also completed an open-ended survey regarding their experience using these journals in the course. Additionally, the instructor of the course kept a journal to reflect on the benefits and challenges of using these journals. Qualitative study methodology was employed for this study. Data from all data sources were analyzed using open coding to look for patterns and themes in the responses.

Results and Discussion

The results of this study suggest that although it was initially a struggle to find a productive method of providing feedback to the preservice teachers on their electronic journals, there were benefits to having students use them. For instance, the instructor was able to easily access the students' journal entries when planning for whole class discussions on the in-progress problems they were trying to solve. The results also suggest that there may need to be more accountability measures to ensure students read the instructor feedback. More research needs to be done regarding how electronic journals can be used to the benefit of teachers' instructional decisions.

The training courses for math teachers have the purpose of providing them with knowledge that translates into changes in the classroom to improve the learning of their students. However, changes in how teachers organize their students' learning do not occur immediately. The complexity of how the diverse types of teacher knowledge are interconnected (Pena-Morales & Pelton, 2016) explains why a new knowledge requires time and intentionality to insert it into the educational system. To the extent that the knowledge required by the teacher involves several elements there are more adaptations in the organization of the learning activities that the teacher should perform. In this report, we describe the transformations that teachers introduce in a kind of mathematical tasks that involve the work of modeling with technology. Training courses for mathematics teachers should involve a more active participation, courses with technology should not include mainly technical questions of the use of hardware, software or applications, but in relation to the potential of mathematical learning that can be get. For the purposes of this research, a teacher training workshop was designed with the knowledge of modeling integration, graphing and technology (Suárez, 2014), consisting of four elements: 1) reflection, 2) mathematical work, 3) use of technology and 4) creating new learning situations. The question of research is: Which of these four elements the teacher adopts better? The workshop was designed with the purpose of working mathematical situations of the movement, analyzed with graphics and technological tools to generate a teacher reflection on the nature of school modeling in high school.

The workshop had four moments: (1) teachers reflected on the modeling and use of technology; (2) in a second moment they were presented with a mathematical modeling activity that required a graphical (pencil and paper) response, 3) the third time integrated modeling, plotting and technology, a tutorial Tracker was presented as an aid to generate and analyze graphs of motion and 4) were asked that they propose a new mathematical task capable of integrating learning experience, with the second and third moments. Among the main conclusions is seen that teachers have an open, reasoned and immediate attitude to reflect about the integration, however, in the sections of real integration in the resolution of tasks with technology and implementation of new learning situations, participation is lower and longer response times.

With the growing number of jobs within STEM fields that require technology and abstract thinking, it is beneficial for mathematics and CS education to consider computational thinking as a basic and necessary skill. Computational thinking, a concept typically reserved for undergraduates in CS, involves an iterative design and problem solving process that engages learners in multiple levels of abstraction (Guzdial, 2008; Wing, 2006). Finite-State-Machines (FSM) are a relatively simple model that can be used to represent and specify technology programs by breaking down computer behavior into a series of states, namely actions and reactions. Our prior research in embodied cognition and mathematics education has shown that using games that use FSM and wearable technology in the classroom can improve performance and motivation for math (Arroyo et. al, 2011; Arroyo et. al, 2016). Teaching students about FSM within a game-based mathematics activity may encourage students to move past surface-level features of technology, engage in a higher level of abstraction, and be a pedagogically-sound method to promote computational thinking and higher-level mathematics.

In this study, we explore whether the act of playing and creating games, explained through a FSM framework, could serve as a vehicle to teach computational and mathematical thinking. In the play activity, students played Estimate It!, an active math game that uses cell phones to set up a scavenger hunt for students to practice estimating the size of objects. In the create activity, students created multi-player math games for 4th-6th grade-level students that involved physical activity. In the adapt activity, students received an introductory lesson on the state-based technology behind Estimate It!, and then were asked to redesign their games to fit a FSM framework and to draw a state-based diagram. We were interested in the ordering effects of whether students played or created the games first. In this poster, we will present examples of the students' games, describe how order affected the nature of discourse and representations of the students' games, and explain how this FSM and games method provides insight into methods for teaching computational thinking in the mathematics classroom.

U.S. mathematics teachers face pressures to keep up with pacing guides and prepare students for standardized tests (Roach, 2014). At the same time, they are called upon to engage students in innovative exploratory activities that incorporate new technologies (National Governors Association Center for Best Practices & Council of Chief State School Officers, 2010; National Council of Teachers of Mathematics, 2014). Amidst these competing priorities, we investigated how mathematics teachers facilitated play in lessons with interactive simulations (sims).

We worked with 4 middle-school mathematics teachers at a public school in the Southeastern United States. Each teacher had at least 7 years of experience but was new to using PhET sims (phet.colorado.edu). Previous research found advantages to including an initial play period in sim-based lessons, during which students explore a sim prior to more structured activities (Podolefsky, Rehn, & Perkins, 2013; Moore, Herzog, & Perkins, 2013). Play offers students time to freely explore the sim, manipulate controls, ask questions, discover relationships, and generate interest in the topic (Podolefsky et al., 2013). Given this recommendation, the teachers planned and taught lessons that included play prior to more structured activities.

We conceptualize play in sim lessons in terms of Sicart's (2014) ecological theory of play—as contextual, carnivalesque, appropriative, disruptive, creative, personal, and autotelic. Some of these characteristics are conducive to learning in a classroom environment, whereas others may not be. Our analysis of 15 mathematics lessons involving play led to the identification of 4 characteristics that distinguish the play phases of these lessons. Based on combinations of these characteristics, we identified 3 profiles of play, which lie at different points along a continuum of priorities from foregrounding students' ideas to keeping pace. In the profile *A Disciplined March*, play serves the purpose of familiarizing students with the sim. In the profile *Wandering Exploration*, play serves the additional purpose that students make and share discoveries. In *Hiking with a Guide*, students make and share relevant discoveries. We discuss the implications associated with each profile of the play phase, and we begin to develop a theory that frames teaching with play as a matter of balancing divergent and convergent modes of activity.

USING DYNAMIC TOYS TO EXPLORE CONTINUOUS THINKING IN PROPORTIONAL SITUATIONS

Chandra Hawley Orrill
University of Massachusetts at Dartmouth
corrill@umass.edu

James P. Burke
University of Massachusetts at Dartmouth
jburke@umassd.edu

Research has shown that teachers and students struggle to conceive of covariational relationships in continuous ways (e.g., Thompson & Carlson, 2017). That is, many people conceive of the relationship in chunks, wherein a relationship is conceived of as a set of instances in time that can be, for example, plotted on a coordinate plane then connected together by drawing a line between them. While this is certainly a practical way to construct graphs, it becomes problematic when trying to understand continuous variation and other concepts relevant in higher-level mathematics.

In our own prior work on proportional reasoning, we tried to address this "chunky" thinking (Thompson & Carlson, 2017) through the use of sketches made in Geometers' SketchPad that allowed the user to perceive the dilation of sketches of animals as continuous movement. In this environment, we asked practicing middle grades teachers whether the relationship between two sketches is always there or whether it is only there when the slider stops and the images are a fixed size. We noted that some teachers believed that two images could only be similar when they were both frozen in time and space whereas other teachers understood the continuous nature of the relationship.

Building from these foundations, we are now developing a virtual "toy box" that is intended to engage middle school teachers in examining the continuity of proportional relationships by engaging them with toys that allow them to play (Bruner, 1972) with the ideas of continuity in proportional situations. For example, one of our toys examines the growth patterns of an alien plant designed to collect and hold water while another toy is a picture dragger that allows resizing of images in both similar and nonsimilar ways. These tools move participants toward continuous thinking when combined with tasks that challenge teachers to think about whether situations stay similar/proportional as they change or only at particular points.

In this poster, we will bring examples of our toys (both images and an iPad with the toys actively running) and the ways in which they promote continuous reasoning in proportional situations. We will explain our goals for this research and projected outcomes from our pilot work to date.

VIRTUAL REALITY IN THE MATHEMATICS EDUCATION OF CHILDREN WITH CEREBRAL PALSY

Brianna Kurtz
University of Central Florida
Brianna.k@knights.ucf.edu

Megan Nickels
University of Central Florida
Megan.Nickels@ucf.edu

Keywords: Technology, Equity and Diversity, Measurement

Affecting 1 in every 323 children, cerebral palsy (CP) is the most common motor disability in the world (Christensen et al, 2014). Few studies have regarded the mathematical learning of children with CP. These studies have uncovered severe disparities in students' problem-solving skills when compared to typically developing children (Jenks et al, 2012). Measurement is a special challenge for children with CP due to the traditional use of manipulatives for tactile reasoning. This study investigates: What effects do immersive virtual reality have on mathematical learning, physiological health, and psychosocial well-being for children with CP? What kinds of unit schemes and reasoning do children exhibit as they encounter measuring tasks in an immersive virtual reality setting? How do children's strategies compare to paper/pencil tasks and known unit measurement trajectories?

Nickels and Cullen's (2017) analytical model of Brousseau's (1997) Theory of Didactical Situations of Mathematics and Sarama & Clement's measurement trajectories (2009) are used as theoretical frames for the design and analysis of the study. We report on a single case study participating in six weeks of task based interviews utilizing previously validated unit measurement tasks (e.g., Barrett et al., 2011). Data collected included: (1) baseline measurement knowledge; (2) VR use and measurement knowledge; and (3) socio-emotional and physiological well-being. As this is an ongoing study, results are preliminary at this time. A positive correlation was found with the use of VR with the child's socio-emotional and physiological well-being. Data regarding the student's measurement content knowledge after using the VR system is still being analyzed.

ANALYZING CLAIMS ABOUT COGNITIVE DEMAND AND STUDENT LEARNING

Samuel Otten
University of Missouri
ottensa@missouri.edu

Zandra de Araujo
University of Missouri
dearaujoz@missouri.edu

Corey Webel
University of Missouri
webelcm@missouri.edu

A commonly accepted claim in mathematics education is that there is a relationship between the cognitive demand of mathematical task enactments and students' subsequent learning. One study often cited to support this claim is Stein and Lane (1996), and in 44% of those citations, Stein and Lane (1996) is the sole reference provided. Citation analysis reveals that many of these claims go beyond the warrants provided by the Stein and Lane study, either by granting more confidence in the relationship than the study design allows or by phrasing the claim causally. A few other studies are occasionally cited in conjunction with Stein and Lane (1996), but there remains a need for replication studies to provide better empirical support for claims about cognitive demand and student learning and to refine our shared understanding.

Keywords: Cognition, Instructional Activities and Practices, Research Methods

Replication studies are rarer in education research than in other fields, leading Makel and Plucker (2014) to call for more replications because such studies can both identify and remedy methodological biases and can be instrumental in buttressing robust findings or clarifying inconsistent findings. In these ways, replications can play a role in the field's systematic accumulation of knowledge (National Research Council, 2002). An area ripe for replication would be a testable, widely-held belief that is resting on a relatively inadequate empirical foundation. One belief seemingly shared by most scholars in mathematics education is that the cognitive demand of mathematical tasks and task enactments (Stein, Grover, & Henningsen, 1996) is important with respect to student learning outcomes. It may be that experiences with cognitively demanding tasks lead to positive learning outcomes or it may be that having students experience cognitively demanding tasks is an end itself. The latter is a philosophical position based on values, whereas the former is a testable position that currently rests on some supporting evidence, but what is the extent of that evidence? In our own past work related to cognitive demand (e.g., de Araujo, 2012; Otten & Soria, 2014), we noticed an extensive literature base on the nature of cognitive demand (Doyle, 1983; Stein, Smith, Henningsen, & Silver, 2009) and factors influencing cognitive demand throughout mathematical task implementations (Jackson, Garrison, Wilson, Gibbons, & Shahan, 2013; Wilhelm, 2014), but a weaker empirical foundation for the direct link between cognitive demand and student learning.

The hypothesis motivating this study was that a single reference—Stein and Lane (1996)—constituted a large portion of the warrants for claims in the mathematics education literature about the link between cognitive demand and learning. If this hypothesis were true, then it would become imperative to critically analyze the research design, evidence, and claims made in Stein and Lane (1996) and to consider possibilities of replication. We examined the claims for which Stein and Lane (1996) was included as a citation and we identified other references, if they existed, that were also cited for those same claims. In the following sections, we briefly summarize the Stein and Lane (1996) study, describe our method for compiling and analyzing citations to Stein and Lane (1996), and then share our key results.

Summary of Stein and Lane (1996)

Stein and Lane (1996) stems from a project well known in mathematics education—Quantitative Understanding: Amplifying Student Achievement and Reasoning (QUASAR). QUASAR involved a university partnership with six urban middle schools with the overall goals of promoting reform-oriented mathematics instruction and investigating the feasibility of such instruction in schools with a history of poor mathematics performance (see Silver & Stein, 1996, for an overview). Within that context, Stein and Lane (1996) sought to “present evidence regarding the degree to which the presence of reform features of instruction are linked to increases in student understanding of mathematics” (p. 51). Their study focused on 4 of the 6 middle schools from the QUASAR project over a three-year period. Data consisted of narrative summary field notes and video recordings of three three-day observation cycles in three teachers’ classrooms in each school each year, a classroom observation instrument completed based on the field notes and video recordings, and Fall and Spring administrations of a project-developed assessment instrument (Lane, 1993). Mathematical tasks were identified and of the 620 main tasks, a stratified random sample of 144 was drawn and the task set-up and task implementation of these 144 tasks were coded for cognitive demand. Levels of cognitive demand were collapsed to 2 (high and low). A 25% sample of the 144 tasks was double coded with 79% agreement.

The assessment instrument consisted of 36 open-ended tasks distributed into four forms (9 questions per form) and a 5-point scoring rubric (0–4) for each task. Analysis focused on 11 of the tasks and used not the scores themselves but “the average percentage of student responses across tasks that were scored at the two most proficient score levels (3 or 4)” (p. 68) and how this average percentage shifted between Fall Year 1 and Spring Year 3.

To generate their findings, Stein and Lane rank ordered the four schools based on their gains in percentage of students at the top two levels of proficiency and then focused on Site A, which had gained the most (36%), and Site D, which had gained the least (17%). They compared these learning gain rankings with the school profile for task enactments and noted the following:

> Site D’s profile can be seen as embodying a more conventional mathematics program in which many or most tasks lent themselves to being solved with a single strategy, using only one representation (usually symbolic), and without much explanation and/or discussion. Site A’s profile, on the other hand, suggests a well-functioning reform program that is successfully utilizing tasks that invite and support students’ use of multiple solution strategies and multiple representations, along with student discussion of their work. (p. 71)

In other words, the tasks in Site D classrooms were often set-up and implemented at low levels of cognitive demand whereas tasks in Site A classrooms were often set-up and implemented at high levels, and Site D had the lowest proficiency gains whereas Site A had the highest.

The fact that the sites conformed to a positive relationship between cognitive demand and gain scores seems, on the surface, to be compelling. The number of sites, however, is quite low for making even correlational claims about the relationship between task features and student achievement. Moreover, the use of only 11 items to measure learning over a three-year period gives pause. In addition, sites were only compared in relation to each other, not to a standardized score, raising questions about the size of the differences between the outcomes of the different sites. The study also did not account for differences among teachers within the same site. The authors acknowledged “the possibility that the findings of this study may partially reflect differences in school-level variables in addition to the documented differences in instructional practices” (p. 75), but in other instances the authors shifted from discussing the results in terms of correlations to suggesting causation. For example, the authors drew the following conclusions:

> [S]tudents appear to **benefit more from** inconsistently implemented tasks that began with the encouragement to use multiple solution strategies, multiple connected representations, and explanations, than they do from tasks that—from the start—required only single solution

strategies, single representations, and little or no mathematical communication (p. 74, emphasis added)

The authors appropriately hedged this statement with the word "appear" but the language in bold suggests not just that Site A used more high demand tasks and performed better, but that the use of high demand tasks was a primary reason for higher student achievement. This claim seems to extend beyond the actual warrants of the study given its limitations. Yet, as we show below, the hedged claims appear to have been accepted widely by several researchers and national organizations alike, frequently in an unhedged fashion. Although Stein and Lane recommended that a replication of their study be carried out, to our knowledge this has not occurred except a substantially modified replication (Otten, 2012) involving 12 middle school classrooms in which cognitive demand was decidedly not correlated with measured student learning.

We wish to emphasize that by pointing out some of the limitations of the study, we do not mean to criticize the study itself but rather to raise caution about the claims that can be made—by Stein, Lane, or others—based on this single study's evidence. These cautions led us to investigate the claims that have been made based on Stein and Lane's (1996) work.

Method

Compiling Citations of Stein and Lane (1996)

Similar to Leatham and Winiecke (2014), we used the "cited by" tool on Google Scholar to obtain a list of articles in which Stein and Lane (1996) was cited. This initial search yielded 298 sources. Because we were interested in how the field of mathematics education specifically draws upon this reference, we retained only those articles that were published in mathematics education journals that received an A-grade in Toerner and Arzarello (2012, December) and also appeared as a top-five journal in the rankings compiled by Nivens and Otten (in press). These journals were *Educational Studies in Mathematics*, *Journal for Research in Mathematics Education*, *Mathematical Thinking and Learning*, *Journal of Mathematical Behavior*, *Journal of Mathematics Teacher Education*, and *ZDM – The International Journal of Mathematics Education*. This constraint yielded 26 articles. We then expanded our search beyond the Google Scholar results to include other forms of codified mathematics education literature—namely, the *Second Handbook of Research on Mathematics Teaching and Learning* (Lester, 2007) and two major policy documents from NCTM (2000, 2014). This additional search led to the identification of 4 handbook chapters and one policy document (NCTM, 2014) that cited Stein and Lane (1996). The 31 analyzed resources are marked with * in the reference list.

Analyzing Citations of Stein and Lane (1996)

The goal of our analysis was to understand the claims for which authors cited the Stein and Lane (1996) study. Within the 31 sources, we located the Stein and Lane (1996) citations in text, yielding 60 excerpts. We then used analytic memos to briefly describe the claim that was being supported by the Stein and Lane citation and met to identify the recurring themes and further refine them into codes. We came to a consensus on four codes (see Table 1), which we used to code all but one of the excerpts.

To gain a more nuanced understanding of the ways in which authors used the Stein and Lane reference, we subdivided the learning claim excerpts into two groups based on whether the claim was causal or non-causal. For example, the following excerpt was coded causal because the authors' state that tasks result in an increase in student understanding:

> As the research conducted by the QUASAR project indicates, when teachers choose tasks that require a high-level of cognitive demand, set them up and implement them in ways that maintain

> a high-level of cognitive demand, **the result is** an increase in student understanding and reasoning (Stein & Lane, 1996). (Arbaugh & Brown, 2005, p. 527, emphasis added)

In the same article, we coded an earlier reference as non-causal:

> The relationship between the types of tasks students engage in when learning mathematics and the mathematics they learn has been a subject of research for many years (see, for example, Hiebert & Wearne, 1993; Marx & Walsh, 1988; Stein & Lane, 1996). These research studies indicate that **a relationship exists** between the level of student thinking required by a mathematical task and the nature of students' understanding of mathematics. (Arbaugh & Brown, 2005, p. 505, emphasis added)

Table 1: Coding Scheme for Citations of Stein and Lane (1996)

Code Descriptions	Examples
Claim about a relationship between tasks and student learning [**learning claim**]	"There is evidence that solving a task of high cognitive demand or a cognitively demanding task (CDT) has a positive impact on students' conceptual understanding (Stein & Lane, 1996)." (Wilhelm, 2014, p. 637)
Claim that tasks (or task implementations) and learning have been studied [**study claim**]	"Research has focused on instructor questions across the K–16 spectrum and examined … the value of questions to student learning (Silver, 1996; Stein & Lane, 1996)." (Fukawa-Connelly, 2012, p. 332)
Claim about the levels of cognitive demand (but no connection to student learning) [**cognitive demand claim**]	"[Stein and Lane] use four categories: Memorization, Procedures without Connections, Procedures with Connections, and Doing Mathematics." (White & Mesa, 2014, p. 678)
Claim about a research method used [**method claim**]	"Of particular note are the procedures developed by Stein and Lane (1996) and Stein et al. (1996) for sampling and coding mathematical tasks and linking those findings to student outcomes." (Gearhart et al., 1999, p. 309)

We also distinguished four levels of attribution within the learning claims, from weak to strong—(1) the author(s) state that others have made claims about the relationship but the authors do not necessarily endorse the claims themselves, (2) the authors state the relationship with an explicit hedge (e.g., it is "suggested" or there is "possibly" a relationship) or as being found specifically in the context of the cited study, (3) the relationship is stated as something found in past studies and the authors explicitly or implicitly endorse the findings beyond the cited study's context, and (4) the relationship is stated as a generalized fact. We independently assigned each of the learning claim excerpts a level of attribution and met to discuss any differences until we came to a consensus.

Results

Table 2 contains frequencies for the codes described in Table 1. The most common claim for which Stein and Lane (1996) was used as support was the notion that the cognitive demand of mathematical tasks or task implementations is somehow related to student learning. More than three-quarters (77.4%) of the resources made claims of this sort, encompassing 60% of the total Stein and Lane citations analyzed. Of the 36 learning-claim citations of Stein and Lane (1996), 16 (44.4%) cited only Stein and Lane. This supports our hypothesis that Stein and Lane (1996) often stands alone as the empirical basis for such claims. A substantial minority (25%) of the claims (spanning 41.9% of the resources) did not involve student learning but instead focused solely on the construct of cognitive demand or task implementation. Six claims (10%) simply acknowledged that studies such as Stein and Lane (1996) existed and two (3.3%) referenced the type of study design that Stein and Lane employed. Overall, the citations of Stein and Lane (1996) predominantly involved the relationship between cognitive demand and student learning.

Table 2: Frequencies of Claims for which Stein and Lane (1996) was Cited

Code	Number of Excerpts	Number of Sources
Learning claims	36 (60.0%)	24 (77.4%)
Study claims	6 (10.0%)	6 (19.4%)
Cognitive demand claims	15 (25.0%)	13 (41.9%)
Method claims	2 (3.3%)	1 (3.2%)
Other	1 (1.7%)	1 (3.2%)

Of the 36 learning claims, 25 (69.4%) were correlational claims and 11 (30.6%) were causal. Although correlational claims are more justified than causal claims, few alluded to limitations of the Stein and Lane (1996) study. Furthermore, we found 11 citations that made causal claims. For example, Wilhelm (2014) stated, "There is evidence that solving a task of high cognitive demand or a cognitively demanding task (CDT) **has a positive impact** on students' conceptual understanding (Stein & Lane, 1996)" (p. 639, emphasis added).

Returning to the 36 learning claims overall, Table 3 summarizes their attribution level. More than half (58.3%) of the claims were Level 2—that is, rephrasings of Stein and Lane (1996) or hedged claims that stated what Stein and Lane (and possibly others) had found, without implying that it was a generalized result. For example, Otten and Soria (2014) wrote that "**Stein and Lane (1996) argued** that maintaining high cognitive demand has positive benefits with respect to student learning" (p. 816, emphasis added). Such instances are defensible because it is true that Stein and Lane argued for the benefits of high cognitive demand tasks.

Table 3: Attribution Levels for Learning Claims Supported by Stein and Lane (1996)

Attribution Level	Number of Excerpts	Number of Sources
1 (non-endorsed)	4 (11.1%)	4 (12.9%)
2 (hedged or context-specific)	17 (47.2%)	10 (32.3%)
3 (study-supported)	9 (25.0%)	8 (25.8%)
4 (general fact)	6 (16.7%)	5 (16.1%)

Yet, 41.7% of the learning claims went further by referring in some sense to a general relationship (level 3 or 4 attribution). For example, NCTM (2014) wrote about the relationship in a general fashion, as a matter of fact:

> Learning is greatest in classrooms where the tasks consistently encourage high-level student thinking and reasoning and least in classrooms where the tasks are routinely procedural in nature (Boaler & Staples, 2008; Hiebert & Wearne, 1993; Stein & Lane, 1996). (p. 17)

In this case, NCTM did not mention cognitive demand specifically but instead mentioned key features related to cognitive demand. They also cited studies in addition to Stein and Lane (1996) as support for their claim, but due to space limitations, we will not describe those studies here.

Discussion

Our citation analysis revealed that, across primary journals in our field, Stein and Lane (1996) was used to support a substantial number of claims about the link between cognitive demand of mathematical tasks and students' mathematical learning. Of those claims, 55.6% also involved additional references beyond Stein and Lane, but these were often policy or practitioner works rather than empirical research, perhaps aligning with a philosophical stance on cognitive demand but not an empirical one. The U.S. Department of Education and the National Science Foundation (2013) described six types of education research: foundational, exploratory, design and development, efficacy, effectiveness, and scale-up. Exploratory research "examines relationships among important constructs in education and learning to establish logical connections that may form the basis for future interventions or strategies to improve education outcomes" (p. 9). They indicate that exploratory "connections are usually correlational rather than causal" (p. 9). Certainly, the work of Stein and Lane (1996) and others (e.g., Hiebert and Wearne, 1993; Tarr et al., 2008) provides valuable information about a potential relationship between cognitive demand and student learning, but based on the evidence, we judge this work to be at no higher than the exploratory level. Replications are needed to test whether this relationship holds under various conditions (design and development research), and a significant amount of work would need to be done in order to make causal claims that could estimate the average impact of using high cognitive demand tasks. As Stein and Lane said in 1996, "the analyses discussed herein should be replicated" (p. 75), but rather than answering this call, the field has instead justified the belief that cognitively demanding tasks relate with (or cause) higher student learning outcomes by drawing on studies in the initial stages of the research progression.

Though we argue for the need of later-stage research studies to examine the link between cognitively demanding tasks and student learning, we do not dismiss the value of smaller-scale studies. We recognize the importance of a wide array of research; however, certain types of claims (e.g., factors that generally relate to measureable student outcomes) are best supported empirically by larger-scale study designs. If we include such claims in our work, we should be cognizant of the nature of the empirical support, and modify claims accordingly. And if claims are value-based rather than empirical, that is appropriate, but they should be written as such.

At the center of this article is a deep question about the relationship between cognitively demanding mathematical tasks and students' mathematical learning, broadly construed. Although we have critiqued some of the sources of evidence for claims made about this relationship, it is not our intention to cast doubt on the relationship itself. In fact, we believe it is highly likely that a positive relationship does exist. Yet, as a field, we should not be satisfied with shared beliefs based on insufficient evidence. Instead, we should strive for a body of evidence that would convince not only someone who is already predisposed to value cognitively demanding experiences but that would convince a skeptic. Therefore, we join Makel and Plucker (2014) and Warne (2014) in encouraging editors and agencies to open the door to replications, even—or perhaps especially—if it investigates claims that many already take to be true.

DETECTING MATH ANXIETY WITH A MIXTURE PARTIAL CREDIT MODEL

İbrahim Burak Ölmez
University of Georgia
i.burakolmez@hotmail.com

Allan S. Cohen
University of Georgia
acohen@uga.edu

The purpose of this study was to investigate a new methodology for detection of differences in middle grades students' math anxiety. A mixture partial credit model analysis revealed two distinct latent classes based on homogeneities in response patterns within each latent class. Students in Class 1 had less anxiety about apprehension of math lessons and use of mathematics in daily life, and more self-efficacy for mathematics than students in Class 2. Moreover, students in Class 1 were found to be more successful in mathematics, mostly like mathematics and mathematics teachers, and have better educated mothers in comparison to students in Class 2. However, gender, attending private or public schools, and education levels of fathers did not appear to differ between the classes. Capturing such fine-grained information extends recent advances in measuring math anxiety.

Keywords: Affect, Emotion, Beliefs, and Attitudes; Middle School Education, Research Methods

Identifying affective characteristics, such as anxiety and depression, that students experience in school settings and dealing with these characteristics are significant challenges for educators. Math anxiety, as one such characteristic, can be defined as "feelings of tension and anxiety that interfere with the manipulation of numbers and the solving of mathematical problems in a wide variety of ordinary life and academic situations" (Richardson & Suinn, 1972, p. 551).

Math anxiety has been shown to cause low academic performance (Ashcraft, 2002), reduced cognitive information-processing (Young, Wu, & Menon, 2012), and low perceptions of one's own mathematics abilities (Hembree, 1990). Low math abilities and low working memory, as well as non-supportive teachers can also be considered as important risk factors for the existence of math anxiety (Ashcraft, Krause, & Hopko, 2007). As a result, math anxiety can lead to avoidance of selecting career paths involving mathematics (Ashcraft & Moore, 2009). Previous research on mixture item response theory (IRT) models (e.g., Mislevy & Verhelst, 1990; Rost, 1990) has suggested that these models may be useful in detecting latent classes of individuals that differ along one or more cognitive or affective characteristics. Latent classes are statistically determined groupings of individuals who are homogeneous on such characteristics. Latent classes are latent because they are not directly observable as gender or ethnic groups. Previous research has demonstrated that latent classes in a population may differ on multiple kinds of characteristics including problem solving (Bolt, Cohen, & Wollack, 2001), test speededness (Cohen & Bolt, 2005), mathematical knowledge (Izsák, Jacobson, de Araujo, & Orrill, 2012), reading comprehension (Baghaei & Carstensen, 2013) and on personality traits such as depression (Hong & Min, 2007). In view of the negative, long-term impacts of math anxiety, it would be useful to distinguish latent classes of students who differ in their math anxiety. Such an identification of the latent classes would potentially help teachers improve the affective environment in school settings by applying specific interventions based on the needs of students in each latent class.

The purpose of this study was to investigate the utility of a mixture IRT methodology for detection of latent classes of middle grades students' math anxiety. The following research questions were addressed in this study:

1. Are there distinct latent classes of middle grades students that differ in their math anxiety?
2. What does the existence of these latent classes imply about the different response patterns of math anxiety that exist in this population?

3. What are the effects of manifest variables such as mathematics achievement, gender, liking mathematics, liking mathematics teachers, attending to private or public schools, education levels of mothers and fathers on latent class membership?

The present study makes at least two contributions. First, past research has attempted to identify students' math anxiety levels based on their total scores on a math anxiety scale. Results from the present study suggest that relying on use of total scores may miss important qualitative and quantitative differences in students' math anxiety and for understanding the structure of math anxiety. Second, past research has traditionally focused on explaining math anxiety by measuring its dimensions through exploratory and confirmatory factor analysis (e.g., Baloğlu & Zelhart, 2007; Kazelskis, 1998) and on the structural equation modeling of the relationship between math anxiety and variables such as mathematics achievement (e.g., Harari, Vukovic, & Bailey, 2013; Meece, Wigfield, & Eccles, 1990). However, to our knowledge, there has been no study yet reported in the literature on the detection of different latent classes of the math anxiety population by using relatively new psychometric models, such as mixture IRT models. Therefore, the present study demonstrates that a mixture IRT model can be useful for identifying characteristics of latent classes and for obtaining fine-grained information about particular strengths and weaknesses of middle grades students' math anxiety. Results of this study suggest one potentially useful route for mathematics education research in the future by providing a unique approach on identifying math anxious students in school settings.

Theoretical Framework

The theoretical framework for this study is based on the mixture Rasch model (MRM; Rost, 1990), which is a combination of a latent class model and a Rasch model. Unlike the standard Rasch model, which assumes that the same Rasch model applies to all examinees in the population, the MRM assumes that distinct latent classes exist in the population and that a different Rasch model applies to each. In the MRM, the relative difficulty of ordering the items is determined by a class membership parameter, and the number of items which the examinee is expected to answer or endorse is influenced by a continuous latent ability variable specific to the latent class. For each item, the MRM specifies a separate item difficulty for each latent class and for each examinee, a probability of being a member of a particular latent class.

In contrast to the dichotomous form of the MRM with scoring of an item in two categories such as agree or disagree, the polytomous form of the model can be used when items are scored with more than two categories such as strongly agree, agree, disagree, or strongly disagree, and this form is called a partial credit model (PCM; Masters, 1982). The probability of an answer for the mixture form of this model, the mixture partial credit model (MixPCM), can be written as

$$P(x_{ij}=k|\theta_{jg}) = \frac{\exp[\sum_{r=1}^{k}(\theta_{jg}-\delta_{irg})]}{\sum_{t=0}^{m_i}[\exp\sum_{r=1}^{t}(\theta_{jg}-\delta_{irg})]} \qquad (1)$$

where P is the probability that examinee j gives a response in category k of item i, θ_{jg} is a latent trait of examinee j, and δ_{irg} is a threshold parameter indicating the intersection of adjacent category response curves.

The MixPCM enables one to detect homogeneities in the ways examinees in different latent classes respond to items on a scale. As in equation (1), the relationship between the probability of selecting a response category and the latent trait varies across latent classes. The differences in response patterns to each item of a scale reflect homogeneities in characteristics of members of each latent class. In the MixPCM, the relative difficulty of the ordering of a particular response category among the ordered categories is determined by a class membership parameter, and the number of items answered. In this way, the MixPCM could assign two examinees with similar scores on a scale to different latent classes as a result of the differences in their response patterns.

Methods

Participants

The sample consisted of 244 Turkish 6th and 7th grade students attending public and private schools in Turkey. While the number of male and female students is similar (N=128 and N=116 for males and females, respectively), their range of age was around 13-14 years. A written consent form was obtained from one of the parents of each student before the study.

Instruments

The *Math Anxiety Scale* (MANX; Erol, 1989), is a four-point Likert type scale written in Turkish with options for each item ranging from "never" to "always." There were 45 items yielding minimum and maximum scores of 45 and 180, respectively. Higher scores demonstrate a higher math anxiety level. An internal consistency reliability estimate of .90 was obtained in this study. This was consistent with previous results of .92 on a sample of 754 middle school and high school students (Erktin, Dönmez, & Özel, 2006). Erktin et al. detected four factors, which were *test and evaluation anxiety*, *apprehension of math lessons*, *use of mathematics in daily life*, and *self-efficacy for mathematics*.

Demographic information was also obtained regarding students' mathematics grade at the end of the previous semester, their gender, whether or not they liked mathematics and mathematics teacher, the type of school they attended, and parents' education levels.

Data Analysis

The data were analyzed using the MixPCM as implemented in the computer program WINMIRA (von Davier, 2001). First, different numbers of latent classes were estimated in separate models to determine the relative fit of each model. That is, the MixPCM was estimated with one class, two classes, three classes, and four classes. Second, three indices for each model were compared to select the best fitting model: the Akaike's information criterion (AIC; Akaike, 1974), the Bayesian information criterion (BIC; Schwarz, 1978), and the consistent AIC (CAIC; Bozdogan, 1987). These indices are defined as AIC = $-2 \log L + 2p$; BIC = $-2 \log L + p (\log N)$, and CAIC = $-2 \log L + p (\log N + 1)$ where L is the maximum likelihood value, p is the number of estimated parameters, and N is the sample size. AIC, BIC, and CAIC all include penalty functions to modify the -2 log likelihood for either the number of parameters or the sample size or both. BIC has been found to more accurately select the best fitting model for dichotomous mixture IRT models (Li, Cohen, Kim, & Cho, 2009). In this study, the model with the smallest BIC value was selected as the best fitting model. Next, we analyzed the characteristics of each latent class by focusing on places where item locations differed significantly by latent class and places where members of one latent class considered items to be easier or harder to endorse than other latent classes. In addition, independent sample t-tests and chi-square tests were conducted to examine the relationships between manifest variables and latent class membership.

Results

Unidimensionality for the Scale

An exploratory factor analysis using maximum likelihood estimation as implemented in the SPSS 16.0 software (SPSS Inc., 2007) indicated eigenvalues of the first three factors as 14.1, 2.6, and 2.5.

The total variance explained by the first factor was 31.4%. Reckase (1979) reports that if the amount of variance explained by the first factor is 20% or more, then the scale can be considered as essentially unidimensional. Based on these results, the MANX was considered to be essentially unidimensional.

Number of Latent Classes

The information indices for model selection are given in Table 1. Minimum values for AIC, BIC, and CAIC of 12883.82, 13705.72, and 13978.72, respectively, all suggested a two-class solution in the data. Class 1 had 126 students (51.5%) and Class 2 had 118 students (48.5%).

Table 1: Model Fit Indices of the Mixture Rasch Model

Model	AIC	BIC	CAIC
One class	13757.02	14166.47	14302.47
Two classes	**12883.82**	**13705.72**	**13978.72**
Three classes	13091.45	14325.81	14735.81
Four classes	13335.07	14981.88	15528.88

Note. AIC = Akaike information criterion; BIC = Bayesian information criterion; CAIC = Consistent Akaike information criterion; the smallest information criterion index is bold.

Item thresholds indicate the point on the trait scale between each adjacent score category and indicate the relative ease of endorsing each item in each latent class. Item thresholds for each class are plotted in Figure 1 and Figure 2. Thresholds lower on the scale (e.g., -3, -2) indicate that examinees had a greater propensity to endorse that response category. Similarly, thresholds higher on the scale (e.g., 2, 3) indicate that examinees had a greater propensity to endorse a higher response category. Thresholds may differ by latent class, meaning that relative propensity for endorsing a category of an item is specific to each latent class. Because the MANX has four response categories ranging from "never" to "always," there are three possible thresholds that can be used to interpret the math anxiety level for each item as follows:

Categories: "never" "sometimes" "usually" "always"
Scores: (1) (2) (3) (4)
Thresholds: |--------T1--------|--------T2--------|--------T3--------|

For example, if an examinee's trait level is smaller than T1 (i.e., the first threshold), then the response is expected to be "never." If an examinee's trait level is smaller than T2 (i.e., the second threshold) but larger than T1, then the response is expected to be "sometimes."

Figure 1 and Figure 2 present plots of the item thresholds for Class 1 and Class 2. It is clear that students in Class 1 were more variable in endorsing or agreeing than students in Class 2, with thresholds ranging from -7.41 to 9.00. Students in Class 1 also had lower tendency to endorse items above threshold 1, and greater tendency to endorse items above threshold 3 than students in Class 2. On the other hand, students in Class 2 were more constrained in endorsing items with the range of thresholds from -2.186 to 2.249.

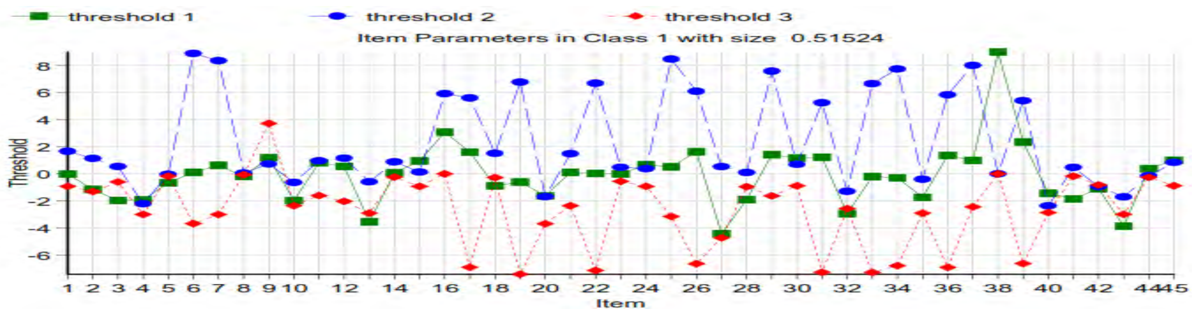

Figure 1. Item thresholds for class 1.

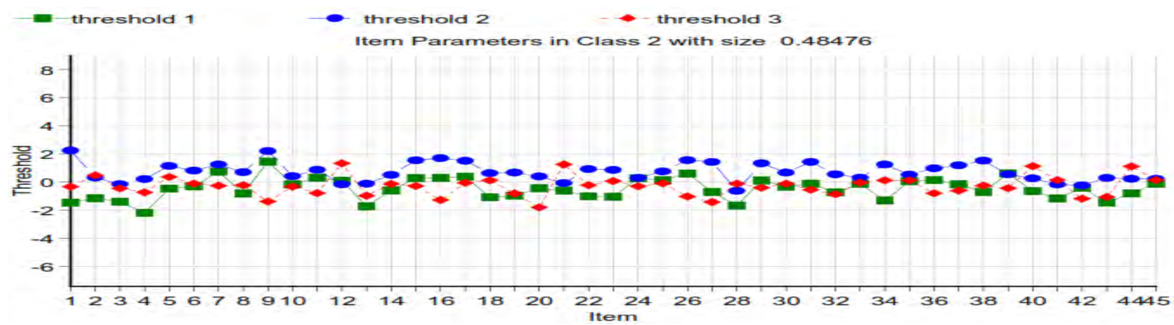

Figure 2. Item thresholds for class 2.

Analyses of Item Locations and Item Response Distributions

The item location is the mean of all item thresholds for an item. Higher mean thresholds indicate lower propensities of endorsement (Masters, 1982). Thus, item locations suggest which items cause differences in response patterns between latent classes.

In addition to the analysis of item locations, item response distributions between the two latent classes were compared to examine similarities and differences in item responses for each latent class. Analyses of item locations and item response distributions led to three main results: (1) Students in Class 1 were less anxious than students in Class 2 in terms of having anxiety about *apprehension of math lessons* and *use of mathematics in daily life*, (2) students in Class 1 had more *self-efficacy for mathematics*, and (3) students in both latent classes had similar levels of *test and evaluation anxiety*.

Figure 3 presents item locations for each latent class. Based on the figure, it can clearly be said that Class 1 had different and more variable item locations than Class 2.

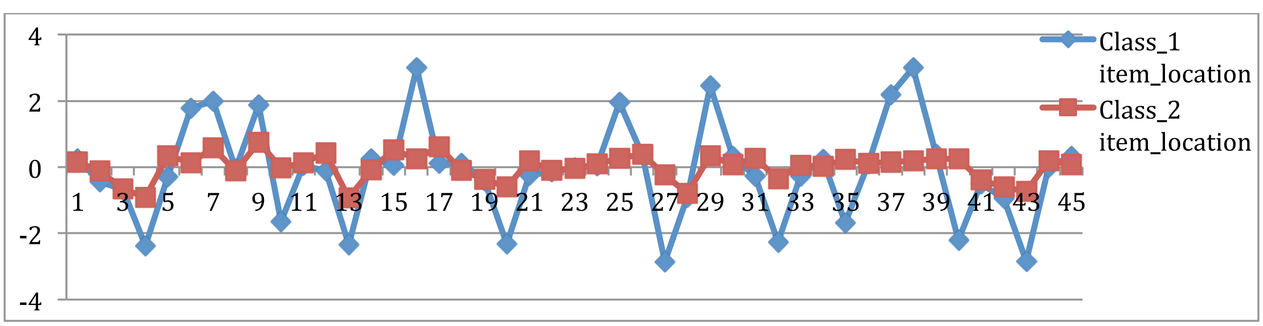

Figure 3. Item locations for class 1 and class 2.

Items with a difference on the scale of 1 logit or more were considered as indicating differences between the two latent classes. Based on the item locations for the two latent classes (see Figure 3), items 4, 6, 7, 9, 10, 13, 16, 20, 25, 27, 29, 32, 35, 37, 38, 40, and 43 appeared to have different response propensities for Class 1 and Class 2.

Items reflecting anxiety about *apprehension of math lessons* (i.e., Items 6, 7, 16, and 37) were more difficult to endorse for Class 1 than Class 2 (see Figure 3). For example, for Item 16, "Math book bothers me," the item location for Class 1 was 3 but for Class 2, it was .25. The proportions selecting the options of "never" and "always" in Class 1 were 98.7% and 0% respectively, in contrast to 53.3% and 15.1% in Class 2, respectively. On items such as Item 6 and Item 7, which asked students to identify how much they panic when a lot of mathematics problems are given as homework and how uncomfortable they feel when studying a hard mathematics topic (For Item 6 and Item 7, Class 1 item locations were 1.78 and 2; Class 2 item locations were .14 and .58), students in Class 1 mostly agreed with the option "never" (80.2% for Item 6 and 87.1% for Item 7) than students in Class 2 (38.6% for Item 6 and 64.2% for Item 7).

On the other hand, students in Class 1 endorsed more easily items with positive statements such as enjoying numbers (i.e., Items 4, 10, 13, 20, 32, 35, and 40). For example, for Item 40, "Opening any book on math and looking at one of its pages full of mathematics problems makes me happy," (Class 1 and Class 2 item locations were -2.21 and .25, respectively), the proportion selecting "always" was 70.3% in Class 1 as opposed to 7.8% in Class 2.

Items focusing on anxiety about *use of mathematics in daily life* (i.e., Items 9, 29, and 38) were harder for students in Class 1 to endorse than for students in Class 2 (see Figure 3). For Item 29, "When I am asked to help a primary school student with his/her homework, I may refuse to help because I feel afraid that there may be some problems that I could not solve" (Class 1 item location was 2.46; Class 2 item location was .35), almost all students in Class 1 (93.5%) and half of the students in Class 2 (50.5%) selected the option "never." On items that asked students to rate their ideas about *test and evaluation anxiety* (i.e., Items 2, 3, 8, 11, 14, 18, 19, 21, 22, 24, 25, 28, 30, 33, 41, 42, and 44), item locations as well as the distributions of responses were similar across choices for both classes.

Finally, on items involving *self-efficacy for mathematics* (i.e., Items 27, and 43), item locations and the distribution of responses were different for the two classes. For Item 43, "When I think I succeeded at a math exam, I feel relaxed and peaceful while waiting for the announcement of the results" (Class 1 item location was -2.84; Class 2 item location was -.73), the proportion selecting "always" in Class 1 was 72.8% as opposed to 39.5% in Class 2.

The Relationships Between Manifest Variables and Latent Class Membership

To obtain detailed information about the characteristics of each latent class, we examined the relationships between manifest variables and latent class membership using independent sample t-tests and chi-square tests. Regarding mathematics achievement, students in Class 1 were significantly more successful than students in Class 2 (t (df = 111) = 3.71, $p < .01$). In terms of gender, there was no significant association between the two classes ($\chi^2(1) = .98$, $p = .32$). The associations between students' liking mathematics and liking their mathematics teachers, and latent class membership were significant ($\chi^2(1) = 11.83$, $p < .01$ and $\chi^2(1) = 6.30$, $p < .01$, respectively). However, there was no significant association between the type of school attended and latent class membership ($\chi^2(1) = .57$, $p = .45$). Finally, education level of mothers was higher for students in Class 1 than Class 2 (t (df = 136) = 2.36, $p < .02$), but there was no significant difference in terms of education levels of fathers (t (df= 136) = 1.07, $p = .29$).

Discussion

In this study, we examined the utility of a mixture IRT methodology, named MixPCM, for detecting latent classes of middle grades students' math anxiety. With respect to the first research question, two latent classes were detected with distinct patterns of math anxiety. With respect to the second research question, Class 1 consisted of students who were reported being less anxious about *apprehension of math lessons* and *use of mathematics in daily life*, and as having more *self-efficacy for mathematics* than students in Class 2. However, there did not exist any difference between Class 1 and Class 2 in terms of *test and evaluation anxiety*. With respect to the third research question, students in Class 1 were found to be more successful in mathematics, mostly like mathematics and mathematics teachers, and have better educated mothers in comparison to students in Class 2. Moreover, there was no significant association between the two classes in terms of gender, attending private or public schools, or education levels of fathers.

The results reported here on the relationships between math anxiety and the manifest variables were consistent with the findings in the literature. Similar to the previous findings indicating that math anxiety was negatively related to mathematics achievement (e.g., Hembree, 1990), students in Class 1, in the present study, were reported being less anxious and more successful in mathematics. Previous research on the effects of positive attitudes and education levels of mothers on math anxiety has led to a consensus that positive attitudes towards mathematics and education levels of mothers were negatively associated with math anxiety (e.g., Engelhard, 1990; Meece, Wigfield, & Eccles, 1990). In this study, students in Class 1 were found to be less anxious but be more likely to have positive attitudes such as enjoying mathematics and liking their mathematics teachers, and to have mothers with higher education levels than students in Class 2. Including the analysis of manifest variables along with results from the MixPCM and obtaining consistent results with previous research strengthen the validity of the interpretations about the characteristics of each latent class reported in this study.

The results of this study have important implications for teachers and researchers. First, it may be misleading to compare all students based on their total scores on a scale of math anxiety. Rather, within a population of students, there exist latent classes that differ in their math anxiety. Relying on only single total score, therefore, might hinder gaining insight about particular characteristics of students. In this regard, the MixPCM was found to be a useful tool for identifying those students with different patterns of math anxiety in classroom settings. This, in turn, could help teachers make interventions specific to the needs of each student. For example, they can focus on reducing some particular students' anxiety levels towards mathematics lessons by not calling on these students to solve a problem at the board; engage some students with more mathematics related activities in daily life by presenting simulated real-life situations and asking word problems in a real-life context; and help some students build self-confidence for mathematics through asking mathematical problems from simple to more complex.

In conclusion, the present study was the first study that examined the utility of the MixPCM for detection of distinct latent classes based on different patterns of math anxiety. The results reported here provide initial evidence that the MixPCM, when applied to a scale like the MANX, can provide fine-grained information about latent classes of middle grades students population and their characteristics of math anxiety. Future studies should continue on conducting similar studies with other popular math anxiety scales in different populations.

"THEORY AT THE CROSSROADS": MAPPING MOMENTS OF MATHEMATICS EDUCATION RESEARCH ONTO PARADIGMS OF INQUIRY[1]

David W. Stinson
Georgia State University
dstinson@gsu.edu

Margaret Walshaw
Massey University
M.A.Walshaw@massey.ac.nz

In this essay, traveling through the past half-century, the authors illustrate how mathematics education research shifted, theoretical, beyond its psychological and mathematical roots. Mapping four historical moments of mathematics education research onto broader paradigms of inquiry, the authors make a case for the field to take up a theoretical "identity" that refutes closure and keeps the possibilities of mathematics teaching and learning open to multiple and uncertain interpretations and analyses.

Keywords: Equity and Diversity, Research Methods

Introduction

Over the past half-century, mathematics education research could be characterized as shifting from searches for certainty to acknowledgments of doubt (cf. Skovsmose, 2009). Discussions about theory during this time have grown from being nearly nonexistent in the 1960s to filling a visible and frequently contested space for productive scholarly debate in more recent times. For instance, in the mid-to-late 1990s, Steffe, Kieren, Thompson, and Lerman debated the often-dichotomized theoretical traditions of radical constructivism and social constructivism (Lerman, 1996, 2000a; Steffe & Kieren, 1994; Steffe & Thompson, 2000). In the late 2000s, Gutiérrez and Lubienski debated the uses (or not) of broad socio-cultural and -political theories (and methods) when reporting on the mathematics "achievement gap" (Gutiérrez, 2008; Lubienski, 2008; Lubienski & Gutiérrez, 2008). And Confrey and Battista (Battista, 2010; Confrey, 2010), individually, in the early 2010s, responded to Martin, Gholson, and Leonard's (2010) rejoinder to the assumptive question: "Where's the math (in mathematics education research)?" (Heid, 2010, p. 102) These debates hinged largely on the theoretical traditions taken up by the researchers, which, in turn, determined what questions might be asked and how data might be collected, analyzed, and represented (see Lester & Wiliam, 2000; Valero, 2004).

The productive theoretical debates that have engaged mathematics education researchers since the 1990s are in stark contrast to the debates (or lack thereof) from the 1960s and 1970s. In those early developmental years of mathematics education research, the chief method of establishing legitimacy for the field was for researchers to align themselves with the existing epistemologies of mathematics and the developing theories of psychology (Kilpatrick, 1992). This allegiance was formally instituted in 1976 when the International Group for the Psychology of Mathematics Education was founded during the 3rd International Congress for Mathematical Education (ICME-3). Overall, in research reporting during these early developmental years, theoretical considerations were merely implicit. When researchers discussed theory, it was most often in the context of developing a single theory or theoretical network specific to research on mathematics teaching and learning (e.g., Becker, 1970).

The Emergence of Theoretical Discussions

The allegiance to "traditional" psychology waned in the late 1970s and early 1980s, as theories (and methodologies) began to be adapted from the disciplines of anthropology, cultural and social psychology, history, philosophy, and sociology (Lester & Lambdin, 2003). Over three decades ago, Higginson (1980) proposed that mathematics education be informed not simply by mathematics and

Galindo, E., & Newton, J., (Eds.). (2017). *Proceedings of the 39th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* Indianapolis, IN: Hoosier Association of Mathematics Teacher Educators.

psychology, but also by sociology and philosophy. He noted that allegiance to mathematics is self-evident and that the "battle for the recognition of a psychological dimension in mathematics education has been won, for almost all purposes, for some time now" (p. 4). Higginson then made a two-pronged argument for the recognition of a sociological dimension: (a) the need to more fully understand the social role of schooling and the interpersonal and intrapersonal dynamics among teachers, students, and the mathematics being taught and learned; and (b) the need to more fully understand the influences of cultural values, economic conditions, social structures, and emerging technologies on schools generally and on teaching and learning specifically.

In arguing for the inclusion of philosophy, Higginson (1980) cautiously noted that with the inclusion of sociology, "it might appear [to some] that the gates have been open too far already" (p. 4). But for Higginson, the inclusion of philosophical considerations in mathematics education (research or otherwise) was important because all human "intellectual activity is based on a set of assumptions of a philosophical type" (p. 4). These assumptions, he argued—

will vary from discipline to discipline and between individuals and groups within a discipline. They may be explicitly acknowledged or only tacitly so, but they will always exist. Reduced to their essence these assumptions deal with concerns such as the nature of "knowledge", "being", "good", "beauty", "purpose" and "value". More formally we have, respectively, the fields of epistemology, ontology, ethics, aesthetics, teleology and axiology. More generally we have the issues of truth, certainty and logical consistency. (p. 4)

Higginson's (1980) point was soon taken up. For example, in 1984 a new Topic Study Group on Theory in Mathematics Education [TME] was formed at ICME-5. The purpose of the group, as Steiner (1985) summarized, was "to give mathematics education *a higher degree of self-reflectedness* and *self-assertiveness,* to *promote another way of thinking* and of *looking* at the problems and their interrelations" (p. 16; emphasis in original). Steiner also provided a list of 10 topics that the TME Group might explore in the future; these topics included (among others): definitions of mathematics education as a discipline; use of models, paradigms, theories in mathematics education research; relationships between theory and practice; and explorations of ethical, societal, and political aspects of mathematics education.

Mathematics education research of the 1990s and beyond certainly reflects this list of topics, broadening not only possible theoretical traditions that might be taken up but also expanding the very identity of mathematics education as a research domain (see Sierpinska & Kilpatrick, 1998). By way of example, conferences held since the mid-1980s include Political Dimensions of Mathematics Education (1990, 1993, 1995); Critical Mathematics Education: Toward a Plan for Cultural Power and Social Change (1990); Mathematics Education and Society (1998, 2000, 2002, 2004, 2008, 2010, 2013, 2015, 2017); and Mathematics Education and Contemporary Theory (2011, 2013, 2016). Furthermore, edited books published since that time include *Equity in Mathematics Education*: *Influences of Feminism and Culture* (Rogers & Kaiser, 1995); *Ethnomathematics*: *Challenging Eurocentrism in Mathematics Education* (Powell & Frankenstein, 1997); *Sociocultural Research on Mathematics Education* (Atweh, Forgasz, & Nebres, 2001); *Which Way Social Justice in Mathematics Education* (Burton, 2003); *Mathematics Education within the Postmodern* (Walshaw, 2004); and *Culturally Responsive Mathematics Education* (Greer, Mukhopadhyay, Powell, & Nelson-Barber, 2009). These listings are by no means exhaustive but merely illustrative of the conferences and books that have assisted in shifting mathematics education research beyond its psychological and mathematical roots.

Theory Defined

Conferences and books like those mentioned have indeed contributed to the broadening of theoretical (and methodological) traditions within mathematics education research. However, we have not yet defined or described what we mean by *theoretical tradition* or *theory* here. This is an intentional omission. In our view, theory often conveys different meanings and assumes different purposes. For instance, Sriraman and English (2010) have drawn attention to the notion of a "grand" theory sought by some researchers (e.g., Becker, 1970; Silver & Herbst, 2007), while Lester (2005) has suggested that mathematics education researchers adapt theoretical concepts and ideas from a range of perspectives. Brown and Walshaw (2012) have argued that mathematics education researchers use "theory as a vehicle for new productive possibilities in mathematics education" (p. 3).

These different purposes signal that theory is being conceptualized at different levels. To that end, E. A. St. Pierre (personal communication, June 2000) has proposed a three-tier structure for discussing theory: high-level, mid-level, and ground-level theories. High-level theories are the larger philosophical traditions in which a researcher might position her or his science (e.g., analytic philosophy or continental philosophy). These traditions rest on a set of assumptions about epistemology, ontology, ethics, aesthetics, teleology, and axiology or, more simply stated, about truth, certainty, and logical consistency (Higginson, 1980). Mid-level theories are the various theoretical traditions and ideas that might be derived from one or more broader philosophical traditions (e.g., activity theory, cognitive theory, constructivist theory, critical theory, poststructural theory, sociocultural theory). Ground-level theories, not to be confused with grounded theory (Glaser & Strauss, 1967), are the theories or models developed or used to make sense of the data collected during data analysis; that is, the theory that is on the ground, closest to the data (e.g., cognitively guided instruction; see, e.g., Fennema et al., 1996). It is important to note, however, that a specific ground-level theory is only possible through the set of philosophical and theoretical assumptions, beliefs, values, and perspectives operating in the context of the high- and mid-level theories taken up by the researcher (E. A. St. Pierre, personal communication, June 2014). The danger in too much of the existing mathematics education research, however, is that researchers often do not acknowledge the philosophical assumptions present in the high- and mid-level theories that make the ground-level theories they develop or use possible.

For our purposes here, our focus is on high- and mid-level theories or what taken together could be called the *paradigm of inquiry* in which the researcher resides. That is, when using the word theory or the phrase theoretical tradition we are concerned about the epistemological stance of the researcher as she or he conducts research within a set of assumptions about truth, certainty, and logical consistency, being mindful that science, social or otherwise, is always already entangled with and in these broader concerns of philosophy (St. Pierre, 2011).

The Paradigm Wars and Education Research

Generally speaking, the broadening of theoretical traditions in mathematics education has been played out in the larger paradigm wars of education social science (see Gage, 1989; Guba & Lincoln, 1994; Lather, 2006; St. Pierre, 2006). The use of Kuhn's (1962/1996) concept *paradigm* is meant to describe shifts in the traditions of "normal science" (i.e., firmly based historical traditions of science) that are differentiated not by failure of one method to another but rather by the "incommensurable ways of seeing the world differently and of practicing science in it" (p. 4). Although the use of the term paradigm in social science research has been contested (see Donmoyer, 2006), Guba and Lincoln (1994) have pointed out that inquiry paradigms highlight for researchers "what it is they are about, and what falls within and outside the limits of legitimate inquiry" (p. 108). Inquiry paradigms, they have argued, are defined by responses to three fundamental and interconnected questions—the ontological question, the epistemological question, and the methodological question. The three questions are interconnected "because the answer given to any one question, taken in any order, [more times than not] constrains how the others may be answered" (p. 108).

Much has been written in the past 50 years or so about the beginning (early 1960s), the aftermath (late 1980s), and the resurgence (early 2000s) of the paradigm wars (see Lather, 2006; St. Pierre, 2006). Writing in 1989, in a futuristic account of education research at the turn of the 21st century, Gage proposed (and hoped for) an armistice of sorts as "researchers came to a new realization that paradigm differences do not require paradigm conflict" (p. 7). But rather than an armistice, paradigm conflicts have seen a resurgence as both experimental and quasi-experimental research have been hailed as the "gold" standard in educational research (see, e.g., National Research Council, 2002). St. Pierre (2006), underscoring the gravity of the resurgence, has argued—

> The stakes are high because the very nature of science and scientific evidence and therefore the nature of knowledge itself is being contested by scholars and researchers who think and work from different epistemological, ontological, and methodological positions as well as by those postmodernists who challenge the metaphysical project altogether. If one believes that different theoretical frameworks are grounded in and structured by different and, perhaps, incommensurable assumptions about the nature of knowledge, truth, reality, reason, power, science, evidence, and so forth, then one can see why educators are taking sides in this debate that is already organizing the limits and possibilities of what we can think and know and, thus, how we can live in the complex and tangled world of educational theory, research, policy, and practice. (pp. 239–240)

Within the complex and tangled world of U.S. mathematics education research, this resurgence of paradigm conflicts is visible within the pages of *Foundations of Success*: *The Final Report of the National Mathematics Advisory Panel* (NMAP; 2008) and in a special issue of the *Educational Researcher* (Kelly, 2008) published in response. Throughout the pages of both the final report and the response special issue it is often noted, explicitly and implicitly, that supporting certain theoretical and methodological traditions does not mean complete abandonment of others. The authoring committee of the NMAP final report, however, included only experimental and quasi-experimental research to make evidential knowledge claims about mathematics teaching and learning. So as politics took the place of scientific inquiry (Boaler, 2008), the authoring committee took direct aim at some epistemological possibilities, and thus theoretical and methodological possibilities. For instance, they erased "race" from the conversation on mathematics teaching and learning altogether (Martin, 2008). In the end, as a proliferation of paradigms to think about and do science became possible within the decades of the 1980s and 1990s (Lather, 2006), both education research in general and mathematics education research in particular experienced a backlash in the early 2000s and beyond. The war rages on as the battles over the nature of knowledge, truth, reality, reason, power, science, evidence, and so forth, continue.

Mapping Moments to Paradigms of Inquiry

In an attempt to make sense of the proliferation of theoretical traditions used in mathematics education research since the 1970s, Stinson and Bullock (2012) have identified four distinct yet overlapping and simultaneously operating shifts or historical moments: (a) the process–product moment (beginning in the 1970s); (b) the interpretivist–constructivist moment (beginning in the 1980s); (c) the social-turn moment (beginning in the mid-1980s); and (d) the sociopolitical-turn moment (beginning in the 2000s). These moments of mathematics education research are not intended to suggest that movement among the moments occurs in some linear fashion, arriving at a "best" or "better" place across a continuum. Rather, the moments are merely arranged in loose historical chronological order. As a case in point, Frankenstein (1983) and Skovsmose (1985) began exploring the sociopolitical implications of critical mathematics education several years before the sociopolitical-turn moment identified as beginning in the 2000s. Table 1 maps the four moments of mathematics education research onto one and, in some cases, two paradigms of inquiry. Representing an adaptation of a conceptualization offered by Lather and St. Pierre (see Lather, 2006), four broad paradigms are singularly worded by their general intentions: prediction, understanding, emancipation, and deconstruction (see Stinson & Bullock, 2015).

Table 1: Mapping Moments of Mathematics Education Research to Paradigms of Inquiry

- Process–Product Moment (1970s–)→***Predict***
- Interpretivist–Constructivist Moment (1980s–)→***Understand***
- Social-turn Moment (mid 1980s–)→***Understand*** (albeit, contextualized understanding) or ***Emancipate*** (or oscillate between the two)
- Sociopolitical-turn Moment (2000s–)→***Emancipate*** or ***Deconstruct*** (or oscillate between the two)

Paradigms of Inquiry

Predict	***Understand***	***Emancipate***		***Deconstruct***
*Positivist Experimental Quasi-experimental Mixed Methods>	*Interpretivist Social Constructivist Radical Constructivist Sociocultural> Phenomenological Ethnographic Symbolic Interaction	*Critical <Feminist> Critical Race Theory> Latino/a Critical Race Theory> Critical Theories of Race> <Participatory Action Research Critical Ethnography	*BREAK*	*Poststructural/ Postmodern Postcritical Postcolonial Posthumanist Post-Freudian <Discourse Analysis

*Indicates the term most commonly used < or > Indicates cross-paradigm movement

The Break in the original Lather and St. Pierre table indicated a shift from the Enlightenment humanist paradigms on the left to the post-Enlightenment, posthumanist paradigm on the right. Here it indicates a hybrid, in-between space where the researcher might adopt a critical postmodern theoretical tradition (see Stinson & Bullock, 2012, 2015).

Paradigms of Inquiry adapted from Lather and St. Pierre in Lather, 2006, p. 37.

The purpose in mapping the moments to larger inquiry paradigms is to illustrate the different theoretical and methodological possibilities within each moment. Although the table does not exhaust all possibilities, it does provide an expansive list of the kinds of research that might be undertaken within mathematics education. For instance, Table 1 illustrates that research in the process–product moment (beginning in the 1970s) is marked by attempts to predict "good" mathematics teaching by linking mathematics teachers' classroom practices (process) to student outcomes (product). Grounded both theoretically and methodologically in positivist inferential statistics, cognitive and behavioral theories derived from experimental psychology and behaviorism are the primary theoretical traditions (e.g., Good & Grouws, 1979). The interpretivist–constructivist moment (beginning in the 1980s) attempts to understand mathematics teaching and learning rather than to predict it; interpretivist and constructivist theories derived principally out of sociology and developmental psychology are the primary theoretical traditions (e.g., Steffe & Tzur, 1994; Thompson, 1984). The acknowledgement that meaning, thinking, and reasoning are products of social activity in contexts marks the social-turn moment (beginning in the mid-1980s; see Lerman, 2000b); theories drawn from disciplines such as cultural and social psychology, anthropology, and cultural sociology are the primary theoretical traditions (e.g., Boaler, 1999; Zevenbergen, 2000). And a shift toward recognizing knowledge, power, and identity as interwoven and arising from and constituted with and in sociocultural and sociopolitical discourses distinguishes the sociopolitical-turn moment (beginning in the 2000s; see Gutiérrez, 2013); here critical and poststructural theories are the primary traditions (e.g., Gutstein, 2003; Walshaw, 2001).

Closing Thoughts

In the foreword to Mathematics Education as a Research Domain: A Search for Identity, Sierpinska and Kilpatrick (1998) wrote—

> The theme of the ICMI Study reported in this book was formulated as a question: 'What Is Research in Mathematics Education and What Are Its Results?' No single agreed-upon and definite answer to the question, however, is to be found in these pages. What the reader will find instead is a multitude of answers, various analyses of the actual directions of research in mathematics education in different countries, and a number of visions for the future of that research. (p. x)

These multiple answers and various analyses are clearly visible within the moments of mathematics education research as depicted in Table 1. Indeed, similar to researchers in education generally, researchers in mathematics education have experienced a proliferation of paradigms to think with when conducting research on the teaching and learning of mathematics. Similar to Lather (2006), we believe that this proliferation of paradigms is a good thing. Is it possible, then, to characterize mathematics education research? What can we say about its identity? In our view, an identity for mathematics education research is one that is fragmented, incomplete, and continually reconstituted within sociopolitical relations of power. Such a perspective refutes closure and keeps the possibilities for mathematics teaching and learning open to multiple and uncertain interpretations and analyses.

ANALYTICAL FRAMEWORK FOR STUDYING INDUCTIVE REASONING IN MATHEMATICS TEACHERS WHEN SOLVING TASKS

Landy Sosa Moguel

landy.sosa@gmail.com

Guadalupe Cabañas-Sánchez
Autonomous University of Guerrero
gcabanas.sanchez@gmail.com

An analytical framework is presented in order to characterize and analyze the evolution of inductive reasoning in mathematics teachers in relation to mathematical conceptualization. It is made up of four components: heuristic strategies, mathematical content, representations and stages of reasoning. It was constructed in order to analyze the written productions of secondary school teachers when solving generalization tasks by means of induction, implemented in a professional teaching development program focusing on the development of inductive reasoning. The use and scope of this analytical framework is discussed herein.

Keywords: Reasoning and Proof, Teacher Education-Inservice/Professional Development, Middle School Education

Introduction

In general, it is accepted that the development of inductive reasoning maximizes mathematical learning processes, for example, in the recognition of patterns and regularities in the solution of non-routine problems, by establishing conjectures, carrying out generalizations, developing arguments and mathematical tests (NCTM, 2000; Common Core State Standards Initiative, 2010). Empirical research supports the idea that argumentation based on inductive reasoning contributes to and supports the justification of conjectures and the construction of deductive tests (Papageorgiou, 2009; Conner, Singletary, Smith, Wagner & Francisco, 2014; Martinez & Pedemonte, 2014).

Various studies have examined inductive reasoning from a cognitive point of view in relation to the understanding of mathematical knowledge in elemental education students, with some adhering to the definition of Klauer, Willmes and Phye (2002), who conceive this type of reasoning as an analytical skill focused on the detection of regularities and irregularities between the attributes and relationships of objects (e.g. Barkl, Porter & Ginns, 2012; Csapó, 1997). Other studies also in a cognitive framework have been based on Peirce's notion of reasoning (e.g. Christou & Papageorgiou, 2007; Papageorgiou, 2009). Some research (Cañadas & Castro, 2007: Cañadas, Castro & Castro, 2008; Castro, Cañadas & Molina, 2010) has transcended to a wider, more complex vision of that which is inductive as a process inherent to the construction of mathematical knowledge and has placed emphasis on the formulation of a theoretical model of inductive reasoning by means of the identification of stages in its development in secondary school students. This paper is based on that vision.

Within the framework of the professional development of teachers, on which the paper reported herein focuses, some have questioned the relationship between mathematical reasoning (inductive and deductive) and learning styles (Arslan, Ilkörücü and Seden, 2009), identifying types of reasoning in a mathematics class for trainee teachers (Soler-Álvarez and Manrique, 2014), as well as recognizing the connection between abductive – inductive reasoning in the generalization of patterns (Rivera & Becker, 2007). Very few studies have examined how to incorporate the inductive nature of reasoning associated with the construction of mathematical knowledge in experiences of the professional development of mathematics teachers. As a first step, in order to advance in this direction, we sought to characterize the inductive reasoning of working mathematics teachers in relation to their mathematical conceptualization. Bearing this in mind, the following analytical framework is proposed.

Analytical Framework of Inductive Reasoning in Their Solution of Tasks

The analytical framework is based on a conceptual positioning of inductive reasoning or induction based on the epistemology of mathematics and science. Historically, the construction of mathematical knowledge has been socioculturally located in empirical inductive practices, as a way to move from the observation of concrete or individual realities to general abstract realities. Induction has been inherent in social and cognitive processes of construction of knowledge, which primarily begin with the study of specific cases and local patterns, which are rationalized in order to carry out a generalization. In this respect, the vision of inductive reasoning discussed in Castro et al. (2010) is shared.

The framework is an adaptation of the model proposed by Cañadas y Castro (2007), in so far as it incorporates components that allow us to not only understand the reasoning, but also recognize the epistemic nature of mathematical concepts by the teacher. This is made up of four components. The first consists of the seven *Stages of inductive reasoning* of the aforementioned model, in which three components are incorporated as analysis tools: the heuristic resolution strategies, the mathematical content that is mobilized and the semiotic representations that allow us to recognize cognitive processes of reasoning and elements of mathematical conceptualization. The unit of analysis is comprised of each solution of tasks that involve inductive generalization processes for their solution. As far as methodical matters are concerned, the analysis components are:

A. **Stages of Inductive Reasoning**. These do not necessarily occur in a linear form and some may not be necessary or may not appear in the solution. The stages of the model are (Cañadas y Castro, 2007, p. 69): *Work with specific cases, organization of specific cases, identification of patterns, formulation of conjectures, justification of the conjectures, generalization and demonstration.*
B. **Heuristic Strategies**. According to Guzman (2007), the resolution of mathematical problems includes a heuristic component in relation to thinking processes and another component relating to the specific content of mathematical thinking. The analysis of heuristics is not only useful for elucidating the extent to which both concepts are linked, but also allows us to recognize the specific inductive strategies used by teachers and thus situate their level of reasoning. Cañadas, Castro and Castro (2008) define them as “the type of strategies that can be described in problems where induction can be used as heuristic” (p. 139).
C. **Mathematical Content**. It is assumed that the mathematical conceptualization in teachers consists of signification and resignification processes based on the recognition of the epistemic nature of the concepts in a triadic relationship: procedural, conceptual and structural (Aparicio, Gómez & Sosa, 2017). All mathematical concept has a double complexity, the first is its dual nature: process – object (Gray & Tall, 1994). The idea of *process* refers to the “*operational*” or procedural quality that any mathematical object must have in order to act as an instrument, to be able to manipulate reality and express it in mathematical terms (signs, symbols and operations). The idea of *object* refers to the cognitive part (the notion, the idea, the thought, in general, that which is conceptual), which allows us to conceptualize a reality and look at it systemically. Such aspects need to be viewed as a more complex *mathematical structures* up to grade of using, explaining, and connecting relationships between objects in an aware way. Mason, Stephen and Watson (2009) call it structural thinking.
D. **External Representations**. The cognitive processes of reasoning can be expressed and described using representations (e.g. Cañadas et al. 2008). Likewise, they are means of objectification for generalization (e.g. Radford, 2010).

Design of the Tasks

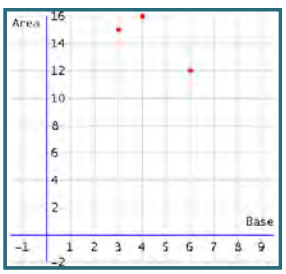
Inductive reasoning involves the process of generalization oriented to the perception of the general in the particular (Kodnik y Manfreda, 2015). For the analysis, three tasks (T) were designed and structured so that the solution would lead to a process of *generalization by induction*. The epistemic elements of mathematics in designed tasks are associated with quadratic behavior between quantities and/or variables and imply notions such as: quadratic functions for modeling the area of a family of rectangles (T1), successions with quadratic behavior presented using geometric dot configurations (T2), and squared binomials as expressions of algebraic generalization of numerical relationships (T3). They focus on the establishing and justification of a conjecture, explicitly requested only in the third.

Two examples of these tasks are shown in Figure 1, which were solved individually using a pencil and paper by two groups of secondary school mathematics teachers in Mexico.

<table>
<tr>
<td>

T1. With regards a family of rectangles, information has been provided in relation to the measurements of the base and area of three rectangles in graph form, as shown in the following illustration.

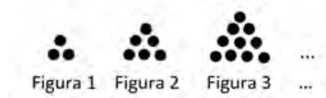
.



Generate an algebraic expression permitting the calculation of the value of the area of any rectangle in that family. Provide a detailed argument of the solution process.

</td>
<td>

T2. Establish an algebraic expression in order to calculate the amount of dots needed for the i-th figure of the following sequence:



Provide a detailed argument of the solution process.

</td>
</tr>
</table>

Figure 1. Examples of tasks for generalization by induction.

In T1, for example, the identification of the quality or regularity between the lengths of the base and the height of a family of rectangles is established. The conjecture relates to the detection of a regularity on the semi-perimeter of the rectangles. The generalization of the conjecture may be established using the algebraic expression of a quadratic function. Said generalization allows for empirical justifications or analytical procedures for their demonstration.

Discussion and Reflections

In experiences of teacher professionalization in Mexico, it has been detected that the inductive reasoning prevails absent in the middle school mathematics teachers' reflections when they propose school treatment of mathematical content and also when they interpret and solve problems. The analytical framework presented is a methodological tool of a study regarding the role of induction as a way to encourage processes of professional development of mathematics teachers.

It has been formulated in order to carry out cognitive analyses (individual and group), which permit the description of inductive reasoning in teachers in relation to mathematical conceptualization based on the external representations used in the solution of generalization tasks by induction. If you are interested in a social analysis in order to identify the variables of the context that influence or optimize the reasoning, then an analysis of the associated arguments would be appropriate. The integration of *mathematical reasoning-content* within the framework is important in order to recognize the aspects of the mathematical thinking of teachers that need to be enhanced, as well as to understand the epistemic nature of mathematics.

This study uses data from 434 students to explore how they think about vectors, and cross products in particular, by analyzing student responses to open-ended questions from an online, conceptually-oriented, multivariable calculus cross product activity. We identify several categories that could outline a conceptual framework of student understanding of vectors and cross product. The analysis also identifies common transitional conceptualizations evidenced in student responses.

Keywords: Technology, Post-Secondary Education, Advanced Mathematical Thinking

Vectors play a foundational role in advanced mathematics; as a topic, they are firmly situated at the crossroads from secondary to post-secondary mathematics. Yet, most research regarding students' understanding of vectors has been related to topics in the physics and engineering curriculum (e.g., Barniol & Zavala, 2014; Flores, Kanim, & Kautz, 2003; Nguyen & Metzler, 2003). There is little research on student understanding of vectors in post-secondary mathematics and what does exist tends to focus on linear algebra or geometry. Stewart and Thomas (2009) considered vectors in linear algebra by combining Dubinsky's (1991) APOS (action-process-object) theory with Tall's (2004) categorization of mathematical ways of thinking. Kwon (2013) worked in college geometry to identify three representations of a vector: vector as a translation, vector as a point and point as a vector, and geometrical vector sum. While basic vector concepts and vector arithmetic are often presented in secondary mathematics, students often do not experience vector dot and cross products until their post-secondary calculus courses.

Previous research, some of which is cited above, suggests that students' concept images of vectors develop in a rather fragmented manner, and students do not develop the rich conceptual knowledge required to relate alternate representations of vectors (Van Deventer & Wittmann, 2007). Despite the regular occurrence throughout the curriculum, students continue to have significant conceptual difficulties with vector concepts and manipulations. For instance, Knight (1995) found ~ 40% of students in a college, calculus-based physics course had no idea what a vector was and not one was able to evaluate a vector cross product.

The purpose of this study is to investigate students' understanding of the cross product of vectors as they work through an online exploration activity with embedded questions.

Theoretical Framing

Conceptual understanding has been reported as "what is known (knowledge of concepts)...[and] the way that concepts can be known" (Star, 2005, p. 408). Many studies work from a deficit model concentrating on what is not known and highlighting misconceptions. However, a more productive way to study student understanding is to focus on how it develops. *Transitional conceptions* relate to students' current notions of a concept that are cued by the task at hand and that may include what some would call misconceptions. Transitional conceptions are often not fully integrated in a coherent manner and tend to be in flux. They represent developing understanding and result from a sense-making activity. They may only address some (but not all) aspects of a concept and may be productive in some (but not all) contexts. The study of transitional conceptions in post-secondary mathematics is gaining traction (Chiu, Kessel, Moschkovich, & Muñoz-Nuñez, 2001; Cho & Moore-Russo, 2014; Wolbert, Moore-Russo, & Son, 2016) and stands to provide a more nuanced view of student understanding (Moschkovich, 1999). To understand meaning-making processes, it is imperative that mathematics educators consider the transitional conceptions that occur when students are learning new concepts.

Past research has considered the many "notions" or "components" associated with a single, particular concept in mathematics (e.g., work on slope by Moore-Russo, Conner, & Rugg, 2011; Nagle & Moore-Russo, 2013). Because there is scant research on transitional conceptions specific to vectors in multivariable calculus classes, this study aims to add to the existing body of knowledge, focusing, in particular, on students' transitional conceptual understanding of the vector cross product. More specifically, this study looks to use student responses to:

1. Identify key notions of vector cross product
2. Determine common transitional conceptions for each key notion identified

Data Collection and Analysis

CalcPlot3D (Seeburger, 2016) is an online, freely available 3D-graphing applet that allows students to visualize and manipulate concepts, including vectors. It also offers discovery-learning activities for students to explore concepts. The data analyzed were the electronic responses of 434 college-level multivariable calculus students to a sequence of four open-ended questions listed in Table 1 from an online activity related to vector cross products. In this activity, students were directed to a visual applet that contained two vectors (one red and one blue) along with their cross product. The two vectors were graphed with initial points situated at the origin in the *xy*-plane. Students could manipulate the length and direction of the two vectors on the *xy*-plane, and based on the students' input, the applet automatically redrew the cross product, computed the magnitude of the cross product, and indicated the angle between the two given vectors. The data were collected over four years from students from a variety of U.S. post-secondary institutions including community colleges, four-year private colleges, and four-year public colleges.

Table 1: Sequence of Open-Ended Data Collection Questions

Question	Description
1	What is the geometric relationship between the cross product vector and the two vectors that form it?
2	How is the cross product vector geometrically related to the two vectors that form it?
3	For vectors of fixed length, but varying the direction of one of the vectors, when is the magnitude of the cross product at a maximum?
4	For vectors of fixed length, but varying the direction of one of the vectors, when is the magnitude of the cross product at a minimum?

A general inductive analysis was used for the data. The research team examined the data with no preconceptions allowing categories to emerge naturally after multiple passes through the data set based on their observations (Thomas, 2006). The first two authors read through the data set at least five times and then created categories for the different notions associated with vector cross product. They consulted with the other two authors to confirm the notion categories that were developed and to refine the category descriptions. The first and second authors coded all responses. With the exception of the miscellaneous category, all codes resulted in Krippendorff's alpha above 0.80. The first and second authors then came to a consensus on the few instances in which they were in disagreement and then further refined the category descriptions with input from the other two authors. Once the notions were identified, the research team then followed a similar process to identify transitional conceptions associated with each identified notion.

Results and Discussion

Table 2 displays the identified categories for seven notions that outline a conceptual framework for student understanding of vector cross product. The analysis also identified common transitional conceptualizations evidenced in student responses associated with these notions. Students also made other statements not directly related to the identified notions that were irrelevant or incoherent and involved x and y coordinates, quadrants, and vector addition. Student responses to the different questions often provided evidence of them having more than one notion about cross product. This would not have been apparent if only one or two open-ended questions had been used for data collection.

Table 2: Notions Associated with Vector Cross Product

Notion	Common Transitional Conceptions
The angle between two vectors must be between 0° and 180°.	Students reported angles between the two vectors that were: • negative • greater than 180° (often a multiple of 180° or π)
The cross product vector is orthogonal (perpendicular or 90°) from the two vectors that form it.	Students made statements that while incorrect, lacking precision, or vague hinted at a consideration of orthogonality, such as the cross product is: • *vertical to the two vectors that form it* • *perpendicular to the intersection of the initial two vectors* • *also in the plane that the vectors do not lie in*
The right hand rule or a statement that correctly addresses the need to attend to orientation of one vector relative to another.	Students made statements that were either not precise or incorrect but suggested some consideration of the right hand rule, such as *you curl your fingers in and the vector goes down*.
The magnitude (length) of cross product is equal to the area of parallelogram formed by the two vectors.	Students wrote statements like the notion description but missing reference to: • the "area" of the parallelogram • the "length" or "magnitude" of the cross product. The frequency of the above cases suggests that this is more than just careless wording. Other students wrote less coherent statements that included the word parallelogram, such as *the cross product forms a parallelogram* or that referenced triangles rather than parallelograms.
The magnitude of cross product equals $\|\|a \times b\|\|=\|a\|\|b\| \sin\theta$, or some related statement that involves a relation between the sine and the two vectors.	Student responded with incorrect statements: • involving multiplication (often related to dot product) • that confused sine and cosine in the formula
The angle between the vectors influences the magnitude of the cross product.	Students made vague statements about how changing the angle between two vectors will affect the length of the cross product, such as *the cross product depends on the angle between the two vectors*.
The length of the two vectors influences the magnitude of the cross product.	Students made statements about the length of the cross product that were dependent on the specific vectors that they had been working with in the online learning activity, such as *the maximum a cross product can be is 4*.

It is hoped that the students develop a more sophisticated conceptualization beyond the transitional understanding evidenced in the data through further instructional intervention, but that was not the focus of this study.

Limitation and Suggestions for Future Work

Future work is needed to continue exploring student understanding of vectors. This should consist of further investigation of student's transitional conceptions. More study is also needed to determine if and how students make connections between the various notions of vector cross product. Continued experimentation should include the study of instructional methods that have been successfully leveraged, either within the classroom or in an online platform, to help students develop a better understanding of vector cross product.

LEARNING TO BECOME A RESEARCHER IN AN ONGOING RESEARCH PROJECT: A COMMUNITIES OF PRACTICE PERSPECTIVE

Okan Arslan

Joshua M. Ruk
Western Michigan University
joshua.m.ruk@wmich.edu

We apply Wenger's (1998) communities of practice ideas to the process of incorporating new researchers into an ongoing mathematics education research project. We illustrate this application by describing how the Leveraging MOSTs research project coding team can be viewed as a community of practice. We describe how we have used this particular community of practice to bring new researchers into the project, and new researchers reflect on their experiences with the coding team. Mutual engagement in project work with experienced researchers and having a rich shared repertoire to draw on led to the new researchers developing a shared understanding of the project and being successfully incorporated into the MOST community. This work speaks to the importance of deliberately creating communities of practice for new mathematics researchers to participate within.

Keywords: Research Methods, Informal Education

Researchers have found that participating in well-designed and effectively-implemented *communities of practice* (Wenger, 1998) supports preservice and in-service mathematics teachers' professional learning (e.g., Goos & Bennison, 2008; Hodges & Cady, 2012). Applying Wenger's ideas to research projects holds promise for increasing both the functionality of the project—by improving ways project staff work in community together—and the learning of new researchers. In this paper, we use Wenger's ideas to make sense of how to develop synergy at the crossroads that occur when new researchers become part of an ongoing research community.

Theoretical Framework: Applying Wenger's Social Theory of Learning

Wenger's (1998) social theory of learning identifies three essential dimensions of a *community of practice* (CoP): *mutual engagement*, *joint enterprise*, and *shared repertoire*. Mutual engagement refers to participants' regular interactions with others in a community; joint enterprise refers to participants' common understanding of, and desires to, achieve the purposes of that community; and shared repertoire refers to the shared ways of doing things developed during mutual engagements for the joint enterprise of that community (e.g., routines, tools, artifacts, stories). Participating in a CoP enables individuals to interact with the others in that CoP, which in turn enables them to acquire meanings from these interactions. Negotiating these meanings with others in the CoP contributes to their learning (Wenger, 1998). Therefore, participation, negotiation of meaning, CoP and learning are all interpreted as interrelated and essential dynamics of Wenger's social theory of learning.

The National Science Foundation Collaborative Research Project *Leveraging MOSTs* (LeveragingMOSTs.org) is an example of a CoP. Researchers from Brigham Young University, Michigan Technological University, and Western Michigan University came together to work on the joint enterprise of investigating secondary school mathematics teachers' productive use of student mathematical thinking during instruction. In line with this joint enterprise, researchers mutually engaged in practices (e.g., online and face-to-face meetings, data collection, data analysis), and these engagements produced tools, artifacts and shared ways of doing things (e.g., research reports, further research ideas, codebooks, meeting notes). As more researchers became involved and the scope of the work broadened, the MOST research project became a constellation. Constellation is a term used by Wenger (1998) to describe individual, but interacting CoPs in a system. For example, in the

MOST research project, teams work on analyzing the same data to answer different research questions; that is, they work on different but related parts of the joint enterprise. The interaction among these CoPs in the MOST constellation is primarily carried out by the principal investigators (PIs) of the project. Wenger (1998) defines such people—those who mutually engage in different CoPs in a constellation—as *brokers*. These brokers enable the joint enterprise and shared repertoire of the constellation as a whole.

Wenger has also likened CoPs to "black boxes." From the outside, it can be seen that there is a box, but since the box is opaque it is not possible to see what is inside it (Wenger, 1990). As newcomers' understanding of a CoP increases, the box becomes more transparent until eventually they can see through it to the workings of the CoP. When the box finally becomes invisible, as if there is no box, the newcomer has been fully integrated into the CoP (Wenger, 1990). The difficult process of making the box transparent may explain why Wenger (1998) claimed that becoming a part of a CoP is a challenging process for newcomers.

In longitudinal research projects, such as MOST, it is highly likely that new researchers will join the research team. Integrating these new researchers into a project CoP is essential for them to fully participate in pursuing the joint enterprise of the research team. Since this integration is a challenging process, there is a need to better understand productive ways for new researchers to join ongoing research projects. Toward this end, we explain our process for integrating new researchers into the MOST project and provide insights into how the opaque box of our CoP gradually became transparent for a recent group of researchers who joined the project.

The MOST Coding Team as a Community of Practice

Coding based on the MOST Analytic Framework (see Leatham, Peterson, Stockero, & Van Zoest, 2015) serves as the foundation for the vast majority of the CoPs in the MOST constellation. Thus, the *joint enterprise* of the coding CoP is to label and organize the data to enable further analysis by the other CoPs of the MOST constellation. As a result, the coding CoP is a logical place for new researchers to begin their participation in the MOST constellation. In the current coding CoP, there are five researchers who are new to the project and two PIs. Initially, all seven researchers met twice a week in online video meetings to work on the shared repertoire of the MOST constellation in general and of the coding CoP specifically. The main reifications in the *shared repertoire* of the MOST constellation for the coding CoP are publications related to the MOST Analytic Framework, the MOST codebook, and meeting notes. During the initial meetings, the PIs and the new researchers began coding a set of training data using the MOST Analytic Framework. After coding individually, the group met to reconcile their coding and discuss any discrepancies, connecting those discrepancies to the shared repertoire of the MOST project. Once the new researchers had established a basic working knowledge of the coding framework and its applications, the new researchers continued these online coding meetings on their own. The PIs occasionally rejoined the coding meetings to discuss issues that arose during the new researchers' discussions and to serve as brokers of knowledge for the CoPs in the MOST constellation. These different types of meetings were the main source of *mutual engagement* for the coding CoP, which enabled the new researchers to negotiate meanings about the coding process.

The Voices of New Researchers: Reflections on How the Opaque Box of the Coding CoP Became Transparent

The first step to participating in the MOST constellation and the coding CoP was to understand the constellation itself. In order to do this, we were given access to artifacts such as published articles, the NSF grant proposal, previous meeting notes, and the MOST codebook. Having this rich shared repertoire helped us to develop a general understanding of the constellation of the MOST project: why this research is being done, how this research is being done, and outcomes of the research. After this process, we had a general sense of the joint enterprise of the MOST research team and the coding CoP, so we tried coding the training data using the MOST codebook—what would become our most important artifact.

At this point, the black box of the coding CoP had only become slightly less opaque for us as new researchers, and we needed mutual engagement with brokers regularly to help make the box more transparent. During our initial coding CoP meetings, the PIs helped us to make sense of an important aspect of the joint enterprise of the CoP through the application and understanding of the coding framework. At first, we asked a lot of questions to help us determine what was in the opaque box, but after the box became a little more transparent, our questions changed to discussions with the brokers about how things should be coded. In other words, we could see into the box enough to discuss its inner workings. Through these mutual engagements, we gained a better understanding of the joint enterprise of the coding CoP.

The next step to becoming full participants in the coding CoP was for us to continue our discussions and try to reach agreements on coding the training data without the direct help of the brokers. At this point, the box had become transparent enough that we could discuss it using the codebook as our main resource. During this period, we felt that we were increasing the transparency of the box. However, our developing understanding did not mean that we had fully internalized the joint enterprise of the coding CoP and were using the shared repertoire in an authentic way. Therefore, occasional mutual engagement with the brokers was still crucial to maintain alignment with the MOST project's joint enterprise and shared repertoire. For example, as new researchers, we thought that it was always important to focus on very small details of what we were coding, but as the brokers explained, we could not do this at the expense of looking at the bigger picture. Eventually, we got to a point where we felt that the box had become transparent and the understanding of the CoP that had been captured by the codebook had been transformed back into understanding for us as new researchers. The brokers agreed that we were well on our way to becoming full participants in the coding CoP. This does not mean that the box was invisible—there were still aspects of the joint enterprise that we did not fully understand—but the box had become transparent enough that we were able to move to more central participation in the coding CoP by engaging with coding not-yet-coded data from the project.

Discussion & Conclusion

The reflections of new researchers in the MOST coding CoP revealed the process they went through during their integration into the MOST project. After developing a general understanding of the project through engaging with reifications of project work, the new researchers improved their understanding of the joint enterprise of the coding CoP through mutual engagements with each other and experienced researchers from the project. As a result of this process, these new researchers moved from being peripheral participants towards being central participants in the MOST research project. There were two significant contributors to their learning to become full participants in the MOST constellation: (1) having a rich shared repertoire, and (2) mutually engaging with the other new researchers and brokers. The rich shared repertoire in the MOST constellation helped the new researchers to gain a general understanding of the joint enterprise of the MOST constellation and the coding CoP. Their mutual engagement with the other new researchers in the coding CoP allowed them to develop their own thinking about the shared repertoire, while the mutual engagement with the brokers of the MOST constellation calibrated their shared repertoire with that of the larger project. Thus, our experiences integrating new researchers into the MOST project support Wenger's (1998) claim that participation and reification work as complementary pieces of learning. It appears that neither rich reifications nor mutual engagements of researchers are sufficient on their own to make the box completely transparent. Rather, making the box completely transparent for new researchers requires blending the shared repertoire of the research team with the mutual engagements of both new and experienced researchers.

Our experience is an example of how Wenger's (1998) *communities of practice* ideas can be used to make sense of how to develop synergy at the crossroads that occur when new researchers become part of an ongoing research community. Applying Wenger's ideas to the MOST research project helped to integrate new researchers into our project and prepared them to be central participants in the work. We encourage other research projects to carefully design and effectively implement CoPs. Specifically, we emphasize the importance of research projects both intentionally developing rich reifications of their shared repertoire to serve as the foundation for new researchers' participation in their projects and deliberately creating opportunities for new researchers to mutually engage with each other and experienced researchers.

MULTILEVEL MODELING OF MATHEMATICS ACHIEVEMENT USING TIMSS 2011

İbrahim Burak Ölmez
University of Georgia
i.burakolmez@hotmail.com

The purpose of this study was to investigate the effects of student-level and school-level factors on mathematics achievement in four countries including Finland, South Korea, Taiwan, and Turkey. Based on 8th grade students' responses to a student questionnaire and a mathematics test, and school principals' responses to a school questionnaire, the data of the Trends in International Mathematics and Science Study (TIMSS) 2011 were analyzed using Hierarchical Linear Modeling. The results revealed that students' having educational resources at home, their self-confidence in mathematics, and schools' emphasis on academic achievement were the common factors that influenced mathematics achievement in all four countries. However, no significant effects of education levels of fathers, fights or physical injuries to other students, and lack of resources for mathematics instruction on students' mathematics achievement were found.

Purpose and Background

Large-scale assessment programs such as the Trends in International Mathematics and Science Study (TIMSS) and the Program for International Student Assessment (PISA) are two main programs that provide countries opportunities to monitor their relative rankings and to shape their educational policies for the sake of improving their education systems. Because countries need citizens with high competence in mathematics and science for surviving in the global economy, it is important to analyze such data sets by detecting similarities and differences across the countries in terms of their students' mathematics and science achievement.

In the analyses of TIMSS and PISA to date, many statistical techniques have been used to explain mathematics and science achievement including analysis of variance (e.g., Pahlke, Hyde, & Mertz, 2013), multiple regression (e.g., Sulku & Abdioglu, 2015), structural equation modeling (SEM; e.g., Kalender & Berberoğlu, 2009), and hierarchical linear modeling (HLM; e.g., Wang, Osterlind, & Bergin, 2012). In this study, HLM was preferred as a statistical technique over other techniques because TIMSS and PISA data are nested in nature (i.e., students are nested within schools) and HLM is an appropriate technique to account for the nesting of students within schools.

Due to the complexity of mathematics achievement, past research has provided contradictory results about the effects of student, home-family background, and school related factors on students' mathematics achievement. For example, while some studies (e.g., Chiu, 2010) pointed out that school related factors have little role in contributing to students' mathematics achievement, some other studies (e.g., Edmonds, 1979) reported that school makes a difference on achievement. Similarly, while some studies (e.g., Papanastasiou, 2002) suggested that students' attitudes towards mathematics and their beliefs about success in mathematics did not influence their mathematics achievement, several other studies (e.g., Berberoğlu, Çelebi, Özdemir, Uysal, and Yayan, 2003) documented that factors such as students' perception of failure or success in mathematics greatly influenced students' mathematics achievement.

The purpose of this study was to compare the effects of student- and school-level factors on 8th grade students' mathematics achievement in Finland, South Korea, Taiwan, and Turkey using TIMSS 2011 data. The results of this study contribute to the literature by helping reconcile the contradictory findings reported so far on the effects of student- and school-level factors, and this will enable policy-makers to distinguish similarities and differences in the four countries and to shape their education systems. In this study, the following research questions were addressed:

1. Which student-level factors contribute to mathematics achievement of 8th grade students in Finland, South Korea, Taiwan, and Turkey?
2. Which school-level factors contribute to mathematics achievement of 8th grade students in Finland, South Korea, Taiwan, and Turkey?

The student-level factors of this study were *MotherEducation* (i.e., Education levels of mothers), *FatherEducation* (i.e., Education levels of fathers), *HomeResources* (i.e., Educational home resources), *Bullying* (i.e., Bullying at school), *LikeMath* (i.e., Like learning mathematics), *ValueMath* (i.e., Value learning mathematics), and *ConfidenceMath* (i.e., Self-confidence in mathematics). In addition, the school-level factors were *IncomeArea* (i.e., Schools' immediate area), *JobSatisfaction* (i.e., Teachers' job satisfaction), *Intimidation* (i.e., Intimidation or verbal abuse among students), *Fights* (i.e., Fights or physical injuries to other students), *LackofResources* (i.e., Lack of resources affecting instruction), *SchoolEmphasis* (i.e., Schools' emphasis on academic achievement), and *SchoolDiscipline* (i.e., School discipline and safety).

Methods

Participants and Instruments

A two-stage sampling design, with the selection of a sample of schools, and then the selection of randomly sampled one or two classes in each school was used in this study.

Table 1: Descriptive Statistics by Country

Country	number of schools	number of students	Rank	Mean Score
Finland	131	3626	8	514
South Korea	147	5015	1	613
Taiwan	149	4958	3	609
Turkey	236	6502	24	452

The data for this study consisted of 8th grade students' responses to the TIMSS 2011 Student Questionnaire about their home and school lives, and the Mathematics Test, and school principals' responses to the TIMSS 2011 School Questionnaire about school environment such as school resources, and roles of the principals (Mullis, Martin, Foy, & Arora, 2012).

Data Analysis

Model building approach using HLM (Raudenbush & Bryk, 2002) was followed in this study to study the incremental contribution of student-level and school-level factors in explaining mathematics achievement. As the first step, unconditional models, which do not contain any student- or school-level factors were estimated for each country. The second step estimated was the random coefficients models containing only student-level factors. Finally, the third step estimated was the full contextual models with both student- and school-level factors.

In each step, model building approach was pursued through model comparisons using Likelihood Ratio Test used to compare deviance values of two nested models. Deviance represents the badness of fit of a given model, and subtracting the deviance of the simpler model from the deviance of the more complex model demonstrates the change in the deviance values. HLM 7.00 software

(Raudenbush, Bryk, & Congdon, 2011) was used to build a two-level HLM model. To handle missing data, listwise deletion was performed before starting the analysis.

Results

HLM models

Unconditional models were found to be same for each country. Regarding intra-class correlation (ICC) values, the largest variance between schools was in Turkey (31%), and the smallest variance was in South Korea (9%), indicating another evidence for the use of HLM in this study. Fixed effects of final mathematics achievement models for each country are given in Table 2.

Table 2: Fixed Effects of Student- and School-Level Factors in the Final HLM Models

	Finland	South Korea	Taiwan	Turkey
Grand mean, γ_{00}	701.17**(10.62)	948.56**(7.38)	975.83**(17.03)	807.34**(17.50)
Student Level				
MotherEducation, γ_{10}	—	—	—	5.21**(0.79)
FatherEducation, γ_{20}	—	—	—	—
HomeResources, γ_{30}	20.13**(2.07)	40.05**(1.93)	35.55**(2.34)	30.27**(2.10)
Bullying, γ_{40}	-4.81**(1.41)	—	—	-3.72*(1.58)
LikeMath, γ_{50}	—	13.46**(1.96)	22.30**(2.26)	—
ValueMath, γ_{60}	2.54*(1.24)	17.95**(1.66)	10.60**(1.87)	—
ConfidenceMath, γ_{70}	47.47**(1.19)	57.77**(2.25)	44.87**(2.42)	63.72**(1.60)
School Level				
IncomeArea, γ_{01}	—	12.30**(2.28)	29.63**(6.92)	—
JobSatisfaction, γ_{02}	—	-1.69(2.22)	—	—

— not statistically significant, and significantly worse model, therefore removed from the model
* $p < 0.01$; ** $p < 0.001$; otherwise, not significant; Round brackets indicate standard errors

Based on Table 2, *FatherEducation*, *Fights* and *LackofResources* had no effects on students' mathematics achievement in any of the four countries. While *MotherEducation* had an effect only in Turkey, *HomeResources*, *ConfidenceMath* and *SchoolEmphasis* were found to influence students' mathematics achievement in all four countries. Moreover, there was a significant negative relationship between *Bullying* and mathematics achievement in Finland and Turkey, but not in South Korea and Taiwan. Similarly, *LikeMath* and *IncomeArea* did not contribute to students' mathematics achievement in Finland and Turkey, but they did in South Korea and Taiwan. Finally, *SchoolDiscipline* was related to students' mathematics achievement in Finland and Turkey, but not in South Korea and Taiwan.

Conclusion and Discussion

Based on the results, in Finland, the final mathematics achievement model consisted of *HomeResources*, *Bullying*, *ValueMath*, and *ConfidenceMath* at the student level; *Intimidation*, *SchoolEmphasis*, and *SchoolDiscipline* at the school-level. Bullying at school and intimidation or verbal abuse among students such as texting might prevent Finnish students from spending less time with mathematics. In South Korea, the student-level factors were *HomeResources*, *LikeMath*, *ValueMath*, and *Confidence-Math*; and the school-level factors were *IncomeArea*, *JobSatisfaction*, and *SchoolEmphasis*. The results suggest that affective characteristics such as enjoyment of learning mathematics, value of learning mathematics, and self-confidence in mathematics are important factors for South Korean students to perform better in mathematics. In Taiwan, the student- and school level factors were found to be exactly the same as those of South Korea except *JobSatisfaction*. In Turkey, the final mathematics achievement model included *MotherEducation*, *HomeResources*, *Bullying*, and *ConfidenceMath* at the student-level; *SchoolEmphasis* and *SchoolDiscipline* at the school level. While the strongest predictors of mathematics achievement for Turkish students were *ConfidenceMath* and *SchoolEmphasis*, the weakest predictors were *Bullying* and *SchoolDiscipline*. Hence, more focus, in Turkey, should be given on placing high academic standards at schools and increasing students' confidence levels.

In conclusion, *HomeResources*, *ConfidenceMath*, and *SchoolEmphasis* were the common factors reported here regarding their contributions to students' mathematics achievement in all four countries. The more educational resources are available at home, the more self-confidence students have and the more emphasis on academic achievement at schools is, the better students' mathematics performances will be. Although there was no causal evidence in this study about the relationships among mathematics achievement and these factors, the consistent positive relationship among them in each country suggests that *HomeResources*, *ConfidenceMath*, and *SchoolEmphasis* are critical and necessary characteristics of mathematics achievement.

In this paper, we present a set of principles used to co-design a statewide professional development initiative to support the implementation of new high school mathematics standards. We describe the focus of our research-practice partnership, use of design-based implementation research to organize a collaborative work, theoretical perspective on learning, and design principles for learning environments and infrastructures to support learning at scale.

Keywords: Standards, Research Methods, Design Experiments

As mathematics educators, we believe that research in our field can improve mathematics teaching and lead to more equitable learning opportunities and outcomes for children in schools. Yet, the disconnect between evidence from the research community and its use in practice and policy remains a significant challenge to educational improvement (Battista, 2007). In recent years, there has been increased interest in collaborative research and development where researchers and practitioners work together on persistent problems of practice. For researchers, research-practice partnerships provide opportunities to design and research innovations that are both timely and useful in practice, thus promoting the development of theories of implementation (Penuel & Farrell, in press). For practitioners, partnerships provide opportunities to work closely with researchers to generate solutions to problems of practice that are timely and relevant. Evidence from implementation research suggests research-practice partnerships are a promising approach for improving practice (Coburn et al., 2013).

The goal of this paper is to present a set of principles that guided the initial design of a multi-year, statewide professional development initiative to implement new mathematics standards and promote more equitable learning opportunities and outcomes for each and every student in schools. As part of a design-based implementation research (DBIR) (Fishman et al., 2013) study to identify and create mechanisms to promote the use of research in practice, this paper describes our initial claims about organizing respectful and productive professional learning opportunities for mathematics teachers and leaders at scale. We begin by describing the background and context of our research-practice partnership. Next, we outline our theoretical perspectives on learning and implementation. We then offer a set of design principles that translate our theoretical perspective into an initial design and provide an example to illustrate the ways the principles reflect our overarching conjecture about learning.

Background

The partnership began when our state initiated a process of reviewing and revising the Common Core State Standards. A group of mathematics teachers, district and state leaders, mathematicians, and education researchers were convened to review data collected from multiple stakeholder groups, a set of recommendations from a legislatively appointed committee, and research on student learning to inform a new set of high school mathematics standards for three integrated and sequenced high school mathematics courses. During the process, the group voiced concerns over previous efforts to implement standards and shared their commitments to better supporting teachers, schools, and districts with timely instructional resources and quality professional learning opportunities. In June of 2016, the new standards were adopted and scheduled to be implemented the next academic year (August, 2016). After the official adoption, the state agency initiated a formal partnership with our institutions to co-design and study a statewide professional development initiative to support efforts to implement the new standards.

We elected to use DBIR to organize our work. As an approach to collaborative research and development, DBIR focuses not only on developing tools and environments for learning but also on creating structures and supports to scale and sustain them (Fishman et al., 2013). Partners agree to focus on a problem of practice and commit resources to co-design tools and learning environments to address the problem with attention to scale. During implementation, they seek to both improve the design and generate theories of learning and implementation through research. They also create supporting infrastructures to develop capacity and sustainability.

Through negotiation, we agreed to focus on designing professional learning opportunities to share research on mathematics learning and teaching as a means of supporting the standards implementation. To this shared problem of practice, partners brought a broad range of resources. Teachers, researchers, and leaders collectively brought expertise in mathematics content, research on teacher learning, mathematics education, educational leadership, state and district policy, and the contexts of classrooms. Some brought experience in establishing systems for communication, others brought knowledge of research underlying revised standards and skills at conducting research. In what follows, we provide an overview of our efforts at co-designing by first describing our theoretical perspective and overarching conjecture about learning.

Theoretical Perspectives

Our initial design follows from a theoretical perspective of learning as a transformation of participation in practice (Lave & Wenger, 1991; Wenger, 1998). Wenger (1998) outlines learning as social participation in the practices of communities and forming identities. He defines practice as representing social, contextual, and historical ways of belonging that reside within and among members of communities. He outlines three dimensions of practice that bring coherence to a community – mutual engagement, joint enterprise, and shared repertoire. Because practice is a defining characteristics of a community, communities are formed by collaboratively engaging with common resources (e.g. routines, tools, language) toward a common goal. As members participate in the practices of the community, they negotiate new meanings and refine their practice. From this perspective, learning occurs as an ongoing negotiation of meaning within the community.

Though boundaries of practice distinguish communities across the social landscape, they are also a source of new learning. In boundary encounters, members of distinct communities come together and negotiate meaning around boundary objects - artifacts that carry meaning in multiple communities and support knowledge exchange. In boundary encounters, as engagement around boundary objects occur, members from these distinct communities introduce, negotiate, and integrate elements of other practices with their own and over time form boundary practices that are distinct to the boundary community. Thus, learning also occurs through ongoing negotiations of meaning in boundary encounters which may result in the incorporation of new elements of practice in their respective communities.

Large enterprises, which may be too diverse to consider a single community or a small set of boundary communities, still share a number of related yet distinct practices with a similar goal. These “constellations of practices” (Wenger, 1998, p. 127), while distinct in some ways, are aligned toward some common focus and share commonalities (e.g. history, shared artifacts, geography). To enable connections of practice among the communities in the constellation, Wenger suggests infrastructures that enable coherence and alignment across the constellation as key components of any design for learning.

Wenger (1998) uses the idea of a "learning architecture" to describe necessary elements and decisions one makes when designing for learning. Central to a learning architecture are infrastructures that enable alignment and meaningful engagement across the design. Given this perspective, we view teachers, school districts, state leaders, and researchers as members of distinct communities of practice within a constellation of mathematics educators within the state focused on implementing new mathematics standards and promoting more equitable learning opportunities and outcomes for each and every student.

Principles for Designing Architecture for Learning

To translate this theoretical perspective into a learning architecture, we began by reviewing literature on learning, professional development, mathematics teacher learning, implementation, and infrastructures to identify key ideas about learning in boundaries. Based on this review and the shared experiences in professional development within the partnership, we articulated a set of design principles to connect our theoretical perspective on learning to the specific learning environments – including the tasks, tools, participation structures, and discursive practices – and the infrastructures we aimed to design. The principles that guide our efforts to co-design a learning architecture to promote and sustain learning across boundaries of practice are described below. Principles related to learning environments that promote professional learning:

1. Build from the consensus view of effective professional development (Desimone, 2009) by providing access to safe and respectful opportunities to learn, fostering professional relationships (Darling-Hammond et al., 2009), and eliciting and using teachers' and leaders' expertise, contexts, and histories as resources for learning (Bransford et al., 2000; Goldsmith et al., 2014).
2. Focus on the social, cultural, and mathematical resources students bring to instruction (Civil, 2002).
3. Balance immediate support with participation structures that foster engagement by elucidating limitations of previous practice (Spillane et al., 2002; Stein & Coburn, 2008).
4. Utilize tools designed to introduce findings from research on student learning in mathematics and mathematics instruction (Bell & Rhinehart, 2016).

Principles related to infrastructures that build capacity for sustained change:

5. Coordinate resources and tools across the architecture to increase coherence (Hopkins et al., 2013; Wenger, 1998).
6. Make tools available for teachers and leaders to enlist parents, families, and community members as partners in students' mathematics education (Dantec & Disalvo, 2013).

To illustrate our use of the principles, we share the design of a closed webspace created for teachers and leaders as part of the implementation efforts. The list below outlines key features of the webspace that follow from one or more of the principles. For example, design feature 3 follows from principles 2, 4, and 5.

1. Use space to focus on discussions of student work and a forthcoming research brief series on equity in mathematics education

2. Use space as a repository for resources and means for discussion
3. Use space to promote the use of research on student and teacher learning through attention to designed content and pedagogy briefs
4. Use space to maintain access to recordings of prior webinars and regional meetings
5. Use space to promote the use of resources to support parents and community in understanding the new standards.

Conclusion

The principles outlined in this paper guided the translation of our theoretical perspective on learning into our initial design. Currently, we are conducting ongoing analyses of teachers' and leaders' participation to refine aspects of the learning architecture, investigate ways of improving infrastructures, and identifying additional elements to promote learning at scale. As we consider the conference theme, "Synergy at the Crossroads", we see partnerships with practitioners, not only sitting at the intersection of theory and practice, but doing so in a way that has the potential of significantly affect change at scale.

REFLECTED ABSTRACTION AND PEDAGOGICAL NEED: TEACHERS' INTERTWINED KNOWLEDGE AND MOTIVATION FOR INSTRUCTIONAL REPRESENTATIONS

Erik D. Jacobson
Indiana Univeristy
erdajaco@indiana.edu

Preparing beginning teachers to use instructional representations remains a significant challenge, in part because both knowledge and motivation are required. In this conceptual paper, the author uses the distinction between the Piagetian constructs of reflecting versus reflected abstraction as a lens to examine the central problem of teachers' intertwined knowledge and motivation for using instructional representations. Learning to use instructional representations of mathematical concepts may require a different kind of cognitive process than does learning the concepts themselves. The author argues that conceptual knowledge decreases teachers' intellectual need for representing foundational ideas. Pedagogical need is introduced as an alternative source of motivation.

Keywords: Teacher Knowledge, Teacher Beliefs, Teacher Education-Preservice

Instructional representations such as base ten blocks and number lines are an essential component of effective mathematics instruction in the elementary grades. Unfortunately, preparing beginning teachers to use instructional representations remains a significant challenge (Inoue, 2009; Kinach, 2002). Effective use requires knowledge (Izsák, 2008; Mitchell, Charalambos, & Hill, 2014), but knowledge is not enough. In a national sample of middle grade teachers—many with elementary certification—Jacobson and Izsák (2015) found knowledge was correlated with representation use in the classroom only to the extent that teachers were also motivated to use instructional representations. Without understanding how teachers' knowledge and motivation are intertwined, the problem of preparing effective elementary teachers remains.

I describe an initial theoretical account of both (1) why it is hard for teachers to develop knowledge and motivation to use instructional representations and (2) how such development might occur. I contrast an example of a student who is using a representation to develop new understanding with a preservice teacher (PST) who is using a representation to explain a concept they already understand. The examples emphasize a key difference between students who are learning mathematical concepts and PSTs who already understand them, a difference that I explicate using the Piagetian construct of reflecting abstraction. Finally, I extend the examples to contrast motivation for understanding new concepts with motivation for explaining concepts that are already understood. I conclude with implications for teacher education and research.

Teachers' Conceptual Understanding of Instructional Representations

Instructional representations feature prominently in characterizations of teachers' professional knowledge. Introducing the seminal notion of pedagogical content knowledge (PCK), Shulman, (1986, p. 9) described two categories of teacher work: appraising students' conceptions and reasoning and selecting and using instructional representations. Because students often use representations to communicate their reasoning, both categories rely on teachers' knowledge of instructional representations.

Distinguishing PCK from disciplinary knowledge reveals a central problem of teacher knowledge: Disciplinary knowledge—the ultimate goal of instruction—is compressed and highly structured and thus insufficient to do the work of teaching; instead, teachers need knowledge that is "unpacked" (Ball & Bass, 2000). The challenge for teacher education is that PSTs often lack both disciplinary knowledge as well as PCK. PSTs who develop disciplinary knowledge in teacher preparation content courses may find that what they know is ‘packed’ and thus less useful for the work of teaching. In methods classes, PSTs may struggle to apply what they understand about mathematics to the problems of teaching and learning.

I draw on a Piagetian distinction to contrast representation to learn and representation of what has been learned. Learners who coordinate simple concepts to achieve a goal can—often unconsciously—encapsulate their coordinated activity as a new concept. This process is driven by *reflecting abstraction* in which knowledge is reorganized to a higher level of cognition (e.g., from physical actions to mental operations; Piaget, 2001). The new resulting concept can then be used to achieve similar goals as previously were achieved through the coordination, but without need of the previously coordinated concepts. Piaget (2001) distinguished reflecting abstraction from *reflected abstraction* which involves *consciously* reflecting on a complex concept to become aware of ways it might arise from reorganizing simpler concepts (Tillema & Hackenberg, 2011). Using the distinction as a lens to examine instructional representations has promise for untangling the central problem of teachers’ disciplinary knowledge.

The work of Kylie, a 4th grade student discussed by Simon, Placa, and Avitzur (2016), illustrates how representations support reflecting abstraction. Figure 1a shows how she solved a fraction task. Asked to find 1/6 given a region named 1/3, she first iterated the region to recreate the whole (Step 2), then partitioned 1/3 (Step 3) to find a part such that 6 parts would make the whole. On the third such task, Kylie found the required part without iterating to the whole or partitioning it; she went directly from Step 1 to Step 4 in Figure 1 by using whole number division to appropriately partition the initial part. This change evidenced reflecting abstraction because she learned a new concept that went beyond the simple concepts she had previously coordinated. Now “she could produce $1/mn$ from $1/n$ by partitioning $1/n$ into m parts” (p. 78), but she no longer needed to think explicitly about the common whole, even less to draw it out.

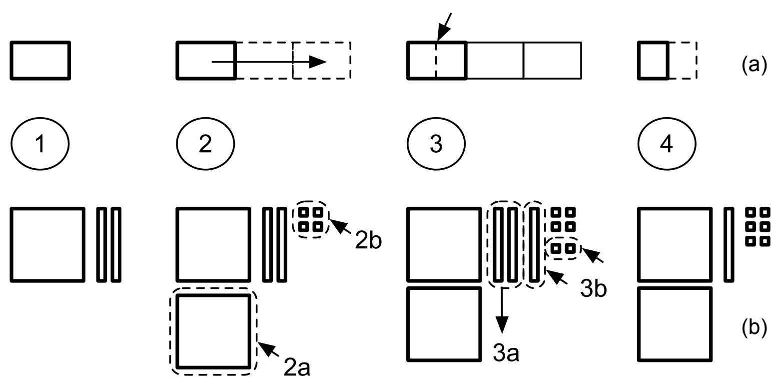

Figure 1. Sequences of instructional representation (a) from Kylie, a student, using drawings to find 1/6 given 1/3 by iterating to find the whole and then partitioning, and (b) from Alan, a PST, using base ten blocks to illustrate how he solved 120 + 96 by adding 100 and subtracting 4.

Reflecting abstraction undergirds mathematics learning but simultaneously it makes teaching difficult. Once a new, more powerful concept is constructed, the simple concepts from which it came—and from which someone else might be able learn—no longer seem relevant because the new concept changes how a problem is perceived. To illustrate this point, consider the instructional explanation offered by Alan, a PST who was asked to use base ten blocks to explain the solution of 120 + 96 to a student (Figure 1b). His said he would add 100 and subtract 4, and he illustrated this by moving in a 100-flat (Step 2a) and four 1-cubes (Step 2b). Then he said the answer was 216 without further explanation. He represented 216 by moving out two 10-longs (Step 3a) and moving in one 10-long and two 1-cubes (Step 3b). From an observer's perspective, the quantitative meaning of the 4 cubes changed dramatically; in Step 2 they represented 4 to be subtracted from 220 but in Step 3 they were part of the remaining 216. Alan gave no indication he was attending to quantitative meaning as he transformed the materials.

One possible explanation for these data is that Alan had already constructed a powerful concept for multi-digit addition; his knowledge was "packed." Because the answer was obvious to him, Step 3 was only a convenient way to show the answer, not an attempt to justify it. It was like a scene change between acts in a play—on stage but not meant to be seen. Alan's representational activity with base ten blocks was different in kind than Kylie's work on the first problem. Unlike Kylie's reasoning before the reflecting abstraction, Alan's reasoning did not depend on the instructional representation because of prior reflecting abstraction.

PSTs' explanations sometimes involve quantitatively incoherent use of instructional representations because after reflecting abstraction solutions do not depend on representation use. This observation clarifies the goals for teacher education: we must help PSTs value representations for showing how simple concepts underlie complex ones. Indeed, prior work has described how instructional representations can be an important catalyst for teacher learning (e.g., Kinach, 2002). Here is the novel insight: Teacher learning from representations can be characterized by *reflected abstraction* (Piaget, 2001). Just as instructional representations can help students learn concepts by providing a context for reflecting abstraction, I conjecture that representations can help teachers by providing a resource for reflected abstraction.

Teachers Motivation to Use Instructional Representations

In this section I start with the premise that motivation is critical to learning, and contribute a novel argument. In sum, the motivation to teach mathematics has a fundamentally different nature than motivation to learn mathematics because the need that drives each activity is different. This difference in motivation parallels the previous difference in representation.

I begin with the concept of *intellectual need*, and I paraphrase of a recent definition provided by Harel (2013). Suppose an individual encounters a mathematical problem that cannot be solved with their current state of knowledge. After some time working on the problem, suppose further that she is able to solve it. We would attribute new knowledge to her, and the intellectual need for that new knowledge is simply the problem that was at first unsolvable. She has an intellectual need for the new knowledge precisely because it enabled her to solve the problem.

To understand how the problem of teacher motivation is related to mathematical knowledge, it is helpful to return to the example of Kylie (Simon et. al, 2016). At first, Kylie said she had no idea how to solve the fraction tasks and had to draw out the whole; yet by the third task, her new concept made drawing unnecessary. Suppose that when Kylie grows up she becomes an elementary teacher. Responsible for teaching the same problem, what would *motivate* her to represent the whole by iterating 1/3 (Figure 1a, Step 2) since, because of her conceptual knowledge, partitioning 1/3 directly (Step 4) is now obvious? Even after reflected abstraction to gain conscious awareness of the fundamental role of the whole in her partitioning concept, the extra drawing is more work, takes more time, and no longer fulfills an intellectual need. Instead of being necessary for Kylie, drawing the whole is inefficient and laborious.

It follows from this thought experiment that representing simple component concepts once one knows the higher-level concept does not satisfy personal intellectual need. Instead of motivating PSTs by focusing on their own personal intellectual need, teacher educators might be more successful at motivating PSTs to use instructional representations if they can clarify and make explicit the pedagogical need that is part of their putative role as teachers.

I define *pedagogical need* as analogous to intellectual need. In view of specific knowledge in the curriculum, a teacher's pedagogical problem is engendering students' intellectual need for this knowledge and the knowledge itself. A teacher has a pedagogical need for the PCK that enables her to solve this pedagogical problem.

In the case of Kylie, the higher-order knowledge that made drawing the whole unnecessary came about in relation to an intellectual need engendered by the sequence of problems she encountered and her concurrent representational activity. The pedagogical problem in this case was how to help Kylie develop this knowledge, and the corresponding PCK includes understanding the sequence of tasks and the importance of drawn representations that lead Kylie to realize her intellectual need and the corresponding knowledge. Therefore, in order to gain motivation for using instructional representations, PSTs must understand how instructional representations can function as a bridge between students' initially simple ideas and the more complex ideas that are the goal of instruction. That is, they must come to understand how instructional representations solve pedagogical problems they may encounter.

Conclusion

I have argued that learning to use instructional representations of mathematical concepts may require a different kind of cognitive process—namely, reflected abstraction—than the cognitive process used to learn concepts themselves. In addition, I have proposed a link between teachers' knowledge and their motivation for using instructional representations by arguing that conceptual knowledge decreases teachers' intellectual need for representing foundational ideas. I propose pedagogical need as an alternative source of motivation for instructional representation.

TAKING MEASURES TO COORDINATE MOVEMENTS: UNITIZING EMERGES AS A MEANS OF BUILDING EVENT STRUCTURES FOR ENACTING PROPORTION

Alik Palatnik
Shaanan Academic Religious Teachers' College
umapalatnik@gmail.com

Dor Abrahamson
UC Berkeley
dor@berkeley.edu

Rhythm is a means of production—a scheme for coordinating the enactment of real or imagined physical movements over time, space, material resources, and concerting participants. In activities requiring the coordination of two or more continuous *motor actions, rhythmic re-assembly of the actions creates a goal event structure mediating the enactment. Yet building that structure requires first unitizing continuity. Unitizing could thus be conceptualized as a cultural–historical strategy for supporting mundane routines by parsing, distributing, and codifying activity as a sequence of iterated actions of equivalent magnitude. Ipso facto, unitizing shifts us from naive to disciplinary activity: articulated rhythm is an ontogenetic achievement driving cognitive growth. We present empirical data of a student spontaneously measuring continuous actions as her means of organizing the enactment of a bimanual task designed for proportions.*

Keywords: Cognition, Measurement

Introduction

Mathematics learning activities designed in accordance with embodiment theories of cognition create opportunities for students to engage in the solution of sensorimotor problems prior to interpreting and representing their solutions formally in normative symbolic register (Lee, 2015). This heuristic design principle is grounded in a constructivist (Boom, 2009) and enactivist (Reid, 2014) consensus that concepts emerge through noticing repeated patterns in perceptual dynamics guiding motor action. Empirical work has corroborated this historical conjecture through combining eye-tracking and clinical data analysis (Abrahamson et al., 2016).

The objective of this paper is to contribute to scholarship on students' passage from sensorimotor action to mathematical reasoning. Our study's empirical context is an action-based embodied design, the Mathematical Imagery Trainer (Abrahamson, 2014), wherein participant students enact a challenging bimanual motor action related to the development of proportional reasoning. By micro-analyzing students' behaviors, we demonstrate spontaneous utilization of measurement units. We argue that emergent rhythmic enactment facilitated discretization that led to evoking measurement units and in turn building an event structure mediating the enactment.

Theoretical Background

Cultural–historical positions view the practice of measuring, along with its artifacts, routines, and discourse, as evolved to serve an essential means of mathematizing human action and thought (Malafouris, 2013). In particular, measure units enhance one's ability to estimate, compare, and calculate continuous quantities (Stavy & Babai, 2016). Cognitive-developmental psychology defines measuring as follows: "To measure is to take out of a whole one element, taken as a unit, and to transpose this unit on the remainder of a whole: measurement is therefore a synthesis of sub-division and change of position" (Piaget, Inhelder, & Szerninska, 1960, p. 3). Measuring competently thus requires: (a) conserving the size of the unit; (b) iterating the unit; and (c) transitively, inferring the relative length of two objects by comparing them to a unit. When we imbue these measurement routines with the temporal dimension, we can discern the enactment of rhythmic actions. Indeed Radford (2015) found structured temporal qualities in analyzing students' performance in algebraic pattern-generating activity: meter, rhythmic grouping, prolongation, and theme. Sinclair, Chorney, and Rodney (2016) used rhythm as their focal analytic construct in investigating the mathematical activity of children interacting with a tablet application designed for learning number. They implicate rhythmic actions as the embodied origin of cognitive structure, preceding planning and reflection. In like vein, Bautista and Roth (2012) documented the role of rhythmical hand movements in students' haptic engagement with geometrical regularities in material solids (cf. Bamberger & diSessa, 2003).

In summary, embodiment perspectives on mathematical cognition conceptualize dynamical sensorimotor problem solving as constitutive of conceptual growth. Positioned within the embodiment paradigm, we present a case of a student who spontaneously evoked measurement operations as her means of regulating the enactment of a challenging bimanual motor task designed to support the development of proportional reasoning. Our objective is to enrich scholarship on the rhythmic qualities of mathematics learning by way of interpreting the circumstances and process leading to her rhythmic mathematization of continuous quantities.

Methods

The empirical context for this study was the Mathematics Imagery Trainer for Proportion (MIT-P; see Figure 1). Unlike earlier studies in this empirical context (Abrahamson & Trninic, 2011), in the current study no mathematical tools were offered, such as a grid or numerals.

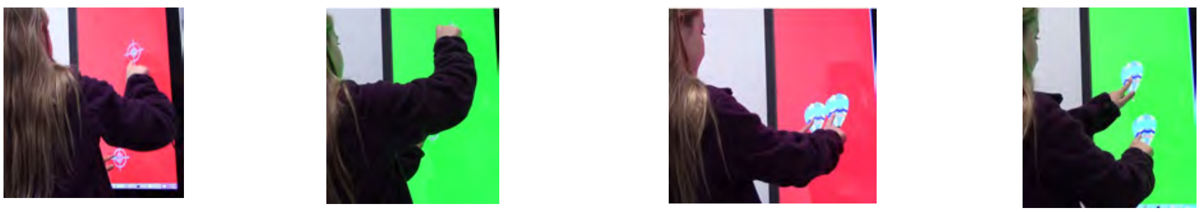

Figure 1. The Mathematical Imagery Trainer for Proportion (MIT-P). The student manipulates two cursors along vertical axes, one by each hand. The task is to make the screen green and then keep it green while moving your hands. The screen will be green only when the heights of the two cursors above the screen base relate by a particular ratio unknown to the user (e.g., here 1:2). Otherwise it will be red. Cursors may be either "stark" (e.g., generic targets; see on left) or "iconic" (e.g., hot air balloons; see on right).

K was an 11-year-old female student, one of 25 students participating voluntarily in a task-based semi-structured clinical interview (for details, see Rosen, Palatnik, & Abrahamson, 2016). The interview lasted in total 19 minutes: a general introduction (1 min.); and the problem-solving phase (18 min.), where she manipulated: (a) hot-air balloons (7 min.); (b) cars (4 min.); and (c) crosshair targets (7 min.). The interview took place in our lab and was audio–video recorded.

We located all the events where the student expressed new insight pertaining to her manipulation strategy. The interview was then parsed into episodes, running from each insight to the next. Episodes were further coded as: (a) either researcher- or self-initiated; and (b) discrete ("finding green" static co-locations) or continuous ("keeping green" while sliding the cursors).

Applying grounded micro-genetic analysis, we focused on the students' range of physical actions and multimodal utterance pertaining to the available media (Ferrara, 2014) as well as on the task-effectiveness of their actions. First, we attended to student actions that preceded their articulation of a new rule for "making green," searching in particular for patterns in the timing and sequencing of student hand movements through space (Sinclair et al., 2016). A notation system emerged for the most frequently used movements. For example, vertical bimanual movement with the right hand going up and the left going down was denoted as "↓,↑ ," and placing both fingers statically on the screen as "●,●." Second, we analyzed K's responses to our recurring question, "How would you explain your strategy for finding green to another person?"

Results: Spontaneous Evocation of Units of Measurement

In our analysis we will attempt to implicate the specific event of K evoking measure units as a formative moment in her progress from unreflective continuous movement to unit-based discrete movement and, through this, in her learning of proportion.

Before evoking measuring units, K had developed two different rhythmical patterns as her task solutions: continuous movement, where the right hand moves twice faster than left (↑ ↑x2): and discrete, where she placed her fingers together (●,●) then vertically apart (↑,↓), traversing along recurring screen locations: bottom, middle, top. In articulating each of her strategies, K implicitly evoked particular qualities of the situation, such as the distance between her hands, as things she noticed and aimed to control even as she was moving her hands. For instance: "Down here my hands were really close, and then up here they were a little apart, and then up here they were really apart." Hoping for greater specificity of her movement rules, the interviewer asked K, "Ok, do you have any sense of… kind of…how this [the distance between her hands] is changing? How much it is changing, how much faster it is moving?" Beginning at 05:29, where she was working with hot-air balloon cursors, K responded by performing a particular action pattern repeatedly, at a constant pace, at three screen locations: bottom, middle, and top, stating that the balloons were: (bottom) "touching each other"; (middle) "There's about a balloon between them….the length of the balloon"; and (top) "Two balloons [apart], maybe." At 6:45 K repeated: "Ammm… [Quick succession of demonstrations: bottom ●,●, ↓,↑; middle ●,●, ↓,↑; top ●,●, ↓,↑] kind of at the bottom, there… it goes *zero* balloons between them, in the middle there is *one* balloon between them, and at the top, *two* balloons between them. So *it grows by one* at a time." K thus spontaneously utilized an available virtual object as a measure unit.

When the interviewer asked her to show "how to keep the screen green," K first gestured and then moved her hands continuously, with one hand moving twice as fast [↑ , ↑ x2]. It is of note that she tried to use her insights from the previous enactment as landmarks, that is, to connect the bottom, middle, and top discrete solutions into a single continuous enactment, as follows:

> (7:15) K: I would say, like, start at the bottom, and put them close together. And then, move one hand up faster… Wait, actually, [inaudible] …and as I said, in the middle, they are separated like one balloon [inaudible], and at the top two balloons.

Thus, a qualitative scheme for finding and keeping green, "one hand moves faster than the other as it goes up," assimilated a quantitative scheme, "it grows by one at a time," to better serve K's goals. Our claim is that the rhythmic qualities of K's actions—iteration, grouping, stability—as well as the interviewer's prompt to quantify ("how much") catalyzed this process. We observed feedback loops, where movements were coordinated into action patterns, and those patterns in turn were iteratively repeated, both spatially (bottom, middle, and top of the screen) and temporally. The linear extents of the hands' respective displacements came to attention *as a result of experiencing/enacting the emergent rhythm*. Namely, the rapid, cyclic repetition of implicitly measured actions gave rise to rhythmic enactment. The unit of measure emerged as a spontaneous combination of a stable pattern of movements and relatively stable perceptual elements, driven by a task demand to reflect on her own actions. Later in the interview, K quickly reenacted the new quantitative scheme in the case of car icons as well as the stark icons.

Conclusion

Rhythm is a means for coordinating physical operations over time, space, and material (or virtual) resources into new sensorimotor schemes. In the absence of any explicit frame of reference, rhythmic enactment bootstraps discretization, thus leading to further evocation of measurement units, which in turn improve performance and are thus adopted and codified. K's actions evolved from independent, explorative, seemingly uncoordinated movements into a stable temporal–spatial choreography comprising a succession of coordinated, measured clusters of movements preserving a relational invariant (see also Sinclair, Chorney, & Rodney, 2016).

K succeeded in coordinating her actions to produce green effectively well before she was able to articulate quantitative properties or her actions. When she first constructed a quantitative scheme for these actions, K was conscious not of a static structure. Rather, she responded to epiphenomenal features in the rhythmic cadence of enacting these coordinated actions. As such, rhythmic enactment mediated a transitioning from naïve to scientific reasoning. The temporal qualities of K's rhythmic enactment across the continuous display assimilated spatial qualities of available objects (hot-air balloons) to deploy motor-action execution over imaginary discrete units of measure. K thus extracted a measure unit from the situation as her means of extending insights from discrete to continuous actions. Unitizing is thus an evolved strategy for enhancing the coordination of continuous action by distributing it over regulated cycles of iterated enactment over projected spatial extensions. Further research is needed to understand the interplay of rhythm, action, and discourse in the elicitation of unitizing operations.

REFRAMING MATHEMATICS DISABILITY: EMERGING CRITICAL PERSPECTIVES

James Sheldon
University of Arizona
jsheldon@email.arizona.edu

Kai Rands
Independent Scholar
randske@gmail.com

Keywords: Equity and Diversity, Research Methods, Problem Solving

This poster, inspired by last year's working group on Rethinking Mathematics Intervention (Sheldon et al., 2016), offers a review of the literature into recent critical perspectives on mathematics disability. Mathematics disability is not a topic normally covered in mathematics education journals; it is mostly relegated to special education journals. (Sheldon, 2013; Lambert & Tan, 2016). We seek to create to bridge the divide between special education and math education by creating intersections between these areas of study.

The purpose of this literature review poster is to explore emerging critical perspectives on mathematics disability, with a particular focus on perspectives grounded in critical theories. In order to conduct the review, we consulted two recent exhaustive literature reviews (Lambert & Tan, 2016a; Lewis & Fisher, 2016), drew upon a database of 107 articles, conducted keyword searches, and contacted scholars interested in mathematics disability.

The review revealed three main themes. First, research related to mathematics disability has reflected methodological conservatism. Second, there is a significant literature calling for mathematics reform within Special Education (e.g. Woodward & Montague, 2002). Third, we found an emerging literature involving critical perspectives. In this emerging literature, mathematics education researchers view disability as a difference rather than as a deficit and propose looking at intersectional notions of disability and the ways in which they affect perceived ability (Lambert, 2016a).

THEORY IN MATHEMATICS EDUCATION: INTRA-ACTION AND (RE)CONFIGURATION

Susan Cannon
Georgia State University
scannon5@gsu.edu

Keywords: Equity and Diversity, Research Methods, Standards

Using (post) qualitative methodology located within a critical postmodern theoretical frame, I will examine the intersection(s) and borders of the field of mathematics education and the posts (post-structural, new materialist, post-humanist, post-qualitative). The "field" in this research will be considered a fluid space that shifts and responds as "new" research is brought into it. The research questions that guide this study are:

1. What are the taken for granted, expectations and norms of these spaces?
2. How are post theories being used/taken up within mathematics education?
3. How are the borders and boundaries of the field of mathematics education shifting in response to these theories and methodologies?

Mapping the Machine

The poster will consider how research is counted or excluded from the body of mathematics education research recognizing that "counting practices are bound up with the production of natural and social orders" (Martin & Lynch, 2009, p. 245). I will map the intersections, "lines of flight" (Deleuze & Guatarri, 1980/1987), and ruptures in the research body and consider how these matter. Drawing on new materialist theories, (Barad, 2007), I will consider the measuring and counting apparatus (math education journals, citations, and conference proceedings) which are always already entangled with the object of measurement (Barad, 2007). I will consider, following Dolphijn and Turin (2013), how "measurements are the entanglement of matter and meaning" (p. 16) and how they are, therefore, "calling data into being" (St Pierre, 2013, p. 223).

The intra-action (Barad, 2007) of theory with mathematics education research will be tentatively mapped giving attention to the complications created in the intra-action that allow (re)configurations of school mathematics (de Freitas & Sinclair, 2014). I will consider places where the intra-action allows for gathering speed and attention and places where intra-action disrupts normative practices in mathematics education research.

NUMBER THEORY AND INTRODUCTORY MATHEMATICS IN HIGHER EDUCATION

Cassondra Gendron
University of Massachusetts at Dartmouth
cgendron1@umassd.edu

Walter Stroup
University of Massachusetts at Dartmouth
wstroup@umassd.edu

Keywords: Curriculum, Technology, Post-Secondary Education

Due to sequential organization of university level mathematics curricula, non-math majors often do not get to experience abstract, higher level mathematics. We present preliminary results from working with students enrolled in an Elementary Statistics course to explore patterns in results related to the accessible, but still unproven, Collatz Conjecture from number theory. Not only does this work provide an account of where a conjecture from advanced mathematics is engaged by students in early, university-level mathematic courses but by analyzing the results from the recursive implementation of Collatz Conjecture (using the agent—based NetLogo programming language) using statistical methods from what they are studying, the work may illustrate how explorations in one area of mathematics can, at a more advanced level, be seen to interact in significant ways with other areas of mathematics.

Paul Erdös said "mathematics is not ready" to analyze the Collatz Conjecture. For our study students were able to generate, using a NetLogo program that we developed for this purpose, results from implementing this conjecture over a large number of user-specified values (e.g., all even numbers between 1 and 10,000). The students' results are displayed and analyzed using techniques from introductory statistics (e.g., linear regression). We present our results from applying a grounded theory methodology to analyze a series of semi-structured interviews conducted with students as they engaged with cycles of NetLogo-based exploration followed by the application of statistical methods to the results (Charmaz, 2008). The longer-term goal of this line of research is to find ways to understand how it might be possible and what it might mean to have students in introductory courses be able to explore topics from advanced mathematics.

ADDRESSING EQUITY AND DIVERSITY ISSUES IN MATHEMATICS EDUCATION: RESETTING AT THE CROSSROADS

Gregory V. Larnell
University of Illinois at Chicago
glarnell@uic.edu

Jennifer M. Langer-Osuna
Stanford University
jmlo@stanford.edu

Joel Amidon
University of Mississippi
jcamidon@olemiss.edu

As the title suggests, this Working Group has a dual focus on issues of mathematics teaching and learning and issues of equity and diversity. Following on the topics discussed at the Working Group between 2009-2016, this year the focus is resetting and reestablishing the purpose of this group and supporting the development of new directions for equity-oriented research working groups. The sessions will focus on regrouping attendees interested in equity, generating and brainstorming new subtopics and potential projects, and working to establish standalone working groups dedicated to furthering research on equity. The purpose of this resetting is to encourage a move away from "big-tent" equity thinking and toward more productive working collectives.

Keywords: Equity and Diversity

Brief History

This Working Group originates from the Diversity in Mathematics Education (DiME) Group, one of the Centers for Learning and Teaching (CLT) funded by the National Science Foundation (NSF). DiME scholars graduated from one of three major universities (University of Wisconsin-Madison, University of California-Berkeley, and UCLA) that comprised the DiME Center. The Center was dedicated to creating a community of scholars poised to address critical problems facing mathematics education, specifically with respect to issues of equity (or, more accurately, issues of inequity).The DiME Group (as well as subsets of that group) has engaged in important scholarly activities, including the publication of a chapter in the *Handbook of Research on Mathematics Teaching and Learning* which examined issues of culture, race, and power in mathematics education (DiME Group, 2007), a one-day AERA Professional Development session examining equity and diversity issues in mathematics education (2008), a book on research of professional development that attends to both equity and mathematics issues with chapters by many DiME members and other scholars (Foote, 2010), and a book on teaching mathematics for social justice (Wager & Stinson, 2012) that also included contributions from several DiME members. In addition, several DiME members have published manuscripts in a myriad of leading mathematics education journals on equity in mathematics education. This working group provides a space for continued collaboration among DiME members and other colleagues interested in addressing the critical problems facing mathematics education.

It is important to acknowledge some of the people whose work in the field of diversity and equity in mathematics education has been important to our work. Over time, the Working Group has encouraged building on and featuring senior scholars' work, including Marta Civil (Civil, 2007; Civil & Bernier, 2006; González, Andrade, Civil, & Moll, 2001), Eric Gutstein (Gutstein, 2003, 2006; Gutstein & Peterson, 2013), Jacqueline Leonard (Leonard, 2007; Leonard & Martin, 2013), Danny Martin (Martin, 2000, 2009, 2013), Judit Moschkovitch (Moschkovich, 2002), Rochelle Gutiérrez (2002, 2003, 2008, 2012, 2013) and Na'ilah Nasir (Nasir, 2002, 2011, 2013; Nasir, Hand & Taylor, 2008; Nasir & Shah, 2011). We have as well been building on the work of our advisors, Tom Carpenter (Carpenter, Fennema, & Franke, 1996), Geoff Saxe (Saxe, 2002), Alan Schoenfeld (Schoenfeld, 2002), and Megan Franke (Kazemi & Franke, 2004), as well as many others outside of the field of mathematics education.

Previous iterations of this Working Group at PMENA 2009 – 2013, and 2015-2016 have provided opportunities for participants to continue working together as well as to expand the group to include other interested scholars with similar research interests. Experience has shown that collaboration is a critical component to this work. These efforts to expand participation and collaboration were well received; more than 40 scholars from a wide variety of universities and other educational organizations took part in the Working Group each of the past five years. Moving forward, we hope to "reset" the group toward providing opportunities for a new generation of scholars whose work intersects with issues of equity/inequity, diversity/inclusion, privilege/oppression, and justice in mathematics education research, practice, and development.

Focal Issues

Under the umbrella of attending to equity and diversity issues in mathematics education, researchers are currently focusing on such issues as teaching and classroom interactions, professional development, prospective teacher education (primarily in mathematics methods classes), factors impacting student learning (including the learning of particular sub-groups of students such as African American students or English learners), and parent perspectives. Much of the work attempts to contextualize the teaching and learning of mathematics within the local contexts in which it happens, as well as to examine the structures within which this teaching and learning occurs (e.g. large urban, suburban, or rural districts; under-resourced or well-resourced schools; and high-stakes testing environments). How the greater contexts and policies at the national, state, and district level impact the teaching and learning of mathematics at specific local sites is an important issue, as is how issues of culture, race, and power intersect with issues of student achievement and learning in mathematics. There continues to be too great a divide between research on mathematics teaching and learning and concerns for equity.

The Working Group has begun and will continue to focus on analyzing what counts as mathematics learning, in whose eyes (and for whose benefit), and how these culturally bound distinctions afford and constrain opportunities for traditionally marginalized students to have access to mathematical trajectories in school and beyond. Further, asking questions about systematic inequities leads to methodologies that allow the researcher to look at multiple levels simultaneously. This research begins to take a multifaceted approach, aimed at multiple levels from the classroom to broader social structures, within a variety of contexts both in and out of school, and at a broad span of relationships including researcher to study participants, teachers to schools, schools to districts, and districts to national policy.

Some of the research questions the Working Group will continue to consider are:

- What are the characteristics, dispositions, etc. of successful mathematics teachers for *all* students across a variety of local contexts and schools? How do they convey a sense of purpose for learning mathematical content through their instruction?
- How do beginning mathematics teachers perceive and negotiate the multiple challenges of the school context? How do they talk about the challenges and supports for their work in achieving equitable mathematics pedagogy?
- What impediments do teachers face in teaching mathematics for understanding?
- How can mathematics teachers learn to teach mathematics with a culturally relevant approach?
- What does teaching mathematics for social justice look like in a variety of local contexts?
- What are the complexities inherent in teacher learning about equity pedagogy when students come from a variety of cultural and/or linguistic backgrounds all of which may differ from the teacher's background?

- What are dominant discourses of mathematics teachers?
- What ways do we have (or can we develop) of measuring equitable mathematics instruction?
- How do students' out-of-school experiences influence their learning of school mathematics?
- What is the role of perceived/historical opportunity on student participation in mathematics?

Specific to the intent of this year's Working Group, we will organize around questions like the ones above in order to create specific, targeted working groups that are charged to address and act around such questions.

Plan for Working Group

Based on feedback from the previous year and the emergence of new working groups related broadly to "equity," this working group should shift toward a renewed focus on facilitating "collaboration within the growing community of scholars and practitioners concerned with understanding and addressing the challenges of attending to issues of equity and diversity in mathematics education." However, we propose to reconfigure the working group toward being a catalyst for new spaces instead of a "destination" for the inclusion of equity discourse within the PME-NA organization. To put it differently, our vision for the working group should be to bring together attendees toward developing their own agendas and specific working groups related to equity-oriented themes--or toward themes that push the field beyond traditional equity discourses yet adhere to the needs and challenges of inequity within mathematics education.

Our plans for PMENA 2017 will proceed as follows. Each session will build on previous sessions, beginning with a facilitated conversation around resetting of the working group. The format for the sessions will include:

- DAY 1: Resetting, Norm-setting, and Brainstorming: On first day, we we lead attendees through introductory activities, collective norm-setting, and a series of small- and whole-group brainstorming activities that will generate new ideas and directions for the working group more broadly.
- DAY 2: Agenda-setting: On the second day, the major focus will be the development and support of new smaller sub-specializing groups based on the reported interests of attendees. We will work with and encourage these subgroups to establish possible common topics of interests, potential products, and planning for the next year to support the growth of their group and topic.
- DAY 3: Working working groups: On the third day, the newly established subgroups will "take flight" and initiate their yearly plan to support their chosen topics.

Previous Work of the Group

The Working Group met for productive sections since 2009. In 2009, participants identified areas of interest within the broad area of equity and diversity issues in mathematics education. Much fruitful discussion was had as areas were identified and examined. Over the past five years subgroups met to consider potential collaborative efforts and provide support. Within these sub-groups, rich conversations ensued regarding theoretical and practical considerations of the topics. In addition, graduate students had the opportunity to share research plans and get feedback. The following were topics covered in the subgroups:

- Teacher Education that Frames Mathematics Education as a Social and Political Activity
- Culturally Relevant and Responsive Mathematics Education
- Creating Observation Protocols around Instructional Practices
- Language and Discourse Group: Issues around Supporting Mathematical Discourse in Linguistically Diverse Classrooms
- A Critical Examination of Student Experiences

As part of the work of these subgroups, scholars have been able to develop networks of colleagues with whom they have been able to collaborate on research, manuscripts and conference presentations.

As a result of the growing understanding of the interests of participants (with regard both to the time spent in the working group and to intersections with their research), we began to include focus topics for whole group discussion and consideration and continued to provide space for people to share their own questions, concerns, and struggles. With respect to the latter, participants have continually expressed their need for a space to talk about these issues with others facing similar dilemmas, often because they do not have colleagues at their institutions doing such work or, worse yet, because they are oppressed or marginalized for the work they are doing. These concerns, in part, informed the focus topics for whole group discussion and consideration. For example, in 2009 research protocols (e.g., protocols for classroom observation, video analysis and interviewing) were shared to foster discussions of possible cross-site collaboration. In 2012, the Working Group explicitly took up marginalization in the field of mathematics education with a discussion about the negotiation of equity language often necessary for getting published; this was done in the context of the 'Where's the mathematics in mathematics education' debate (see Heid, 2010; Martin, Gholson, & Leonard, 2010). Dr. Amy Parks was invited to join Working Group organizers to share reflections on their experiences. In 2013 the Working Group hosted its first panel in which scholars (Dr. Beatriz D'Ambrosio, Dr. Corey Drake, Dr. Danny Martin) shared their perspectives on the state of and new directions for mathematics education research with an equity focus. The success of prior panel discussions have encouraged us to use that format as a launching point for deepening conversations on lingering tensions in the field. We see this working group as questioning critical borders that persist within mathematics education.

Pre-Conference and Follow-up Activities

In order to best plan for working group facilitation and prepare attendees for working group participation, we plan to send out pre-conference communication, including a Qualtrics survey, to former and potential participants in order to gauge the topics and kinds of work being done or sought, as well as the resources and forms of support desired by participants.

This working investigates the design and use of pedagogies of enactment in mathematics teacher education and professional development. These pedagogies, which feature coached rehearsals and enactments, provide a promising way to support preservice and practicing teachers in developing skill with core instructional practices, aligned with ambitious and equitable goals for instruction. Building on existing research and our discussions at PME-NA 38, we will engage in collective investigation around three central issues: articulating theories of and perspectives on teacher learning to frame research and practice, foregrounding issues of equity in this work, and conceiving partnerships to support and scale these efforts. These discussions will lead to immediate takeaways as well as plans for future collective efforts around research and practice.

Keywords: Instructional Activities and Practices, Teacher Education-Preservice, Teacher Education-Inservice/Professional Development

Brief History of the Group

This working group is a continuation of a group that initiated at PME-NA 38 in Tucson, Arizona in 2016. The group is focused on advancing the use and study of "pedagogies of enactment" (Grossman, Hammerness, & McDonald, 2009), specifically the use of coached rehearsals of instructional activities (Kazemi, Ghousseini, Cunard, & Turrou, 2016; Lampert et al., 2013) toward the development of core or high-leverage practices (Ball & Forzani, 2009; McDonald, Kazemi, & Kavanagh, 2013). We, as a group, focus on this work in the context of secondary mathematics teacher preparation and professional development (PD).

Prior to the first meeting at PME-NA 38, a group of secondary mathematics teacher educators (TEs) and researchers (represented, in part, by the leaders of this working group) collaborated informally for five years to consider the work of secondary teacher preparation in relation to recommendations from Grossman and her colleagues for teacher education and the work of Lampert, Kazemi, Franke and their colleagues in the area of elementary mathematics education. As a result of this collaboration, small groups of teacher educators have developed tools for supporting the development of ambitious mathematics teaching that leverages students' work with the Standards for Mathematical Practice (NGA & CCSSO, 2010). These tools included a collection of "instructional activities" (IAs; Lampert & Graziani, 2009) focused on secondary mathematics topics that have been shared across institutions, resulting in focused data collection and inquiry. At PME-NA 38, working group participants were able to discuss and glean insights from current efforts in development and research.

In this proposal, we first outline some background information related to pedagogies of enactment. We then detail the outcomes of our group's initial work at PME-NA 38 and the efforts that have followed. From this, we propose a new set of focal issues that continue to press efforts to design, use, and research pedagogies of enactment moving forward: (1) articulating theories of and perspectives on teacher learning; (2) focusing on issues of equity; and (3) conceiving partnerships.

Finally, we outline how the sessions of the working group will be organized to promote participant engagement around these three focal issues.

Background Information

In this section we frame the efforts of this working group by specifying what we mean by "ambitious and equitable mathematics instruction" and providing an overview of practice-based and practice-focused approaches to teacher education and PD, specifically the use of coached rehearsals as a pedagogy of enactment for teacher development.

Ambitious and Equitable Mathematics Instruction

Teachers must ensure that each student has access to rigorous academic work to develop mathematical proficiency and meet the demands of an increasing mathematically, statistically, and technologically complex society (Kilpatrick, Swafford, & Findell, 2001; National Council of Teachers of Mathematics [NCTM], 2014). These expectations are summed up, in part, by the way in which students must engage with and develop a set of mathematical practices (NGA & CCSSO, 2010). These practices represent the skills individuals in mathematics-related fields utilize in their work and the way in which all individuals make sense of, reason about, and make decisions regarding mathematical and quantitative situations. These opportunities must deliberately be made available to all students, drawing upon students' diverse cultural and linguistic resources in the mathematics classroom and positioning mathematics as a human practice and a tool for social change (Gutiérrez, 2011).

To support these "ambitious and equitable" goals (Jackson & Cobb, 2010), mathematics teachers must enact "skilled practice" (Grossman & McDonald, 2008) to carry out the work in classrooms. Specifically, teachers need skill with a set of core practices (e.g., Grossman et al., 2009; Forzani, 2014) that represent integral aspects of ambitious and equitable mathematics teaching. In our collective work we argue that participation in pedagogies of enactment need not be preceded by changes in teachers' beliefs. Teachers learn to take up ambitious and equitable practices through engagement in pedagogies of enactment.

In our collective work, we focus on core practices that include: leading whole class discussions (Boerst, Sleep, Ball, & Bass, 2011; Chapin, O'Connor, & Anderson, 2009), eliciting and responding to students' reasoning through tasks and questioning (Lampert et al., 2013; Stein, Engle, Smith, & Hughes, 2008), building on student thinking (Leatham, Peterson, Stockero, & Van Zoest, 2015; Van Zoest, Leatham, Peterson, & Stockero, 2016), representing students' reasoning verbally and visually (NCTM, 2014), and steering instruction toward a clear and worthwhile mathematical point (Baldinger, Selling, & Virmani, 2016; Sleep, 2012). Teachers' capacities with these instructional practices have the potential to engage students in key practices of the discipline of mathematics. Efforts have been made to capture a set of core practices for teaching, such as the "high leverage practices" from TeachingWorks (2016) or the eight essential Mathematics Teaching Practices from NCTM's (2014) *Principles to Actions.* This working group focuses on a set of tools and approaches of teacher education and PD experiences that support teachers' development of these skills.

Pedagogies of Practice and Coached Rehearsals

There has been an increased focus on practice-based approaches to supporting teachers' professional learning. A practice-based approach uses "practice as a site of inquiry in order to center professional learning in practice" (Ball & Cohen, 1999, p. 19), and creates opportunities for teachers to examine the everyday aspects of teaching. Grossman, Compton, and colleagues (2009) have called for the need to organize practice-based approaches to professional education around what they call representations, decompositions, and approximations of practice, with the latter referring, "to opportunities for novices to engage in practices that are more or less proximal to the practices of a profession" (p. 2058), though we also consider how to approximate practice to support the development of practicing teachers in our work.

IAs serve as one form of an approximation of practice, containing core practices, pedagogical tools, and principles of high-quality teaching (Kazemi et al., 2009; Lampert & Graziani, 2009). IAs are designed to structure the relationship between the teacher, students, and content in order to put a teacher in position to engage in and develop skill with interactive practices around facilitating rich discussions about mathematics. IAs and the practices they contain serve as a focus of a set of activities that provide teachers the opportunity to both investigate and enact the work of teaching (Lampert et al., 2013; McDonald et al., 2013), often referred to as a "cycle of investigation and enactment." This consists of observing, decomposing, and planning the IA; rehearsing the IA in the teacher education setting with in-the-moment coaching from a TE; enacting the IA in a K-12 classroom setting; and using artifacts of practice such as video and student work to analyze instruction and make connections between teaching practices, student learning, and a broader vision of ambitious and equitable mathematics teaching.

In this working group, we focus on the "enactment" elements of this cycle of activities—both the coached rehearsals of IAs in a teacher education or PD setting and the enactments done in classrooms with students. In a rehearsal, the teacher (or teacher candidate) leads an IA with a particular problem or prompt and aligned goal with their peers serving as the students. The peers may be encouraged to "act like themselves" or may be assigned some standardized role to play, perhaps to put forward a common error. In-the-moment coaching, often by the TE or PD facilitator, is an important and distinguishing part of a rehearsal. The coach may pause the rehearsal to highlight a particular teacher-student or student-student interaction or teaching move that is worthy of discussion (Grossman et al., 2009; Kazemi et al., 2016). The rehearsing teacher is also permitted to pause the rehearsal to ask questions of the coach. The coach may also play the role of student, offering a strategic contribution as part of the rehearsal experience. The immediate feedback offered through coaching allows for a novel development process for all teachers, not just the individual rehearsing. Despite its potential benefits, coaching is complex work and requires the teacher educator to decide how to interrupt (e.g., by asking a question, suggesting a teaching move, highlight a successful move), how often to interrupt, and when to interrupt (Baldinger et al., 2016; Kazemi et al., 2016; Lampert et al., 2013).

Overview of Prior Work at PME-NA

The working group meetings at PME-NA 38 served as an important catalyst to the discussions and action of this group around the design, use, and research of pedagogies of enactment (specifically, coached rehearsals) in mathematics teacher education. The group originally focused on three focal issues: (1) issues of language around instruction and mathematics used in the work, (2) theoretical and methodological choices, and (3) considering multiple settings and boundaries. Over the three meeting sessions, more than 25 conference attendees participated in the discussions—raising questions, offering ideas and experiences, presenting emerging research ideas and efforts, and contributing to the conceptualization of next steps. The three meeting sessions were each organized around a different focal issue listed above.

The framing topic for the first day was, "Enactments of what? Examining choices about instructional practice and content," which provided an opportunity for participants to share and discuss the decisions TEs make regarding what gets focused on and worked on in rehearsals and enactments (both mathematically and instructionally) and what is informing those decisions. We organized a panel with individuals from three active lines of work in this area to prompt the discussion. One takeaway from this discussion was some clarification about the language used in this work, such as what is meant by "coached rehearsal" and how people are using "IA" and "practices" in different ways that shape the nature of their work with teachers (e.g., Arbaugh, Freeburn, Graysay, & Konuk, 2016; Baldinger et al., 2016; Campbell & Elliott, 2015; Campbell, Selling, & Baldinger, 2017). While language continues to be a challenge for researchers, TEs, and other stakeholders, we made some progress on identifying necessary agreement and other areas where reasoned differences were appropriate given one's context or focus. For example, we identified coached rehearsal as the pedagogy of practice we were focused on (though not the only one someone might be interested in). We also identified an IA as a necessary component of that work (e.g., the routine that gets rehearsed), though IAs have different scopes and forms.

The second day focused on the question, "What constitutes evidence of 'skilled practice' and its development?" This session featured a structured poster session in which eight individuals or groups presented ideas about their research or practice around the design, use, and impact of coached rehearsals and enactments. This session served as an important step to move beyond a broad, conceptual discussion of this area of work toward a more specific discussion about tools for practice and research. For example, presenters shared specific IAs they use in their setting, ways they structure their coaching, data collection tools they use (e.g., video, written performance tasks, interviews), and analytic frameworks.

The final session was organized around a discussion focused on "moving forward with an agenda." Participants reflected on ideas from the previous sessions and considered next steps—for themselves or in collaboration with others. Some takeaways from this session included:

- a clarification of "coached rehearsals" as one type of approximation of practice and enactment pedagogy, all embedded in a broader landscape of pedagogies of practice;
- acknowledgement of different approaches taken by individuals in the group and the need to clarify language;
- ambiguity around how teacher learning or development is being theorized to inform both practice and research in this area;
- interest from newcomers in incorporating coached rehearsals into elementary and secondary mathematics methods courses, and the value of speaking and working across elementary and secondary contexts;
- considering a distinction between individuals interested in doing the work in their teacher education practice and individuals interested in research and development efforts;
- a call for sharing resources for supporting activities around coached rehearsal, and;
- structural constraints (e.g., programmatic, school-university partnerships, logistical) that makes incorporating pedagogies of enactment difficult.

These takeaways shaped some of the early follow-up efforts and continue to frame the need for more engagement and collaboration. In part, this discussion highlighted the issue of "considering multiple settings and boundaries," which included the perceived divides between the university and school classrooms or between work with practicing teachers versus teacher candidates. We continue to explore those boundaries and look to reframe them in productive ways.

Focal Issues

In the time since PME-NA 38, working group participants continued the work in various ways. Some new connections supported the incorporation of coached rehearsals into more mathematics methods courses across institutions. Research efforts have continued, evident in a set of sessions at the 2017 Annual Meeting of the Association of Mathematics Teacher Educators (Campbell, Baldinger, & Selling, 2017; Jones & Campbell, 2017; Webb, Wilson, Duggan, & Bryant, 2017). This ongoing work has represented a range of scale—methods courses at a single institution; efforts to bridge the work across methods courses and field placements; designing PD for practicing teachers centered on pedagogies of enactment; efforts to collaborate among TEs, teacher candidates, and practicing teachers; and collaboration efforts across institutions.

From these efforts and takeaways from the previous working group, additional questions have emerged. We propose to address these emergent questions in three focal areas:

1. Articulating theories of and perspectives on teacher learning, development, and practice within the context of rehearsals and enactments;
2. More deliberately focusing on equity, both in thinking about equitable mathematics teaching as well as equitable and responsive mathematics teacher education and PD; and,
3. Conceiving partnerships (e.g., research-practice partnerships) that support and can be supported by efforts around pedagogies of enactment.

We look at all of these foci through two lenses: (1) advancing the work of TEs, and (2) enhancing research on improving teaching. Given the increasing interest in the field in the use of pedagogies of enactment to develop core practices, we see it as a crucial time to make strategic contributions, answer foundational questions, and plan for future collaborations and products.

Theories of and Perspectives on Teacher Learning, Development, and Practice

Much of the existing research around pedagogies of enactment has tended to focus on the rehearsals themselves. Challenges arise when thinking about how to conceptualize and track teachers' development within enactment cycles, across cycles, and across settings. In particular, researchers must make explicit the theories of teacher learning that guide the use of pedagogies of enactment. Past research has advanced that learning skilled professional practices entails developing deliberate practice (Ericsson, 2002), adaptive performance (Hatano & Inagaki, 1986), or disciplined perception (Grossman, Compton, et al., 2009). These ways of noticing and acting involve developing teaching identities for practice (Lampert et al., 2013). For examining the activity system in which learning professional practice takes place, researchers have made use of theoretical lenses such as activity theory (Campbell, 2014; Campbell & Elliott, 2015) and theories of knowing in practice (Cook & Brown, 1999; Lampert et al., 2013).

A compelling question to advance research on pedagogies of enactment is what are the linkages between underlying perspectives on learning and the tools and pedagogies employed within cycles, across cycles, and across settings? Thinking about these issues helps us consider how constellations of teacher learning tools and pedagogies support teachers' capacity to judge what instructional practices are called for and how to deploy them. Attention must also be paid to other outcomes of teacher development that are important to the various stakeholders invested in this work. Without explicit discussion of the theoretical constructs we employ we run the risk of leaving our goals unspecified, of designing instruments misaligned to our goals, and of making claims that are unwarranted given our research designs. A related challenge is identifying methodological tools that build on different theoretical framings that could allow us to systematically document evidence of learning, change, or growth in a range of data sources. As we and others look to make claims about the impact of pedagogies of enactment on teachers' practice, there needs to be more explicit discussion about the theoretical and methodological choices that contribute to research and development.

Focusing on Issues of Equity

A number of important questions have emerged around the relationship between pedagogies of enactment and efforts to help teachers develop more equitable instructional practices (Jackson & Cobb, 2010). Bartell and colleagues' (2017) framework linking equitable teaching and the Standards for Mathematical Practice begins to address this issue. In their research commentary, the authors advance a set of teaching practices that they have found to address inequalities within classrooms and invite researchers to investigate how this set of teaching practices leverages students' learning of mathematical practices. We consider how this framework might influence the use of pedagogies of enactment. We also draw Gutiérrez's (2011) work, framing our thinking about pedagogies of enactment using four dimensions of equity organized into a dominant axis of access and achievement and a critical axis of identity and power. The dominant axis identifies access as necessary, but not sufficient, to ensure achievement in the discipline of mathematics (meaning that which has been seen to ensure economic well-being and is of high value within policy and school mathematics). The critical axis of identity and power highlights the role of agency to meaningfully participate both within mathematics learning and in a democratic society. This axis brings into view that mathematics learning can be a lens for making sense of the world and seeing what and who is marginalized and valorized. Gutiérrez's work calls for us to consider equity in terms of social transformation across spaces and timescales.

In addition to focusing on the role pedagogies of enactment play in supporting the development of equitable instructional practices, we also ask questions about how these pedagogies provide equitable opportunities for learning in the context of mathematics teacher education. How can pedagogical tools such as coached rehearsals of IAs support all those who are working to improve their teaching practice? How can theories of equity and social justice that focus on the mathematics classroom be extended to apply to the teacher education setting?

Developing and Supporting Partnerships Around Practice and Research

To fully consider the implications of pedagogies of enactment, careful consideration must be given to the role of partnerships across contexts in the practice and research of these pedagogies. In particular, we must examine the systems in which these pedagogies are used. Recent efforts to improve educational systems focused on central problems of practice have gained traction in collaborative researcher and practitioner communities. These efforts form a family of models: Research Practice Partnerships (Coburn & Penuel, 2016; Coburn, Penuel, & Geil, 2013; Rosenquist, Henrick, & Smith, 2015), Design Based Implementation Research (DBIR), and Improvement Science, including Networked Improvement Communities. These approaches share common values and strategies that connect to problems of practice, such as bi--directional educational improvement activity (Kazemi & Hubbard, 2008), iterative collaborative design, development of learning and implementation theory, and system-level sustained improvement (Penuel, Fishman, Cheng, Sabelli, 2011). DBIR, for example, has four dimensions: (1) work on problems of practice – those that improve practice, (2) engage in iterative cycles of improvement, (3) authentic partnerships among practitioners and researchers, and (4) attention to system improvement (cohesiveness). This work requires cross institutional learning and attention to individuals, interactions, and organizations to build and coordinate knowledge, practice, and theory. These models help address key questions about the role of partnerships in this work.

Relevance to PME-NA 39

The focus of this working group also provides a contribution in the context of the theme of this year's conference: "Synergy at the Crossroads: Future Directions for Theory, Research, and Practice." We see the focus of this group as fitting with a number of the conceptions of "crossroads." For example, we see this working group as an intersection point, considering the intersections between theory, practice, and research around pedagogies of enactment. Based on the attendance at our past working group, we recognize that mathematics TEs are motivated to attend for a variety of reasons. Some TEs pursue questions to advance theory about teacher development, others pursue learning more about tools to improve teacher education practice, and finally, other TEs are interested in researching teaching and teacher development through the design and use of pedagogies of enactment. Some individuals are motivated to pursue multiple areas of interest, often negotiating how to manage multiple demands or make decisions about what to foreground or background. Because the working group's efforts sit at the intersection of design of innovation and research on innovation to improve practice, the group is positioned to advance and integrate conversations of theory, research and practice across settings and with multiple stakeholder groups—crossroads that are often viewed as a barrier. These interests and needs also serve in representing a crossroads as a potential change in route—reflecting on our past experiences as practitioners, researchers, and collaborators to think about next steps. As such, we will frame each session of the working group to attend to theory, research, and practice.

Plan for Engagement of the Working Group

The three working group sessions are structured around the focal issues outlined above.

Session 1. Examining Theoretical and Methodological Choices

The first session will open with introductions and then briefly frame the purposes and the structure of the working group. The remainder of this session will include a structured poster session that will provide participants with an opportunity to present the theoretical and methodological tools they use to frame their work around pedagogies of enactment, whether in practice or for research. Participants will then debrief and summarize these ideas in a whole group discussion, identifying similarities and differences and discussing implications.

Session 2. Connecting to Visions of Equity in Mathematics Teaching and Teacher Education

The second session will build on the previous day's work to consider how conceptions of teacher learning build on and contribute to visions of equity in mathematics teaching and teacher education. The session will focus on two main questions connected to our dual foci of research and practice. The first question informing practice is: How might recent visions of equity inform pedagogies of enactment? This question will help us think about and identify the tools and practices we employ as TEs to take up equity in authentic ways within pedagogies of enactment. Drawing on Gutiérrez's (2011) four equity dimensions, we will examine Bartell and colleagues' (2017) research framework for linking equitable teaching with the Standards for Mathematical Practice as well as our shared sense of "ambitious mathematics teaching." The second question framing the session, which foregrounds our research lens, is: What are the implications of these visions of equity on research questions, methodologies, and settings related to pedagogies of enactment? To prepare for this discussion, we will provide participants a short synopsis of Bartell et al. (2017) and Gutiérrez (2011) as well as access to the full text. We will take up these questions through initial small group discussions, where participants will be able to engage in careful investigation of these questions as they apply to each unique context. We will then have a broader discussion as a whole group to develop a shared understanding of the ways visions of equity play out in our work with pedagogies of enactment. This discussion with conclude with a summary of next steps, particularly as they relate to theoretical considerations and research.

Session 3. Supporting the Development of Research-Practice Partnerships

The final working group session will provide an opportunity to discuss next steps, with a focus on the initiation and support of research-practice partnerships in local contexts centered on the use of pedagogies of enactment across contexts. From our previous work, we recognize that an important next step in this work is to consider how efforts can be scaled, how work is done across contexts with multiple stakeholders, and how systemic change can be fostered. We will consider frameworks such as DBIR or research practice partnerships to guide our discussion, leveraging experiences and expertise from within the group shared through existing work and

This final working group session will also serve as an opportunity to consider and discuss follow-up activities that could build on the work begun during the working group. Participants will have the opportunity to connect with others about common interests to initiate plans for collaboration about practice or research. We will also discuss a proposed set of follow-up activities (see below) and invite recommendations on other next steps. We will identify participants who can take the lead in facilitating follow-up work.

Anticipated Follow-Up Activities

There are a number of potential follow-up activities to build on the work that will begin during the proposed sessions. We are hopeful that this working group would continue to serve as a catalyst for collaborative activities around designing and studying pedagogies of rehearsals and enactments. For some, this can entail beginning to incorporate rehearsals into a methods course or a PD effort. Others may ask more substantive practice-oriented questions of their use of rehearsals and enactments. Both of these efforts would benefit from opportunities for sharing resources and materials, such as a website, blog, or shared folder. Others will continue to engage in more substantial data collection and analysis to research teacher development, which may serve as pilot projects, eventually leading to proposals to fund collaborative research projects. This is particularly salient in the context of considering the development and support of research-practice partnerships. We are also currently conceptualizing a proposal for funding a focused conference to bring together scholars for focused work around pedagogies of enactment, and the working group will be an opportunity to further pursue or advertise those plans.

Another target activity is the collective dissemination of the ideas that are shared and created through the working group itself. For example, submitting a paper to a journal like *Mathematics Teacher Educator* that outlines similar or contrasting ideas around rehearsals and enactments could provide an appropriate forum and audience for these ideas. Alternatively, collectively writing a research commentary would allow us to focus on theoretical or methodological challenges in researching teacher development in practice-based activities. This could be submitted to a venue such as the *Journal for Research in Mathematics Education* that publishes commentaries. We will also continue to disseminate ideas at national conferences such as those of the Association of Mathematics Teacher Educators, the National Council of Teachers of Mathematics, and the National Council of Supervisors of Mathematics.

Argumentation, justification, and proof are conceptualized in many ways in extant mathematics education literature. At times, the descriptions of these objects and processes are compatible or complementary; at other times, they are inconsistent and even contradictory. The inconsistencies in definitions and usages of the terms argumentation, justification, and proof highlight the need for scholarly conversations addressing these (and other related) constructs. Collaboration is needed to move toward, not one-size-fits-all definitions, but rather a framework that highlights connections among them and exploits ways in which they may be used in tandem to address overarching research questions. Working group leaders aim to facilitate discussions and collaborations among researchers and to advance our collective understanding and conveyed use of argumentation, justification and proof, particularly the relationships among these important mathematical constructs. The 2017 working group sessions will provide continued opportunities for participants to discuss existing definitions and descriptions, with increased focus on how these definitions and descriptions are used by researchers and practitioners within particular contexts and applications. Participants will examine data through a variety of lenses to investigate the use of particular conceptualizations and discuss implications of such use.

Keywords: Reasoning and Proof, Advanced Mathematical Thinking

Brief History of the Working Group

The *Conceptions and Consequences of What We Call Argumentation, Justification, and Proof* Working Group (AJP-WG) met for the first time in 2015 at Michigan State University in East Lansing, Michigan during the 37th Annual Meeting of the North American Chapter of the Psychology of Mathematics Education (PME-NA), and again the following year for the 38th Annual Meeting of PME-NA in Tucson, Arizona. The working group's primary focus is on the field's conceptualization of the interrelated objects and processes of argumentation, justification, and proof. Previous working groups at PME and PME-NA had focused on either proof or argumentation, but the present working group is the first to attend specifically to the connections among these three constructs.

During the working group's initial meeting (2015), attendees made progress on considering the interrelationships among argumentation, justification and proof, and we deepened our understandings of our own perspectives and the range of perspectives held by others in the group. The goal during this meeting was not consensus or deciding a best approach. Rather, we sought to better understand the complexity and diversity of individuals' perspectives with respect to their research agendas and professional practice. We were encouraged that our efforts were well received, with 46 scholars, including at least 10 graduate students, participating in the working group the first year.

The second gathering of the AJP-WG was held in 2016 at the annual meeting for PME-NA in Tuscon, AZ. Thirty-six scholars attended the sessions, which continued the group's focus on the interrelationship between and among the concepts and terms related to argumentation, justification, and proof. Specifically, participants considered their definitions for these concepts and how such definitions may change given different contexts and foci. Additional information about the first two meetings of the AJP-WG is included later in the proposal.

Summary of Focal Issues

There is a large and growing body of research in mathematics education focused on argumentation, justification, and proof. The research on proof, for example, includes studies on the role of proof in the discipline; proof in school mathematics and at the undergraduate level; what counts as a proof; proof schemes and categories; teachers' conceptions of proof; students' abilities to write valid proofs; and what teaching proof looks like in classrooms at various levels (e.g., Boero, 2007; Harel & Sowder, 2007; Reid & Knipping, 2010; Stylianou, Blanton, & Knuth, 2009). At the same time, researchers and policy documents have issued calls to engage K-12 students with disciplinary practices such as constructing viable arguments, justifying conclusions, critiquing the reasoning of others, and constructing proofs for mathematical assertions (National Council of Teachers of Mathematics [NCTM], 2000; National Governors Association Center for Best Practices [NGA] & Council of Chief State School Officers [CCSSO], 2010).

Yet, as the field moves forward to maximize students' learning opportunities for engaging in these disciplinary practices, mathematics educators need to refine their notions of these terms in scholarly activities and in policy documents (Cai & Cirillo, 2014). How, when, and why decisions related to word choices are made (e.g., 'argument' versus 'proof') in curriculum materials, policy documents, and research is an open question. In fact, some researchers have hinted that these choices are not always purposeful. For example, Lynn Steen, a member of the 1989 NCTM Standards Committee, claimed that uncertainty about the role of proof in school mathematics caused NCTM in its 1989 *Standards* document to resort to, what he called, "euphemisms" such as "'justify,' 'validate,' 'test conjectures,' [and] 'follow logical arguments'" (Steen, 1999, p. 274). Rarely, he stated, did the document use the term 'proof.' Although Steen's comments were published more than 15 years ago, we argue that his proposition, that the role of proof (as well as argumentation and justification) in school mathematics is uncertain, continues to be true today.

One additional challenge of reading extant research or developing a research agenda related to these disciplinary practices is that the classifications offered differ according to the perspective of the researcher, the focus of the research, and the particular data being analyzed (Reid & Knipping, 2010). Only recently have we begun to see mathematics educators offering explicit definitions of these constructs in their work; this is ironic given the importance of definitions in the field of mathematics itself and particularly in the activity of proving.

Although proof has received more attention in extant research, argumentation as a concept seems to be garnering new prominence with increasing attention in the mathematics education literature (Conner, Singletary, Smith, Francisco, & Wagner, 2014; Staples & Newton, 2016; Stylianides, Bieda & Morselli, 2016) and as a process that is playing an important role in policy and curricular documents across many disciplinary fields. The notion of constructing and analyzing arguments appears in the most recent standards of four core K-12 disciplines – English, mathematics, social studies and science. For example, the *Common Core State Standards for Mathematics (CCSSM)* includes as one of its standards for mathematical practice, "Construct viable arguments and critique the reasoning of others" (NGA & CCSSO, 2010a) Similarly, *CCSS for English Language Arts* devotes a portion of an appendix to "The Special Place of Argument in the Standards," emphasizing argumentation as critical for success in college and careers (NGA & CCSSO, 2010b, Appendix A, pp. 24-25). The National Council of the Social Studies (NCSS) highlights argumentation as an aspect of historical thinking, with a focus on causation and argumentation (NCSS, 2013). A summary table of where and how references to arguments or argumentation appear in the policy documents is included in Table 1.

On a related note, although not an explicit Standard for Mathematical Practice, we find evidence in past and current mathematics standards documents that *justification* is considered an important mathematical practice. For example, in the 1989 *Standards*, it was noted by the authors that throughout the document, "verbs such as *explore, justify,…describe, develop,* and *predict* are used to convey this active physical and mental involvement of children in learning the content of the curriculum" (NCTM, 1989, p. 17). In particular, students are asked to "justify their answers and solution processes" (p. 29) as part of the Mathematics as Reasoning Standard. In *Principles and Standards for School Mathematics (PSSM)* (NCTM, 2000), geometry is positioned as a natural site for the development of students' "reasoning and justification skills" (p. 41). Justifying is also explicitly linked to the Reasoning and Proof, Communication, and Problem Solving Process Standards in *PSSM*. Finally, the authors of *CCSSM* (NGA & CCSSO, 2010a) consider "the ability to justify, in a way appropriate to the student's mathematical maturity, *why* a particular mathematical statement is true or where a mathematical rule comes from" (p. 4) to be a hallmark of mathematical understanding. Looking across time, analyses of standards adopted prior to that of *CCSSM* suggest a relatively infrequent inclusion of the terms justify/justification in content standards language (Larnell & Smith, 2011), with a significant increase in such usage in *CCSSM* (Kosko & Gao, in press). Furthermore, and along the same lines as argumentation, justification as a topic of study has seen increased recent attention in the research literature (Lesseig, 2016; Lin & Tsai, 2016). Together, these examples demonstrate that justification has been considered to be important in school mathematics, with increased focus in recent years.

Table 1: Summary of References to Argument(ation) in Policy Documents

Standards	**Role in Standards**	**Specific Reference for Practice or Recommendation**
Common Core State Standards for Mathematics	One of eight Standards for Mathematical Practice that should be developed in students	3. Construct viable arguments and critique the reasoning of others. (p. 6)
Common Core State Standards for English Language Arts & Literacy	Argumentation identified as the first of the Standards' "Three Text Types"	The Special Place of Argument in the Standards in Appendix A: Research Supporting Key Elements of the Standards (p. 24)
Next Generation Science Standards	One of eight Science and Engineering Practices in the NGSS identified as essential for all students to learn	7. Engaging in argument from evidence (Appendix F, p. 13)
National Curriculum Standards for Social Studies	One of three factors related to "powerful" social studies teaching and learning	Teachers show interest in and respect for students' thinking and demand well-reasoned arguments rather than opinions voiced without adequate thought or commitment. (p. 13)

Highlights from the Year 1 Working Group Discussions

A focal activity during the initial working group sessions in 2015 was the development of Diagrams/Concept Maps in which each participant generated a representation of the relationships among argumentation, justification, and proof from his or her perspective. Discussion surrounding the relationships between constructs was supported by an initial presentation by Keith Weber on Day 1, followed by a panel presentation, moderated by Samuel Otten, with Kristen Bieda, AnnaMarie Conner, and Pablo Mejía -Ramos serving as our expert panelists (i.e., Bieda - justification; Conner - argumentation; and Mejía-Ramos – proof). The panelists shared how they conceptualized the interrelationships among argumentation, justification and proof; they explicated how they came to use the central construct they use in their research and why they felt that choice was productive for their work; and they offered their thoughts on the current state of the field and what we might need to tackle next in relation to these constructs. The final day of the 2015 working group sessions offered the opportunity to revisit participants' Diagrams/Concept Maps, though now potentially informed by additional perspectives and questions gained from the prior two sessions.

Three products were generated from the 2015 meeting. First, a pair of podcasts generated by Samuel Otten are available worldwide: The first podcast is of Weber's talk (http://mathed.podomatic.com/entry/2015-11-16T07_01_19-08_00), and the second podcast is the moderated panel discussion (http://mathed.podomatic.com/entry/2015-11-19T07_19_37-08_00). The second product was a white paper that was developed by the working group organizers, the panelists, and several other participants from the working group who volunteered to participate in the online publication (Cirillo et al., 2016). The white paper summarized the working group activities and discussions and also includes the set of 44 Diagrams/Concept Maps that were generated as well as annotations and analyses. At the time of this writing, the white paper has garnered over 230 reads since its online publication six months ago. The final product was a poster presentation for PME-NA 2016 that was based on the analyses of the Diagrams/Concept Maps (Strachota et al., 2016).

Weber's presentation highlighted different traditions and points of disagreement, for example, citing Reid's (2001) observation that research simultaneously suggests that secondary students struggle to construct proofs, while at the same time suggesting that primary children are capable of engaging in proof. Weber prompted the group to consider how different traditions may inform each other in order to advance the field collectively. In particular, he outlined three broad traditions in proving: *proving as problem solving, proving as convincing,* and *proving as socially embedded activity.* Each corresponds to a different focus for research and/or instruction. Weber offered two thought-provoking suggestions, both of which may help us understand the lack of convergence in results and definitions. One suggestion was that proof may not be a singular, easily defined concept, but rather a *cluster concept,* as used by Lakoff (1987). In this sense, there is no list or decision procedure to identify a proof, but rather there is a set of features associated with the concept, and many - but not all - apply in any one instance.

The second suggestion was that the features or properties associated with proof may be closely interrelated for mathematicians, but not for students. In particular, for mathematicians, a convincing argument and socially sanctioned argument are often one-in-the-same. For students, however, those are not tightly connected and may describe very different types of arguments. He suggested, "Perhaps much of the disagreement amongst mathematics educators is that they are using proof as a shorthand to denote things that are different to students but similar for mathematicians" (Cirillo et al., 2016, p. 7).

The panel discussion on our second day further raised awareness of how crucial it is to not only define one's terms, but also to specify the context of one's work. For example, Bieda and Conner both work closely with students and teachers in secondary settings, and in that context, they have found proof and proving to be terms that distance or invoke conceptions of end product and formality. Consequently in their work, they have chosen different focal constructs. Both Bieda and Conner articulated an explicit link of their work to students' proof-producing capacities at the tertiary levels, but they do not centralize that term in their research in school mathematics.

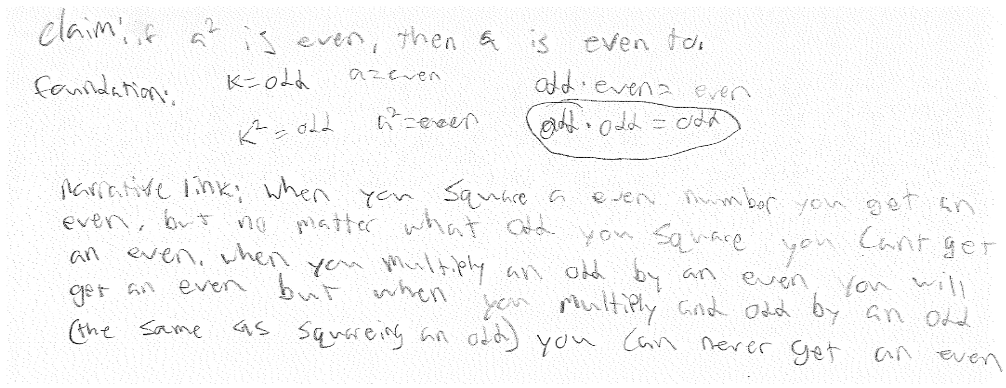
Our discussions and subsequent analyses of the Concept Diagrams/Maps offered additional information about the variety of ways these three important constructs are understood in relation to one another. During the gallery walk and subsequent analyses across the Concept Diagrams/Maps, we could discern little to no agreement about the relationship between justification and argumentation. It seemed that participants held these two constructs (justification and argumentation) either fully distinct from the set of things we call proof, or that proof was a very specific version of each of these. Some considered justification a subset of arguments; others positioned arguments as a subset of justifications; and still others had them as overlapping, but not concurrent, sets.

Proof (and proving) seemed to be of a different nature than argumentation and justification for our participants, and proof participants either positioned it at the far end of a continuum of the constructs, a plane above, or as a separate entity. Alternately, however, others considered proof to be a specific subset of arguments and justifications. Additional details can be found in the White Paper (Cirillo et al., 2016). A question raised in the discussion on Day 3 was whether proof was so valorized that we position it as the "desired end product" for all arguments, even when that might not be a productive or educative goal. This lack of not only convergence but general clarity provides an important opportunity for further exploration and raises questions about the consequences of these different concepts. It implores us to continue to work to develop a framework to connect these constructs and clarify not only our commitments and definitions but the interrelationships among these important ideas.

Highlights from the Year 2 Working Group Discussions

During the first session of the second meeting of the AJP-WG, Samuel Otten moderated panel presentations on differing applications of definitions provided by Eric Knuth, David Yopp, and Orit Zaslavsky. On the second day, participants examined data artifacts from different grade levels and were asked to consider whether and in what ways they would define features in the data with respect to argumentation, justification, and proof. All participants were provided two common artifacts (a transcript of a high school math class discussion & five samples of grades K-3 writing samples) as well as one additional artifact of choice (middle school, high school, or tertiary level artifact). Discussion surrounding the artifacts provided an opportunity for participants to consider how their definitions were affected by application to the differing data. It provided an arena in which to see how each definition served as a lens for viewing the artifacts and how these different lenses might lead one to position a work sample in different ways, depending on the type of mathematical activity represent in the work sample based on the definition. This discussion continued through to the final session. Further, the discussion surrounding the artifacts facilitated initial organization of three networking groups–one focused on reading and sharing journal articles and two focused on producing written products. One product available from this second AJP-WG meeting is a podcast of the panel discussion produced by Samuel Otten (https://www.podomatic.com/podcasts/mathed/episodes/2016-11-14T07_10_36-08_00). A second product is a white paper (available at https://www.researchgate.net/publication/317267228) summarizing the working group activities and discussions of the artifacts from year two (Staples et al., 2017). The final product is the organization of networking groups for continued collaboration related to, but independent from, the working group. Thus, activity across both years of the working group has facilitated the continued development of a community of mathematics education researchers who we anticipate will continue these discussions over several years.

During the panel discussion, our panelists shared how they used and defined justification, argumentation, and proof and how their definitions and applications of these constructs influenced, and were influenced by, their research questions or contexts. A key point arose from David Yopp's juxtaposition of his definition of proof with Stylianides' (2007) definition of proof in relation to a particular 8th-grade work sample. Yopp argued that by Stylianides' definition, the student's work was not a proof (violating two of three conditions). By Yopp's definition, however, the student's work was a proof. Yopp stated that a proof eliminates the possibility of counterexamples. Thus, from the student's perspective—and perhaps class's perspective—he had eliminated the possibility of counterexamples, thus providing proof of the claim (see Figure 1).



claim: if a^2 is even, then a is even too

foundation: k=odd a=even odd·even= even

k^2=odd a^2=even odd·odd = odd

narrative link: when you square a even number you get an even, but no matter what odd you square you cant get an even. when you multiply an odd by an even you will get an even but when you multiply and odd by an odd (the same as squareing an odd) you can never get an even.

Figure 1. Student work samples shared by David Yopp.

We then turned our attention to reviewing artifacts of K-16 classrooms, to provide a concrete opportunity to see how definitions might interact with context. Participants were offered two artifacts in common, from elementary grades work samples and a high school transcript, and then could choose a third artefact to review, from middle school, high school or tertiary level. Although it became apparent was that we offered too much in too short a time frame, our discussion was productive, and we recap a few of the key ideas offered here.

One question raised was how much context we needed to know in order to engage the question, is this a proof? Or is this an argument? This question was posed based on recognizing that both Yopp and Stylianides offered definitions of proof that dependent to a degree on a child's/class's conceptual sphere. In Stylianides' definition, this context element comes through with the criteria that all must be "known by" or "within the conceptual reach" of the community. In Yopp's, this context element comes through with the idea that one must eliminate all possible counterexamples, so if a student is not aware of, say, complex numbers, s/he does not have to offer a proof that accounts for all complex numbers. The student can only attend to and eliminate the possibility of counterexamples (actively) from his or her realm of possibility. Continuing with the general idea of context, questions were raised about how grade-level dependent a proof was, and whether one needed to know more about what was taken-as-shared in a class to evaluate whether an argument did or did not comprise a proof. One of the final points raised was that a proof is not a stand-alone entity; we need to know what the norms and assumptions are in order to understand if something is operating as a proof in that context.

In our final session, we sought to continue the discussion from the previous session and also organize toward "networking groups" for those interested in sustaining or advancing conversations with respect to argumentation, justification and proof during the year. Participants each wrote brief questions they were interested in pursuing and indicated a level of commitment they might have for the pursuit (e.g., discussion groups, reading groups, research group). Our time then was devoted to participants having conversations to connect with one another around shared areas of interest and similar levels of desired future commitment.

The networking time yielded three distinct follow-up groups. Each group also identified some goals for the upcoming year and shared these with the larger group. Please note that all participants in the working group were welcome to join these groups.

Galindo, E., & Newton, J., (Eds.). (2017). *Proceedings of the 39th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* Indianapolis, IN: Hoosier Association of Mathematics Teacher Educators.

AJP Journal Club. This group aims to read and discuss two articles per quarter related to issues of interest to its members. One goal is to investigate how authors attempt to make explicit their definitions of argumentation, justification, and proof relevant to their work.

Argumentation Research Commentary. This group aspires to write a research commentary that (a) describes research on argumentation in our field, and (b) explores reasonable guidelines for productive research on mathematical argumentation.

Op Ed piece. This group intends to pursue an op-ed piece making the case that the mathematics education community needs to take concerted efforts to eliminate two-column proof from geometry courses in the United States.

Focus for Year 3

Our focus for Year 3 is to generate interest and commentary for a book proposal that will engage members of the community in a more structured analysis of data using different perspectives and definitions of argumentation, proof, and justification. In doing so, we intend to continue to facilitate communication and collaboration among members of the mathematics education community with interests in the areas of argumentation, justification, and proof.

As we learned in Years 1 and 2, members of our community have widely differing perspectives on the definitions of and relationships among argumentation, justification, and proof (see Cirillo et al., 2015; Staples et al., 2016). Likewise, the consequences of these definitions and the contexts in which they are applied are varied, leading to a diverse set of conclusions and implications about the teaching and learning of argumentation, justification, and proof. This was illustrated in Year 2 of our working group, particularly by the conversations about David Yopp's artifact (see Figure 1).

In Year 2, we began to investigate how context, interpreted primarily as grade band, when combined with particular definitions, impacted our interpretation of data. We found that, to some extent, the written or verbal nature of the data also impacts our interpretations. Thus in Year 3 we will continue to dig into the interactions between context and definition in our examination of relevant data. We plan to build upon what we learned in Years 1 and 2 about different perspectives on argumentation (arguments), proving (proofs), and justifying (justifications). We intend to leverage ideas and relationships from our first two years into a book proposal in which chapters will highlight analyses of particular sets of data (artifacts) from different perspectives/definitions. This book will address how definitions, commitments, and contexts interact to produce different insights into the teaching and learning of mathematics. In particular, the book will highlight the importance of defining, distinguishing, and integrating argumentation, justification, and proof in mathematics education research and its applications. We will continue to facilitate communication and collaboration among members of the mathematics education community who are involved in research and scholarship using constructs that include argumentation, proof, and justification. As we explore the roles of definitions and the contexts in which we work in determining our definitions and how we use them, we will continue to facilitate connections among people with similar interests in hope of facilitating lasting collaborations to further knowledge related to argumentation, proof, and justification in the field.

Plan for the Working Group

Session 1: Looking at the Past and Toward the Future

In Session 1, we will begin with introductions, review our progress from Years 1 and 2, and hear reports from the three networking groups established in Year 2. We will then present our current idea for the book proposal and solicit feedback, input, and advice from participants.

In Year 2, we established the aforementioned networking groups with different purposes. During this session, we will invite the leaders and members of these groups to report on the progress and products accomplished during the past year. As appropriate, we will invite session attendees to join established groups or to create new ones.

During this session, we will present the rationale and structure of our proposed book, asking attendees to critique the ideas presented, make suggestions, and consider contributing to the book.

Session 2: Examining Data from One Context

Prior to the conference, working group leaders will analyze data and write an initial draft of two chapters for the book, analyzing data from a single context from at least two perspectives. In Session 2, we will focus on the data from this context, including transcript and written work. We will ask participants to examine the data (in small groups), encouraging them to make their assumptions about and definitions of argumentation, justification, and proof explicit. We will share snippets of these conversations with the whole group. We will then hear a short presentation from one group of researchers who previously analyzed the data. This group will describe the definitions of argumentation, justification, and proof used to analyze the data and present conclusions and implications from the analysis. Working group participants will be invited to critique the interpretations and offer alternative ways to examine or interpret the data.

Session 3: A Second Perspective on the Data

In Session 3, we will again focus on the data presented in Session 2. We will hear a short presentation from the second group of researchers with different commitments to argumentation, justification, and proof detailing their analyses and interpretations of the artifacts. Working group participants will be invited to critique the interpretations and offer alternative ways to examine or interpret the artifact. Participants will then compare and contrast the different conclusions together with their definitions and commitments, and we will facilitate a discussion about the differing affordances of the different ways to analyze the data, as well as any questions prompted by this examination.

During Session 3, we will revisit the plan for the book, soliciting feedback from participants on the structure and outline presented in the first session. We will finish Session 3 with an invitation to continue to participate in the work of the working group by proposing chapters with different analytic frames, writing commentaries on the analyses presented or on future chapters, or by participating in one of the networking groups discussed in Session 1.

Anticipated Follow-Up Activities

We anticipate that the products and follow-up activities from Year 3 will build on the activities and products from our two previous years. A major follow-up activity for the following year will be the development of a book proposal accompanied by drafts of several chapters for the book. A table of contents, introductory chapter and at least one chapter with accompanying commentary will be developed and revised for the submission of the book prospectus.

We will continue to encourage networking groups, which will likely shift and expand from Year 2. New working groups interested in collaborating on chapters for the book will be invited and encouraged. Additional networking groups with other related interests will also be encouraged.

Research on mathematics and disabilities traditionally has been conducted within a special education paradigm, which often implicitly or explicitly adopts a deficit model of the learner. The deficit model locates the "problem" within the individual student rather than in the social, discursive, political, or structural context. Instruction for these students tend to focus primarily on rote algorithms and calculation skills rather than the solving of rigorous, high cognitive demand problems. As mathematics education researchers and practitioners we are poised at the crossroads, ready to reclaim work traditionally relegated to special education. Our working group is composed of researchers and educators who draw upon critical theories, such as Disability Studies in Education, Critical Race Theory, and DisCrit, in order to offer an alternative vision of mathematics education based around a different conceptualization of disability and learning differences. We consider both the framing of these students as well as how to reframe classroom practice utilizing models like Complex Instruction (CI) and Universal Design for Learning (UDL) to create classrooms in which all students are able to access the curriculum in meaningful and rigorous ways.

Keywords: Equity and Diversity, Instructional Activities and Practices, Classroom Discourse

Overview of the Working Group

The purpose of this working group is to assemble researchers and practitioners who bring a critical lens to issues of mathematics education and disability. Historically, the consideration of disability in mathematics education has been examined from a special education lens, which pathologizes student difference and aims to "remediate" these perceived defects. There is a well-known epistemological difference between special education and mathematics education. We have come to a crossroads, where we must decide how to address this theoretical divide between special education and mathematics education. As mathematics educators we believe a critical perspective on disability, drawing upon disability studies, critical race theory, and discrit, can address this divide and offer an alternative vision of mathematics education and disability. Our working group is designed to create sustainable opportunities for researchers and practitioners interested in bringing a critical lens to understanding disability and difference in mathematics education. In this proposal we briefly present the history of this working group, the theoretical perspectives that this group draws upon, and our plans for collaboration.

History of the Working Group

Our PME-NA working group met for the first time last year. Fifteen researchers (faculty and graduate students) and 2 educators met during PME-NA 2016 in Tucson, AZ. In this first series of working group meetings, participating group members shared theoretical perspectives of disability they employed within their work in mathematics education, current projects they were engaged in related to disability and mathematics education, and critical issues members often found themselves confronting in taking up this complex work. Conversations that took place during this time were exciting. Many common interests were uncovered and shared among group members. At the conclusion of our time together at the conference, many of the group members were hopeful that the working group in subsequent years could serve as a foundation for continued work and conversation. This group has the potential to serve as a main platform and organizing structure as we embark upon this paradigm-shifting work.

The impact and work of this group continued through the year. We established an email list-serv which members have used regularly to share and solicit feedback on work and to organize our collective efforts. We are in the process of submitting an AERA conference grant to provide a multi-day venue for members of this working group to meet and work on an edited book project. We are also planning to submit a book proposal.

In this coming year we plan to continue and expand collaborations between members of this working group. We hope to provide time to learn with and from each other and to establish the foundation for collaborative work throughout the year. Although we are actively pursuing opportunities to bring this group together for a more extended period of time (through AERA/National Science Foundation (NSF) conference grants), maintaining our PME-NA working group is essential. It not only provides an opportunity to connect with others, engage in ongoing projects, but also to invite new researchers and educators to join our community. As we have experienced in other working groups, each year brings new members, and provides a synergistic place for an ever-growing number of researchers to come together to begin collaborations around these challenging issues. We hope this working group can provide a space for scholars who are taking a critical lens to explore disability related to mathematics education. Our efforts to recruit new members have been ongoing since our first meeting. We have promoted and advertised this group at national mathematics education conferences (AMTE & RCML), made announcements in Review of Disability Studies, promoted it on the Disability Studies in the Humanities listserv, and posted on various facebook groups (e.g., Teaching Disability Studies and Mathematics Education Researchers and STaR). In addition, many of the original members have reached out to their informal networks to invite others who have expressed an interest in joining this group.

Paradigm Shifts for Disabilities in Mathematics

Gathering together a group of researchers, graduate students, undergraduate students, and classroom teachers interested in developing an alternate paradigm around disability, we have begun to explore the different theoretical frameworks that we can use to analyze and change this situation within mathematics education. Heeding Lather's (1986) call for researchers to utilize multiple theoretical schemes in their work, our working group believes that this work requires the participation of multiple paradigms of critique. Our working group draws upon critical theories such as disability studies, critical race theory, and other poststructural theories (including queer studies and trans studies) in this analysis. A commonality among these perspectives is that each problematizes normativity. We welcome the participation of those with other perspectives as well. In the following sections, we describe a sampling of these perspectives in order to frame the work of the group.

Critical Theories

Although the notion of critique dates back to antiquity, the phrase critical theory originally referred to a body of work coming out of the Frankfurt School and Institute for Social Research in the late 1920s through the early 1940s. Critical theory seeks to reshape reality, not merely explaining things. As Karl Marx (1845) wrote almost a century earlier, "The philosophers have only interpreted the world, in various ways; the point is to change it." Critical theory has come to mean not just the work of the original critical theorists, but any theory that seeks to transform rather than merely explain society. The Stanford Encyclopedia of Philosophy gives three main criteria for a critical theory, that "it must explain what is wrong with current social reality, identify the actors to change it, and provide both clear norms for criticism and achievable practical goals for social transformation." All of the theoretical perspectives that our working group draws upon are in some ways "critical theories."

Disability Studies and Disability Studies in Education

Many of the members of our working group utilize disability studies (DS) and disability studies in education (DSE) as a mode of inquiry in order to questioning the taken-for-granted assumptions and practices in mathematics education and the intervention paradigm. DS and DSE provides a framework for exploring questions such as: who is labeling, who is being labeled, whose voices we value, and how do we advance more equitable practices for all students. Disability studies calls into question the medical/individual model of disability in which disability is seen as a deficit within an individual that requires "curing."

In contrast to the medical model, many disability studies scholars and activists have adopted a social model of dis/ability, which locates dis/ability in an inaccessible environment. Those who adopt the social model of dis/ability make a distinction between impairment, as any physical or mental limitation, and disability, as the "social exclusions based on, and social meanings attributed to, that impairment" (Kafer, 2013, p. 7). Kafer (2013), however, argues that such a sharp distinction between impairment and dis/ability is unhelpful because it "fails to recognize that *both* impairment and disability are social" (p. 7). In the book *Feminist Queer Crip*, Kafer suggests the term "political/relational model" to refer to perspectives recognizing that both impairment and dis/ability are socially constructed. Within this social framing of disability is the acknowledgement that individuals with disabilities should be included within the research process itself. Traditional approaches to researching disabilities are oppressive to individuals with disabilities, as the researchers determine the questions asked, the methods of data collection, and the meaning made of the data, with no input from the individuals with disabilities. The social model of disability acknowledges that these individuals have unique insights into their lived experiences and empowers them to engage directly in the research process.

In educational settings, this construction of dis/ability manifests in the double education system that splits general education and special education. Scholars have traced the ways in which special education "serves as a vehicle for preserving general education in the midst of ever increasing diversity" (Reid & Valle, 2004, p. 468, paraphrasing Dudley-Marling, 2001; also see Skrtic, 1991, 2005). Rather than using research-validated frameworks like Universal Design for Learning (UDL) and Complex Instruction (CI) to deliver rigorous, high-cognitive demand instruction to all mathematics students, the system of special education shunts certain students (especially students of color) into an inferior, segregated mathematics education, thus providing a band-aid to a broken general education system and preventing larger, more systematic changes. One line of research pursued by working group members involves developing understanding and theorizing the research divide between special education and mathematics.

Institutional schooling practices such as writing Individual Education Plans (IEPs) construct certain students as having disabilities; however, from a disability studies perspective, "the label of students with IEPs [can be viewed] not as an inherent and static determinant of individual ability, but as a school-based designation which reflects and recreates differential ability within the classroom" (Foote & Lambert, 2011, p. 250; also see Dudley-Marling, 2004; McDermott, Goldman & Varenne, 2006; Skrtic, 2005). Certain students are chosen for this assessment and intervention, and this selection process is not objective and often singles out those students who are not from a dominant cultural background.

Returning to the assumptions inherent in the concept of intervention, a disability studies perspective problematizes the taken-for-granted assumption that what is "wrong" with the situation requiring intervention is a pathology or deficit within students. Instead, the problem is located in the inaccessibility of the environment; in other words, what needs to be changed is not the student, but rather the environment to allow access for students who differ from one another. As Reid and Valle (2004) assert, "the responsibility for 'fitting in' has more to do with changing public attitudes and the development of welcoming classroom communities and with compensatory and differentiated instructional approaches than with individual learners (Shapiro, 1999). In other words, our focus is on redesigning the context, not on 'curing' or 'remediating' *individuals'* impairments" (p. 468). Different working group members have been addressing this in their current work in different ways. One scholar, draws upon a Vygotskian framing of disability and identifies the ways in which standard mediational tools (e.g., mathematical representations or symbols) are inaccessible to some learners. She reframes the word "remediation" as "re-mediation" to make an explicit move away from the deficit framing and toward a framing of disability in terms of access to mediational tools (Lewis, 2017). A second scholar, conceptualizes interventions as increasing *participation* rather than specific skills (Lambert & Sugita, 2016). That is, what interventions might contribute to more equitable participation and deeper engagement across students in mathematics classrooms? This has been explored through empirical research focused on equitable participation in a Cognitively Guided Instruction algebra routine (Foote & Lambert, 2011). Moreover, a political/relational model suggests that inaccessibility is embedded in the context of power relations. Finding ways to "intervene" to make the environment accessible, then, also requires analyzing the power relations involved in maintaining inaccessibility. A third scholar uses her work in learning trajectories to critique notions of "fixing" students and viewing difference as something that is "wrong" as opposed to a natural strength that can be leveraged in instruction (Robertson & Ne'eman, 2008). Specifically, she critiques a static interpretation of trajectory as an instructional directive to move children across levels or stages of a progression at the expense of paying attention to the reasoning children employ and working to support children to explore, revise, and advance that reasoning (Hunt, Westenskow, Silva, &Welch-Ptak, 2016). Such a use of trajectories could be viewed as an example of the social effects of difference that disable rather than natural biological variation (Siebers, 2008).

Critical Race Theory and DisCrit

Critical race theory (CRT) is another theoretical framework that informs the work of the group. According to CRT, racism is 'normal' rather than an anomaly in U.S. society (Delgado, 1995). Critical race theorists assert that the U.S. was founded on property rights, and specifically the fact that enslaved African Americans were considered property, rather than civil rights (Ladson-Billings & Tate, 1995). CRT reveals the way race and racism continue to structure U.S. society. In relation to educational interventions, critical race theorists have addressed the issue of over-representation of students of color in special education.

Often, however, these analyses leave ableist assumptions in place; similarly, DS perspectives often fail to adequately consider race. DisCrit is a perspective that acknowledges that racism and ableism are both "normalizing processes that are interconnected and collusive. In other words, racism and ableism often work in ways that are unspoken, yet, racism validates and reinforces ableism, and ableism validates and reinforces racism" (Connor, Ferri, & Annamma, 2016, ch. 1). Studies of administrators' and teachers' perceptions related to overrepresentation of students of color in special education have revealed that their perceptions tend to be rooted in "deficit thinking and infused with racial and cultural factors" (Connor, Ferri, Annamma, 2016, ch. 1; also see Abram et al., 2001 and Skiba et al, 2006). DisCrit perspectives, therefore, identify the individual problematic attitudes of teachers and administrators as one "accessible entry point for intervention" (Connor, Ferri, Annamma, 2016, ch. 1).

Summary of the Problem

This working group will investigate issues related to disability in mathematics education. Using multiple theoretical frameworks, the working group participants will analyze current practices in mathematics interventions, including the power relations involved, and develop and elaborate on alternatives. The working group participants will also plan ways to evaluate these alternatives in various educational settings and contexts.

Plan for Active Engagement of Working Group Participants

Session 1

In the first session, the organizers will introduce the rationale for the working group and its one-year history. We anticipate spending some time again hearing about how each of the members is theoretically addressing disability from a critical perspective in our ongoing work. The group will collaboratively refine the goals of the working group.

Session 2

In the second session, (based on input from session 1) participants will either:

- brainstorm potential collaborative endeavors,
- brainstorm how to position this critical work to make inroads into historically inhospitable venues for this work (e.g., Council for Exceptional Children)
- break up into subgroups to make progress on collective projects (e.g., NSF Conference grant, book proposal, collaborative work)
- discuss how to develop projects around member's PMENA presentations or
- discuss a shared reading (distributed to the list-serv before the conference and handed out during session 1) to push our thinking and shared understanding of critical perspectives.

Session 3

Session 3 will be devoted to planning our ongoing collaboration and distributing responsibilities for the group's shared endeavors (e.g., conference / book proposals, developing a shared online repository of research and teaching resources).

Plan for Sustainability: Anticipated Follow-up Activities

The working group sessions during the conference are designed to enable the participants to develop concrete plans for collaborative work beyond the end of the conference timeframe. We plan on continuing to communicate between working groups through our email list-serv. Specifically, the third session is allotted for developing specific plans for future collaborative work.

In this working group, we consider design and research methodologies related to teacher learning in online professional development contexts. We describe the extant literature on online professional development, including a review of digital technologies and the applicability of this practice to teacher learning in education. We then describe an innovative project designed to support the development of middle school mathematics teachers in rural contexts, with a focus on three distinct forms of online learning: digitally communicated demonstration lessons, an online course, and online video coaching. Given recent technological advances and demands to support teachers in various contexts, we contend that researching and understanding these online models, as well as other online models is important for the broader field of mathematics education. As a result, the proposed discussion group will combine whole-group and subgroup time to converse about: (a) the challenges of online professional learning experiences, (b) research tools, methods, and analyses, (c) the connections among different projects and studies, and (d) future collaborations and research.

Keywords: Teacher Education-Inservice/Professional Development, Research Methods, Learning Theories

All teachers need access to high quality professional development in order to meet the needs of students and to teach rigorous mathematics as outlined in college and career-ready standards (Marrongelle, Sztajn, & Smith, 2013). Given the limited resources in some areas, including rural and urban school districts, online professional development has the potential to provide access to a wider range of teachers than what is possible face to face. Furthermore, given the propensity of millennials to seek online learning experiences, we feel that more attention needs to be given to the design, dissemination, and research of online professional development. Given the emerging importance and availability of online professional development, we propose a working group that will focus on the design, dissemination, and research on online professional development. The working group participants will analyze current practices in online professional development, including the technology affordances and limitations. Major themes that will be addressed are:

- affordances of online platforms,
- affordances and constraints of synchronous vs. asynchronous experiences,
- challenges related to scaling up high-quality online professional development, and
- methodologies used to research professional learning in online contexts.

As schools turn to digital learning contexts, it is inevitable that professional development will follow a similar trend. It is imperative to have research-based models that demonstrate how the features of high quality face-to-face professional development can be matched or augmented in online contexts. As an example of necessity, teachers in rural areas face constraints in terms of accessing the expertise and resources required for high-quality professional learning experiences, often because of lack of proximity to such resources as institutions of higher education and critical masses of teachers required to collectively reflect on problems of practice (Howley & Howley, 2005). Rural contexts are thus ideal sites for online professional development, which can be offered at a distance and can involve geographically dispersed participants (Francis & Jacobsen, 2013). At the same time, teachers in urban and suburban areas may have more regular access to professional development, but online formats afford conveniences and other applications that may not be available in face-to-face settings. Digital learning contexts provide opportunities for connections and visual supports that may otherwise not be accessible through more traditional forms of professional development. As a result, we consider it necessary to research and study online learning in these contexts and consider the importance of engaging in dialogue with mathematics educators and researchers about advancing technologies, specifically online professional learning, as related to mathematics professional development. This working group is intended to advance the practices of designing and researching online professional learning experiences by investigating the challenges of balancing high quality learning experiences and accessibility for teachers.

Below we provide an overview of the literature related to professional learning in online contexts. Then we describe one model of online professional development that is being implemented with funding from the National Science Foundation (NSF). We will devote part of the first session explaining the components of the project as a means of introducing possible models and methodologies to study online professional development, leaving opportunities over the next working sessions to incorporate discussion of other models and methodologies. We then discuss Focal Issues in the Psychology of Mathematics Education, and conclude with aims for the 2017 working group.

Overview of Literature Related to Online Professional Learning

Digital Technologies

Online professional learning experiences combine longstanding and emerging digital technologies to provide high-quality, interactive, content-focused professional development. Longstanding digital technologies (e.g., electronic learning management systems) have been used to implement online courses to design and implement professional development for the past couple of decades. Emerging digital technologies involve an internet-based platform to implement online video coaching, or other online communications, in ways that augment the interactivity of face-to-face coaching. Online video coaching emerges from the content-focused face-to-face coaching that the project personnel have engaged in over the last ten years.

Research shows that while online communication lacks some of the modalities (e.g., gestures, facial expressions) and spontaneity of face-to-face communication (Tiene, 2000), there are also affordances unique to its asynchronous and text-based nature. In online discussions, communication tends to be more exact and organized (Garrison, Anderson, & Archer, 2001; McCreary, 1990), involve more formal and complex sentences (Sotillo, 2000; Warschauer, 1995) and incorporate critical thinking, reflection, and complex ideas (Davidson-Shivers, Muilenburg, & Tanner, 2001; Marra, Moore, & Klimczak, 2004). Research on synchronous online communication – which can include text chat windows and shared space in learning management systems – shows that it is experienced as more social than asynchronous spaces (Chou, 2002). Synchronous sessions induce *personal participation*, which Hrastinski (2008) compared to *cognitive participation* in that personal communication in synchronous spaces "involves more intense interaction … while cognitive participation is a more reflective type of participation supported by asynchronous communication" (p. 499). Furthermore, synchronous communication fosters multiple communication channels based on emerging networks within the larger group, including the use of chat boxes and personal email during synchronous sessions (Haythornthwaite, 2000, 2001). Researchers have reported positive outcomes from professional development involving synchronous exchanges via typing (e.g. Chen,

Chen, & Tsai, 2009). However, synchronous verbal online discussions and group activities have not been a focus of research.

Online Professional Development in Education.

Despite the growing popularity of online professional development, there is a need for empirical research regarding its quality and effectiveness (Dede, Ketelhut, Whitehouse, Breit, & McCloskey, 2009). Prior research has not demonstrated advantages for online professional development in terms of teacher outcomes (cf. Fishman et al., 2013), in part due to the lack of online professional development contexts that involve teachers in sustained, intensive reflection on their practices. Furthermore, teacher learning in online spaces can be challenging, especially related to complex forms of learning. Sing and Khine (2006) found that a number of factors make it difficult for teachers to engage in complex or difficult forms of learning in an online context, such as teachers' roles as implementers rather than producers, cultural norms where disagreement is seen as confrontational, and the cognitive demands relative to the available teacher time. Teacher learning in online contexts is discussed in more detail below.

In order to illustrate professional learning in an online context, we present a model that the authors are currently using in a project situated in rural contexts. We present the model in order to begin the discussion of this model and other potential models, as well as the learning platforms and other features, such as the synchronous or asynchronous nature of learning in online environments.

A Model of Online Professional Development

The innovative online professional learning experiences in the author's project focus on the development of teacher capacity to enact ambitious, responsive instruction aligned with the rigorous content and practice elements of the Common Core State Standards for Mathematics (CCSSM). We use the term *professional learning experiences* to denote that the professional development we employ differs from traditional workshop or other models that are too short or fragmented to be effective (Garet, Porter, Desimone, Birman, & Yoon, 2001).

In the project, we identified three primary research goals. To study and understand: (a) the ways online-based professional development can help teachers improve their instructional practices and their ability to notice and respond to student thinking; (b) the characteristics of the feedback cycles in the online coaching, the role of video feedback, and the asynchronous components of feedback cycle; and (c) the features of the professional development model that would inform efforts to scale up the model, including the resource commitments, the requisite capacity of the course instructors and coaches, and the logistical requirements of the courses and coaching. We are currently in year one of four years of the project. The following describes the three online components of our project. In the working group, we envision these and other components used by other researchers serving as the catalysts for dialogue around online professional learning.

Demonstration "Fishbowl" Lessons

In order to address the challenges of engaging teachers in learning complex practices in an online context, we include a component aimed at initiating and reinforcing relationships between participants and project personnel and at helping participants to understand the types of learning experiences and design and feedback cycles that will be the core of the project. Research on lesson study (e.g., Amador & Weiland, 2016; Stigler & Hiebert, 1999) has led to an emphasis on demonstration lessons where teams of teachers collectively plan, enact, and reflect on lessons in ways that make public the features of the lessons and teachers' instructional practices (Saphier & West, 2009). Consequently, one component of our project is a collaborative classroom activity (a demonstration "fishbowl" lesson) that builds from the *studio classroom* model developed by the Teachers Development Group (2010), with features consistent with content-focused coaching (West

& Staub, 2003). For each lesson, a group led by project personnel plans a lesson around a cognitively demanding task. On the day of the lesson, project participants review the lesson plan and explore the task, the mathematics embedded in the task and anticipated student approaches to solving the task, and the related CCSSM practice and content standards, making necessary revisions to facilitate the lesson. The project personnel then enact the lesson while the rest of the group observes and collects evidence of student thinking and learning. The group then collectively reflects on the experience, with a focus on describing evidence for student understanding using the data gathered by the teachers and observers. This process is repeated regularly with participants.

In the beginning of the project all demonstration lesson activities are face-to-face. However, by the third demonstration lesson this model is moved to an online format of synchronous and asynchronous activities. The planning and debriefing portions are held via a video conferencing platform, Zoom, allowing for synchronous engagement in both whole group and small group discussions of the lessons. Asynchronous activities include watching and reflecting on the video recording of the demonstration lesson between the planning and debriefing sessions. Discussion in the working group will center on the affordances and constraints of the online model and possible modifications to ensure the intended professional development goals are met.

Online course - Orchestrating Mathematical Discussions

The second component of our project is the two online course modules, *Orchestrating Mathematical Discussions Parts One and Two*, aimed at orienting the participants toward high-leverage discourse practices that facilitate mathematically productive classroom discussions (Smith & Stein, 2011). In this course, the participants solve and discuss a series of high cognitive demand tasks, activities that will be accompanied by synchronous and asynchronous discussions around the *5 Practices for Orchestrating Productive Mathematics Discussions* (i.e. anticipating, monitoring, selecting, sequencing, connecting; Smith & Stein, 2011). The courses are designed to develop awareness of specific teacher and student discourse moves that facilitate productive mathematical discussions, to understand the role of high cognitive demand tasks in eliciting a variety of approaches worthy of group discussions, and to further develop participants' mathematical knowledge, particularly the rich connections around big mathematical ideas that are helpful to teach with understanding (Ball, 1991; Ma, 1999). The discourse moves are designed to expand student participation in the development of mathematical ideas in the classroom. These actions position students as actively constructing mathematical knowledge, and consequently develop productive mathematical dispositions and students' mathematical identities (Boaler & Staples, 2008; Chapin, O'Connor, & Anderson, 2003; Choppin, 2007a; 2007b; 2014; Herbel-Eisenmann, Steele, & Cirillo, 2013; O'Connor & Michaels, 1993).

In order to take advantage of the affordances of both asynchronous and synchronous characteristics of online communication, the course is embedded in a learning management system (LMS) that: allows for synchronous whole class and small group interaction; the sharing of artifacts, including those collectively developed in the LMS; and asynchronous discussion threads. In the online course modules in the LMS, the facilitator verbally presents a challenging task to the participants, which is viewed in the shared work space. The course instructor then assigns participants to virtual breakout rooms, in which the participants work synchronously in a common workspace, creating virtual white boards to share with the other groups. They can talk to each other, work simultaneously in the virtual space, and use the chat window to communicate. The course instructor can listen to and participate in these group discussions to determine when the groups are ready to present their solutions. The course instructor then closes the virtual breakout rooms, which automatically returns all participants to the main room to conduct a summary discussion of the different strategies, in effect modeling the practices in the *5 Practices* book. Asynchronously, the group can continue to go back and reflect and comment on the task and related solutions, as well as on the readings from the *5 Practices* book using discussions threads in the LMS. Participants are also encouraged to share resources, lesson plans, and student work as appropriate. The working group will discuss this format for online professional learning as well as other formats and tools that have proven beneficial for users.

Online Video Coaching

The third – and most innovative – component of our project's professional development program is the online video coaching that builds from models of content-focused coaching (West & Staub, 2003). More recently, thanks to the advent of improved internet-based software aimed at increasing collaboration around video data, the project personnel have begun conducting online video coaching with teachers. The coaching cycles are focused on identifying and unpacking the mathematics with the teacher, while anticipating likely student strategies, conceptions, and misconceptions. The coach helps the teacher identify evidence for demonstrating how students are thinking (from the video as well as from student artifacts) and make connections between different student approaches in order to help the teacher structure the summary discussion of the lesson.

The online coaching experiences involve synchronous and asynchronous components, with the goal of engaging participants in reflective or deliberative practice. The online coaching has features similar to face-to-face coaching, such as video conferencing conversations via Zoom, in which the coach and participant collaborate to plan lessons and reflect on the qualities of lessons. However, the online coaching includes an innovative component that involves asynchronous collaboration and feedback that structures the post-lesson collaborative reflection, features that augment or surpass the kind of feedback that can be given face-to-face. Teachers video-record themselves using Swivl, which allows them to place a camera (iPhone or other device) on a robot that tracks them around the room, allowing for teacher-focused video without the necessity of someone operating the camera. The video is automatically uploaded into a password-protected site and processed, and is immediately accessible to view and notate. The notation feature in Swivl allows the coach and the candidate to separately view and annotate the video. For example, a teacher can stop the video by hitting the pause button and type in a comment or question that is synced with the video, so that when the coach watches the video, she can read the comment during the point in the video referenced by the comment. The coach can do the same. The video can be viewed repeatedly, which allows for more thorough reflection and analysis. The notation provides for more in-depth and substantive feedback, pointing to specific instances of practice. The discussion group will focus on this model for professional coaching as well as other models or avenues for supporting individual teachers in online professional learning.

Researching Online Professional Learning Experiences

There is a dearth of research on online professional development, especially online professional development that is sustained and intensive. Similarly, while there have been 15 years of intensive efforts to implement coaching in schools, much of the research have revolved around the role and impact of coaches (Coburn & Russell, 2008; Penuel, Riel, Krause, & Frank, 2009), and less around the impact on reflective or deliberative practice. Although coaching has now been around for over ten years, there is limited research on the effectiveness of coaching in terms of improving teacher quality (Matsumura, Garnier & Spybrook, 2012). The greatest dearth of research involves online video coaching in education, as opposed to face-to-face video coaching, which has no peer-reviewed research yet associated with it.

Structure of the Working Group Sessions

Within this working group we propose to explore the following questions related to researching online professional learning experiences:

1. What are various platforms and models for online professional development?
2. What theoretical framework and methodologies are salient for researching online digital technologies and online professional learning experiences?
3. What data analysis methods are suited to the data captured in online environments?
4. In what ways can online professional learning experiences help teachers improve their instructional practices and their ability to notice and respond to student thinking?
5. In what ways can the characteristics of the feedback cycles in online coaching, the role of video feedback, and the asynchronous components of feedback cycle inform the design on online professional learning experiences to maximize teacher learning?
6. What features of the professional development model would inform efforts to scale up the model, including the resource commitments, the requisite capacity of the course instructors and coaches, and the logistical requirements of the courses and coaching?

Plan for Working Group:

In Session 1, the organizers will present brief reports on the Author's project and research design. Subgroups will be formed to explore current design and implementation efforts with online professional learning experiences from their own research and current efforts in the field.

During Sessions 2 and 3 we will provide the subgroups time to continue collaborating. Participation in the subgroup work times will involve: a) identifying the challenges of online professional learning experiences that are the most challenging and why, b) refine research tools, methods, and analyses, c) explore connections among different projects and studies, and d) discuss future collaborations and research. We will close Session 3 with time to review group progress and discuss next steps for our work as shown in Table 1. Meeting notes, work, and documents will continue to be shared and distributed via our Google Folder (set up for this Working Group). The use of Google documents allows members to create an institutional memory of activities during the working group that we will continue to use and add to following the 2017 working group. This shared folder will also provide a shared space for future collaborations and writing projects related to online professional learning experiences within the 2017 working group members.

Table 1. Overview of Proposed Working Subgroup Sessions

	Activities	**Guiding Questions**
Session 1	1. Introductions and Agenda 2. Brief Presentations of Authors' Project and Research Questions 3. Subgroup formation and initial work time - designing Online PD experiences	1. What research is being done related to online professional development? 2. Which aspects of online professional learning experiences are the most challenging and why? 3. Goals of attendees for attending this working group

Session 2	1. Overview of subgroup's work from previous day 2. Subgroup work time - engagement in online professional learning experiences 3. Brief sharing of work in subgroups	1. Identifying factors of engagement in online professional learning experiences 2. What platforms are used for online learning? What are the affordances of various platforms? 3. How can online learning support teacher learning? 4. What are the affordances and constraints of synchronous and asynchronous experiences?
Session 3	1. Overview of subgroup's work from previous day 2. Subgroup work time - researching online professional learning experiences 3. Brief sharing of work in subgroups 4. Final reflections – future collaborations and research	1. What theories and theoretical frameworks have informed the design of your research project(s)? 2. How might your work inform theory in researching online professional learning experiences? 3. What issues and challenges have you faced in designing studies in this area? 4. What challenges may exist for scaling up high-quality online professional development?

This working group will discuss mathematics teacher leaders and the assessment and evaluation of programs for their professional development. Mathematics teacher leaders (MTLs) are school-based, teacher leaders who are responsible for supporting other teachers with mathematics teaching and learning. Mathematics teacher leaders learn to lead professional development, coach other teachers, and work on school-level initiatives for mathematics. The challenge is that understanding of the role is still evolving as are the areas in which they need the most professional development. Many programs focus on developing their mathematical content knowledge for teaching, but they also need to learn about curriculum, assessment, pedagogy, and leadership for school change. This working group will start by discussion of existing tools and resources for documenting the work and development of MTLs. The discussion will continue with setting an agenda for research about their professional development.

Keywords: Assessment and Evaluation, Design Experiments, Teacher Education In-service/Professional Development

Defining Mathematics Teacher Leaders

The organizers of this working group find common purpose in considering the roles, responsibilities, knowledge and development of school-based mathematics teacher leaders (MTLs), specifically on their role as leaders of other teachers. An ongoing challenge and opportunity in research and development is the diverse interpretations and implementations of mathematics teacher leadership. Such leaders may have formal titles like “mathematics specialist” or “mathematics coach.” While in this role, MTLs may support teachers of mathematics, continue to teach whole mathematics classes, work with small groups of students or lead within the school in an informal capacity. This working group is focused on the MTLs leadership role with the purpose of examining the learning experiences and assessments that need to be created to understand their work. In some settings, MTLs are referred to as elementary mathematics specialists or coaches so we draw on literature and background for those roles in crafting this working group.

Knowledge & Skills

While MTLs are accomplished mathematics teachers, an additional layer of knowledge and skills is required to be a leader (e.g., Bitto, 2015). Notably, the Association of Mathematics Teacher Educators (AMTE) Standards for Elementary Mathematics Specialists (AMTE, 2010 & 2013) distinguish the role of teacher of mathematics from the role of teacher leader. This separation of roles recognizes that the knowledge and skills for being a teacher of mathematics are distinct from the knowledge and skills to be a mathematics leader. Specific leadership skills required of MTLs to support adult learning include: leading professional development, working one-on-one with teachers, collaborating with teacher professional learning communities, and creating school-level initiatives.

Brief History of the Working Group

The organizers originally convened at a meeting run by the Brookhill Institute in 2015 to examine research and create working groups of researchers to study MTLs, specifically mathematics specialists and coaches. Since then, the organizers have published a book about elementary mathematics specialists (McGatha & Rigelman, 2017), presented at conferences (McGatha & Rigelman, AMTE, 2017; Larsen, Bailey & Baker, National Council of Supervisors of Mathematics [NCSM], 2017), written book chapters (Baker, Bailey, Larsen, & Galanti, 2017) and published articles related to mathematics teacher leadership (McGatha, Davis, & Stokes, 2015). While this is the first organized working group of these leaders at a PME-NA conference, the proposed working group is a continuation of previous efforts and seeks to engage additional researchers in examining research and development projects related to MTLs. A significant goal in this effort is to build on the momentum that began at the 2015 Brookhill meeting and advance the mathematics teacher leadership research community. Significant research is still required that centers on MTLs including: their professional development, knowledge, and practices particularly in terms of their leadership development and their work with teachers both individually and in groups (McGatha et al., 2015).

Rationale for Working Group

In 2015, McGatha, Davis, and Stokes published an NCTM Research Brief that examined the current compilation of MTL literature. Comprised of 24 articles, an increase from the 9 articles available in 2009 (McGatha et al., 2015), the need for additional research on MTLs was illuminated. Specifically, the NCTM Research Brief included a review of literature centered on MTL experiences, roles and effectiveness to impact both mathematics teachers and students. Studies were placed on a continuum from less-directive to most-directive. In less-directive activities, MTLs encouraged teachers to reflect through activities that promoted the thoughtful practice of teaching mathematics. The opposite end of the continuum, most-directive, involves the MTL reflecting and doing most of the work. The teacher or collaborative team are passive participants, not active in the planning, taking the materials provided and accept being told what actions need to occur. In the middle of the continuum were actions, such as co-teaching and co-planning, that involved the MTL and classroom teacher collaborating to improve instruction and student learning. McGatha, et al., (2015) concludes that more research needs to be conducted on the work of the MTL while coaching individual and groups of teachers, their roles as leaders in their schools, how systems might establish and support the MTL, and what are the actions that lead to transforming instruction and productive student outcomes.

The 2015 NCTM Research Brief guided A Critical Analysis of Emerging High-Leverage Practices for Mathematics Specialists (Baker, Bailey, Larsen & Galanti, 2017) which was presented at the 2017 AMTE annual conference. In this book chapter, the authors present an analysis of the 24 articles through two distinct lenses that aim to identify effective practices for MTL: 1) the NCTM CAEP Standards (2012); and 2) the potentially productive coaching practices which included engaging in mathematics, examining student work, analyzing classroom video, rehearsing, lesson study or studio day, co-teaching, and modeling (Gibbons & Cobb, 2012). The analyses revealed that co-teaching and modeling were the practices most frequently mentioned in MTL research, with eleven and twelve mentions respectively. With respect to the role and actions of the MTL, engaging in mathematics and lesson study was discussed in five articles each (Alloway & Jilk, 2010; Campbell & Malkus, 2011; Chval, et al., 2010; Gibbons, 2015; Polly, 2012), two of the research articles employed analyzing classroom video (Alloway & Jilk, 2010; Campbell & Malkus, 2011) and rehearsing was not mentioned at all. Although the frequency of MTL actions speaks to the need for additional research, the research on MTLs did not provide enough specific information about the practices used so that they might be replicated to provide evidence of impact or transform instruction.

Baker et al. identified a need for MTL researchers to develop and use a common language to achieve the clarity and cohesiveness required to advance the work of the MTL.

The work of the MTL and transforming instruction takes time with the leaders requiring support in their work (Borko, Koellner & Jacobs 2014; Campbell, 2012; Chval, et al., 2010). Campbell (2011) posits that stakeholders on a global scale (e.g. policymakers, mathematics educators, mathematicians, professional developers) need to come together with research to further the work of MTLs in a "non-competitive sense of mutual obligation and responsibility." A support structure must exist that includes the opportunity to share the implementation and research challenges.

Background and Theoretical Perspective

Elementary Mathematics Specialists: A Movement to Advance MTLs

A single MTL can have an incredible impact on the development and effectiveness of others. Leaders in mathematics education at all levels of the school or district organization are crucial for ensuring attainment of high-quality school mathematics programs. In response to such leadership needs Elementary Mathematics Specialist (EMS) programs and job roles have been created across the United States. Many have made the case that practicing elementary school teachers are not adequately prepared to meet the demands for increasing student achievement in mathematics (NCTM, 2000; National Mathematics Advisory Panel, 2008; National Research Council, 1989). The main reason given to explain this insufficiency is that most elementary teachers are generalists—that is, they study and teach all core subjects, rarely developing in depth knowledge and expertise in teaching elementary mathematics.

More recently, the National Mathematics Advisory Panel (2008) noted that ―the use of teachers who have specialized in elementary mathematics teaching could be a practical alternative to increasing all elementary teachers' content knowledge (a problem of huge scale) by focusing the need for expertise on fewer teachers. Building on the Panel's recommendations, Wu (2009) advocated for mathematics specialists by suggesting the "problem of scale" could be addressed by utilizing a smaller cadre of well-prepared teachers to focus on mathematics at the elementary grades. Over the past two decades, others made similar recommendations (Battista, 1999; Conference Board of the Mathematical Sciences, 2001, p. 11; Learning First Alliance, 1998; National Council of Teachers of Mathematics, 2000, pp. 375–376; Reys & Fennell, 2003).

Beginning in 2009, under the leadership of then President Barbara Reys, AMTE began its advocacy for Elementary Mathematics Specialist certification and programs. They developed the EMS Standards (2010 & 2013) to support establishment of state certifications and development of programs. From there, they collaborated with ASSM, NCSM, and NCTM to develop a position statement, host two state certification conferences, and a conference for those with research connected to EMS. In this time, the number of states with EMS certification has increased from 9 to 20 which has resulted in an increase in the number of programs for EMS.

Together with AMTE, the Association of State Supervisors of Mathematics (ASSM), NCSM, and NCTM (2010) endorsed and recommended the use of elementary mathematics specialists to "enhance the teaching, learning, and assessing of mathematics in order to improve student achievement" (p. 1). Furthermore, they recommended that "every elementary school have access to an EMS [elementary mathematics specialist]. Districts, states/provinces, and higher education should work in collaboration to create: (1) advanced certification for EMS professionals; and (2) rigorous programs to prepare EMS professionals" (AMTE, ASSM, NCSM, & NCTM, 2010, p. 1).

The hope of state-level EMS certification would be to provide formal recognition, opportunities, and incentives for teachers to increase their knowledge and skill to teach or to lead others in teaching mathematics in elementary classrooms. With a formal certificate program, school and district administrators would be better positioned to create EMS positions and identify qualified personnel, thus, improving support for their teachers and students. Expectedly, with the increase in the call for mathematics specialist and increase in formal certification programs, the need for additional evaluation and research about mathematics specialist is critically needed. Articulating the knowledge and skills needed by EMS professionals is a necessary step in initiating state-level certification and program development. Although there is substantive and ongoing research on the effectiveness of EMS "as coaches," research related to elementary mathematics teachers is almost nonexistent (McGatha 2009; McGatha et. al., 2015).

Numerous publications and presentations have resulted from the work to develop Elementary Mathematics Specialist programs that now spanned more than two decades. Notably, EMSs have demonstrated the potential to positively influence teachers' instructional practices and beliefs in results from both qualitative and quantitative research (e.g., Baldinger, 2014; Campbell, 1996; Race, Ho, & Bower, 2002); however, some studies have noted limited changes in teachers' beliefs and practices even after the coaching process (e.g., Ai and Rivera, 2003; Olson & Barrt, 2004). EMSs have also shown to be effective on positively impacting students' mathematics learning and achievement (e.g., Balfanz, Mac Iver, & Byrnes, 2006; Campbell & Malkus, 2011). Large-scale projects focused on the relationship between EMSs and students' mathematics achievement provide evidence that these instructional leaders may provide schools the avenue needed for improved student performance (Balfanz et. al., 2006; Brosnan & Erchick, 2010; Campbell, 1996; Campbell & Malkus, 2011; Foster & Noyce, 2004). However, study limitations and the narrow number of empirical studies requires additional research to corroborate these promising findings.

Assessment and Evaluation of Elementary Mathematics Specialists

Many EMS programs are in their infancy and while the curriculum may exist the assessment and evaluation plan may not be fully developed. This is due in part to the various roles of an EMS as an elementary mathematics teacher, mathematics teacher leader, mathematics intervention specialist, and mathematics coach (McGatha & Rigelman, 2017) and the lack of specificity of the high leverage practices associated with the varied roles (Baker et al., 2017).

In a late 2014 survey of AMTE members (n=70), only 21% of the programs represented by survey respondents had program evaluation systems in place. Those without evaluation systems reported that their program was new and that program evaluation was under development. Respondents describe their EMS programs as aligned with state competencies for EMS professionals, NCTM/NCATE/CAEP EMS Standards, and/or AMTE EMS Standards. Of the programs with evaluation systems, 92% of the respondents commented on their program evaluation as tied to periodic reviews at the local, state, or national level.

Of those programs with evaluation plans in place, only two (17%) characterized their evaluation as innovative. Typical of the EMS program evaluation models described was an assessment process parallel to other advanced degree programs in the department/school (e.g., key assessments in particular courses, course evaluations, action research projects). Some programs use a portfolio as a measure of outcomes, while others use mathematics content knowledge assessments. A few commented on gathering data pre- and post-program on teacher beliefs and their ability to analyze classroom practice. Those programs with the most robust and for program evaluation described their work as based on their grant evaluation.

EMS program developers can learn from the various recommendations to teacher education programs about how to best assess teacher knowledge and skills. Researchers discuss the need to include assessments of practical knowledge, determine through multiple measures (AMTE, 2017; Beijard & Verloop, 1996; Darling-Hammond, 2006; Dwyer, 1993, NCTM, 1995). Some describe the potential of a teaching portfolio (Beijard & Verloop, 1996; Darling-Hammond, 2006; Zeichner,

2001) as a performance-based measure which could provide evidence of teacher leaders learning in and from their practice (Ball & Cohen, 1999). Program developers need to consider both the possibilities and limitations of the various tools they select for candidate and program assessment.

Session Organization and Plan for Engagement

This working group aims to explore the current avenues of and intentionally develop approaches for studying the improvement of mathematics teacher leaders, their preparation programs and professional development experiences. We first focus on the examination of existing assessment and evaluation tools, as well as the recommendations from the professional literature regarding high-quality candidate and program assessment. After generating questions of practice, participants will break into two groups to develop a plan of research that both builds capacity among and advances the research centered on MTLs.

Session 1: Examination of Assessment and Evaluation Tools

The first session will begin with introductions that share the areas of interest and expertise of each participant. Session leaders will provide a brief overview of the current status of the evaluation and assessment of mathematics teacher leader candidates and programs. Afterwards, session leaders will facilitate a large group discussion that connects the current status of candidate and program assessment with participants' research. This discussion will result in a list of collaboratively-generated research questions. Sample anticipated questions from the small group collaboration are:

- What might it look like to align EMS candidate and program assessment with high quality assessment principles?
- What are examples of key assignments, rubrics, and other instruments that have effectively measured the knowledge, skills, and practices of EMSs? To which aspects of the EMSs' role and/or knowledge needs do they attend? What are our development needs?
- Often, when programs are developed with support of grant funding, they develop robust candidate and program evaluation to comply with funders' expectations. What might it look like to maintain a robust assessment and evaluation system after the grant is over?
- What are some ways that programs can effectively maintain access to their graduates so they can determine efficacy of the EMS and/or programs that prepared the EMS?
- In what ways is the work of a MTL supported or hindered by various stakeholders? How can advocacy of the position of a MTL increase?
- Which aspects of the work of an MTL are most impactful for teachers and students?

Group members will then break into small groups to explore existing assessment and evaluation tools for not only mathematics teacher leaders and programs, but also other school personnel and university programs in which there is intersectionality and overlap in roles and responsibility (e.g. reading specialists, school administrators, special educators). During this time participants will determine how the provided tools might be adapted for their current research contexts and aligned with the group generated research questions. The session will conclude with small groups sharing their conversations and session leaders recording the tools into a matrix that connects the group-generated research questions with purposefully identified tools for one of two categories: Tools to Evaluate and Assess Mathematics Teacher Leaders and Tools to Evaluate and Assess Preparation Programs and Professional Development.

Session 2: Developing a Common Research Agenda

Initial whole group conversations during the second session will center on participant reflections from the matrix created on the first day. Participants will then determine their research interest and split into two to three small groups to: 1) allow participants to flexibly meet their needs based on context; and 2) align their research interests with a population they have access to. Session leaders will divide among the groups based on their own research experiences and interests, as well as the size of the groups. The group discussions will explore the following questions aimed at developing a common context, language and purpose:

- What access or relationships do you have to either candidates or programs (e.g. individuals, schools, districts, universities)
- Which of the research questions generated from the first session are of interest?
- What research tools are available or adaptable that will support the exploration of the identified research questions?
- In what ways can we align our research interests with the available populations and tools?

The session will conclude with each group sharing their conversations and questions as they develop a common research agenda.

Session 3: Designing Research Studies

In the third session, participants will build on the collaborative work they began in the second session and further design a research study. Session leaders will facilitate group discussions that support the participants in developing an outline of a research study. Conversations will center on creating an outline of a research study that includes the following aspects: research question, participants/location, specific evaluation or assessment tool that will be used/modified during the study, identified research activities, a timeline for research activities with set goals and a method of communication. After each group shares the outline of their research study, the session will conclude with the session leaders providing information on the anticipated follow-up activities and possible research products and outcomes.

Anticipated Follow-Up Activities

It is anticipated that the participants from this working group will continue to meet virtually over the course of the year using Google Tools, synchronous online platforms, social media and phone conferencing to develop several research products. Although the participants will influence the direction of the research, session leaders are prepared to develop the following products with participants: a database or list of the mathematics teacher leader and program assessment and evaluation tools, collaborative share results of studies at mathematics education conferences (e.g. AMTE, NCSM, NCTM-Research) or in journal submissions, the exploration of grant funding to advance the collaboration, submitting a symposium for PME-NA 2018, and developing a proposal for the continuation of the working group at PME-NA 2018.

Embodied cognition is growing in theoretical importance and as a driving set of design principles for curriculum activities and technology innovations for mathematics education. The central aim of the EMIC (Embodied Mathematical Imagination and Cognition) Working Group is to attract engaged and inspired colleagues into a growing community of discourse around theoretical, technological, and methodological developments for advancing the study of embodied cognition for mathematics education. A thriving, informed, and interconnected community of scholars organized around embodied mathematical cognition will broaden the range of activities, practices, and emerging technologies that count as mathematical. EMIC builds upon our 2015 and 2016 working groups with a specific focus on examining the embodied nature of mathematical collaboration. In particular, we view collaboration as a type of crossroad that brings together people and artifacts, from which EMIC communication and activities can emerge.

Keywords: Classroom Discourse, Cognition, Informal Education, Learning Theory

Motivations for This Working Group

Recent empirical, theoretical and methodological developments in embodied cognition and gesture studies provide a solid and generative foundation for the establishment of **a regularly held Embodied Mathematical Imagination and Cognition (EMIC) Working Group** for PME-NA. The central aim of EMIC is to attract engaged and inspired colleagues into a growing community of discourse around theoretical, technological, and methodological developments for advancing the study of embodied cognition for mathematics education, including, but not limited to, studies of mathematical reasoning, instruction, the design and use of technological innovations, learning in and outside of formal educational settings, and across the lifespan.

The interplay of multiple perspectives and intellectual trajectories is vital for the study of embodied mathematical cognition to flourish. Partial confluences and differences have to be maintained throughout the conversations; this is because instead of being oriented towards a single and unified theory of mathematical cognition, EMIC strives to establish a philosophical/ educational "salon" in which entrenched dualisms, such as mind/body, language/materiality, or signifier/signified are subject to an ongoing and stirring criticism. A thriving, informed, and interconnected community of scholars organized around embodied mathematical cognition will broaden the range of activities and emerging technologies that count as mathematical, and envision alternative forms of engagement with mathematical ideas and practices (e.g., De Freitas & Sinclair, 2014). This broadening is particularly important at a time when schools and communities in North America face persistent achievement gaps between groups of students from many ethnic backgrounds, geographic regions, and socioeconomic circumstances (Ladson-Billings, 1995; Moses & Cobb, 2001; Rosebery, Warren, Ballenger & Ogonowski, 2005). There also is a need to articulate evidence-based findings and principles of embodied cognition to the research and development communities that are looking to generate and disseminate innovative programs for promoting mathematics learning through movement (e.g., Ottmar & Landy, 2016; Smith, King, & Hoyte, 2014). Generating, evaluating, and curating empirically validated and reliable methods for promoting mathematical development and effective instruction through embodied activities that are engaging and curricularly relevant is an urgent societal goal.

Past Meetings and Achievements of the EMIC Working Group

The first meeting of the EMIC working group took place in East Lansing, MI during PME-NA 2015, and has been continuing to expand ever since into a website (https://sites.google.com/site/emicpmena), a second EMIC working group in Tucson, AZ, at PME-NA 2016, and a sister pre-conference workshop event at the upcoming Computer Supported Collaborative Learning conference (Williams-Pierce et al., accepted). It has a somewhat longer origin, dating back to the 2007 AERA symposium, "Mathematics Learning and Embodied Cognition." By now, several research programs have formed to investigate the embodied nature of mathematics (e.g., Abrahamson 2014; Alibali & Nathan, 2012; Arzarello et al., 2009; De Freitas & Sinclair, 2014; Edwards, Ferrara, & Moore-Russo, 2014; Lakoff & Núñez, 2000; Ottmar & Landy, 2016; Radford 2009; Nathan, Walkington, Boncoddo, Pier, Williams, & Alibali, 2014; Soto-Johnson & Troup, 2014; Soto-Johnson, Hancock, & Oehrtman, 2016), demonstrating a "critical mass" of projects, findings, senior and junior investigators, and conceptual frameworks to support an on-going community of likeminded scholars within the mathematics education research community.

Since our first meeting at PME-NA 2015, some of **our collaborative accomplishments** include:

1. Creating a contact list with names and emails of attendees, and other interested scholars who could not attend PME-NA 2015 or 2016
2. Developing a group website using the Google Sites platform to support ongoing interactions throughout the year, and regularly adding additional resources/activities
3. Joint submission of an NSF DRK-12 by members who first met during the 2015 EMIC sessions
4. Some senior members joining a junior member's NSF ITEST and Cyberlearning grant proposals
5. Submission to the IES CASL program to study the role of action in pre-college proof performance in geometry (Funded 2016-2020 for Nathan & Walkington)
6. Submitting a proposal for the continuation of the EMIC WG to PME-NA 2016
7. Examining the potential for an NSF Research Coordination Network (RCN)
8. Application for a grant from Association for Psychological Science (APS) to develop a better website and offer stipends for contributors
9. Proposing a pre-conference workshop to CSCL 2017 on the embodied tools to promote STEM education, which was accepted as a full-day event (Williams-Pierce et al., accepted)

Current WorkingGroup Organizers

As the WorkingGroup has matured and expanded, we have a broadening set of organizers for the coming year that represent a range of institutions and theoretical perspectives (and is beyond the limit of six authors in the submission system). This, we believe, enriches the WorkingGroup experience and the long-term viability of the scholarly community. The current organizers for 2017 are (alphabetical by first name):

- Candace Walkington, Southern Methodist University
- Carmen J. Petrick Smith, University of Vermont
- Caro Williams-Pierce, University at Albany, SUNY
- David DeLiema, University of California, Berkeley
- David Landy, Indiana University
- Dor Abrahamson, University of California, Berkeley
- Erin Ottmar, Worcester Polytechnic Institute
- Hortensia Soto–Johnson, University of Northern Colorado
- Martha W. Alibali, University of Wisconsin-Madison
- Mitchell J. Nathan, University of Wisconsin-Madison
- Rebecca Boncoddo, Central Connecticut State University

Focal Issues in the Psychology of Mathematics Education

Emerging, yet influential, views of thinking and learning as embodied experiences have grown from several major intellectual developments in philosophy, psychology, anthropology, education, and the learning sciences that frame human communication as multi-modal interaction, and human thinking as multi-modal simulation of sensory-motor activity (Clark, 2008; Hostetter & Alibali, 2008; Lave, 1988; Nathan, 2014; Varela et al., 1992; Wilson, 2002). These views acknowledge the centrality of both unconscious and conscious motor and perceptual processes for influencing conscious awareness, and of embodied experience as following /producing pathways through social and cultural space. As Stevens (2012, p. 346) argues in his introduction to the *JLS* special issue on embodiment of mathematical reasoning,

> it will be hard to consign the body to the sidelines of mathematical cognition ever again if our goal is to make sense of how people make sense and take action with mathematical ideas, tools, and forms.

Four major ideas exemplify the plurality of ways that embodied cognition perspectives are relevant for the study of mathematical understanding: (1) Grounding of abstraction in perceptuo-motor activity as one alternative to representing concepts as purely amodal, abstract, arbitrary, and self-referential symbol systems. This conception shifts the locus of "thinking" from a central processor to a distributed web of perceptuo-motor activity situated within a physical and social setting. (2) Cognition emerges from perceptually guided action (Varela, Thompson, & Rosch, 1991). This tenet implies that things, including mathematical symbols and representations, are understood by the actions and practices we can perform with them, and by mentally simulating and imagining the actions and practices that underlie or constitute them. (3) Mathematics learning is always affective: There are no purely procedural or "neutral" forms of reasoning detached from the circulation of bodily-based feelings and interpretations surrounding our encounters with them. (4) Mathematical ideas are conveyed using rich, multimodal forms of communication, including gestures and tangible objects in the world.

Alongside these theoretical developments have been technical advances in multi-modal and spatial analysis, which allow scholars to collect new sources of evidence and subject them to powerful analytic procedures, from which they may propose new theories of embodied mathematical cognition and learning. Just as the "linguistic turn" in the social sciences was largely made possible by the innovation that enabled scholars to collect audio recordings of human speech and conversation

Galindo, E., & Newton, J., (Eds.). (2017). *Proceedings of the 39th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* Indianapolis, IN: Hoosier Association of Mathematics Teacher Educators.

in situ, growth of interest in multi-modal aspects of communication have been enabled by high quality video recording of human activity (e.g., Alibali et al., 2014; Levine & Scollon, 2004), motion capture technology (Hall, Ma, & Nemirovsky, 2014; Sinclair, 2014), developments in brain imaging (e.g., Barsalou, 2008; Gallese & Lakoff, 2005), multimodal learning analytics (Worsley & Blikstein, 2014), and data logs generated from embodied math learning technologies that interacts with touch and mouse-based interfaces (Manzo, Ottmar, & Landy, 2016).

Theme: The Crossroads of Collaboration

Inspired by the PME-NA 2017 theme, we will specifically focus on the ways in which people can influence one another. Examples that we will use during the Working Group include: the interactions of two middle school-aged friends playing a mathematics game together and using both physical and digital gesture to augment their spoken communication (Williams-Pierce, 2016); a teacher guiding the movements of a learner exploring ratios (Abrahamson & Sánchez-García, 2016); pre-service teachers using their distributed gestures to explore a mathematical conjecture and establish its truth and justification using embodied and extended cognition (Walkington, Woods & Nathan, under review); pre-service teachers interacting with designed dynamic algebraic notations as a means of engaging embodied aspects of mathematical derivation (Jacobson, Landy, & Ottmar, in prep); having students and teachers play and create embodied technology games to teach mathematics and computational thinking (Arroyo & Ottmar, 2016), and pairs of elementary students working together on a series of body-based tasks centered on angle concepts (Smith et al., 2016).

Through these examples, we will explore questions such as: when students meet within a common arena, how might an activity design motivate them to develop mathematical notions through making pragmatic ideas mutually intelligible, and how do they accomplish this feat? What are the roles of more knowledgeable members of the community in facilitating this process? During the conference, participants in our EMIC workshop will engage in dedicated activities and guided reflections as a basis for exploring the interpersonal and interactive crossroads of goals, action, and discourse as these play out in the emergence of mathematics learning. This investigative effort will be crafted so as to align with recent developments in embodiment literature, whereby scholars are struggling to model individual sensorimotor learning within established cultural practices, norms, and values.

Plan for Active Engagement of Participants

Our formula from PME-NA 2015 and 2016 proved to be effective: By inviting participants into math activities at the beginning of each session, we were rapidly drawn into those very aspects of mathematics that we find most rewarding. We plan to facilitate collaborative EMIC activities, followed by group discussions (and we now have many activities and members who can trade off in these roles!) that will help us all to “pull back” to the theoretical and methodological issues that are central to advancing math education research. Within this structure of beginning with mathematical activities and facilitated discussions, on **Day 1** we plan to begin with activities that forefront collaboration around EMIC activities, with four different groups engaging in different activities. These activities will serve as the foundation for a broad group discussion about the varied roles of collaboration in EMIC. See Figure 1 below for examples of collaborative activities from PME-NA 2016.

Figure 1. Collaborative activities. Martha Alibali and two participants form a triangle together with their arms (left); a group just finished jointly assembling a large icosahedron in an activity facilitated by Dor Abrahamson and Leah Rosenbaum (right).

In previous years, we have found that the full first session will generally be taken up by introductions and and a round of activities followed by discussion. If there is additional time, we will begin brainstorming new collaborative EMIC activities - if there is not, then we will ask attendees to jot down any new activity ideas they have to share at the following session.

On **Day 2**, we will begin the session with technology-based collaborative activities, with four stations that pairs of participants rotate through. Examples of two of those stations are in Figure 2. Continuing with the routine established in Day 1, a full group discussion will follow, with a particular focus on designing EMIC digital contexts to support collaboration.

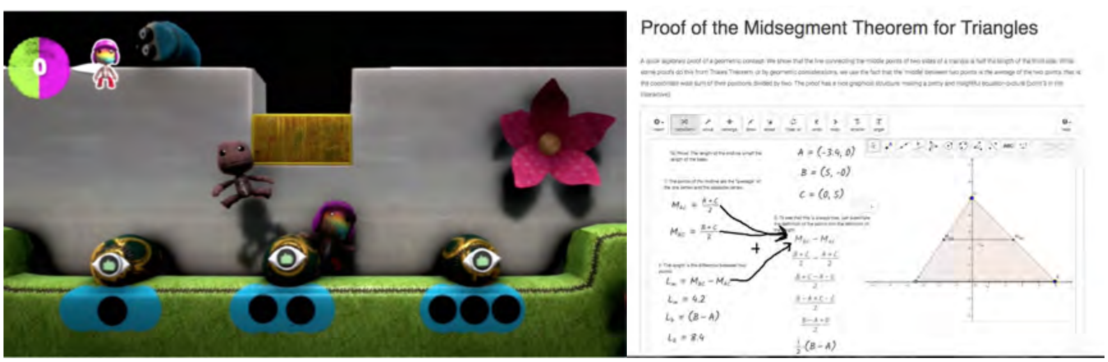

Figure 2. Digital collaborative activities. *Rolly's Adventure* by Caro Williams-Pierce (left); and *Graspable Math* by David Landy and Erin Ottmar (right).

After the discussion, we will discuss different EMIC activity ideas that participants began jotting down the day before, with the goal of developing additional collaborative activities that can be used in various research and learning contexts. The final activities will be shared on the EMIC website.

Day 3 is agenda-setting day, where we all discuss how we will keep the momentum going, such as developing an NSF Research Coordination Network (RCN), as a potential complement to the PME-NA Working Group. The RCN is not intended to promote any one particular research program, but rather to build the networked community of international scholars from which many fruitful lines of inquiry can emerge. Commensurate with the aims of the RCN, we will explore ways to

> share information and ideas, coordinate ongoing or planned research activities, foster synthesis and new collaborations, develop community standards, and in other ways advance science and education through communication and sharing of ideas.

Another example is to develop a proposal for a special issue of the *Journal of Research in Mathematics Education* that focuses on sharing the different theoretical perspectives, research activities, and operationalization of EMIC by the working group members.

In order to find common ground for the RCN submission and the JRME special issue, we may perform a live concept mapping activity that is displayed for all participants to explore the range of EMIC topics and identify common conceptual structure. We will discuss different general foci, such as teacher professional development with EMIC, designing EMIC games or museum exhibits, etc. Then, harkening back to the four major ideas that we developed earlier, sample seed topics for organizing this activity will be explored, such as:

1. Grounding Abstractions
    a. Conceptual blending (Tunner & Fauconnier, 1995) & metaphor (Lakoff & Núñez, 2000)
    b. Perceptuo-motor grounding of abstractions (Barsalou, 2008; Glenberg, 1997; Ottmar & Landy, 2016; Landy, Allen, & Zednik, 2014)
    c. Progressive formalization (Nathan, 2012; Romberg, 2001) & concreteness fading (Fyfe, McNeil, Son, & Goldstone, 2014)
    d. Use of manipulatives (Martin & Schwartz, 2005)
2. Cognition emerges from perceptually guided action: Designing interactive learning environments for EMIC
    a. Development of spatial reasoning (Uttal et al., 2009)
    b. Math cognition through action (Abrahamson, 2014; Nathan et al., 2014)
    c. Perceptual boundedness (Bieda & Nathan, 2009)
    d. Perceptuomotor integration (Ottmar, Landy, Goldstone, & Weitnauer, 2015; Nemirovsky, Kelton, & Rhodehamel, 2013)
    e. Attentional anchors and the emergence of mathematical objects (Abrahamson & Bakker, 2016; Abrahamson & Sánchez–García, 2016; Abrahamson et al., 2016; Duijzer et al., 2017)
    f. Mathematical imagination (Nemirovsky, Kelton, & Rhodehamel, 2012)
    g. Students' integer arithmetic learning depends on their actions (Nurnberger-Haag, 2015).
3. Affective Mathematics
    a. Modal engagements (Hall & Nemirovsky, 2012; Nathan et al., 2013)
    b. Sensuous cognition (Radford, 2009)
4. Gesture and Multimodality
    a. Gesture & multimodal instruction (Alibali & Nathan 2012; Cook et al., 2008; Edwards, 2009)
    b. Bodily activity of professional mathematicians (Nemirovsky & Smith, 2013; Soto-Johnson, Hancock, & Oehrtman, 2016)

c. Simulation of sensory-motor activity (Hostetter & Alibali, 2008; Nemirovsky & Ferrara, 2009)

We will also discuss the implications of this work and the different areas of the concept map for teaching, and discuss ideas for bridging the gap between research and practice.

Finally, we will introduce the EMIC website (publicly available at https://sites.google.com/site/emicpmena/home). On this website, we have a list of members with their emails and bios, information about our PME-NA presence, and short personal introduction videos. We've also created a space for members to share information about their research activities – particularly for videos of the complex gesture and action-based interactions that are difficult to express in text format. In addition, we have a common publications repository to share files or links (including to ResearchGate or Academia.edu publication profiles, so members don't have to upload their files in multiple places). At our 2015 working group, some junior members expressed particular interest in this literature support for their pending theses, while more senior members were eager to share and organize the emerging body of work on embodied math education. We've also linked the Google Sites platform directly to a Google Group, so members can participate in online forums (or the linked listserv), and discuss cutting edge topics, share in-progress working papers for review, or advertise for conferences, special issues, or other EMIC-relevant opportunities.

Follow-up Activities

We envision an emergent process for the specific follow-up activities based on participant input and our multi-day discussions. At a minimum, we will continue to develop a list of interested participants and grant them all access to our common discussion forum and literature compilation. Those that are interested in the NSF RCN plan will work to form the international set of collaborations and articulate the intellectual topics that will knit the network together; and those that are interested in the JRME special issue proposal will outline a specific timeline for progressing. One additional set of activities we hope to explore is to introduce educational practitioners at all levels of administration and across the lifespan to the power and utility of the EMIC perspective.

In the past three years, we have seen a great deal of progress. This is perhaps best exemplified by coming together of the EMIC website, the ongoing collaborations between members, and the proposals here and to CSCL, which each draws across multiple institutions. We thus will strive to explore ways to reach farther outside of our young group to continually make our work relevant, while also seeking to bolster and refine the theoretical underpinnings of an embodied view of mathematical thinking and teaching.

EXAMINING SECONDARY MATHEMATICS TEACHERS' MATHEMATICAL MODELING KNOWLEDGE FOR TEACHING

Kimberly Groshong
The Ohio State University
groshong.4@osu.edu

Joo Young Park
Florida Institute of Technology
jpark@fit.edu

This 3rd year working group addresses the research question: What knowledge do secondary teachers need to possess to advance and foster mathematical modeling abilities in students? In the previous sessions, definitions and exemplar task distinguishing modeling mathematics and mathematical modeling were made. A task analysis framework, with three distinct features – openness, authenticity, and complexity, was created to investigate differences between mathematical modeling tasks and other problems. The group identified characteristics for both mathematical and modeling knowledge. Researchers considered the content and real world knowledge required when using different types of mathematical models, e.g. mechanistic and deterministic. The type of pedagogical knowledge needed for using different types of modeling tasks in classrooms still needs considerable research. While pedagogical knowledge discussions occurred during previous sessions, the nature of this knowledge was fully developed. This will be the primary focus of this year's work so that a more complete Mathematical Modeling Knowledge for Teaching (MMKT) can be defined to inform teacher training programs. Progress on grant writing, national survey distribution, and current journal writing from previous years' work will be reported. New research questions will be developed during these sessions.

Keywords: Modeling, Mathematical Knowledge for Teaching, Teacher Knowledge, Teacher Education-Inservice/Professional Development

The Common Core State Standards for Mathematics (CCSSM), launched in 2009, are the current academic standards in 42 states. The CCSSM includes modeling mathematics as both a content standard and a mathematical practice (National Governors Association & Council of Chief State School Officers, 2010). The CCSSM, as well as the standards from other states such as Texas (TEA, 2015) and Virginia (VDOE, 2017), specifically include *mathematical modeling* in their high school mathematics content and *modeling with mathematics* in their elementary and middle grades mathematics materials. Mathematical modeling (MM) and modeling with mathematics (MWM) differ in problem authenticity, degree of task openness, and complexity of mathematics and decision making needed. Modeling with mathematics (MWM) activities can either be mathematical in context or consider real life situations whereas mathematical modeling problems are drawn from authentic real life phenomena. MWM require the problem solver to make fewer decisions than mathematical modeling situations indicating that the MWM tasks are less open, in that, their problem statements reduce the number of assumptions, variables, and relationships needed. Because of their less complex nature, MWM tasks allow the student fewer mathematical approaches available, which limits the number of solutions students can generate.

Mathematical modeling provides a decision-making process to address the messy, ill-posed problems found in real life. For example, when asked to identify the stopping distance of a vehicle (NGA & CCSSO, 2010), the student must identify a problem statement in the less structured world environment, make simplifying assumptions, identify needed variables, and recognize constraints in order to produce and manipulate a mathematical model that may describe or make predictions about the real world situation (Jensen, 2007). The model's success depends on the decisions made by the student, and these decisions are influenced by the student's experiences, which means that each student may travel a different solution path and produce a different mathematical model for the same situation (Confrey & Maloney, 2007).

Because few teacher education programs include specific training to develop secondary teachers' mathematical modeling abilities, both as mathematicians and as teachers of mathematical modeling, implementing the academic standards surrounding mathematical modeling is challenging (Goos, 2014). From discussions in previous working group sessions, mathematics educators and researchers have confirmed this challenge and expressed concern about the limited availability of training materials including access to previously used mathematical modeling problems with potential solutions and pedagogical guidance for planning, implementing and assessing learning when using these ill-posed problems. This proposed working group will continue to collect mathematical modeling resources and share mathematical modeling experiences to build understanding about the mathematical and modeling content knowledge teachers' need. Research attention will be focused on the pedagogical demands that surround these types of problems. It is the intent of this research to more fully understand teacher knowledge surrounding mathematical modeling in order to increase the body of research on this topic and inform teacher training programs, which may ultimately promote a richer environment for student learning so that students may better understand the world that surrounds them.

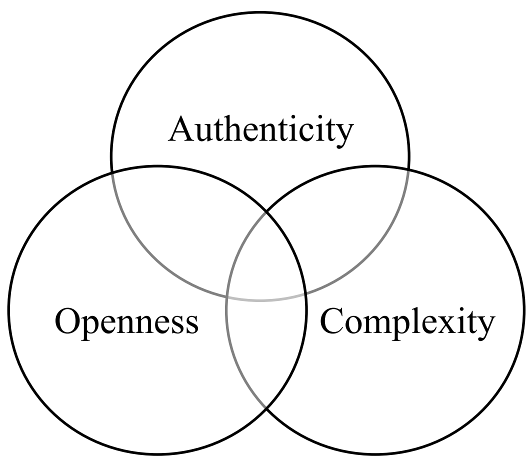
Progress From Previous Working Group Sessions

The fundamental research question for this working group asks, "*What knowledge do secondary teachers need to possess to advance and foster mathematical modeling abilities in students?* This knowledge includes the facts and skills a person acquires either through education or life experiences (Oxford University Press, 2016), and this knowledge expands through increased exposure to different types of modeling activities (Doerr, 2007). Through collaborative discussions of published research regarding mathematical modeling activities in K-12 education, basic definitions for modeling with mathematics and mathematical modeling were founded, then the working group considered the types of knowledge needed by teachers when working with mathematical modeling problems and the group considered that this knowledge may change according to the problem context, which draws upon both conceptual and experiential knowledge of the world as well as the breadth of mathematical topics potentially needed for the problem-solving process, and the type of modeling situation the teachers experienced, which requires a specific set of mathematical skills to answer questions that are descriptive, explanatory, or predictive. For example, the knowledge and skills needed to answer "how far will a vehicle travel when coming to a stop" may vary if the question was more predictive, such as "what is the likelihood the vehicle will stop in 20 feet". To provide insight into the complexity of mathematical modeling knowledge, the researchers facilitated discussions with session participants about the cognitive demands surrounding both the context of mathematical modeling tasks, which resulted in the development of a task analysis framework, and the purpose of the mathematical modeling question, which introduced session participants to different types of mathematical modeling situations, e.g. descriptive or analytic, qualitative or quantitative, and deterministic or mechanistic.

During the process of distinguishing modeling applications and modeling with mathematics from mathematical modeling problems, the mathematical modeling task analysis framework (Figure 1) was created and operational definitions for authenticity, complexity, and openness were stated to aid in revealing the cognitive demands surrounding the problem's context. The framework also provided a method to promote individual and group participation while analyzing mathematical modeling tasks and discussions found in research literature.

Both *authenticity* and *complexity* have two components. *Authenticity* measures the closeness of fit in the mathematical modeling experience between the classroom and the research field with regards to the data sources, computer techniques and software, and modeling approach (Vos, 2011). *Authenticity* also addresses the genuineness of the real life context in being situated in a subject area outside of mathematics (Niss, 1992) and originating from reality outside the classroom (Lesh & Lamon, 1992) in that it describes a real event, asks a meaningful question, and produces a realistic solution (Palm, 2007). *Modeling complexity* depends on the amount of assistance the students need, the number of techniques available, and the number of modeling techniques needed to reach a solution (Stillman, 2000). *Mathematical complexity* relies on the degree of mathematical sophistication used in creating the mathematical model (Jensen, 2007). *Openness* describes problems with multiple solutions, interpretations, answers, and new questions (Abrams, 2001, p.18).

Figure 1. Mathematical modeling task analysis framework (Groshong & Park, 2015).



Given that mathematical models can describe, explain, or predict events, it is possible that the way students and teachers think about these different models changes with each type of mathematical model, so studying modeler's experiences in different modeling situations may reveal gaps in our understanding of mathematical modeling knowledge. Each type of mathematical model can be classified by its characteristics, properties, and features (Groshong, 2016). When reading about mathematical modeling in literature, the same mathematical model can be described using several terms, which can be very confusing for students, educators, and researchers (Figure 2). *Empirical* models are sometimes referred to as data models because of their reliance on data whereas *mechanistic* models are also called theoretical models as they originate with theoretical statements. *Deterministic* models are fixed and generate nonrandom outputs, but their counterparts, *stochastic* models, include randomness in their output (Edwards & Hamson, 2007).

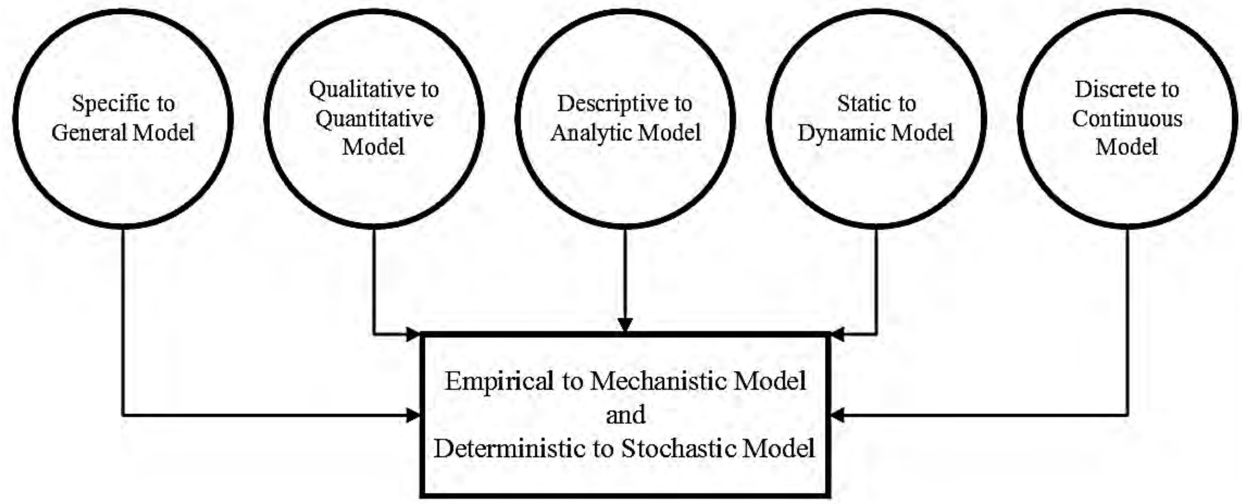


Figure 2. Different types of mathematical models (Groshong, 2016).

When the problem statement requires a single solution to meet exact criteria, a *specific model*, is produced; but when the model needs to address multiple yet similar situations, *general models* are the result. *Quantitative models* are mathematical expressions for predicting or explaining phenomena, and *qualitative models* use logical arguments explaining patterns and trends. In the initial modeling stages, *descriptive models* provide narratives or representations to state assumptions, define variables, and describe real-life issues (Tam, 2011), but *analytic models* capture the full modeling process and generate exact solutions using sophisticated mathematical methods. When time is held constant, *static models* describe this equilibrium condition, but when the situation changes with the passage of time, *dynamic models* examine the changing conditions. *Continuous models* allow variables to assume any value between two endpoints acceptable, but *discrete models* consider variables to have distinct, finite, and countable values.

Mathematical Modeling Knowledge for Teaching Framework

Adapting the 3-d representation of mathematical modeling competency by Jensen (2007), this framework defines three types of knowledge needed by teachers when planning, implementing, and assessing student learning with mathematical modeling activities (Figure 3). Each category of knowledge can be increased through formal and personal learning as well as experience. *Mathematical Knowledge* includes mathematical content and skills and the knowledge needed to apply mathematics to relevant situations. *Modeling Knowledge* consists of the understanding and ability to navigate the mathematical modeling process using a variety of mathematical methods and in different modeling situations. *Pedagogical Knowledge* comprises the broad set of information and practices teachers need in order to prepare for and facilitate modeling lessons guiding and assessing student learning throughout the activity (Groshong & Park, 2015).

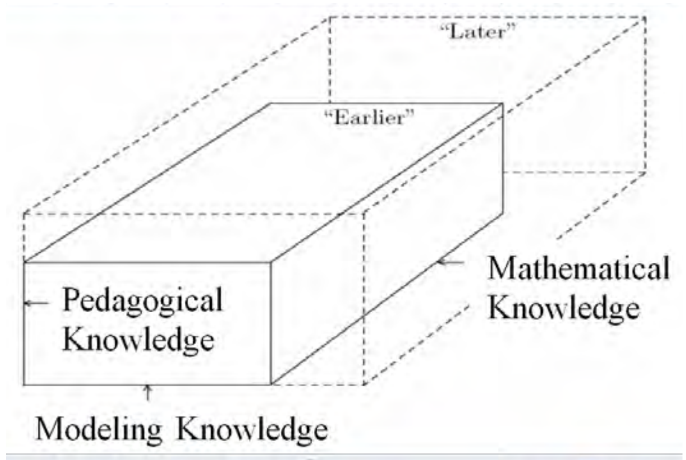

Figure 1. Mathematical modeling knowledge for teaching framework – MMKT (Groshong, Gomez, & Manouchehri, 2015; Groshong & Park, 2015).

In the previous working group session, it was noted that difficulties in one area of knowledge influenced performance in other areas of knowledge causing the participant to struggle with progressing through the modeling process. Throughout the time spent on this task analysis, participants frequently shifted their discussions from being a mathematician, a modeler, and a teacher. The historic activity was initially proposed by Wagner (1976) and asks the modeler to determine the maximum area a sofa can take as the sofa moves around a right angled hallway. The authentic context strikes a chord of familiarity with modelers in that most people have experienced the challenge of moving furniture. The openness of this problem challenges mathematics, computer science, and engineering students. A high school variation of the problem is found in Gould, Murray, and Sanfratello (2012) and provides students more structure by providing fixed dimensions for the sofa and hallway and asking students to determine if it is possible to move a fixed length, width, and height sofa around a fixed dimension hallway corner. Students need to generate and test a specific model. Although providing students with prescribed dimensions reduces the number of decisions students need to make and reduces the generality of the model, it does not reduce the complexity of the problem, as there are still many solution approaches that can be made, as was demonstrated in the discussion by the working group participants. One participant asked when the teacher should allow students to construct physical or computer models of the situation versus solving it mathematically. This led to the pedagogical discussion surrounding the importance of learning objectives to guide both mathematical and modeling skill and knowledge development. As researchers, the need to spend considerable time studying the breadth and depth of pedagogical knowledge required by teachers became apparent.

Mathematical Knowledge for Teaching

Areas of the mathematical modeling knowledge for teaching may be linked to the more generalized mathematical knowledge for teaching (MKT), which distinguishes teachers' mathematical content knowledge from their pedagogical knowledge (Ball, Thames, & Phelps, 2008). The working group researchers are making considerable progress in connecting an extensive literature review that defines sub-areas of MKT to the pedagogical discussions that occur during the task analysis activities focusing on areas of distinction between the mathematical knowledge for teaching other mathematics topics from the specific mathematical modeling knowledge for teaching when working with modeling activities.

In Ball, Thames, and Phelps' (2008) framework, the mathematical content knowledge, which has been demonstrated by participants during the task analysis as important features in the mathematical knowledge component of MMKT, are *common content knowledge* (CCK) that describes the average mathematics needs of educated adults as they carry on their lives; *specialized content knowledge* (SCK) that separates the mathematical knowledge of citizens from that of teachers who needed to present information to students, explain concepts, and predict areas of difficulties; and, *horizon content knowledge* (HCK) links mathematics to other academic subjects and across grade levels.

In working with the "moving the couch" problem, participants demonstrated CCK in qualitative statements of length and width explaining their experiences with moving furniture of fixed dimensions in fixed spaces. SCK was observed as participants described their problem solving steps as they progressed through the mathematical modeling process suggesting that SCK may be a component of both mathematical and modeling knowledge in the MMKT. The teacher's understanding of how mathematics fits in the world, including the depth of encyclopedic knowledge the breadth of factual knowledge from other disciplines that inform the real life situation (Stillman, 2000), is involved in HCK. In the couch problem, engineering comments about constructing scaled, physical models of the situation were evidence of HCK in using bodies of knowledge from other disciplines to aid mathematical problem solving.

Currently, working group participants are including mathematical modeling activities in teacher training programs with the intent of identifying mathematical and modeling content knowledge along with the experiential knowledge of the world and encyclopedic knowledge of other disciplines with regards to the CCK, SCK, and HCK deliberated during the workshops. Research is continuing in the area of needed content knowledge when employing different types of mathematical models, and reports on this progress may encourage other researchers to identify features of CCK, SCK, and HCK as they specifically apply to mathematical modeling events.

This year's working group focus will consider in detail Ball, Thames, and Phelps' (2008) *pedagogical content knowledge* (PCK), which may aid in defining the MMKT framework. With regards to mathematical modeling in the classroom *knowledge of content and students* (KCS) may be demonstrated not only as teachers predict, recognize, and assist students in overcoming mathematical barriers but also as teachers assist students in prevailing over modeling obstacles, which can impede students' mathematical modeling performance. *Knowledge of content and teaching* (KCT) can be evident in selecting appropriate mathematical modeling task when teachers take into account the advantages and disadvantages of using or the appropriate sequencing of open and complex problems. *Knowledge of curriculum* (KC) may include teachers' knowledge of where mathematical modeling fits in their course curriculum as well as in the courses that precede or follow and in other disciplines. In considering teachers' PCK, the amount and influence of experiential and encyclopedic knowledge of the real-world and of other academic disciplines needed by teachers and students in order to be successful mathematical modelers is still an area that needs extensive research.

Working Group Plan

The working group plans to continue expanding on our understanding of mathematical content and modeling knowledge through year-long research. The focus of the working group sessions will be directed towards discussing the mapping of the PCK knowledge subcategories outlined by Ball, Thames, and Phelps (2008) to mathematical, modeling, and pedagogical content areas of the MMKT in hopes of recognizing common areas or identifying gaps to increase our understanding of the scope of knowledge needed by teachers in order to promote student learning through rich mathematical modeling experiences. Discussions will also consider whether this PCK changes with the type of modeling task used in classroom instruction. Thus, the primary discussion topic will address the following research question: *What pedagogical knowledge is needed for working with different types of mathematical modeling tasks?*

Working Group Plan for Active Engagement of Participants

Participants are eagerly invited to join this working group to actively participate in defining this important research area. To continue examining this research question, we propose that members of the working group will divide into smaller groups, in order to provide an intellectual support system, to continue critiquing the definitions, taxonomies, and MMKT framework; to discuss the suggested focus questions; and to generate new research questions. The working group is committed to the goals of PME-NA while emphasizing collective reflection and collaborative inquiry, addressing challenges, and expanding the field of research. The working group will meet three times during the conference and will be invited to continue meeting virtually during the course of one year.

Session 1: Foundation

To welcome new participants and lay a solid foundation for future work, the first session will review the definitions of applications, modeling with mathematics, and mathematical modeling determined by the previous year's work; and review the task analysis framework and the MMKT. A report of current research projects, the status of publications, and the dissemination of the secondary mathematics teachers' survey will be given. Goals of this years' research along with an outline of session activities will be presented. Since it has been successful in furthering member participation and solidifying common understanding with regards to definitions, taxonomies, and frameworks, members will again be provided a mathematical modeling task and using the task analysis framework, they will identify areas of mathematical and modeling knowledge. The final part of the session will include sharing contact information, providing participants access to the group's on-line information, and encouraging the formation of research groups based on the interests of the participants.

Session 2: MMKT Framework – Pedagogical Knowledge - Introduced

The second session will continue the work from the previous session to further explain the MMKT as defined with mathematical knowledge, modeling knowledge, and pedagogical knowledge components. Employing a sample task and the task analysis framework as a vehicle to elicit understanding of the different knowledge types, participants will discuss the role of the teacher in selecting tasks, such as the exemplar, planning learning experiences, implementing activities, and assessing learning. The next step will be a discussion mapping Ball, Thames, and Phelp's (2008) MKT and a potential MMKT framework more clearly focusing on the pedagogical knowledge subcategories. Participants will revisit last year's lively discussion about the influence of the real world contextual knowledge and experiences in modeling and, then, consider the placement of the knowledge of the real world, with regards to its influence on pedagogy, in the MMKT framework.

Session 3: MMKT Framework – Pedagogical Knowledge - Detailed

The last session will summarize the previous days' findings, articulate research goals, and outline a working plan for designing research projects to be conducted during the upcoming year. Participants will be encouraged to join the ongoing research discussions virtually.

Post-Conference

To promote the working group's efforts, the results of all sessions and meetings will be documented and disseminated to all members. Following the conference, participants will be invited to continue discussing research interests in this area through a virtual meetings as a platform for suggesting and reviewing research, posing and critiquing mathematical modeling tasks, posting and discussing teacher and student solutions, developing an archive of useful and productive mathematical modeling tasks, and writing scholarly summaries of findings.

Conclusion

While this working group is still young, significant progress has been made in formalizing definitions, grounding work on theoretical principles, summarizing literature for research gaps, establishing a clear research focus, and developing active research projects. By articulating clear definitions and considering the influence a taxonomy of mathematical modeling types may have on teacher and student learning, a theoretical basis for areas of mathematical, modeling, and pedagogical knowledge has been outlined. Research projects, grants, and a large-scale survey have been developed and are in the process of being implemented. This research and these working group sessions are needed to expand understanding and inform the field of research in mathematical modeling teacher knowledge.

The purpose of this working group is to continue to bring together scholars with an interest in examining the use of and access to large-scale quantitative tools used to measure student- and teacher-related outcomes in mathematics education. The working group session will focus on (1) updating the workgroup on the progress made since the first working group at PME-NA in Tucson, Arizona, specifically focusing on the outcomes of the Validity Evidence for Measurement in Mathematics Education conference that took place in April, 2017, in San Antonio, (2) continued development of a document of available tools and their associated validity evidence, and (3) identification of potential follow-up activities to continue this work. The efforts of the group will be summarized and extended through both social media tools and online collaboration tools to further promote this work.

Keywords: Assessment and Evaluation; Research Methods

Introduction

There is value in the knowledge that large-scale quantitative research can bring to the field in terms of generalizability to educational practice when appropriately conducted (American Statistical Association, 2007; Hill & Shih, 2009). The American Statistical Association's report (2007) on *Use of Statistics in Mathematics Education Research* states:

> If research in mathematics education is to provide an effective influence on practice, it must become more cumulative in nature. New research needs to build on existing research to produce a more coherent body of work… Studies cannot be linked together well unless researchers are consistent in their use of interventions; observation and measurement tools; and techniques of data collection, data analysis, and reporting. (pp. 4-5).

As education has shifted more towards data driven policy and research initiatives in the last 25 years (Carney, Brendefur, Thiede, Hughes, & Sutton, 2016; Hill & Shih, 2009), the data for policy-related aspects are often expected to be quantitative in nature (e.g., end-of-course assessments and numerical value of reform-oriented teaching). Funding agencies encouraging research (i.e., National Science Foundation and Institute of Education Sciences) often request proposals to employ quantitative measures with sufficient validity evidence (see http://ies.ed.gov/ and http://www.nsf.gov/).

Measure (instrument) quality strongly influences the quality of data collected and relatedly, findings of a research study (Gall, Gall, & Borg, 2007). Measures with a clearly defined purpose and supporting validity evidence are foundational to conducting high quality large-scale quantitative work (Newcomer, 2009). There are few syntheses of quantitative tools for mathematics educators to employ and even fewer discussions of the validity evidence necessary to support the use of measures in a particular context. Syntheses of measures for use in mathematics education can be found in the literature but these are typically not intended as a comprehensive analysis. For example, Carney et al. (2015a) conducted a brief review of self-report instructional practice survey scales applicable to mathematics education. Boston, Bostic, Lesseig, & Sherman (2015b) conducted a review of three widely known classroom observation protocols to assist mathematics educators in determining the appropriate tool for their particular research question and context. Both reviews provided a background on existing measures and their associated validity evidence in relation to a new measure under development. It is important that this type of work continues and is encouraged by the field. Thus, this working group aims to increase conversation around quantitative tools for use on a large-scale with this working group. We share three goals for this proposed working group: (a) To bring together scholars with an interest in examining the research on quantitative tools and measures for gathering meaningful data; (b) To spark conversations and collaboration across individuals and groups with an interest in large-scale tools and those conducting research on student- and teacher-related outcomes; (c) To generate products to disseminate widely across the field of mathematics education scholars.

Related Literature

Historical Context, Terms, and Rationale for Working Group

The National Mathematics Advisory Panel (2008) found that only a "small proportion of those [reviewed] studies have met methodological standards. Most ….failed to meet standards of quality because they do not permit strong inferences about causation or causal mechanisms" (pp. 2-7). Sound methodology is guided by appropriate measure or instrument choice. Good research takes on quantitative, qualitative, and at times both methodologies to become mixed-methodologies (Hill & Shih, 2009; Cresswell, 2012). Our focus for this proposal is quantitative-inclusive methodologies, specifically focusing on measures and tools associated with them, to support mathematics educators use of and need for quantitative tools that may be used in large-scale studies.

Near the core of any methodology is the measure or instrument used to collect data (Newcomer, 2009). The American Psychological Association, National Council on Measurement Education, and American Educational Research Association ([APA, NCME, AERA] 2014; 1999) provide clear guidelines regarding measurement validity and reliability. At a minimum, sufficient evidence for five variables must be shared related to validity: (1) content evidence, (2) evidence for relationship to other variables, (3) evidence from internal structure, (4) evidence from response processes, and (5) evidence from consequences of testing (AERA, APA, & NCME, 1999, 2014; Gall et al., 2007). Unfortunately, "evidence of instrument validity and reliability is woefully lacking" (Ziebarth, Fonger, & Kratky, 2014, p. 115) in the literature. Validation studies of quantitative measures are noticeably absent from mathematics education journals, which present the challenge of determining whether an instrument is appropriate for a given study much less whether it will generate valid and reliable data for analysis (Hill & Shih, 2009). Hill and Shih (2009) reported that eight of 47 studies published in the *Journal for Research in Mathematics Education* provided any evidence related to validity and the majority provided only psychometric evidence. Our goal for this literature review is to present a need for a working group at PME-NA 39 that will bring individuals together from North America to conduct more syntheses and further explore needed areas of tools that can be used to study both student- and teacher- related measures in large-scale research by mathematics educators.

Examining Student-Focused Measures

Quantitative measures of student's mathematics content knowledge, problem solving, beliefs, and other factors have been employed across various contexts. We share an initial set of literature to frame the thinking for working group participants. Moreover, we welcome those that have interests not necessarily listed in this section.

Mathematics content knowledge. Students' mathematics content knowledge has been assessed in large-scale studies using end-of-course (high-stakes) measures during the last decade, Trends in Mathematics and Science Study (TIMSS), and National Assessment for Educational Progress (NAEP). Researchers who developed the PISA and NAEP report the validation process; however, the end-of-course measures are often shrouded by commercial entities (e.g., American Institutes of Research and Pearson). The latter group makes examining the quality of the measures for content knowledge problematic. Broadly speaking, it is challenging for researchers aiming to make decisions regarding use of items (or previously used measures) without syntheses describing measure qualities as well as similarities and differences across measures. Thus, a measure may claim to measure students' (at one grade- or developmental-level) content knowledge but how is content knowledge defined for each measure?

Beliefs. Students' beliefs of mathematics, mathematics teaching, and usefulness of mathematics for the real world have been examined in various ways. Students taking the NAEP assessment also responded to questions designed to measure their perceptions of mathematics (Dossey, Mullis, Lindquist, & Chambers, 1988). In the survey created by Dossey and colleagues, students responded to several Likert scale items regarding their attitudes and beliefs about mathematics. Similarly, Lazim, Osman, and Salihin (2004) created a mathematics belief questionnaire that had four belief dimensions: "[about] the nature of mathematics, about the role of teachers, about teaching and learning mathematics, and about their competency in mathematics" (p. 5). Again, the instrument consisted of Likert scale items self-reported by the students. The authors claim they achieved high reliability after the development of the survey but it was not reported. Hence, greater examination of these instruments is needed to benefit mathematics education research.

Examining Teacher-Focused Measures

A couple articles have provided syntheses of the literature related to quantitative teacher-focused measures. We explore three sets here: observation protocols (of instruction), teachers' content knowledge, and teachers' beliefs. Again, we use this as a starting point and welcome interests within teacher-focused measures that are not necessarily represented within this frame.

Observation protocols. In 2015, Boston and colleagues compared the Reformed Teaching Observation Protocol, Mathematical Quality of Instruction, and Instructional Quality Assessment. A key finding of the study was that these three unique large-scale teacher-related observation protocols provided three unique lenses into teachers' instruction (Boston et al., 2015b). The authors encouraged the field of mathematics education to execute further work to closely examine other observation tools and share syntheses of relevant literature.

Teachers' content knowledge. The components of the Mathematical Knowledge for Teaching (MKT) construct (Ball, Thames, & Phelps, 2008) can serve as a useful tool for exploring and examining quantitative measures of teachers' knowledge. Quantitative measures designed for teacher certification purposes (e.g., the Praxis series) tend to focus on the component of common content knowledge, ignoring other important components of the MKT framework often deemed important to mathematics educators. Other assessments are designed specifically with the intent of measuring teachers' knowledge of particular content areas (e.g., Knowledge of Algebra for Teaching measure, McCrory, Floden, Ferrini-Mundy, Reckase, & Senk, 2012) or grade bands (e.g., Diagnostic Teacher Assessment in Mathematics and Science, Saderholm, Ronau, Brown, & Collins, 2010). The most commonly used quantitative measures for teachers' content knowledge in mathematics come from the Learning Mathematics for Teaching (LMT) project (2005). The LMT assessments aims to measure teachers' content and pedagogical knowledge for teaching and are parsed into different content areas (e.g., K-6 geometry, 6-8 Number and Operations, and 4-8 proportional reasoning; LMT, 2005). A review of the NSF database for measures of teachers' math content knowledge for teaching (a) generating quantitative data, (b) with reliability and validity evidence, and (c) could be used in large-scale studies resulted in 16 measures, 11 of which were part of the set from the LMT series. While tools such as the NSF database or the National Council for Teachers of Mathematics Handbook Chapter "*Assessing teachers' mathematical knowledge: What knowledge matters and what evidence counts*" (Hill, Sleep, Lewis, & Ball, 2007) provide a brief summary of some potential measures a mathematics education researcher could use to examine teachers' knowledge, it does not provide a comprehensive synthesis that might aid in determining which measure to use for a given research question, much less describe the validity evidence associated with the measure. Again, there is no available synthesis of available tools to measure teachers' knowledge of mathematics.

Beliefs. Philipp (2007) defines beliefs as "held understandings, premises, or propositions about the world that are thought to be true. …Beliefs, unlike knowledge, may be held with varying degrees of conviction and are not consensual" (p. 259). Beliefs and attitudes are different; they are related and at times have been discussed synonymously in the literature (Philipp, 2007). One of the oldest and still used measures is the Fennema-Sherman Mathematics Attitude scale (see Fennema & Sherman, 1976). This measure uses a Likert-scale to assess respondents' attitudes towards several domains. The study describes four Likert-scale self-report measures and accurately suggests the limited scope of self-report measures with regards to validity evidence. The Integrating Mathematics and Pedagogy (IMAP, 2004; see also Ambrose, Clement, Philipp, & Chauvot, 2004) is a web-based survey with open-ended items. This measure overcame the challenges of Likert scales, the lack of context for an overall score, and that respondents may give an opinion when one is not naturally held (Ambrose et al., 2004). A search of academic journals for measures of mathematics teachers' beliefs provided numerous hits but few are found in mathematics education journals, much less a synthesis of those available with validity and reliability evidence to be used in studies with large data samples. Put simply, no syntheses of measures in this are shared.

Session Organization and Plan for Engagement

The purpose of continuing this working group is to reconvene individuals from the previous meetings held at PME-NA 38, as well as include new participants across North America, interested in the appropriate use of quantitative tools in mathematics education that can be used in studies with large samples to examine student- and teacher-related outcomes. The primary goal of this group is to bring together scholars with an interest in examining the research on quantitative tools and measures for gathering meaningful data, and to spark conversations and collaboration across individuals and groups with an interest in synthesizing the literature on large-scale tools used to measure student- and teacher-related outcomes.

The sequencing of the activities for the purposes of this working group will begin with a review of the products and outcomes from the previous working group meetings and the Validity Evidence for Measurement in Mathematics Education (V-M^{2}Ed) conference, a conference funded by the National Science Foundation that brought together researchers from different theoretical and methodological perspectives to contextualize current conceptions of validity within the field of mathematics education. The organizers of the working group also led the V-M^{2}Ed conference. This segues into further growing the products developed at these meetings. We primarily focus on two of the main themes for PME-NA 39:

1. Crossroads as access.
2. Crossroads as a place of community.

Prior Work

The idea for this working group proposal started at PME-NA 37 (2015). We explored interest across the field from potential attendees before writing this proposal. We sought feedback from colleagues using the Association Mathematics Teacher Educators' (AMTE) bulletin board feature as well as the Service, Teaching, and Research (STaR) list-serv. An interest survey was shared broadly with both groups (i.e., AMTE and STaR members) to gather an idea of the level of interest in this idea. Twenty-six people expressed interest, including from individuals who could not attend AMTE's 2016 annual meeting. We held a follow-up meeting at AMTE to meet with fourteen individuals who expressed interest and were attending AMTE's annual meeting. A majority of those at the AMTE follow-up meeting shared that they planned to attend the working group if accepted for PME-NA 38 (2016). The proposal for PME-NA 38 was accepted and in total, 27 different individuals attended the meetings and 12 were present for all three meetings. We received numerous inquiries for future meetings and continuing our work in face-to-face as well as online mediums. Although there are numerous mathematics education conferences, all of which include quantitative and/or measurement researchers, there is no specific conference that brings them together. This working group serves as a "crossroads as a place of community" (https://www.conf.purdue.edu/landing_pages/pme-na/submission.aspx) because it not only provides space for this group of researchers to meet, but PME-NA's working group is the only conference format which allows for this type of work to happen.

To that end, we plan on organizing the sessions in the following manner to address our two primary goals for the PME-NA 39 working group session.

Session 1

The first session of PME-NA 39 will focus on what the working group has accomplished in the past year, beginning with the PME-NA 38 working group sessions. Specifically, we will re-visit our generated definitions of the terms "quantitative tools" and "large-scale," as well as the framework that we used for organizing our discussions around quantitative tools that can be used with large samples to examine student- and teacher-related outcomes. During PME-NA38, the working group leadership and attendees created an initial instrument database that includes quantitative measures that have validity evidence. We will also summarize the work and outcomes of the V-M^{2}Ed conference for those in the group that were unable to attend. That conference was held April 1-2, 2017 just prior to the National Council of Teachers of Mathematics' Research Conference. The goal of this review session is to update all of the participants about the status of the work so that the entire group can move forward together on the tasks of Sessions 2 and 3: building the criteria for a future repository of quantitative measures.

Session 2

The focus of the second session is to decide two key aspects of the repository: (1) What are the necessary and sufficient criteria for including an instrument in the database? (2) What information should be presented to the user of this database? Both of these aspects build from the work of the previous year. The second session will begin with a discussion of the criteria necessary for including an instrument in a database of quantitative measures. This future database addresses the conference theme of "crossroads as access" by providing researchers access to quantitative tools as well as the guidance to use these tools appropriately. Moreover, access is distinctly grounded in use of tools that have met some or all of the standards for evaluation (AERA, APA, NCME, 2014). This unique grounding in validity evidence and arguments assures access and rigor to users of the database. We are offering the field opportunities to approach research questions in different ways. Group facilitators will offer two examples for the larger group to discuss as a means to explore criteria for including an instrument and how results might appear to a user.

Session 3

The third session will primarily be a working session, focusing on placing instruments within the database. Logistically, attendees will divide into small-group teams based on interest, with each group working on their own tools and then presenting to the whole group towards the end of the session. At PME-NA 38, we started to create an instrument database during the third session as a result of the working group. At the time, we had not considered necessary and sufficient criteria for including an instrument nor the associated validity evidence. The purpose was merely to include instruments. Thus, our working group makes progress on our broad goal as well as sub-goals specific to this proposal. By the end of this third session, we intend to have a draft database of some instruments and their associated validity evidence. We do not anticipate this will be comprehensive at this time; the work will continue after PME-NA 39. We plan to conclude session 3 with a discussion of anticipated follow-up activities to determine the level of interest and commitment from the group in continuing with this work.

Anticipated Follow-up Activities

As a result of our working group discussion and document development, we anticipate several potential follow-up activities. Participants will greatly influence the specific follow-up activities; however, we outline a potential progression of activities to guide discussion of potential 'next-steps'.

One outcome of the working group sessions is a draft database inclusive of the available tools and their associated validity evidence. An anticipated outcome will be to determine how this should be further refined and later distributed. For instance, if attendees are interested and willing to continue this work then we will generate plans to move it forward and become more available to the broad scholarly community.

We see several possible venues for further conversations and work related to access to quantitative tools in mathematics education that can be used with studies of large-scale samples to examine student- and teacher-related outcomes. First, we anticipate using both social media tools (e.g., creating a Facebook group) and online collaboration tools (e.g., Google hangouts and documents) to promote these syntheses. Second, we anticipate using mathematics education conferences venues to further the conversations and synthesis work around the project. More specifically, we plan on proposing to continue the PME-NA 40 (2018) working group. In addition, we anticipate submitting for a symposium at the 2018 annual meetings of the Association of Mathematics Teacher Educators and National Council of Teachers of Mathematics Research Conference. Finally, there is potential to apply for grant funding through an NSF proposal to provide the means to actually create an instrument database, which connects with the aim of this working group as well as the V-M^{2}Ed conference.

The purpose of this working group is to examine the use of co-planning and co-teaching in clinical experiences of pre-service, secondary mathematics teachers, especially during their internship. We have developed an Apprenticeship Model for Learning where mentor teachers and pre-service teachers co-plan and co-teach focusing on learning, and our network improvement community is currently using improvement science to study co-planning and co-teaching during the internship experience. This working group is appropriate for those interested in (or already engaged in) co-planning or co-teaching as part of secondary mathematics clinical experiences. Our sessions will 1) introduce specific co-teaching and co-planning strategies, 2) consider the challenges and complexities of implementing co-planning and co-teaching, 3) provide an overview of our productivity so far, and 4) allow time for participants to share their ideas and work. We would also like to set up a plan to continue research efforts related to co-planning and co-teaching by arranging consistent follow-up meeting times to support research efforts, grant writing, and future submissions for working groups, conference proposals, and articles for publication.

Keywords: High School Education, Instructional Activities and Practices, Teacher Education-Preservice, Teacher Education-Inservice/Professional Development

Introduction

One of the most important areas of pre-service teacher (PST) development is the clinical experiences component. However, there is often a disconnect between theoretical course work for PSTs and what the PST encounters in the field of practice (Darling-Hammond, 2006), leaving interns and novice teachers to make connections on their own. This disconnect is exacerbated by adherence (implicit or explicit) to very dissimilar theories of learning. Other areas of disconnect include school-university differences in philosophy regarding the teaching and learning of mathematics, insufficient opportunities for professional learning that might assist novice teachers implement new standards and curriculum materials, and challenges with the recruitment and retention of mathematics teachers for high-needs schools (Sears et al., 2017). Further, many mentor teachers often are uncertain about how to mentor (Anderson, 2007), many interns believe they are ill-prepared to teach mathematics (Ingersoll, 2012), and university faculty may be less than effective in the role of change agent (Veal and Rikard, 1998).

Based on the experiences of the working group members, one of the most difficult pieces for PSTs to master (or even become marginally competent in) is the workable lesson plan – not the plan that one submits to the mathematics methods instructor, but the one enacted in the mathematics classroom. Following close behind, in terms of difficulty, are the moves and decisions the novice teacher makes in the classroom during instruction. Given these challenges, a number of universities are using co-teaching and co-planning as an integral part of their teacher preparation (Sears et al., 2017).

In addition to the possible efficacy of co-teaching to assist interns with the minute-by-minute decision-making process and the potential of co-planning to expose some of the mystery of the lesson planning process, there are other benefits for using these particular innovations. Notification and subsequent dialog about co-teaching and co-planning address the problem of insufficient communication between school and university personnel (Zeichner, 2010). The innovation provides a solid reason for mentors and interns to gather for common professional development (Grady et al., 2016), which sets the stage for goal setting, provides common professional learning opportunities, and casts university personnel in leadership roles for providing new ideas to be used during the internship experience. Simply, the professional development needed to implement co-teaching and co-planning provides a reason for mentors, interns, and university faculty members to come together, develop common language and goals, and deepen their understanding of the differences and similarities within their varied roles. When implemented properly, co-teaching and co-planning provides a platform for transparency into the implicit decisions for planning and teaching made by mentor teachers, making them explicit for the PST. Thus, there is potential for what is often unseen to be seen.

Related Literature

Background and Rationale for Working Group

The current members of the proposed working group are part of the Mathematics Teacher Educator Partnership (MTEP), itself a working group of university faculty members who are addressing the challenges in secondary mathematics teacher preparation from recruitment to induction. The MTEP operates under the Association of Public and Land Grant Universities and is part of the work of the Science and Mathematics Teaching Imperative. Organized in 2012, MTEP "provides a coordinated research, development, and implementation effort for secondary mathematics teacher preparation programs to promote research and best practices in the field" (http://www.aplu.org/projects-and-initiatives/stem-education/mathematics-teacher-education-partnership/). Members of the partnership are organized into Research Action Clusters (RAC), including the Clinical Experiences RAC within which the members of this group work. Given the Clinical Experiences group is large and there are many different types of experiences, one portion of the group operates as the Co-Teaching and Co-Planning sub-RAC. This sub-group has worked over the past three years to identify issues, develop tentative solutions, and then research the efficacy of its work. The research is done using the Carnegie model for continuous improvement, particularly through network improvement communities (more about that later in the paper).

The proposed working group at PME-NA 39 will allow for the current group to expand, bringing new ideas and providing additional opportunities to test these ideas. Certainly, there are mathematics education researchers doing work with co-teaching and co-planning whose universities are not part of MTEP, and this working group will provide a platform for cross-collaboration. Work done with the group is at the heart of what PME-NA promotes, helping develop a deeper and better understanding of the psychological aspects involved in mathematics teacher preparation.

Co-Teaching

Co-teaching began in special education as a new way for general-education and special-education teachers to work together in the classroom (Friend et al., 2010). The ideas have since come to be more widely used in other settings, particularly in teacher education programs as PSTs and their mentors seek to find new ways to engage in full-time internships (Bacharach et al., 2010).

Table 1: Co-Teaching Strategies (Adapted from Bacharach, Heck, Dahlberg, 2010; Murawski and Spencer, 2011)

Strategy	Definition	Benefits	Concerns
One Teach, One Observe	One teacher leads instruction, while the other teacher gathers specific information.	Extra set of eyes; provides data about instruction or student learning; easy to implement.	Easy to become a habit; must agree in advance what is to be observed.
One Teach, One Assist	One teacher works with the whole class, while the other assists individual students or groups of students.	Provides assistance to individual students; easy to implement; may provide a "voice" to share student concerns.	Too easy to become a habit and for one teacher to always feel like an assistant; changing roles is essential.
Station Teaching	Students divided into three or more groups; students rotate through multiple stations; teachers facilitate individual stations or circulate among stations.	Smaller groups are better for instruction, assessment, and class management; allows for differentiation, movement, and hands-on activity.	Teachers may need to use space differently; class management and transition needs to be structured; independent stations need to be carefully planned.
Parallel Teaching	Each takes half the class. Groups may be doing the same or different content in the same or different ways. Groups do not switch during lesson.	Smaller groups better for instruction, assessment, and class management; teachers have their own groups; interns teach same lesson/mirror teacher.	Teachers need to be willing to use their space differently; both teachers need to plan for their group; class management needs to be structured.
Alternative Teaching	One teacher works with large group of students, other teacher works with smaller group (re-teaching, pre-teaching, or enrichment).	Good for smaller and more specific group work; good for addressing IEP/504 goals; teachers can plan separately.	DO NOT always pull the same kids; need place for group to meet; watch noise levels; plan how to integrate group back into class.
Team Teaching	Both teachers presenting. This may take the form of debates, modeling information, compare/ contrast, or role-playing.	Demonstrates parity and collaboration between teachers; good for modeling; fun for role-playing.	Takes willingness to "share the stage"; both need to feel comfortable in front of the class.

More recently, members of the Clinical Experiences Research Action Cluster of the Mathematics Teacher Education Partnership have worked to adapt the ideas for use in secondary mathematics classrooms and begun to study the effectiveness of both co-teaching and co-planning in these settings (Sears et al., 2017; Grady et al., 2016).

Co-teaching is more than just a collection of strategies for how two teachers work together in a single classroom setting; especially in an internship setting, it is a paradigm shift in how what it means to be an intern and a mentor teacher. Many traditional internship programs tend to have sink-or-swim structure, in which interns may go directly from observing their mentor to taking on entire responsibility for teaching of a class (Bediali, 2010). In the co-teaching model, the emphasis is on shared responsibility for instruction from the beginning to the end of the internship. The level of responsibility may shift over time and even vary from day to day as different co-teaching strategies are employed but both teachers maintain an identity as a teacher in the classroom.

The literature on co-teaching provides some specific strategies for engaging in co-teaching. Table 1 provides a synopsis of these strategies, along with some potential benefits and concerns of each.

Co-Planning

Similar to co-teaching, we view co-planning as an environment where two or more teachers actively engage in planning together. When co-planning together teachers need to agree on instructional goals for a lesson, as well as the timeline for how the instruction will occur. Co-planning involves analyzing student learning, as well as development of instructional tasks to reach learning goals. The teachers must work together to select instructional tools to utilize and create their own learning tools when necessary. Another important aspect teachers must agree upon is an assessment plan to ascertain student understanding in relation to the learning goals.

Research identifies co-planning as an integral component for successful co-teaching (e.g., Howard & Potts, 2009; Magiera, Smith, Zigmond, & Gebauer, 2005). As described above, the literature defines specific ways that two teachers may share instructional responsibilities, organizes their physical space, and articulates the role each co-teacher might assume during co-teaching. Conspicuously absent from the literature base are similar strategies for co-teachers to co-plan effectively to support co-teaching. This is a major concern when considering pre-service teachers entering their internship experience. The internship experience marks a crossroads in a pre-service teacher's program where their skills in planning for instruction are put to the test. Due to their lack of experience, interns are likely to have more difficulty than experienced teachers, such as their mentor teacher, being flexible and attentive to student needs as they plan for instruction (Borko, Livingston, & Shavelson, 1990; Leinhardt & Greeno, 1986; Livingston & Borko, 1989). Another issue that arises as the intern must shift from planning several lessons during methods courses, where their access to students varies, and planning for daily instruction to promote student learning. Co-planning has the potential to bridge the gap between these expectations.

Realizing the need to provide a bridge for the gap described, the mathematics educators at one of the presenting institutions developed six specific co-planning strategies. These strategies, summarized in Table 2, operationalize the process of co-planning between an intern and mentor teacher to provide structure and support for intern development.

Table 2: Co-Planning Strategies

	Definition	Benefits	Concerns
One Plans, One Assists	Each co-teacher brings a portion of the lesson, although one clearly has the main responsibility. The team works jointly on final planning.	Better instructional materials; intern sees how a good lesson can be improved; final planning done jointly.	Initial planning done separately may not mesh well; critical that intern not remain in assistant role.
Partner Planning	Co-teachers take responsibility for about half of the components of the lesson plan. Then they complete the plan collaboratively.	It is efficient; each teacher provides initial planning for only part of a lesson.	Pieces of lesson may not mesh well; requires initial visioning together.
One Reflects, One Plans	Mentor thinks aloud about the main parts of the lesson and the intern writes the plan.	Lesson content is a reasonable fit; Intern is not planning blindly; provides transparency early in planning process.	May be a gap between what the mentor spoke out loud and what the intern heard; excessive use of this strategy may not support intern development.
One Plans, One Reacts	One co-teacher plans and the other makes suggestions for improvement.	Provides opportunity for good feedback and discussion of lesson plan elements, primarily for the intern; gives interns space for creativity in initial plans.	Provides response after the fact instead of in real time; initial approach may be off base; one may feel like an assistant.
Parallel Planning	Each member of the co-teaching team develops a lesson plan, and the two bring them together for discussion and integration.	Allows for compare and contrast of examples and points of emphasis; gives both teachers opportunity for creativity in planning.	Duplicate work done; teachers may become heavily invested in their own plan, making collaboration difficult.
Team Planning	Both teachers actively plan at the same time and in the same space with no clear distinction of who takes leadership.	Resulting lesson plan may be better than a plan done independently by either; may be more efficient because feedback and collaboration happen in real time.	One co-teacher, likely the intern, may be less prepared to contribute than the other; requires a very high level of trust and communication.

Theoretical Approach to Examine Co-Planning & Co-Teaching

Our work with co-teaching and co-planning during pre-service teachers' internship experiences is grounded in Lave's (1991) construct of situated learning. As interns go out into the field, their learning moves from a predominately academic experience to an apprenticeship in a community of practice. In such a setting the working relationship between intern and mentor teacher becomes a major determining factor in the intern's ability to participate productively and collaboratively in the practice of classroom teaching. In our work we consider ways to expand traditional visions of this working relationship between intern and mentor, envisioning mentor and intern as collaborators in classroom planning and instruction.

In a co-planning and co-teaching internship, the instructional responsibilities for the mentor and the intern change over time (Figure 1). As Figure 1 indicates, the mentor initially assumes more instructional responsibility, with the intern gradually increasing their level of responsibility.

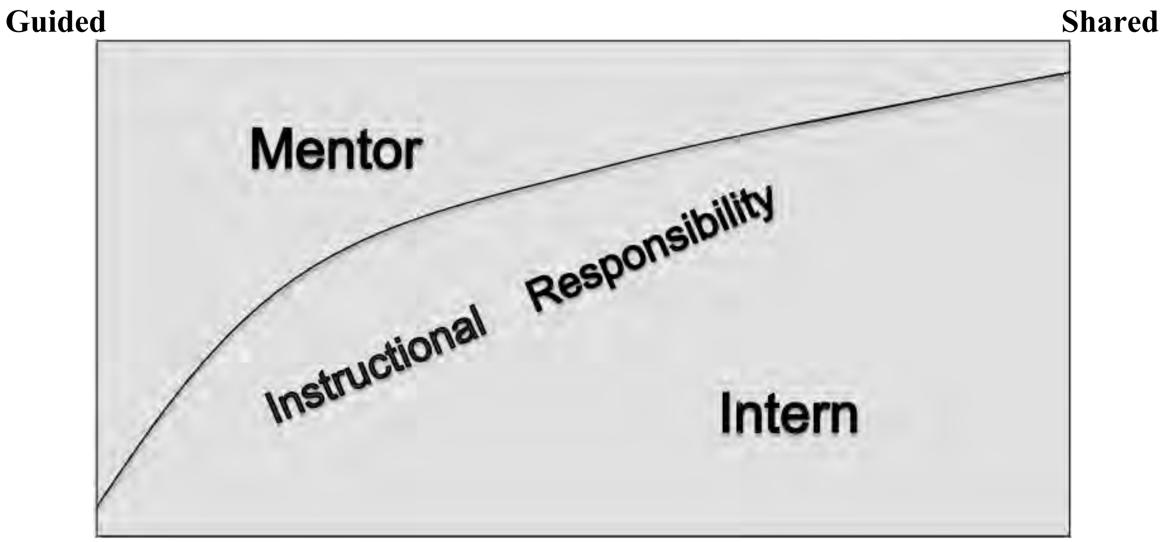

Figure 1: Instructional Responsibilities for Co-Teaching Internship (Brosnan, Jaede, Brownstein, & Stroot, 2014).

Notice that the intern eventually takes on the majority of instructional responsibilities; however, within a co-planning/co-teaching paradigm the mentor remains an active, participating teacher throughout the internship experience.

A common issue with the implementation of innovative ideas in education is that the research so often lags behind the pace of implementation. By the time we have examined the effectiveness of an innovation, it has often either been abandoned because there were perceived issues with implementation or fully adopted because serious concerns had not yet been identified. Improvement science research methods, with their emphasis on short improvement cycles, offer an alternative that may better meet some of our needs as educators. Improvement science is designed to study practices, make modifications, and provide a cycle of continual improvement (Bryk, Gomez, Grunow and LeMahieu, 2015). Improvement science is based on three questions, "1. What specifically are we trying to accomplish? 2. What change might we introduce and why? 3. How will we know that a change is actually an improvement?" (Bryk et al., 2015, p. 114). The process of inquiry is based in the Plan-Do-Study-Act cycle, in which plans are made for possible improvements in a system, the plan is enacted and studied, and then decisions are made about adjustments to make for the next PDSA cycle. This iterative process provides a mechanism for modifying interventions and research methods as the study progresses. At this time, the co-planning/co-teaching research group from the Mathematics Teacher Education Partnership has enacted several PDSA cycles, each of which has resulted in modifications to the implementation of co-planning/co-teaching and each increasing the scale on which the research is being conducted.

Connections to PME-NA

Our working group objectives fit well with the overall goals of PME-NA by promoting and stimulating interdisciplinary research and the exchange of scientific information in the area of clinical experiences for PST, as we involve mathematics teacher educators, mathematics teachers, and pre-service teachers, all working to learn more about the psychological foundation necessary for a prospective mathematics teacher to develop the particular knowledge and skills to be a successful mathematics teacher. With respect to the 2017 PME-NA theme – Synergy at the Crossroads: Future Directions for Theory, Research, and Practice – the combined work of the group has the potential of pushing our efforts further that the sum of the individual parts. We clearly are attempting to move theory into practice, research this effort, refine our theory and practice, and then research its impact. The working group format has the potential to greatly increase the scale of our work as other partners come on board. With respect to crossroads, our work is at an intersection, where we are ready to move from the state highway to the interstate, allowing more participants to test drive the work done so far and help push the thinking forward.

Session Organization and Participant Engagement

Presenting institutions have a range of experience from a few years to more than a decade related to co-teaching and co-planning, and we invite anyone interested in co-teaching or co-planning, regardless of prior work in these areas. The sequence of sessions will provide working group participants with the opportunity to engage in discussions related to co-teaching and co-planning during internship experiences. Paradigm shifts from more traditional internship experiences to co-teaching, as well as co-planning with a focus on student learning will frame the first two sessions. Specific co-teaching and co-planning strategies will be shared, and presenting institutions will discuss current co-teaching and co-planning training materials and research efforts. Working group participants will be invited to share what their institutions are doing (or may be interested in doing) related to co-teaching and co-planning as part of each session.

Session 1: Transitioning from Traditional Internship Experience to Co-Teaching

The first session will begin by contrasting the role of the intern and mentor teacher in traditional versus co-teaching internship settings. Presenting institutions will share their experiences navigating the crossroads between these two models, explain where they are currently in the process of implementing co-teaching, and discuss issues related to the process of shifting paradigms, including buy-in from all stakeholders involved in the process. The session will continue with a review of specific co-teaching strategies, followed by sharing current training materials utilized by presenting institutions to train university supervisors, mentor teachers, and interns. The session will conclude with discussion of the data collection and instruments we are currently using to capture co-teaching during the internship experience. During each phase, particular emphasis will be placed on having working group participants share where they are in the process of co-teaching, as well as how we can coordinate our efforts to support each other.

Session 2: Focus on Student Learning & Co-Planning

The second session will focus on co-planning as a critical support for co-teaching. The session will begin with our description of planning for student learning. Planning for learning pushes interns and mentor teachers to think deeply about instructional decisions to focus on their students. We utilize three guiding questions to frame co-planning for student learning; 1) What do students need to learn? (content), 2) How will you know if they have learned?

(formative/summative assessment), and 3) What tasks/activities will students engage in to ensure learning happens? (pedagogy). The session will continue with a description of six co-planning strategies developed at one of the presenting institutions, as well as co-planning training materials utilized with university supervisors, mentor teachers, and interns. The session will culminate with a discussion of how presenting institutions are collecting data to capture co-planning during the internship experience, and where each institution is currently in navigating the shift toward co-planning. During each portion of the session, working group participants will be asked to share their ideas about co-planning, where they are in relation to co-planning during the internship experience. A by-product of this session will be to document strategies to support each other in the implementation of co-planning during co-teaching or traditional internship experiences.

Session 3: Mine, Yours, and Ours

The third session will be a working session incorporating the information and ideas gleaned from the first two sessions. We will consider what presenting and participating institutions are doing in relation to co-teaching and co-planning to review the research questions currently under study, and we will also discuss what tools are being used for training and research. This process will inform our discussion of possible gaps in our work and will provide participants in the working group an opportunity to identify further research questions related to co-teaching and co-planning. The goal of this session will be to bring these pieces together to create a collective set of training and research materials to support work at presenting institutions and working group participants that allow for the individualities of each context. One product will be a draft PDSA cycle for data collection and research across interested institutions. We will also discuss potential next steps including, but not limited to, collecting/sharing training and data collection materials, future working group sessions at other conferences, and grant opportunities to support our work.

Anticipated Follow-up Activities

One of the first follow-up activities will be to create a collective space to share and refine training and research materials. Potential tools for this include Dropbox and Google Drive, as well as other suggestions from working group participants. A second activity will be periodic virtual meetings to check in about data collection and research. A third activity will be to submit future working group proposals to AMTE and PME-NA to continue our work with co-teaching and co-planning. One longer-term goal will be to utilize data collected during the 2016-2017 and 2017-2018 PDSA cycles to submit research symposium proposals at conferences. These data results may also be utilized to submit as research manuscripts, as well as grant proposals to continue work across institutions.

Acknowledgments

We would like to thank the Association of Public and Land Grant Universities and the Mathematics Teacher Education Partnership (MTE-P) for their unwavering support in our work with co-planning and co-teaching. Additionally, we wish to express gratitude to Dr. Marilyn Strutchens from Auburn University who serves as the research action cluster leader for clinical experiences.

This working group will engage PMENA members to consider ways in which early introduction to mathematical modeling can promote 21st century skills such as critical thinking, creativity, collaboration and communication, as well as connect to interdisciplinary topics in STEM. In particular, we will gather interested individuals to deepen our understanding of the learning progression of mathematical modeling that can connect elementary to secondary mathematics education. Second, we will discuss efforts to design and implement professional development that introduces K-8 teachers to mathematical modeling. Finally, based on the interests of the participants, we will devote work time to finding synergistic collaborative topics to pursue for future research and practice.

Keywords: Mathematical Modeling, Elementary Education, Teaching Practices, Professional Development, Learning Progressions

Overview of the Working Group

This is a new working group that will build on PMENA's long tradition of working groups on *Models and Modeling.* Our goal is to broaden the access of mathematical modeling to elementary grades and advance the field's collective understanding of the interrelated processes of mathematical modeling in the elementary grades and beyond. Although there has been a long history of mathematical modeling at PME and PMENA, the focus has primarily been on middle, high school and university levels. We believe it is critically important to understand the learning progression of mathematical modeling from elementary to secondary grades to ensure coherence and rigor in the mathematics curriculum. Implementing mathematical modeling in the elementary grades is not just going "light" with the high school math modeling curriculum. Instead we advocate integrating aspects of mathematical modeling in the early grades effectively to enhance student learning and to help build their competency in real-world problem solving using their current mathematical knowledge. The latter content knowledge is expected to evolve as students continue to learn new mathematics as they progress towards high school and beyond.

The working group leaders come from a three university collaboration working with school districts (with diverse populations) to understand the nature of mathematical modeling in the elementary grades. In our design-based implementation research, each university site worked with the collaborating district's teacher leaders to co-plan the professional development. Teachers became co-designers of the mathematical modeling curriculum for the elementary classrooms. In our project, we engaged elementary teachers in considering mathematical modeling using real world tasks that contained several of the following attributes: (a) Open-endedness; (b) Problem-posing; (c) Creativity and choices; d) Iteration and revisions.

Why focus on early grades? In addition to the direct benefits of modeling, the elementary school environment affords many advantages that complement work in mathematical modeling. Elementary students often rely on using concrete referents such as objects, drawings, diagrams, and actions or pictures to help conceptualize and to construct carefully formulated arguments to solve a problem. Such arguments can make sense and be correct, even though they are not generalized or made formal until later grades (CCSSO 2010). Young students have high potential to become fluent – native speakers, thinkers and dreamers of mathematics. Thinking creatively may come more easily to children first learning and exploring mathematical concepts. Kindergarten students can use manipulatives to independently solve traditional multiplication or division problems they have never seen before, which is evidence that students come with knowledge--we don't have to wait to incorporate modeling activities until we have "shown them how" to do everything. Because early grade teachers are generalists, they can address several subjects simultaneously through modeling activities. Mathematical Modeling is of interest and relevance to the mathematics education community especially because it connects to the need for professional development focused on mathematical modeling in the elementary grades.

Our researchers used Design-Based Implementation Research methodology, DBIR (Fishman, Penuel, Allen, Cheng, & Sabelli, 2013) to examine the design of our professional development and to study and enhance our design through feedback from our iterative implementation cycles. DBIR was a method of choice for our study because it has (1) a focus on problems of practice from multiple stakeholders' perspectives; (2) a commitment to iterative, collaborative design; (3) a concern with developing theory and knowledge related to both classroom learning and capacity for sustaining change in systems (Fishman, Penuel, Allen, Cheng, & Sabelli, 2013, p. 136).

Through our work, we are gaining a better sense of teaching practices and classroom routines that support modeling. We are contributing to the understanding of what is possible in early elementary grades and how these processes support the development of critical 21st century skills. As we continue in our research to consider what constitutes the practice of Mathematical Modeling (MM) and how it could be implemented in classrooms at different grain size, we invite the larger PMENA community to build on this knowledge. Over the past decades, working group leaders have individually and in subgroups, been theorizing about as well as collecting, analyzing, and reporting on data relating to mathematics modeling. This Working Group builds on and extends the work of previous Model and Modeling tradition by discussing current work from leading scholars from diverse perspectives.

Relevance to Psychology of Mathematics Education

The purpose of this working group is to invite individuals across the research community interested in synthesizing the literature and collaborating on research focused on mathematical modeling along the developmental continuum. Our goal of mapping a learning progression of mathematical modeling from K-12 education, particularly starting from elementary to middle grades is critically important to provide coherence in the mathematics curriculum.

The primary focus for this working group will be around the following three goals:

1. Bring together scholars with an interest in examining research with meaningful data consisting of student MM artifacts and teachers' content and modeling competencies.
2. Map the learning progression for mathematical modeling and task design for K-6 mathematics education and beyond.
3. Begin dialogue and collaboration among individuals and groups conducting research on student- and teacher-related outcomes related to implementing mathematical modeling, ways mathematical modeling promotes 21st century skills, and interdisciplinary skills in STEM.

Related Research

The complexity of the modern world places more demand and importance in developing students' abilities to deal with demands of our society (e.g. Gravemeijer, Stephan, Julie, Lin, & Ohtani, 2017). These abilities include interdisciplinary problem solving, techno-mathematical literacy, flexibility in applying numerical and algebraic reasoning, thinking critically, and constructing, describing, explaining, manipulating and predicting complex systems (English, 2013). Mathematical modeling (MM) is seen as a powerful tool for advancing students understanding of mathematics and for developing an appreciation of mathematics as a tool for analyzing critical issues in the real-world, that is, the world outside of the mathematics classroom (Greer & Mukhopadhyay, 2012). Traditionally, MM has been implemented primarily in secondary schools, but recent research examines this approach with elementary students to promote their problem solving and problem-posing abilities (e.g. English, 2010). MM provides the opportunity for students to solve genuine problems and to construct significant mathematical ideas and processes instead of simply executing previously taught procedures and is important in helping students understand the real world (English, 2010).

It must be pointed out that the phrases *mathematical modeling* and *modeling mathematics* are used in different ways. Cirillo, Pelesko, Felton-Koestler, and Rubel (2016) succinctly describe *modeling mathematics* as the use of representations to communicate mathematical concepts or ideas. The central characteristic of *modeling mathematics* is that the process "begins in the mathematical world, rather than in the real world (Cirillo et al., 2016, p. 4). For example, Lesh, Post, and Behr (1987) describe five representations that support students in understanding mathematical concepts or ideas: pictures, manipulatives, written symbols, oral language and real-world situations. For Lesh et al. (1987), the real-world situations provided a context for the problems; the representations began in the mathematical world. A form of mathematical modeling instruction introduced by Lesh & Doerr, 2003, Model-eliciting activities (MEAs), incorporate client-driven, real-life contexts and open-ended problem solving. *Mathematical modeling* is a process that starts in the real world and makes sense of non-mathematical situations in a mathematical format (English, Fox and Watters, 2005). The *mathematical modeling* process involves both the creation and the continuous modification of models of empirical situations to both understand them better and enhance decision-making in real-time. As students create and modify mathematical models to understand and solve real-world problems, they engage in a cyclical process of generating and validating their model and results. The figure below illustrates a cycle used with elementary students to help organize reasoning in mathematical modeling by using terms comprehensible to young math modelers.

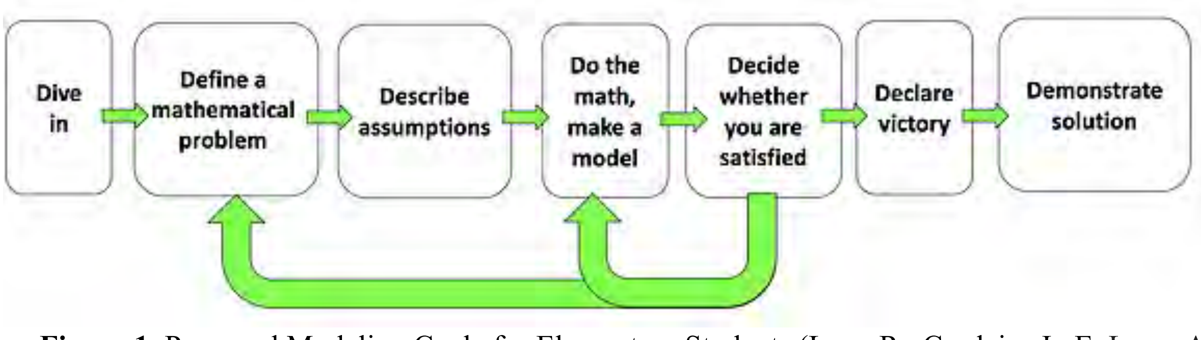

Figure 1. Proposed Modeling Cycle for Elementary Students (Levy R., Cordeiro J., E. Lane, A. Sierra, Sinclair D., Yang L. & Matson K., 2016).

So what does mathematical modeling look like in the elementary grades? One of the ways, the researchers in this working group approached MM in the elementary grades was to immerse students in a real world situation within their local context that was relatable to and personally meaningful. To keep the initial problem open-ended, students were encouraged to develop the habit of mind of being problem posers by identifying the many questions around the real phenomenon, then defining a mathematical problem that can be solved by way of mathematics. After the identification process of the problem, the modeler makes assumptions, eliminates unnecessary information, and identifies important quantities in order to form the model. This real-world model becomes a mathematical model when the processes are replaced by mathematical symbols, relations and operations. It should be noted that there can be several mathematical models for a given real-world situation. Next, the model is solved mathematically and results are translated back to the real-world and interpreted in the original context. The problem solver then validates the model by checking whether the solution is appropriate or reasonable for the purpose. This process of making assumptions, identifying variables, formulating the model, interpreting the result, and validating the model is iterative in nature and is modified or changed and repeated until a satisfactory solution has been obtained and communicated (Blum, 2002). It is important to note that teachers play a crucial role in MM. The teacher must be able to: (a) provide opportunities for students to acquire mathematical competencies and make connections between the real world and mathematics; (b) maintain the high cognitive demand of the MM process; and (c) provide classroom management that is learner-centered (Blum & Ferri, 2009).

Previous work with elementary school children demonstrated it is feasible for them to develop a disposition towards realistic mathematical modeling (Lieven & De Corte, 1997). One of the issues in implementing MM at the elementary level is that MM can be difficult for both teachers and students to implement (Blum & Ferri, 2009). MM can be difficult for teachers to implement as they must be able to merge mathematical content and real-world applications while teaching in a more open-ended and less predictable way (Blum & Ferri, 2009). It can be a challenge for students because each step of the modeling process presents a possible cognitive barrier (Blum & Ferri, 2009). As stated in the Common Core Standards for Mathematical Modeling, *"Real-world situations are not organized and labeled for analysis; formulating tractable models, representing such models, and analyzing them is appropriately a creative process. These real-world problems tend to be messy and require multiple math concepts, a creative approach to math, and involves a cyclical process of revising and analyzing the model"* (Carter et. al., 2009).

In a previous PMENA report, Suh, Matson, Williams and Seshaiyer (2016) reported the challenges and affordances of mathematical modeling in the early grades.

Teacher Challenges.The challenges teachers faced when implementing mathematics modeling in the elementary grades included: a) Novelty and ambitious nature of the *modeling process*-When implementing MM in the classrooms for the first time, teachers found it was difficult to move students through the full process as it was a novel approach and students had never been introduced to creating and validating their mathematical models; b) *Managing discourse*- Another difficulty encountered by teachers in the MM process was in defining their role as facilitators. The teachers commented that "...it is really difficult as a teacher to help students find a direction to go with their solution but not direct or guide them toward a teacher goal."; and c) *Constraints around mandated standards*-Participants acknowledged that MM takes time to implement in the classroom and that additional class time to implement these tasks would be helpful. An additional challenge noted by teachers was that mathematical modeling didn't go the way they expected it to and they wrestled with the need to meet state standards.

Affordances of Mathematical Modeling. The main affordances our teacher-designers mentioned were that mathematical modeling provided opportunity for content to be covered without direct instruction, had interdisciplinary connections, and provided mathematical relevance, and student engagement: a) *Content covered without direct instruction*- When teachers implemented MM in their classrooms for the first time they were amazed at the amount of content that could be covered without direct instruction. Students could see how the mathematics could serve their needs as they used the mathematics they learned while other times, the mathematics related to future learning objectives which allowed them to revisit their model as their learning progressed; b) *Interdisciplinary opportunities*-Another positive take-away from implementing MM in these teachers' classrooms for the first time was how MM created a space where content covered was interdisciplinary connecting to social studies, STEM and language arts; c) *Relevance*-By providing authentic tasks for students to grapple with through the MM process, mathematics became relevant to the students; d) *Student engagement*-A number of our teachers indicated how engaged their students were in their MM tasks. Mathematical modeling inspired these teachers' endeavors and provided pictures of practices that served as the proof of concept they needed to sustain their professional commitment to mathematical modeling.

Support Teachers Need. The three main areas of support teacher-designers requested were access to MM resources, pictures of practice, time and collaboration with like-minded teachers: a) *Resources and pictures of practice*-Teachers indicated a desire to use MM in their classrooms but indicated a need for a bank of open-ended MM lessons and new ideas for continuing to create these lessons; b) *Time*-Teachers expressed the need for more time to work through and become comfortable with implementing the modeling process in their classrooms. Teachers noted it was only in working through the MM cycle several times that they felt comfortable with the process and felt their students were able to understand the whole MM process; and c) *Teacher collaboration*-Teachers indicated a desire to continue to work with a cohort to build MM lessons; to observe other teachers implement MM in their classrooms; and to work alongside a colleague who valued MM and with whom they could share ideas.

Other related research the team will share include, Carlson, Wickstrom, Burroughs & Fulton's (2016) work, *A Case for Mathematical Modeling in the Elementary School Classroom*, where they provide a teaching framework for MM using the "organize - monitor - regroup" cycle to support the teachers' work in engaging young students in modeling. Wickstrom, Carr and Lackey (2017) will showcase an engaging article using mathematical modeling to explore Yellowstone National Park. Suh, Matson, & Seshaiyer (2017) will also share ways in which mathematical modeling enhanced students creativity, collaboration, critical thinking and communication skills and exposed students to interdisciplinary themes of service learning and STEM integration.

Plan for Active Engagement of Participants

The working group will meet three times during the conference and virtually during the course of one year. In each session, PMENA members will engage in mathematical modeling while sharing their perspectives in teaching and learning mathematics, considering synergistic areas fruitful for future research and practice, and finding collaborators within our group.

Session 1: Exploring the Nature of Mathematical Modeling in the Early Grades

The first session will focus on better understanding the nature of mathematical modeling in the elementary grades while considering the student perspective and recognizing the importance of teachers knowing their students and the contexts that are meaningful to their students. We will examine how mathematical modeling used by K-6 teachers demonstrates the interdisciplinary nature of mathematical modeling, the diversity of mathematical approaches taken by student modelers, and the multiple pathways the teacher can use to elicit students' mathematical thinking. Exemplar tasks that emphasized local contexts and tapped into students' funds of knowledge and student artifacts will be shared to illustrate the child's perspective and the developmental progression. These topics will facilitate group discussions exploring the learning progression for mathematical modeling thinking and habits of mind that can develop for emergent mathematical modelers from an early grade.

Session 2: Identifying the Knowledge of Content and Pedagogy Needed for Mathematical Modeling in the Elementary Grades

In our second session, we will focus on clearly defining modeling teaching practices and competencies needed for mathematical modeling and outlining research goals and objectives to monitor the enactment of these practices. We will detail classroom routines, such as the "organize - monitor - regroup" cycle (Carlson, et al. 2017), and the Pedagogical Practices for Mathematical Modeling (Suh, Matson, & Seshaiyer, in press) as we share designed activities and lesson vignettes to solicit more ideas around high leverage MM teaching practices. We will explore what mathematical knowledge is needed to "successfully" facilitate mathematical modeling tasks in elementary grades.

Session 3: Finding the Synergy Between Mathematical Modeling and the 21st Century Skills Frameworks and PBLs in STEM

The third session will outline several 21st century skill frameworks and teaching approaches and how mathematics educators, researchers and practitioners can find a synergistic way to bring important process skills without overwhelming teachers and students. We will discuss the ways elementary teachers can make connections between the problem-based ways they have engaged students in mathematical modeling and STEM. The teachers are able to take advantage of interdisciplinary opportunities across the subjects they teach and find complementary connections between subjects and common classroom practices that support MM.

Anticipated Follow-up Activities and Goals of Working Group

In the spirit of exploring the theme of the *Synergy at the Crossroads: Future Directions for Theory, Research, and Practice,* each session will engage participants to share their research interests related to mathematical modeling and form groups that might pursue research collaboratively based on the interests of the participants. Some of the questions include:

- What defines successful mathematical modeling lessons at different grade levels?
- What can we learn from teachers who implement MM regularly in their classrooms?
- How can we support teachers enacting MM through lesson plans and other resources?
- How can we map out the learning progression of MM across grade levels?
- How and what can we learn about models elicited from student artifacts from MM tasks?
- What do "successful" modeling practices look like in our elementary mathematics classrooms? How are they similar or different from practices in secondary classrooms?
- What does it mean to "see the math" in the components of mathematical modeling?

- How do teachers select and/or develop modeling problems? How can PLCs or Teacher Study Groups help teachers anticipating how students will answer the MM questions?

Our goal is for the working group leaders to propose an edited handbook or a special issues journal venue for mathematical modeling where participants interested in submitting manuscripts can work together to provide a comprehensive research trajectory documenting the progression of mathematical modeling from emergent levels to more sophisticated levels of modeling.

Acknowledgments

This working group was funded by NSF 1441024-STEM C.

Modeling continues to be a central feature of mathematical teaching and learning from both researcher and teacher perspectives. It is one of eight core mathematical practices called out in the Common Core State Standards for Mathematics; 2016 APME yearbook was dedicated to the theme of modeling; and international volumes reporting on new developments in Europe are expected out in 2017. The Models and Modeling Working Group at PME-NA has provided a venue for discussing and collaborating on research projects fundamental to this area since the first PME-NA conference in 1978. We propose to convene this Working Group at PME-NA 39 to build on energetic discussions that took place at PME-NA 37 and 38 and to establish a collaborative framework for shared research projects that integrate interested newcomers with established researchers within the Models & Modeling Perspective.

Keywords: Modeling, Problem Solving, Design Experiments

The Models and Modeling Working Group has been a significant presence in the community of PME-NA since the Conference was inaugurated in 1978. It has used the working-group format not only to support substantive research efforts, but also to grow collaboration and mentoring relationships between researchers in this field. An important historical purpose of the Working Group has been to pursue innovations in design-based research – in particular to discuss and extend the ways in which a focus on models and modeling can be used both to support learning in mathematics, science and engineering, and to study such learning processes in action. Moreover, we found that many of our participants in the Group meeting in PME-NA 38 were engaged in work that addressed teacher-identified problems of practice, and we expect that opportunities for such innovations will continue to be foregrounded for participants in this year's meeting.

Early in its history, the Group focused heavily on the design and analysis of particular activities that enabled groups of learners to engage in a deep form of modeling and that produced an auditable trail of thinking, exposing their thought processes to teacher and researcher observers. In this phase of the field's development, a primary effort involved elaborating design principles for these activities as learning environments and documenting the idea development they promoted. Gradually over time, however, researchers associated with the Group have expanded their perspective to consider implementations and curricular sequences that have longer time-duration, and that integrate models and modeling into the experience of learning mathematics in more extensive ways. Several broad patterns in this more extensive and disseminated approach to modeling in the curriculum have emerged, and there is no sense that we have yet exhausted the space of possibilities. These broader perspectives open both exciting opportunities and significant challenges. On the one hand, new questions can be researched, opening the way for new forms of contact and interaction with classroom practice; on the other, the approach raises new challenges at the level of methodology, data analysis, and forms of evidence that are convincing backings for claims about learner activity.

We propose convening the Group at PME-NA 39 to continue work begun at PME-NA 37 and expanded at PME-NA 38. Based on our experience in these previous working group sessions, we propose a work-session structure that can serve two dual purposes: (a) integrating newcomers to Models and Modeling as a research area and (b) making substantive progress in concrete work – planning collaborative research and framing a shared writing project. For this Working Group, these two goals are both essential: we do not propose to gather as a closed expert group (Broadening exposure to this kind of learning design is important to the individuals of the Group as well as to the group as a collective whole). And we also do not aim only at providing an initial introduction to the forms of learning enabled by Model-Eliciting Activities (There are urgent problems and opportunities of research and practice which we see the Working Group as providing essential means for addressing). In the following sections, we provide a very brief overview of the field of research represented by the Models and Modeling Perspective; we outline patterns in research efforts that have extended modeling activities over longer timescales; we identify key themes that the Group will address in its discussions; and we describe our plan of work in detail, illustrating how these goals are addressed as well as how we plan to productively integrate newcomers to the Group over the three working sessions of the Conference.

The Models and Modeling Perspective (M&MP)

For nearly forty years, M&MP researchers and educators have engaged in design research directed at understanding the development of mathematical ideas among groups of learners. A key principle behind this work has been that learners' ideas develop through, and in relation to conceptual entities called *models*, which we define as follows:

> conceptual systems (consisting of elements, relations, operations, and rules governing interactions) that are expressed using external notation systems, and that are used to construct, describe, or explain the behaviors of other system(s)—perhaps so that the other system can be manipulated or predicted intelligently (Lesh & Doerr, 2003, p. 10)

As conceptual systems expressed through representational media, models can provide illumination into how students, teachers, and researchers adapt, formulate, and apply relevant mathematical concepts (Lesh, Doerr, Carmona, & Hjalmarson, 2003). An early finding was that, under appropriate conditions, groups of learners can be supported in rapidly producing and expressing such models. Once expressed, these productions can become objects of reflection by learners and collaborative groups, and they can form the basis for rich exploratory communication. In particular, when individuals and groups encounter problem situations with specifications that demand a model-rich response, their models are observed to grow through relatively rapid cycles of development toward solutions that satisfy these specifications.

It should be noted that the above account is not an account of *development* (of learners), nor even yet an account of *learning*. Instead, it is an account of *idea development*, as observed in the discourse and other representations produced by groups of learners as they iteratively work to mathematize and formulate a solution that meets the needs of a concrete *client* in a realistic setting. This note is important, in order to distinguish the analytical work of the early M&MP from accounts of microgenesis of learning and development, for instance those expressed in the debates about whether learners have "theories" about the world (as held by the so-called "theory-theory," (McCloskey, 1983), or whether their knowledge is better represented as a loose and context-dependent assemblage of knowledge "pieces" (as held by the Knowledge-in-Pieces perspective, (diSessa, 1993; diSessa, Sherin, & Levin, 2016) as well as by some connectionist approaches to modeling knowledge (e.g., Minksy, 1986). The M&MP was initially agnostic to these debates, as the questions at hand had to do with the interactional achievement of small groups when exposed to particular kinds of realistic problem. In fact, it was an important apparent paradox of this research that some features of *idea development* during these activities have appeared to mimic or shadow aspects of cognitive development as reported by Piaget, van Heile, or other accounts (Lesh & Harel, 2003). We defer discussion of the relation of the M&MP to such questions of learning and development until the section on longer instructional sequences on modeling, below.

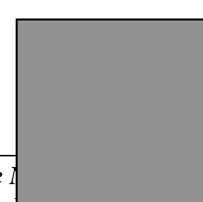
Thus, originally, the M&MP tradition was focused squarely on very local conceptual development (Lesh & Harel, 2003): that is, on investigating the nano-evolution of ideas in teachers and students. Thus, the resources and tools produced were first and foremost designed to *study* idea development (as opposed on one hand to serving teaching or curricular goals and on the other hand to explaining the phenomena of group productions by reference to a theory of individual cognition or learning). The results of this work include a body of *Model-Eliciting Activities* (MEAs), in which students are presented with authentic, real-world situations where they repeatedly express, test, and refine or revise their current ways of thinking as they endeavor to generate a structurally significant product—that is, a model, comprising conceptual structures for solving the given problem. These activities differ markedly from some "problem-solving" settings, which emphasize applications. In contrast, MEAs give students the opportunity to create, apply and adapt scientific and mathematical models in interpreting, explaining, and predicting the behavior of real-world systems (Zawojewski, 2013). Extensive research with MEAs has produced accounts of learning in these environments (Lesh & Doerr, 2003; Lesh, Hoover, Hole, Kelly, & Post 2000), design principles to guide MEA development (Doerr & English, 2006; Hjalmarson & Lesh, 2007; Lesh, et. al., 2000; Lesh, Hoover, & Kelly, 1992) and accounts and reflections on the design process of MEAs (Zawojewski, Hjalmarson, Bowman, & Lesh, 2008).

Example MEA: The Shadows Problem

Students are usually introduced to the Shadows Problem by reading a "math rich newspaper article" that describes an exhibit at a nationally-known children's museum. The newspaper article focuses attention on the optical phenomena of the exhibit and places it in a mathematical and historical context. The students' challenge in the Shadows Problem is to assist exhibit designers in a local museum who want to create a similar experience. Thus, these 'clients' are interested in ways in which the optical perception one particular shape (a square) can be produced through shadows cast by different shapes and light sources. Below is the statement of the problem as given to students:

> A local museum is interested in building an interactive show on the topic of optical illusions. Inspired by a shadows exhibit that they saw at the Indianapolis Children's Museum (ICM), they are interested in creating something similar for one of their show's stations. The exhibit at the ICM used a small flashlight that had a point source of light, and it showed surprising shadows that different shapes could cast. Their museum designers' goal for this station is to make square shadows using a point source of light and shapes like the ones shown below (similar shapes are included in your packet). For the purposes of the exhibit, the "stranger" the shape that can cast a square shadow, the better.

> Your Task: Write a letter to the museum's show designers, explaining, for as many as possible of the shapes: (a) exactly how to hold the light and shapes so that they make square shadows on a wall (like the one shown here), and (b) which, if any, of the shapes



Galindo, E., & Newton, J., (Eds.). (2017). *Proceedings of the 39th annual meeting of the N[illegible]hapter of the International Group for the Psychology of Mathematics Education.* Indianapo[illegible] Association of Mathematics Teacher Educators.

> can *never* make a square shadow – no matter how you tilt the shape and the light with respect to the wall. If it is impossible to make a completely square shadow with a given shape, explain why. If you have additional ideas about the show, include them as well.

Student groups iteratively develop solutions to this problem in the time allotted—usually 50-60 minutes for this MEA. Afterwards, the teacher may choose to organize a structured "poster session" event. In one version of this activity structure, one member of each 3-person group hosts a poster presentation showing the results of their group. The other two students use a Quality Assurance Guide to assess the quality of the results produced by other groups in the class. These instruments are submitted to the teacher and contribute to assessment in various ways, providing evidence for the achievements of both individuals and groups.

MEAs like the Shadows problem present learners with situations in which familiar procedures and constructs are *applicable* but also *insufficient*. That is, on the one hand they are accessible to learners from a wide range of levels of ability, experiences, or knowledge (upper elementary school through graduate school). On the other hand, learners encountering these problems find that they have no ready-made solution they can apply to address the client's needs. As a result, learners engage in sense-making and solution-construction processes that put them off balance in comparison to typical school-mathematics tasks. Indeed, this uncertainty is part of the design of MEAs, illuminating fundamental conceptual issues associated with the core mathematical structures involved.

MEA Design Principles

Historically, as individual MEAs emerged, an intense period of design research ensued to establish these activities as a compelling genre of learning tasks that would (a) stimulate mathematical thinking representative of that which occurs in contexts outside of artificial school settings (Lesh, Caylor, & Gupta, 2007; Lesh & Caylor, 2007); (b) enable the growth of productive solutions through rapid modeling cycles; and (c) leave behind researchable traces of learners' ways of thinking during the process. This line of work produced the notion of Thought-Revealing Artifacts and Model-Eliciting Activities (MEAs) (English et al., 2008; Kelly & Lesh, 2000; Kelly, Lesh & Baec, 2008). The success of MEAs as research tools was both enabled by and illustrated through the articulation of a set of six design principles for such activities (Hjalmarson & Lesh, 2007; Lesh & Harel, 2003; Lesh et al., 2000); these principles indicate the key structural and dynamical elements in MEAs as contexts for problem solving. Table 1, below, also indicates "touchstone" tests for whether each of these six principles has been realized in a given implementation setting.

Table 1: Six Design Principles for MEAs

Principle	Touchstone Test for its Presence
Reality Principle	Students are able to make sense of the task and perceive it as meaningful, based on their own real-life experiences.
Model Construction Principle	To solve the problem, students must articulate an explicit and definite conceptual system (model).
Self-Evaluation Principle	Students are able to judge the adequacy of their in-process solution on their own, without recourse to the teacher or other "authority figure".
Model Generalizability Principle	Students' solutions are applicable to a whole range of problems, similar to the particular situation faced by the "client" in the MEA.
Model-Documentation Principle	Students generate external representations of their thinking during the problem-solving process.

Simplest Prototype Principle	The problem serves as a memorable representative of a kind of mathematical structure, which can be invoked by groups and by individuals in future problem solving.

Nested Levels of Modeling: Multi-Tiered Design Research

In parallel with learner-focused research using MEAs, researchers also have observed that *teachers'* efforts to understand their students' thinking involve yet another process of modeling: In this case, teachers engage in building models of student understanding. Although these teacher-level models are of a different category from student-level models, students' work while engaged in MEAs does provide a particularly rich context for teachers' modeling processes. Following this line of inquiry, the M&MP community has also produced tools and frameworks that can be useful to teachers in making full use of MEAs in classroom settings, while also providing *researchers* with insights into *teachers'* thinking.

Finally, at a third level of inquiry, researchers' own understandings of the actions and interactions in *curricular activity systems* (Roschelle, Knudsen, & Hegedus, 2010) involving students, teachers, and other participants in the educational process can also be studied through the lens of model development. Multi-tier design experiments in the M&MP tradition have done precisely this, involving researcher teams in self-reflection and iterative development as well (Lesh, 2002). Therefore, multi-tier design research involves three levels of investigators— students, teachers, and researchers—all of whom are engaged in developing models that can be used to describe, explain, and evaluate their own situations, including real-life contexts, students' modeling activities, and teachers' and students' modeling behaviors, respectively.

From Single Activities to Curricular Materials Supporting Modeling at Larger Timescales

Over the past 10 years, M&MP researchers have continued this direction of work in their own teaching and in partnerships with K-12 classroom teachers. Within the domain of statistical thinking in particular, this effort has produced resources and tools sufficient to support *entire courses* in several versions and including accompanying materials related to learning and assessment aimed at both student and teacher levels. Because the courses supported by these materials were designed explicitly to be used as research settings, for investigating the interacting development of students' and teachers' ways of thinking, the materials were modularized so that important components could be easily modified or rearranged for a variety of purposes in different implementations. In particular, by selecting from and adapting *the same basic bank of materials*, parallel versions of the course have been developed for: (a) middle- or high-school students, (b) elementary and secondary preservice teachers, and (c) in-service teachers. When these courses have been taught by M&MP researchers familiar with the underlying theory, they have produced impressive gains (e.g., Lesh, Carmona, & Moore, 2009).

Moving beyond a single MEA and sustaining modeling over longer timescales will bring M&MP research more directly into contact with theories of learning and development (including the questions mentioned in the first section, above). This will spur theoretical and methodological reflections on topics such as the relations of *models* to constructs seen to mediate perception and understanding in emerging experts (e.g., *coordination classes* [diSessa & Sherin, 1998] or *disciplined perception* [Stevens & Hall, 1998]).

Approaches to Longer-Timescale Modeling Research

At a more pragmatic level, however, ongoing investigations are exploring ways of integrating M&MP work into larger time-scale curriculum structures. And as might be expected, different approaches to sequencing and integrating modeling activities within curricular structures to expand the scale of modeling reveal different aspects of students' and teachers' thinking. In broad terms, we distinguish these approaches on the basis of the relationship that they create between individual MEAs and the structure of the larger instructional unit or course (Eames, Brady, Jung, & Glancy, in review).

In a common form of initial curricular integration, MEAs are deployed in a *series*, allowing students and the teacher to experience the type of learning characteristic of MEAs several times. Here, each new iteration offers opportunities for teachers to revise their approaches to facilitating MEAs, based on their emerging expectations of how students will engage with problems, their experiences of implementing them, and their knowledge of students' mathematical thinking.

This "series" experience of modeling through MEAs is how many teachers first experience activities from within the M&MP. However, our research has led us to ask how ideas and practices that emerge in these settings can build toward supporting longer-term disciplinary goals, norms, and concepts. These are critical issues in helping modeling to move beyond "island" activities and impact the core experience of mathematics learning for students. Here, we identify two approaches to modeling at this course-level scale that have emerged.

In the first, students' work in MEAs is seen to produce rich but idiosyncratic mathematical ideas and products that need to be *unpacked* and placed into relationship with each other and with more canonical concepts, practices, and procedures from the discipline. Thus, a family of activities is elaborated around the MEA, focusing on refining and extending student modeling work. These "Model Development Sequences" or *MDSs* (e.g., Brady, Eames, & Lesh, 2015; Brady, Lesh & Sevis, 2015; Doerr & English, 2003; Lee et al, 2016; Lesh, Cramer, Doerr, Post, & Zawojewski, 2003) provide opportunities for classroom groups to reflect on and refine the thinking they have done in MEAs. Research over the last 15 years on MDSs has helped to elaborate a suite of *tools* and *activity types* along with cases of their use to support model exploration, extension, adaptation, and analysis.

An alterative approach to course-level modeling has emerged through work in engineering education. Hamilton, Lesh, Lester, & Brilleslyper (2008) have argued that MEAs themselves connect mathematics and engineering, and many researchers have found success using MEAs to develop engineering concepts in K-12 and undergraduate settings (e.g., Diefes-Dux, Moore, Zawojewski, Imbrie & Follman, 2004, English & Mousoulides, 2011, Moore, Miller, Lesh, Stohlmann, & Kim, 2013, Yildirim, Shuman, & Besterfield-Sacre, 2010). In a project coming out of this tradition, larger-timescale modeling units were developed with an engineering focus, engaging learners in extended inquiry on a theme. This engagement was patterned on the shape of inquiry cycles, similar in nature to the modeling cycles that characterize student work within a single MEA, though at a much larger time scale. Thus, this approach aims to scale up qualities of the MEA experience itself to help structure the dynamics of a project that extends over weeks of sustained work. In doing so, researchers hope to see how model development continues over longer time scales along as well as how effectively the MEA design principles extend to larger course or time units.

Research and Discussion Themes to Guide the Working Group

Our working group in Tucson brought together 25 participants from the US, Canada, and Mexico. Participants were interested in wide range of grade levels, engaging in a diverse array of modeling projects. In their work, they applied a variety of interpretive lenses and frameworks to the activity of modeling. Throughout the conference, and particularly on the final day, we had significant participation from teachers and researchers from Mexico, interested in bringing both materials and research publications from the M&MP to Spanish-speaking teachers and researchers in Mexico and across Latin America. Leadership from the Tec of Monterrey and supporting enthusiasm from both Canada and the US gave evidence that this could be a strong area for future work.

One of the principal efforts of the 2016 working group was to identify possible topics and areas for future collaborative research and writing, as well as to imagine structures that would support and encourage such collaborations. At the level of research themes, a large number of possible synergies were identified, including the following questions or areas of study. This list was not generated to be exhaustive but rather to reflect identified common areas of interest during the immediate discussions of the working sessions themselves.

Student-Level Modeling

How might we gain analytic purchase on topics such as students' motivation and engagement; creativity and innovation; patterns in discourse and interpersonal dynamics in small group work; and student's epistemologies and beliefs about the nature of mathematics?

Teacher Professional Development and Implementation Issues

What knowledge and competencies do teachers need, to facilitate modeling activities? To pursue larger-timescale modeling sequences along any of the three approaches described above? How do modeling practices change in the presence of software environments that provide dynamic representations? How do the MEA design principles help teachers to conceptualize STEM integration in math? What is the impact of decisions to sequence model-based activities in different ways, and to sequence modeling activities with more traditional activities in different ways? What are the differences in student modeling behavior across different grade bands? Is group work necessary for modeling activities?

Social Justice, Equity, and Cultural Relevance

What community and cultural connections are possible within modeling task? How can modeling tasks be designed or adapted to increase cultural relevance? What connections can MEAs have with social justice concerns? Is it possible to establish client-type relations with community members to structure modeling tasks?

Classroom Structures, Interactions, and Behavior

How do individual and group learning interact? How do enactments of "the same" MEA in different classrooms illuminate classroom 'cultures' and local communities? What mathematical practices and competencies do students take away from repeated exposures to modeling tasks? How do elementary-school, middle-school, and high-school classroom contexts differ with respect to MEAs (including procedures and supports for setup, facilitation, and poster-session sharing)? How do age differences affect the design and implementation of activities that surround MEAs?

The Development of Mathematical Concepts and Practices

How do we describe the relation between modeling sequences and standards for content and practices? Is it possible to use MEA tasks repeatedly (multiple encounters with the same task) to gauge changes in the mathematics tools and content that learners bring? How does developing a solution to an MEA relate to content mastery?

Assessment Issues

Can modeling tasks be a context where it is possible to discern evidence not only of students' appropriation of the modeling practice but also of connections between this practice and other practices? Similarly for connections between content areas? What evidence do teachers need to evaluate student learning/growth in MEAs?

These themes and questions, illustrate the breadth of the common ground that 2016 participants found in their research interests. This has prompted us to organize the 2017 meeting around elaborating specific shared research and writing projects.

Concrete High-Leverage Actions Identified by the Group as Desirable Projects

In addition to identifying themes of common interest, participants at the Tucson meetings identified activities and projects to pursue in future working group sessions, including:

1. Opportunities to familiarize themselves with more of the curricular materials and research from the M&MP (Concretely: establishing guided pre-reading for before the working group, along with opportunities to discuss during the conference, though perhaps extending outside of the three time-limited sessions)
2. Time and supports to establish a collaborator network for one or more shared writing projects. Two ideas discussed were:
3. Implementing the same MEA across two or more contexts and collaboratively analyzing the data generated.
4. Formulating a successor volume to *Beyond Constructivism*
5. Related to project 2a, the group identified a need for identifying solutions to institutional barriers to cross-institutional collaboration and exploring/proposing solutions (specifically, writing IRB proposals that may allow data sharing, including video)
6. Creating an online repository of materials and tools for both research and teaching in the M&MP.
7. Developing translations and localizations of materials and research papers into Spanish, to support the growth of research and practice in Mexico and elsewhere in Latin America.

In the time since the PME-NA 2016 meeting, the Group has gotten a preliminary start on possible project 2a, above, supporting planning and implementation of an MEA by a participant at the Tucson sessions, collecting data to allow cross comparisons with two other implementations with contrasting learner populations. Analysis of these data will provide a ‘proof of concept’ for this proposed line of collaborative research, as well as offering an indication of what is to be gained in such a comparative study. Further work to test the viability of other suggested strands of work will continue in advance of the Indianapolis meeting, so that the Group can “hit the ground running.”

Working Group Session Outline: Advancing our Agendas While Building Community Capacity

The working group will meet in three sessions over the course of the conference. As preparatory work continues, the precise contents of each of these sessions will be more clearly defined, but the broad outlines are given in this section.

The concrete research projects identified in the section above will be a primary focus of the 2017 meetings. During the summer months, the facilitator group will meet to plan activities to address the desires expressed by participants in Tucson. Then, approximately 2 months before the Conference, we will send out a draft agenda for comment to our email list of all Tucson attendees, plus collaborators and researchers in the field that have participated in the past (approximately 60 names). This will enable final refinement of the agenda as well as circulation of the “pre-reading” requested in point #1, above. Collaboration prior to, during, and after the Conference will be supported by a Google Group (Models and Modeling), a Working Group wiki, and a website for hosting materials and collaborative products (https://sites.google.com/view/modelsandmodelingpmena/home).

In addition to these project goals, our agenda will also ensure that we serve the “building capacity” objective of the working group, inviting newcomers to the M&MP and providing them with an engaging introduction to the experience of MEAs.

Session One

The capacity-building objective for this session is to introduce newcomers to the M&MP

tradition and its approach to research. At the same time, more experienced participants want to get an early start on defining collaborative work toward the several high-leverage projects that the group has identifies. Thus, in Session 1 we will be divided into two groups:

The Newcomer Group will have the opportunity to experience an MEA as a student. We will use the Pelican Nesting Ground MEA that we used in 2016, to enable newcomers to discuss their experience with any participant from the Tucson meeting, ensuring a common ground of experience. This Newcomer Group will be facilitated by a researcher who has experience with this MEA and has seen a variety of learner responses to the task. By the end of Session 1, each modeling team within the Newcomer Group will have developed their solution and prepared a presentation for Session 2.

In the meantime, the More Experienced Group will gather to discuss collaborative efforts toward the projects of Shared Implementation of a particular activity or joint production of an edited volume. Email discussions will likely lead to a group-level decision about which of these two possible projects to pursue during the Conference. By the end of Session 1, each project team of the More Experienced Group will have prepared a plan for collaborative work to be presented in Session 2.

Session Two

The first half of this day will be dominated by presentations. The Newcomer and More Experienced groups will be re-joined as a larger community. Newcomers will present their solutions to the MEA as well as reflect briefly on the experience and their modeling process. The More Experienced Group teams will present the proposed collaborations for comment and review by the larger group. By the end of this day, newcomers will select a collaboration group to join with, with either the objective of participating in the project or getting a deeper understanding of the practice of M&MP research by watching the discussion unfold. By the end of Session 2, small working groups will have formed and begun to dig into their project work.

Session Three

Project working groups will continue to press forward on their agendas during this session, which we leave flexibly structured. By the end of the session, each group will publish to the wiki their "roadmap" for collaborative work. Time permitting, we will have working groups report out verbally to allow other groups visibility into progress and plans.

Throughout our agenda for the Conference sessions, we will be particularly attentive for opportunities to foster mentoring relations between established names in the M&MP tradition and newcomers. One of the signature strengths of the M&MP has been the generosity of leading names in the field, who act as advisors to the Working Group as well as periodic participants. We anticipate attendance by one or more of these senior leaders in Indianapolis, and we will take the opportunity to organize activities for younger scholars to interact with and learn from them.

This working group was formed to create collaborative opportunities for researchers/practitioners from math and special education, with an intention to move forward the teaching and learning of mathematics involving students with learning disabilities/difficulties in mathematics (LDM). This working group was driven by following premises: (1) students with LDM are capable of and need to develop conceptual understanding of mathematics, and (2) special education instruction needs to transition toward this focus. Participants will (a) continue to develop and refine collaborative research agenda for the group, (b) brainstorm specific research questions that will address that agenda, and (c) continue the dissemination effort.

Keywords: Instructional Activities and Practices, Learning Trajectories, Mathematical Knowledge for Teaching, Equity and Diversity

About five to ten percent of school-age children have been identified as having mathematics disabilities, whereas students whose math performance was ranked at or below the 35 percentile are often considered at risk for learning disabilities or for having learning difficulties in mathematics (LDM). Recent National Assessment of Educational Progress (NAEP, 2015) data indicates that mathematics performance gap between students with disabilities and their same-age peers has not been closing—in fact, it seems to get wider. The purpose of our working group (WG) is to explore issues of research around the intersection of mathematics education and special education. Substantial work exists that focuses on development of mathematical cognition and reasoning of students in general education. However, much less is known about the mathematical development of students with disabilities or how to support the learning of these students. The absence of research addressing this subset of students may be due in part to theoretical orientation of the field of special education, which emphasizes explicit teaching of targeted skill-sets, rather than exploratory models such as inquiry-based learning. In addition, it seems that many special educators consider "research-validated" curriculum (or intervention) to largely include studies that follow large-scale, Randomized Control Trial (RCT) approaches (Woodward & Tzur, 2017). Often, the role of pedagogical content knowledge of interventionists or how the intervention helps students construct the concept or develop conceptual understanding of mathematical ideas are lost in "data crunching" of RCT studies.

This WG was formed five years ago to create sustainable opportunities for collaborative work between researchers and practitioners from both the fields of math education and special education, with an intention to promote the teaching and learning of mathematics education involving students with LDM. Understanding how students with disabilities /difficulties develop mathematics concepts and skills, an important dimension of the psychology of mathematics education, has several implications for both research and practice.

First, practitioners in both general and special education can benefit from diverse perspectives and gain a richer understanding of how students with LDM learn mathematical concepts. Second, active study of the development of mathematics concepts and skills for students with disabilities provides both researchers and practitioners with mechanisms for moving toward a methodological focus on pedagogy rooted in assessment of what students with disabilities are capable of learning.

For the purposes of continuing the conversation around mathematics in special education, this group is concerned with students who have significant issues with mathematics, including:

- students with learning disabilities specific to mathematics (MD);
- students with cognitive differences in how they understand and process numbers;
- students who are placed in special education and have difficulties with mathematics.

We refer to these students as having learning disabilities or difficulties in mathematics (LDM) in the remainder of this paper. while acutely recognizing those difficulties may reflect, in part, inadequate teaching (Tzur, 2013).

History of the Working Group

Our PME-NA/PME working group has met five times; each year our group had good participation of both returning and new members. In 2012, 15 researchers (faculty and graduate students) and 2 practitioners met during PME-NA in Kalamazoo, MI. This first meeting was specifically focused on better understanding mathematical learning disabilities (MD). The working group began with a discussion of the issues around identification and definition of MD. In particular, the group discussed the unique characteristics of students with MD (e.g., slow speed of processing despite average reasoning; fundamental issues with number sense; over learning of procedural knowledge at the expense of mathematical reasoning) and implications for instruction and assessment. We took up a theoretical stance that positioned disability as an issue of diversity and considered the origin of the disability as the inaccessibility of instruction rather than a defect within the individual. Most importantly, within this stance on diversity we agreed to a critical premise that underlies our work, namely, rejection of deficit models of those capable learners and focusing on how research and practice can be integrated to support their mathematical abilities (Woodward & Tzur, 2017). Members shared videotapes of various students with MD solving problems in assessment and teaching situations and discussed the need for teachers to target and teach toward the specific mathematical strengths and weaknesses demonstrated by the student. We further discussed at what point(s) the learning paths of students with MD may differ from what is documented among students in general education, how existing developmental trajectories may or may not fit the population of students with MD, and the need to expand or further document current trajectories to include students with MD. Moreover, discussions focused on issues surrounding motivation related to the design and use of instruction, mathematical tools, and mathematical tasks. A rich discussion was held concerning the nature and sequencing of mathematical tasks, the use of concrete and pictorial representations and the extent to which they are (or not) supportive of the abstraction of mathematical concepts for this population. All WG participants agreed about the need for increased research to inform the creation of adequate, empirically grounded, practitioner tools and resources.

During the first year of our WG, our focus was specifically on MD- those students with a biological and cognitively-based difference in how their brain processes numerical information. Based on our discussions during the first year of our working group we decided to expand from a narrow focus on MD to a more inclusive focus on students in special education who struggle with mathematics (i.e., learning disabilities/difficulties in mathematics, LDM). This stance not only avoids the definitional issues at the forefront of the field of special education (i.e., the lack of assessments to accurately identify students with MD and the resulting conflation of low achievement and MD) but also more accurately reflects the diversity of interests of the members of this group—and how their own work seemed to provide a way forward.

In the second year of our WG (2013), 14 participants focused on collaboration that was a result of the progress made during the first year. Specifically, two faculty members worked together on a teaching experiment about fraction knowledge, a compliment to a 2012 funded National Science Foundation (NSF) CAREER project (Hunt, 2012). Their collaboration resulted in each bringing unique expertise; the mathematics education scholar brought insight into the mathematical thinking of the student, while the special education scholar brought insight into learning differences and opportunities. The goal of the teaching experiment was to document how the foundational scheme of unit fractions (1/n) evolves in the mathematical activity of two cases of students with learning disabilities. The students' evolving conceptions were supported by constructivist-oriented pedagogy. Video data segments (i.e., each girl's conceptualization of the multiplicative nature of and inverse relation ($1/m > 1/n$ if $m < n$) among unit fractions; the girls' solutions to novel problems) from this project served as starting points for discussions in the subsequent PME-NA working group meeting. Specifically, WG members used the video segments and descriptions of the collaboration as a springboard for discussing possible research questions and methods of data analysis to employ in future, collaborative work. The proposed WG is designed to foster further collaboration of this nature.

In 2014, the WG met at the joint PME and PME-NA conference in Vancouver. We continued to expand (25 members), by the opportunity to include members from the international group of PME. During that meeting, two working group members (one from math education and one from special education) shared a multiplicative reasoning assessment tool resulting from their NSF-funded research project (Xin, Tzur, & Si, 2008). Upon examining this instrument, the WG discussed alternative ways for assessing students with LDM and implications for intervention development. Our collaboration in Vancouver yielded two main accomplishments. First, as a group we identified three research subgroups: (a) cognitive characteristics of students with LDM, (b) interventions for students with LDM, and (c) teacher preparation or professional development, that represented the interests of the members. Each research subgroup identified pertinent research questions and an agenda for further collaboration.

Second, as a group, we proposed an idea for developing a proposal for a special issue to be published in an influential special education journal to address the research around the intersection of math and special education. Later in the year, members of the working group developed the proposal for the special issue and worked extensively with the editors of a special education journal *Learning Disabilities Quarterly* (LDQ). The quality of our proposal led to the acceptance of this special issue proposal by the co-Editors of LDQ. Two members from the working group served as co-Guest Editors of this special issue and identified potential contributing works from the working group members. In addition, we invited a well-known scholar from the field of special education for co-authoring a commentary paper as part of this special issue. To date, all five papers of this special issue series, as well as an introduction and final commentary papers (Xin & Tzur, 2016; Woodward & Tzur, 2017) have been recently published in the 2016 and 2017 issues of LDQ.

In 2015 PME-NA, we continued and expanded collaborations between members of this WG, by focusing discussions around two central themes: (a) math concept development and corresponding methodologies for studying its emergence in students with special needs, and (b) framing research questions and designing a research plan around this topic. We invited interested researchers and educators to the WG sessions. We had several new members joining, including international scholars. During that meeting, equity was raised as a new focal point. Following 2015 PME-NA, two members of this working group, along with a new member, formed a new collaboration; and they have been working on writing a practitioner piece pertinent to differentiating instruction for diverse students—that article has been accepted to MTMS.

In 2016, the Math and Special Education Working Session met twice during PME 40 held in Australia. Nine people from five continents attended these sessions, while another three people actively participate in our projects throughout the year. On the first day there were several new members to the group. Thus, we introduced each other and explained the history and goal of the working session. We then discussed a project that we started at PME 38 and have recently concluded, namely, the special series of *Learning Disabilities Quarterly* (LDQ). Our discussions yielded a number of questions that we would like to explore (e.g., challenges and strategies of collaborative work between professionals/scholars from the field of math education and the field of special education) and consider questions from an international perspective.

On the second day of that PME working session, we discussed our next big project for the group. We decided to produce a book that teacher educators can use for teaching undergraduate and graduate students about the intersection between mathematics education and special education. We are committed to working on this book project throughout the year and look forward to discussing our progress on this project at PME-NA-39 in Indianapolis, Indiana.

Issues Relating to Psychology of Mathematics Education

Historically, special education researchers and teachers focused almost exclusively on students' mastery of procedural skills, such as basic number combinations and ability to execute mathematical algorithms (Jackson & Neel, 2006; Fuchs et al., 2005; Geary, 2010; Swanson, 2007; Kameenui & Carnine, 1998). A recent literature review comparing instructional domains for students with disabilities found that the majority of special education research addressed basic computation and problem solving, with the primary focus placed on mnemonics, cognitive strategy instruction (e.g., general heuristic four-step strategy: read, plan, solve, and check), or curriculum-based measurement (Van Garderen, Scheuermann, Jackson, & Hampton, 2009). Instructional practices either focused on task analysis (breaking up skills into decontextualized steps that need to be memorized and followed), flash cards, or general heuristics that do not help with domain knowledge learning and concept development (Cole & Washburn-Moses, 2010). In particular, the procedure-driven instruction and primary focus on rote memorization skills seem to result in students' incomplete and inaccurate understanding of fundamental mathematical concepts, as well as a lack of retention and/or transfer (Baroody, 2011).

Importance of Both Conceptual and Procedural Knowledge

Crucial for rich mathematical understandings that enable retention and transfer of fundamental concepts is the iterative development of conceptual understanding along with procedural proficiency (Rittle-Johnson, Siegler, & Alibali, 2001; Rittle-Johnson & Koedinger, 2005). Rittle-Johnson and Alibali (1999) noted that conceptual knowledge supports procedural generalization. In particular, conceptual knowledge could aid children in mindfully avoiding the use of procedures that fail to work in novel situations. Additionally, an ability to understand and manipulate different mathematical representations to conceptually navigate a mathematical context contributes to conceptual understanding and procedural skill (Ball, 1993; Kaput, 1987; Rittle-Johnson et al., 2001). It seems that any investigation into mathematical cognition, whether related to disability or not, must fundamentally engage with issues of conceptual understanding (Hunt & Empson, 2014).

A focus on procedural skills limits students with disabilities' access to the general education curriculum, which is a requirement of the Individuals with Disabilities Educational Improvement Act (Maccini & Gagnon, 2002). In mathematics, access to the general education curriculum means addressing problem-solving, mathematical modeling, higher order reasoning, and algebra readiness as required by the new Common Core Standards (CCSSI, 2012). To accomplish these Standards, mathematics educators need to actively engage students in making conjectures, justifying and questioning each other's ideas, and operating in ways that lead to deep levels of mathematical understanding (Kazemi & Stipek, 2001; Lampert, 1990; Martino & Maher, 1999; Yackel, 2002).

Pedagogy Based on Conceptual Diagnosis

A pedagogical approach to be explored and advanced during this WG's meeting is one that focuses on *promoting conceptual learning in students with LDM*. This approach is rooted in a constructivist stance (Piaget, 1985; von Glasersfeld, 1995), particularly the notion of assimilation, which stresses the need to build instruction on what students already know and are able to think/do. That is, teaching needs to be sensitive, relevant, and adaptive to students' available ways of operating mathematically (Steffe, 1990). To this end, teachers must learn how to: (a) diagnose students' available conceptions, and (b) design and use learning situations that both reactivate these conceptions and lead to intended transformations in these conceptions.

Building on Simon (2006)'s core idea of hypothetical learning trajectories, Tzur (2008) has articulated such an adaptive pedagogy, which revolves around the Teaching Triad notion: (a) students' current conceptions, (b) goals for students' learning (intended math), and (c) tasks/activities to promote progression from the former to the latter. Key here is that in designing every lesson one proceeds from conceptual diagnosis of the mathematics students are capable of thinking/doing. That is, assessment methods need to focus on dynamic (formative) inquiry into student understandings, as opposed to on testing correct and incorrect answers per se. Such day-to-day diagnosis, which a teacher conducts via engaging students in solving tasks and probing for their reasoning processes, gives way to selecting goals for students' intended learning. Building on such diagnosis, a mathematics lesson begins with problems that students can successfully solve on their own, which Vygotsky (1978) referred as the Zone of Actual Development (see also Tzur & Lambert, 2011). Recent studies of mathematics teaching in China (e.g., Jin, 2012) revealed a strategic, targeted method, *Bridging*, which is geared specifically toward both: (a) bringing forth mathematical conceptions the teacher supposes all students know, and (b) directing their thinking to the new, intended ideas.

Exemplar Research Activities with Students with LDM

Multiplicative Reasoning Project. From 2008 to 2015, two members of this working group (one from math education and one from special education) have been working collaboratively on a federal funded grant project (Xin, Tzur, & Si, 2008). This project integrated research-based practices from mathematics education and special education and was aimed to promote multiplicative reasoning and problem solving of elementary students with LDM. As an outcome of this collaborative project, the research team has developed an intelligent tutor, PGBM-COMPS. The intelligent tutor draws on three research-based frameworks: a constructivist view of learning from mathematics education (Steffe & D'Ambrosio, 1995), data (or statistical) learning from computer sciences (Sebastiani, 2002), and Conceptual Model-based Problem Solving (COMPS) (Xin, 2012) that generalizes word-problem underlying structures from special education.

Rooted in a constructivist perspective on learning (Piaget, 1985; von Glasersfeld, 1995), the PGBM part of the intelligent tutor focused on how the aforementioned student-adaptive teaching approach, which tailors goals and activities for students' learning to their diagnosed available conceptions, can foster advances in multiplicative reasoning. This approach eschews a deficit view of students with learning disabilities. Rather, it focuses on and begins from what students do know and uses task-based activities to foster transformation into advanced ways of knowing. On the other hand, intelligent computer systems can play an important role in students' learning by effectively modeling their thinking and dynamically recommending tasks tailored to their conceptual profiles. Going hand-in-hand, the COMPS part of the program (Xin, 2012) generalizes students' understanding of multiplicative reasoning to the level of mathematical models. At this stage, students no longer rely on concrete or semi-concrete models for problem solving; rather, the mathematical models directly drive the solution plan.

The collaborative research team has conducted several piloting studies to field test the PGBM-COMPS intelligent tutor with elementary students with LDM. The preliminary studies have shown promising results—participating students with LDM who interacted with this intelligent tutor not only enhanced their problem solving skills on a researcher-designed criterion test but also a norm-reference standardized test (Xin et al., 2017). In addition, the results of these studies have shown success in promoting students' conceptual advances (e.g., concept of number, multiplicative reasoning). In fact, a paper resulting from a randomized control trial (RCT) study of this project has been published as part of the special series (Xin & Tzur, 2016) produced by this working group. As a follow up, the research team has continued on this line of work and recently embarked on a new NSF supported project (Xin, Kastberg, & Chen, 2015), which focuses on additive reasoning.

Fraction Project. Another working group member is documenting learning trajectories of elementary school children with LDM as they come to understand fractions as quantities (Hunt & Empson, 2014). In its first year, the goal of this work was to produce models of children's key developmental understandings (KDU; see Simon, 2006), or critical transitions in how children may conceive of a mathematical idea along a carefully sequenced combination of tasks and varying instructional guidance necessary to grow conceptual knowledge not yet well formed (Daro, Mosher, and Corcoran, 2011). During the proposed WG, this researcher will illustrate varying levels of a students' informal notions of fractions, how the mathematical ideas can be elicited, the grappling of ideas a student might experience, and how more solidified notions of mathematics form through a student's activity (i.e., external manipulation or representation; internal mental activity; actions; strategies for problem solving). This research aims to map trajectories that can assist educators looking to individualize instruction for students with LDM and improve students' conceptual understanding of fractions.

As part of that grant's Year 1 activities, the research team has documented an initial trajectory from semi-structured interviews with fifty 2nd, 3rd, 4th, and 5th graders with LDM. Interviews followed a protocol that established a basis for questioning while maximizing researcher flexibility to fully examine student thinking. Information pertaining to the children's specific needs was also collected to allow for an examination of any trends occurring across similar cognitive profiles. The constructed trajectory is also being tested with a smaller subset of four students and an expanded group of tasks from which the trajectory is based. Data collected from mini-interventions will undergo analysis (Siegler, 2006) to confirm the robustness of the preliminary trajectory. That grant's Year 2 activities will use a teaching experiment methodology, much like those used in the collaborative pilot that resulted from this WG, to document how children with LDM construct conceptions of fractions.

As forgoing, the proposed WG participants will use artifacts from projects described above as possible starting points to further explore possible applications of student-adaptive pedagogy (conceptual diagnosis based) as well as conceptual development trajectories in the design of effective/efficient assessment and intervention programs for students with LDM. We believe such approaches are complimentary and have the potential to constitute core methodologies for teaching and studying the conceptual understandings of students with LDM. In a similar way, this working group provides a venue to give and receive feedback on ongoing cutting-edge empirical work, which is reshaping how students with LDM are researched.

Plan for Working Group

The aim of this proposed WG is to continue the productive collaboration and conversation about the intersection of mathematics education and special education. One of the major goals of this year's working group sessions is to draft a proposal for publishing a book that university professors and teacher educators can use for teaching undergraduate and graduate students about the intersection between mathematics education and special education.

This working group intends to accomplish the following:

- identify the content of the book and identify the primary audience for the book
- develop a table of content for this book proposal;
- Identify book titles with which our book will compete and discuss how our book will differ from these titles. What are the selling points of our book?
- Discuss the logistics of collaborations to carrying out the identified tasks, and
- Discuss further collaborations leading to additional publication and funding opportunities.

These goals are further outlined across sessions as follows:

Session 1: Introduction and Progress-to-Date
GOAL: Identify participant's affinity for established sub-groups and identify potential new sub-group possibilities.

- Prior members will briefly introduce the working group's history and describe the collaborations that have emerged in prior years, supposing everybody reads this proposal.
- Participants will each introduce themselves and their current research and interest in students with LDM.
- New sub-groups may be formed among participants on the basis of common (research) interests to be shared.
- Begin discussion of the tentative ideas for the book.

Session 2: Book Proposal Development
GOAL: Brainstorm and draft book proposal.

- Identify the contents and possible sections of the book as well as its primary audience.
- Develop a table of content for this book proposal and list key words to assist readers
- Identify other book titles with which ours may compete; discuss how our book will differ from these titles. What are the "selling points" of our proposed book?

Session 3: Continue the Ongoing Collaboration
GOAL: Establish next steps for both the sub-groups and the whole working group.

- Within the group or sub-groups we will:
    - Articulate the overarching research agenda for the group/sub-group
    - Articulate potential research questions that the group/subgroup would like to address through collaborative work.
    - Explore a variety of methodological and analytic approaches that can be leveraged to address the research questions.
- Discuss the logistics of collaborations to carrying out the identified tasks, and

- Determine what our next whole group meeting will entail (e.g., PMENA working group for the following year)

Anticipated Follow-Up Activities

Throughout the year, the members of this WG are working on research problems of common interest. They will contribute to a common website in which they will update other members of the WG about the progress of the various research collaborations. We will continue our effort in disseminating the collaborative work resulting from this working group to broaden its impact in the field of mathematics education for students with LDM.
