Revision

These proceedings have been revised as follows.

- Duplicate page numbers were removed from chapter 13.
- The correct paper for the working group "Developing a Research Agenda of Mathematics Teacher Leaders and their Preparation and Professional Development Experiences" has been included in chapter 14.
- The table of contents for chapter 14 has been updated.

PME-NA History and Goals

PME came into existence at the Third International Congress on Mathematical Education (ICME-3) in Karlsrühe, Germany in 1976. It is affiliated with the International Commission for Mathematical Instruction. PME-NA is the North American Chapter of the International Group of Psychology of Mathematics Education. The first PME-NA conference was held in Evanston, Illinois in 1979.
The major goals of the International Group and the North American Chapter are:

1. To promote international contacts and the exchange of scientific information in the psychology of mathematics education;
2. To promote and stimulate interdisciplinary research in the aforesaid area, with the cooperation of psychologists, mathematicians, and mathematics teachers;
3. To further a deeper and better understanding of the psychological aspects of teaching and learning mathematics and the implications thereof.

PME-NA Membership

Membership is open to people involved in active research consistent with PME-NA's aims or professionally interested in the results of such research. Membership is open on an annual basis and depends on payment of dues for the current year. Membership fees for PME-NA (but not PME International) are included in the conference fee each year. If you are unable to attend the conference but want to join or renew your membership, go to the PME-NA website at http://pmena.org. For information about membership in PME, go to http://www.igpme.org and click on "Membership" at the left of the screen.

PME-NA Steering Committee

Elected Members

Jeffrey Choppin
Steering Committee Chair
University of Rochester
jchoppin@warner.rochester.edu
2014 – 2017

Karen Hollebrands
Past Steering Committee Chair
North Carolina State University
kfholleb@ncsu.edu
2014 – 2017

Shari Stockero
Chair-Elect
Michigan Technological University
stockero@mtu.edu
2016-2019

Samuel Otten
Membership Chairperson
University of Missouri
ottensa@missouri.edu
2015 – 2018

Ángeles Domínguez Cuenca
Tecnológico de Monterrey México
angeles.dominguez@itesm.mx
2015 – 2018

Jennifer Holm
University of Alberta
jdholm@ualberta.ca
2016 – 2019

Cindy Jong
University of Kentucky
cindy.jong@uky.edu
2016 – 2019

Eva Thanheiser
Secretary
Portland State University
evat@pdx.edu
2016 – 2019

Crystal Kalinec-Craig
University of Texas at San Antonio
Crystal.Kalinec-Craig@UTSA.edu
2016 – 2019

James Sheldon
Graduate Student Representative
University of Arizona
jsheldon@email.arizona.edu
2016 – 2017

Nicola Hodkowski
Graduate Student Representative
University of Colorado-Denver
nicola.hodkowski@ucdenver.edu
2016 – 2017

Appointed Members

Aaron Brakoniecki
Webmaster
Boston University
brak@bu.edu
2017 – 2020

Ji-Yeong I
Treasurer
Iowa State University
jiyeongi@iastate.edu
2017 – 2020

Conference Chairs

Jill Newton
Current Conference Co-Chair
Purdue University
janewton@purdue.edu
2015 – 2018

Enrique Galindo
Current Conference Co-Chair
Indiana University
egalindo@indiana.edu
2015 – 2018

Erin Turner
Past Conference Co-Chair
University of Arizona
eturner@email.arizona.edu
2014 – 2017

Marcy Wood
Past Conference Co-Chair
University of Arizona
mbwood@email.arizona.edu
2014 – 2017

Preface

Welcome

On behalf of the 2017 PME-NA Steering Committee, the 2017 PME-NA Local Organizing Committee, and the Hoosier Association of Mathematics Teacher Educators (HAMTE), we welcome you to the 39th Annual Meeting of the International Group for the Psychology of Mathematics Education – North American Chapter held at the Crowne Plaza Indianapolis Downtown Union Station in Indianapolis, Indiana.

The theme of this year's conference is *Synergy at the Crossroads: Future Directions for Theory, Research, and Practice*. The metaphor of crossroads was inspired by the conference venue - the historic Indianapolis Union Station, as well as by the State motto, a reference to how Indiana is connected to the rest of the United States. PME-NA 39 includes research presentations, discussion, and reflection focusing on four driving questions connecting to the metaphor of crossroads: 1) What have we learned from the routes we have traversed, what are potential routes for mathematics education research in the future, and what considerations are relevant as we make choices about future directions in mathematics education? 2) How do we address issues of access and equity within mathematics education today? 3) How can we lay the groundwork for future crossroads or intersections between theory, research, and practice? and 4) What barriers within research traditions, educational policy, and teaching practice impede researchers', students' and teachers' success and how can we work to overcome these barriers?

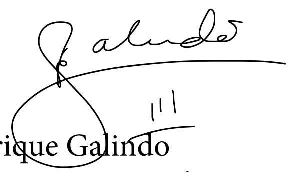
Rochelle Gutiérrez will present the opening plenary talk on Thursday evening, *Living Mathematx: Towards a Vision for the Future*, into which she brings ideas from ethnomathematics, postcolonial theory, aesthetics, biology, and Indigenous knowledge in order to propose a new vision for practicing mathematics. Edd Taylor will serve as discussant for the talk. In the Friday afternoon plenary session, Les Steffe will present several crucial radical constructivist research programs to argue that rather than repeat attempts to make wholesale changes in mathematics education based on mathematical knowledge for adults, what is needed is to construct mathematics curricula *for* children that is based on the mathematics *of* children. Two of Dr. Steffe's former students, Erik Tillema and Amy Hackenberg, will serve as discussants, providing varied perspectives on the continuation of his work. Saturday's plenary session, *Elementary Mathematics Specialists: Ensuring the Intersection of Research and Practice* will include a historical overview by Maggie McGatha followed by a discussion panel composed of Dionne Cross and Jane Mahan, facilitated by Sheryl Stump. A panel discussion of technology in mathematics education with representatives from the three PME-NA member countries will complete the plenaries on Sunday: Ana Isabel Sacristán (*Digital Technologies in Mathematics Classrooms: Barriers, Lessons and Focus On Teachers*); Nathalie Sinclair (*Crossroad Blues*); and Karen Hollebrands (*A Framework to Guide the Development of a Teaching Mathematics with Technology Massive Open Online Course for Educators [MOOC-ED]*).

This year's conference will be attended by about 550 researchers, faculty and graduate students from around the world including the US, Mexico, Canada, Turkey, Australia, South Korea, Malawi, and Iran. We received 529 submissions. The acceptance rate was 39% for research reports as research reports, 57% for brief research reports as brief research reports, 78%

Galindo, E., & Newton, J., (Eds.). (2017). *Proceedings of the 39th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* Indianapolis, IN: Hoosier Association of Mathematics Teacher Educators.

for posters as posters, and 100% for working groups. The accepted proposals included 75 research reports, 142 brief research reports, 167 posters, and 13 working groups. Continuing the efforts started at last year's conference there will be some presentations in Spanish, as well as simultaneous oral interpretation (from English to Spanish, and from Spanish to English) for selected sessions.

We would like to thank the many people who generously volunteered their time over the past year in preparation for this conference. This includes members of the PME-NA Local Organizing Committee, the PME-NA Steering Committee, Purdue Conferences, strand leaders, proposal authors and reviewers. We appreciate all of your hard work and dedication, and your commitment to ensure a high-quality conference program. We also wish to thank the generous financial support of the HAMTE member universities across Indiana.



Enrique Galindo

LIVING MATHEMATX: TOWARDS A VISION FOR THE FUTURE[i]

Rochelle Gutiérrez
University of Illinois at Urbana-Champaign
rg1@illinois.edu

This paper offers specific implications for teaching and learning and brings into conversation ideas from ethnomathematics (including Western mathematics), postcolonial theory, aesthetics, biology, and Indigenous knowledge in order to propose a new vision for practicing mathematics, what I call mathematx. I build upon the work of sustainability in mathematics education and suggest we need to think not only about more ethical ways of applying mathematics in teaching and learning but question the very nature of mathematics, who does it, and how we are affected by that practice.

Keywords: Equity and Diversity, Instructional Activities and Practices

> We need to be constantly considering the forms of mathematics and what they seek to deal with. As society presents new demands, new technologies, new possibilities, we must ask ourselves whether our current version of mathematics is adequate for dealing with the ignorance that we have (Gutiérrez and Dixon-Roman, 2011, p. 32).
>
> The ecology of knowledges enables us to have a much broader vision of what we do not know, as well as what we do know, and also to be aware that what we do not know is our own ignorance, not a general ignorance (Santos, 2007, p. 43).
>
> We are all the product of our worldview—even scientists who claim pure objectivity…Science and traditional knowledge may ask different questions and speak different languages, but they may converge when both truly listen to the plants (Kimmerer, 2013, p.163, 165).

Everyday, we accumulate more evidence that humans are destroying the planet. We need only look at the increasing levels of air pollution, climate change, destruction of the ozone layer, and the elimination of various plant and animal species throughout the world to know that we cannot continue with the forms of living we have come to consider "normal." However, not until recently has the public become aware that the effects will deeply impact us in our lifetime (Kolbert, 2015). One might ask: what role(s) should mathematics play in stopping or slowing the rate of such destruction of the environment? The field of mathematics might serve mainly to: describe the nature of the global problem; offer excellent models for prediction; or provide efficient data analysis and statistics for calculating risk. Mathematics might also offer something else altogether. In what way(s) are current forms of mathematics teaching and learning consistent with the kinds of environmental crises we face? Do we need to think differently about our relationship between mathematics, humans, and the planet? And, if so, how?

In this article, I seek to bring into conversation ideas from ethnomathematics (including Western mathematics), postcolonial theory, aesthetics, biology, and Indigenous knowledge in order to propose a new vision for practicing mathematics, something I refer to as *mathematx*. I do so in order to promote interaction between different knowledges, different ways of knowing, and different knowers. I build upon the work of sustainability in mathematics education and suggest we need to think not only about more ethical ways of applying mathematics in teaching and learning but question the very nature of mathematics, who does it, and how we are affected by that practice. I introduce the concepts of In Lak'ech, reciprocity, and Nepantla to suggest we learn from other-than-human persons, which, in turn, may change our relationships with them. Along the way, I underscore with examples from biology the potential limitations of current forms of mathematics for understanding/interacting with our world and the potential benefits of considering other-than-human persons as having different knowledges to contribute. Finally, I suggest implications for teaching and learning.

Identifying the Problem

The relationship between mathematics, humans, and the planet has been one steeped too long in domination and destruction (O'Neil 2016; Martinez 2016). Due in large part to the way research is funded, the field of mathematics is often in the service of warfare and economics (BooB-Bavnbek and Hoyrup 2003; Gutiérrez 2013; Martinez 2016; O'Neil 2016; Porter 1995). With an emphasis on quantifying, categorizing, and reducing complex and multi-layered relationships between persons to mere abstractions, mathematics often supports a fallacy that modeling, big data, and software can solve anything. Some might suggest there is nothing inherent in the practice of mathematics that leads to domination; we simply need to follow more ethical practices in applying mathematics in the world around us.

Highlighting this role of domination and arguing for a new form of teaching mathematics, Coles and colleagues (2013) note,

> The history of humanity's relationship with the natural environment, at least in the West, can be summarized in one word: domination. The natural environment has been seen as a source of food and raw materials all to be placed in the service of human projects. Where the natural environment gets in the way of such projects, we simply blast our way through… (p. 4)

In an attempt to change this relationship, Coles and colleagues suggest we begin by altering the forms of teaching and the curriculum to which students are exposed. By situating mathematical problems in contexts that relate to such issues as climate change, students will have the opportunity to develop a new relationship to mathematics and new uses of mathematics in making life decisions. That is, students can be encouraged to analyze real-world statistics of temperatures in different regions to make conclusions about both the rates by which the climate is changing and the probabilities that the climate will continue to change. In this way, students would also be allowed to ponder such questions as what kind of mathematical information is necessary to address climate change? What mathematics should the average citizen know in order to make informed decisions about the consequences of their actions and the actions of others? Learning mathematics in real world social and political contexts can help students see relationships between the decisions humans make and the destruction of the planet, thereby urging them to take action to save the planet. In this way, mathematics education can more clearly highlight the roles of ethics (e.g., Atweh 2013; Boylan 2016) and practicality as they relate to the practice of mathematics. Thus, shifting the curriculum to more sociopolitical contexts (Gutiérrez 2010/2013[ii]), what some would refer to as teaching mathematics for social justice (Frankenstein 1990; 1995; Gutstein 2006), could broaden the service of mathematics beyond economics and warfare.

However, attending to *when* and *how* mathematics is in the service of sustainability or ethics may be a necessary but insufficient step towards new relationships between humans, mathematics, and the planet (Gutiérrez, 2002). This, for me, has been one limitation of social justice mathematics (Gutstein 2003; 2006; 2007), as it tends to assume we will keep intact as "classical" what I refer to as "dominant" mathematics rather than challenging whether that version or any single version should remain central. In the social justice mathematics tradition, students are taught to use classical mathematics as a tool to read and write the world, in order to develop their sociopolitical consciousness and mathematical proficiencies. But, in general, the tool itself is not questioned. Recognizing the limitations of using the master's tools to dismantle the master's house (Lorde 1984) leads me to argue that we must also be willing to question and reconceptualize what counts as mathematics in the first place, thereby taking up issues of epistemology and ontology.

I am not alone in suggesting we need to reconsider our definitions of mathematics in light of our current state of global crises. For example, Appelbaum (2016) suggests a different approach through curriculum, where a key component is questioning what counts as mathematics.

> …one key curriculum question that can no longer be pushed to the side is how very narrow, Western, "rational" conceptions of what mathematics "is" have continued to be wielded implicitly as tools of epistemicide, obliterating alternative epistemologies of number, size, quantity, possibility, shape, algorithmic problem solving, analogic representation, and other extended components of mathematical thinking and living. (p. 5)

Similarly, Boylan (2016) considers the role of mathematics in relation to the planet and argues,

> An ecological ethics calls not only for an environmentally informed critical mathematics education but also for a critique of the social construction of mathematics itself as separate and disconnected from the earth (p. 9).

The Program Ethnomathematics offers a useful starting point for broadening the definition of mathematics, something I will discuss later in this article.

Not only must we: a) be conscious of the ways mathematics can dominate and b) constantly question what counts as mathematics and who decides, we must also c) think about how we, as living beings, practice mathematics as we interact with others and ourselves. As we begin to reimagine mathematics, we have the opportunity to reimagine the mathematician—who is considered a mathematician as well as how are mathematicians influenced by the mathematics they do? Many of the current efforts to reconsider mathematics and its role in our global society tend to rely upon a utilitarian version of mathematics that allows us to better survive on this planet. I am suggesting that a form that describes moving through the world and relates to all living beings is more likely to change our relationships with each other in this universe or in others. We need a definition that acknowledges mathematics as a verb and how that practice relates to our bodies, minds, and intentions. For that, we might consider our philosophical stance.

Much of the philosophical research produced in mathematics education centers on European thinkers. For example, we are abundant with theories of postmodernism, poststructuralism, and psychoanalysis that regularly draw upon such writers as Deleuze and Guattari, Ranciere, Foucault, Lacan, Badiou, Derrida, and Freud. As a Chicanx scholar, a cis gender female with Rarámuri[iii] roots, I seek to decenter the field's overreliance on Whitestream views. I use the term Chicanx (as opposed to Chicano, Chicana/o, or Chican@) as a sign of solidarity with people who identify as lesbian, gay, bisexual, transgender, queer, questioning, intersexual, asexual, and two-spirit[iv] (LGBTQIA2S). Chicanx represents both a decentering of the patriarchal nature of the Spanish language whereby groups of men and women are normally referred to with the "o" (male) ending as well as a rejection of the gender binary and an acceptance of gender fluidity. The "x" signifies a variable to represent any gender form. My choice to use this term reflects my respect for how people choose to name themselves.

In this article, I introduce three Indigenous concepts that have guided my work over the years—In Lak'ech, Nepantla, and reciprocity—and suggest they can serve as guiding principles of a new practice of mathematics.

Indigenous Epistemologies

Why privilege Indigenous concepts when considering the relationship between mathematics, humans, and the planet? The answer to that question lies partly in the way (Western) mathematics is viewed as universal (being able to explain everything in reality) and highly valued in society. When challenges of discontinuity or undecidability arise, mathematicians often protect the universal view by suggesting that mathematics still holds true if we simply begin with different axioms (Barrow 1992). Yet, no knowledge could fully describe or attend to our universe and our relations with/in it. If we look to the role that Aboriginal[v] knowledges have played in the reading of signs of distress from the land (i.e., predicting the global crises we face), the preservation of biodiversity, and the role of survival in general, we see the limits of Western mathematics/science practices as a means for intervention (Berkes et al. 2000; Brayboy and Maughan 2009; Cajete 1999; Deloria 1979; González 2001; Heinrich, et al. 1998; LaDuke 1994; Little Bear 2000; 2009; Tallbear 2013; Watson-Verran and Turnbull 1995). I claim neither that all Western thought is colonizing/hegemonic nor that all Indigenous thought does not have the ability to dominate. However, modern Western thinking has been hegemonic in ways that erase Indigenous thought. In this way, I use the term "Western" to refer to the modern version that has tended to colonize and "Indigenous" or "Aboriginal" to refer to the version that has tended to be erased throughout history.

Acknowledging the limits of Western mathematics is not to discount the value of mathematical knowledge in other realms. However, such limitations suggest that, in contrast to the global push to get more students to enter Science, Technology, Engineering, and Mathematics (STEM) fields in order to deal with the complexity and challenges in our world, we cannot fully address our problems through a reliance on Western mathematics/science.

Santos (2007) suggests that the problem of domination may lie not in *which* knowledge is authoritative, but rather in our overreliance on any single knowledge as authority. As such, he suggests an epistemology of knowledges, underscoring the view that all knowledge is legitimate, partial, and interdependent. In fact, with respect to ignorance, learners do not just lack knowledge, they have "misknowledges" (i.e., stereotypes, incorrect knowledge) about others (Kumashiro 2001). And, those misknowledges may not easily be replaced by the introduction of new knowledge because desconocimiento (ignorance) can be a "refusal to know" when what is new disrupts what was previously believed to be true (Anzaldúa 2000).

Yet, from a postcolonial perspective, it is important to unlearn what one thinks one knows, both to recognize a form of epistemological arrogance (thinking that one's ways of knowing are superior to others') and to learn to see oneself in relation to others (Andreotti, Ahenakew, and Cooper 2011). Such a perspective acknowledges that our ignorance is our own, not a general form that cannot be known or is not yet known (Santos 2007). That is, just as there is no unity of knowledge, there is no unity of ignorance. Each of us has knowledge and ignorance that is, to a certain extent, unique. Consistent with this epistemological pluralism, some scientists have argued against trying to develop a theory of everything (Gleiser 2015).

Ecology of knowledges does not follow a single abstract universal hierarchy among knowledges. Rather, it sees knowledge practices as context dependent. In that sense, it recognizes that different knowledges can address our understanding and ability to relate to one another depending upon our different purposes (e.g., the ways we aim to connect, the problems we seek to solve, the ways we invite joy into our lives) (Little Bear 2009). For example, by seeking to be predictive, generalizable, reductionist, and quantifiable in nature, Western perspectives tend to privilege knowledge as a form of (re)presentation and explanation of reality (Aikenhead and Michell 2011). Yet, given the global crises we face, we might be better served by knowledge as action—a form of intervention (Santos 2007; Andreotti 2011).

Given these different purposes, it is important to create inter-knowledges, whereby learning another's knowledge does not negate knowing one's own knowledge (Santos 2007). In this way, learning how other living beings perform mathematics does not eliminate what is known in terms of academic mathematics. But, it does help us know what we do not know. Recognizing these inter-knowledges can go a long way towards embodying humility and establishing the need for responsibility, and therefore reciprocity, *toward* another, as opposed to *for* another (Spivak, 1987).

While Santos is referring to an epistemology of knowledges that would include scientific/mathematical versus social scientific, I am arguing that within mathematics, we might acknowledge and value an epistemology of knowledges. That is, mathematically, we might come to see that different ways of knowing, different knowers, and different forms of knowledge are all legitimate, partial, and interdependent. Epistemological pluralism recognizes that there will be tensions, contradictions, and politics in translating Indigenous knowledges into Western categories/languages (Andreotti, et al. 2011). As such, an epistemology of knowledges is destabilizing because it interrogates the politics of knowledge and, unlike Western knowledge, does not presume causal outcomes—that is, that we can know the potential from any given actual. Therefore, the production of knowledge is an ongoing process that is not cumulative but relational.

Centering Indigenous Knowledges

To be clear, there is no universal "Indigenous worldview." Within the US, alone, there are 567 peoples federally recognized as American Indian and many more that are not recognized. Within México, there are 62 peoples recognized as Indigenous, comprising 13 percent of the nation's population. Within Canada, there are 634 peoples recognized as First Nations, plus peoples who are Métis and Inuit, all accounting for 5.6 percent of the nation's population. And, these populations cover only North America, not the globe. The use of particular languages and ties to particular lands create unique views held by Aboriginal peoples throughout the world and by individuals within those groups. And, many Aboriginal writers refuse to refer to themselves as Indigenous, Indian, or First Nations, as those categories are reflections of a colonizing history that blurs specificity. Even so, at times, "strategic essentialism" (Spivak 1987) is important for joining peoples and advancing common resistance tactics. As such, I speak of commonalities across the range of Indigenous knowledges. The perspectives I share are my view and do not necessarily reflect the views of others.

Indigenous knowledges recognize that we are part of a system of intelligent and sentient beings, also referred to as persons, with interconnected spirits, including rocks and bodies of water. Plants, for example, have lived on this planet for millions of years before humans. In that sense, plants are our older brothers/sisters and have developed ways of efficiently using space, relating with other living beings, and sustaining life not just for themselves but for others, often with few resources at any given moment. They have been able to withstand long droughts, communicate about impending dangers, and collaborate in order to protect others in the community in ways that appear to be selfless acts. They have much to teach us; and we may have something to teach them. Breaking with a human/non-human binary is consistent with queer theory, which recognizes the violence that is justified when some are viewed to be more human than others (Chen 2012).

Our choice to destroy the planet to serve our immediate/capitalistic/technology needs is a form of settler colonialism that perpetuates violence. That is, because a Western worldview does not consider plants, animals, and rocks as living beings of equal value with the same rights to this universe as humans, the result is that plants, animals and rocks suffer the same treatment as Indigenous peoples have endured throughout time. For example, like American Indians who were stripped of their lands and communities and forced to live in boarding schools, plants are yanked from their families and forced to assimilate into Western ways of doing things (e.g., to become suburban gardens). By respecting animals, plants, and even rocks as living beings, we can avoid some of the human/material binary that has plagued the sciences in the past.

By referring to humans as a young species, I do not mean to imply a sense of posthumanism or transhumanism. That is, I am not looking to make humans better or into a fuller version of themselves by combining with technology, fiction, or art (Haraway 1990; but also Chela Sandoval's extension). An Indigenous perspective, for me, seeks not to transform humans into another form of being; rather it serves to help us recognize our place in this world as the younger brothers/sisters of animals, plants, and rocks who have much to teach us about making sense of and remaining connected to this planet and possibly other planets. In this sense, by changing our world view—how we move through this world and possibly into others—we will necessarily change ourselves, but not in a way that is separate from other living beings, not in a way that is necessarily tied to technology. There may be things we cannot yet access or understand because we are a young species. Other persons may have ways of accessing information that can be helpful for us.

While our Elders have long spoken of the sentient capabilities of plants and rocks and of the collective spirit they/we share, only recently have modern scientists begun to acknowledge that claim with experiments that prove this to be the case, suggesting trees are sentient and intelligent (Haskill 2017; Jahren 2017; Wohlleben 2016). For example, tracing isotopes of carbon dioxide gas offered to sample trees shows they turn that carbon dioxide into sugars that travel down through the trunk and use a complex system of roots, fungi, and mycelium to share that resource with other trees nearby, even trees of a different species (Simard et al. 2012). Similarly, when a tree is injured or attacked by pests, it is able to communicate by way of pheromones to nearby trees to tell them to start changing the chemistry of their leaves to be unfavorable to the intruder (Wohlleben 2016). And, mother trees are able to both reduce their root system to make room for their offspring as well as send defense signals through their mycorrhizal network to increase the resistance of their offspring to future stress (Teste, et al. 2009).

Beyond embracing the intelligence and sentience of other living beings, Indigenous epistemologies connect place, body, spirit, and consciousness. They reflect understandings of land, history, culture, identity relationships, and therefore, politics (Deloria 1979). Many Indigenous knowledges have been developed with roots in survivance; that is, not surviving in the colonialist depiction of escaping catastrophe or being positioned as victims, but resisting dominance in a way that renews Indigenous knowledges that are particular and have always been present (Vizenor 2008). While there are many Indigenous concepts that could be fruitful to revisioning mathematics, I present three that have been important in my upbringing. I do so in order to set the stage for an epistemology of knowledges that can guide our practice of mathematics.

In Lak'ech

The Mayan definition of human being (huinik'lil) translates to "vibrant being" in recognition of the idea that all human beings are part of a universal vibration (Arguelles 1987; Paredez 1964). Acknowledging that all beings are connected, Mayan philosophy includes the important concept of *In Lak'ech* woven into everyday thought and action. When a person meets another, they begin with the saying In Lak'ech (You are the other me), to which the receiver responds with Ala K'in (I am the other you). This greeting highlights for all persons (human and other-than-human) their connection with each other and the need to protect each other. Consistent with Indigenous knowledge, I use the terms "living beings" and "persons" interchangeably, as each term refers to all things living.

Seeing a version of oneself in other living beings or persons is a powerful reminder to move through the world with compassion, gratitude, and interdependence. For me, In Lak'ech suggests that if we look closely, we can see ourselves in others and others in us, but not in a way that implies an erasure of our uniqueness, even while recognizing that uniqueness does not imply a sense of self without others. To be clear, In Lak'ech does not translate to "I am you; You are me." Seeing a version of oneself in others and others in us is a kind of mirror, an affirmation; while the concept also recognizes we are not exactly the same. In the same way that a mirror refracts light, produces words that are backwards, and has imperfections from the glass, In Lak'ech reminds us that each person is unique. In this sense, other persons also serve as a kind of window, a way of viewing another world, another self, another (possibly better) you.

Over time, Chicanx scholars have brought the concept of In Lak'ech into poems and theater as reminders of how we should move through the world.

> Tú eres mi otro yo.
> You are my other me.
> Si te hago daño a ti,
> If I do harm to you,
> Me hago daño a mi mismo.
> I do harm to myself.
> Si te amo y respeto,
> If I love and respect you,
> Me amo y respeto yo.
> I love and respect myself. (Valdez and Paredez n.d.)

Through this poem and other writings (e.g., Valdez 1971), Valdez highlights the ways in which Chicanx might relate to others in order to move with the cosmos. The meaning of In Lak'ech is similar to the Lakota saying Mitakuye Oyasin "we are all related" (Cajete 1999 cited in Hatcher et al. 2009). The idea that we are all related can, in some ways, bring us joy, a simultaneous affirmation of self and others. Building upon the idea that we are all interconnected, an Indigenous production of knowledge to benefit others is in opposition to knowledge production as performance that benefits mainly oneself and that is seen in most White institutions or places that value Western thought. Brayboy and Maughan (2009) remind us,

> Indigenous communities have long been aware of the ways that they know, come to know, and produce knowledges, because in many instances knowledge is essential for cultural survival and well-being. Indigenous Knowledges are processes and encapsulate a set of relationships rather than a bounded concept, so entire lives represent and embody versions of IK (p. 3).

Reflecting these relationships, In Lak'ech focuses not on description of reality but on movement through the world and metaphysics. By metaphysics, I simply mean a set of first principles by which we make sense of the world around us (Deloria 1979).

Reciprocity

Extending the idea of In Lak'ech, the second concept upon which I draw is reciprocity. The concept of reciprocity highlights the idea that different persons have different strengths and needs, and thus must rely on others for what they lack. More than simply recognizing that reciprocity enables persons to do things they could not otherwise do alone, it underscores a kind of ethic that is valued in maintaining harmony of the cosmos. In this sense, reciprocity is not only the productive thing to do, it is the right thing to do. Whereas In Lak'ech acknowledges the nature of the relationship between self and others, reciprocity highlights the actions that should result.

As a botanist and a member of the Citizen Potawatomi Nation, Kimmerer (2013) weaves the view of a scientist with an Indigenous view on the role of reciprocity and suggests that when we honor other living beings (e.g., plants), it changes our relationships with them. She says,

> When I speak of the gift of berries, I do not mean that Fragaria virginiana has been up all night making a present just for me, strategizing to find exactly what I'd like on a summer morning. So far as we know, that does not happen, but as a scientist I am well aware of how little we do know. The plant has in fact been up all night assembling little packets of sugar and seeds and fragrance and color, because when it does so its evolutionary fitness is increased. When it is successful in enticing an animal such as me to disperse its fruit, its genes for making yumminess are passed on to ensuing generations with a higher frequency than those of the plant whose berries were

> inferior…what I mean is that our human relationship with strawberries is transformed by our choice of perspective…when we view the world this way, strawberries and humans alike are transformed. The relationship of gratitude and reciprocity thus developed can increase the evolutionary fitness of both plant and animal. (p. 29-30)

Can we come to understand mathematics as a living practice that needs actors and can respond to their needs? Are there already ways in which these concepts play into mathematics?

Kimmerer highlights how in the Thanksgiving Address, humans are reminded of the importance of balance and harmony, "We have been given the duty to live in balance and harmony with each other and all living things" (p. 107) and she asks the non-Native reader, "What would it be like to be raised on gratitude, to speak to the natural world as a member of the democracy of species, to raise a pledge of *inter*dependence?" (her emphasis, p. 112)

This is very similar to Cajete's notion of laws of interdependence. What might it look like to view mathematics (what it is, how we practice it, who is considered a mathematician, what knowledge we produce) as having a basis in interdependence? Kimmerer expands,

> Cultures of gratitude must also be cultures of reciprocity. Each person, human or no, is bound to every other in a reciprocal relationship. Just as all beings have a duty to me, I have a duty to them. If an animal gives its life to feed me, I am in turn bound to support its life. If I receive a stream's gift of pure water, then I am responsible for returning a gift in kind. An integral part of a human's education is to know those duties and how to perform them. (Kimmerer, p. 114)

If we keep in mind our duties to others, might we think about the forms of mathematics we are producing and practicing as well as how those forms impact other persons, not just ourselves or other humans?

In describing the relationship between beans, corn, and squash, referred to collectively as Las Tres Hermanas (the Three Sisters), Kimmerer highlights, for me, the particular way in which these sisters perform mathematics.

> The corn stands eight feet tall; rippling green ribbons of leaf curl away from the stem in every direction to catch the sun. No leaf sits directly over the next, so that each can gather light without shading the others. The bean twines around the corn stalk, weaving itself between the leaves of corn, never interfering with their work. In the spaces where corn leaves are not, buds appear on the vining bean and expand into outstretched leaves and clusters of fragrant flowers. The bean leaves droop and are held close to the stem of the corn. Spread around the feet of the corn and beans is a carpet of big broad squash leaves that intercept the light that falls among the pillars of corn. Their layered spacing uses the light, a gift from the sun, efficiently, with no waste. The organic symmetry of forms belongs together; the placement of every leaf, the harmony of shapes speak their message. Respect one another, support one another, bring your gift to the world and receive the gift of others, and there will be enough for all. (p. 131-132)

Phyllotaxis, the study of the ordered position of leaves on a stem, highlights the fact that many plants grow in ways that mirror "Fibonacci[vi]" numbers and the ratios of two consecutive numbers tend towards the golden ratio (Douady and Couder 1992). Interestingly, scientists who have studied Las Tres Hermanas have documented that when grown together, they out-produce what the plants would if cultivated individually (Mt. Pleasant 2006). That is, the corn makes light available; the squash reduces weeds; and the beans turn atmospheric nitrogen into mineral nitrogen fertilizer. Reciprocity is modeled in their relationship. This form of reciprocity is also present in research methods used by indigenous scholars and scholars of color (e.g., Dance, Gutiérrez, and Hermes 2010; Kovach 2009; Rigney 1999; Smith 1999).

Drawing upon ten years of teaching integrative science that acknowledges both Western science and Indigenous sciences, Hatcher et al., (2009) argue that knowledge is only passed on from one living being to another when a relationship between the two is formed and when the receiver is ready. In this sense, knowledge is a verb; teacher and learner both play constructive parts in it, highlighting the role of reciprocity. In fact, the Mi'kmaq word netukulimk means to "develop the skills and sense of responsibility required to become a protector of other species." While a Whitestream view might privilege the problem solving/utilitarian aspect of reciprocity, I see reciprocity (along with In Lak'ech) as related to experiencing connections and joy—knowing that one's actions are positively affecting oneself and others.

The overall point I am making is for us to live in harmony, without domination, as a form of metaphysics, and to continue to note the similarities and differences between our modes of being and those of other-than-human living beings. Recognizing other persons as having something to "teach" us is not to begin with a stance that other living beings are a means to our end, in order to better ourselves and our time on this planet or in our multiverse, though that can be a byproduct. Rather, this stance is simply reflective of a deep belief that we must show respect for others, a form of ethics, because in doing so, we are showing respect for ourselves, a frame of mind consistent with In Lak'ech.

Nepantla

Nepantla is the third concept upon which I draw. Nepantla is the Nahuatl (Aztec) term for the interstitial space between worlds. Gloria Anzaldúa explains,

> Nepantla can be seen in the dream state, as well as in transitions across borders of class, race, or sexual identity. Nepantla experiences involve not only learning how to access different kinds of knowledges—feelings, events in one's life, images in-between or alongside consensual reality. They also involve creating your own meaning or conocimientos[vii]. (Anzaldúa 2000; p.267)

In many ways, Nepantla serves as a space of tensions, of multiple realities. Anzaldúa highlights those tensions, explaining how as a lesbian Chicana poet, she is neither fully accepted by her White feminist colleagues who do not acknowledge her Indigeneity nor by the Chicano community who does not recognize her as a lesbian. She is neither and both at the same time; she is in Nepantla. The same could be said for people who identify as two-spirit, a translation of niizh manidoowag, the Anishinaabe (Ojibwe) term for spiritual people who walk in two worlds, one foot in female and one foot in male. In fact, Nepantla has been compared to the action of walking, whereby one is constantly in motion and where each step shifts the center of gravity so there is no solid grounding. Anzaldúa highlights this movement and potentiality,

> Nepantla, where the out boundaries of the mind's inner life meet the outer world of reality, is a zone of possibility. You experience reality as fluid, expanding and contracting. In Nepantla, you are exposed, open to other perspectives, more readily able to access knowledge derived from inner feelings, imaginal states, and outer events, and to "see through" them with a mindful, holistic awareness. (Anzaldúa and Keating 2002, p. 544).

For Anzaldúa, being able to see through human acts of identity, knowledge, and construction allows us to question when/if the actions of some violate the actions of others, thereby attending to issues of dehumanization.

It is not simply the "space" of Nepantla that is powerful, but the power of being a Nepantlerx[viii]-one who chooses to live in a place of tensions—as a border crosser, so as to birth new knowledge.

> For Nepantleras[ix], “to bridge is an act of will, an act of love, an attempt toward compassion and reconciliation, and a promise to be present with the pain of others without losing themselves to it.” (Anzaldúa and Keating 2002; p. 4)

Bridging between two different views requires deep intellectual and emotional work. It means being willing to hold two or more contradictory views in one’s mind at the same time with the goal of not quickly coming to a conclusion that subsumes both ideas under an umbrella but maintains some of those views and reaches a third space that is neither and both of those views. The idea of Nepantla is consistent with Aboriginal knowledge of the metaphoric mind where we have the ability to hold two completely different thoughts simultaneously (Cajete 2000).

Nahua metaphysics recognizes the shared collective consciousness of the cosmos. As such, a person is both *in* Nepantla and *is* Nepantla. That is, I am situated within a space of tensions and multiple realities that is called Nepantla. And, by virtue of being in that space, I am also the thing called Nepantla; I contribute to its essence. Therefore, Nepantla dictates how we move through the world. We are conscious of the multiple realities and energy in which we participate and to which we contribute as well.

Elsewhere, I have argued that Nepantla can help mathematics education researchers think differently about knowledge (Gutiérrez 2012) and provide a guiding principle for teacher education (Gutiérrez 2015). Here, I am suggesting that Nepantla can help us interrogate the idea that mathematics is both a universal endeavor and not a universal endeavor. That is, the practice of mathematics is not universal in the sense that it is always localized and particular to the needs of those who practice it (e.g., D’Ambrosio 2006; Ascher 2002; Gerdes 1997; Powell and Frankenstein 1997; Knijnik 2007; Restivo 2007). Yet, many of the forms that are practiced throughout the world have been identified as falling within six general forms: counting, locating, measuring, designing, playing, and explaining (Bishop 1988).

For Hatcher et al. (2009), this is two-eyed seeing, learning to see with one eye through Indigenous ways of knowing and the other eye on Western ways of knowing.

> The principles of Two-Eyed Seeing are used for the purposes of collateral learning or colearning where Western Scientific concepts are constructed side by side with minimal interference and interaction with Indigenous Scientific concepts (p. 149).

Unlike Hatcher’s goals, I choose to privilege the view of a Nepantlerx—seeing the interconnectedness between Indignenous and Whitestream knowledge of mathematics. I choose the term Whitestream instead of European American to highlight the role of global White supremacy in the enterprise of mathematics education. Like Hatcher et al., Ogawa (1995) advocates for a kind of multi-science teaching, seeing from multiple views. Aikenhead (2017) echoes this focus on seeing more than one reality, saying,

> Indigenous cultures, for instance, generally share presuppositions characterized as value-laden, contextualized, cultural, ideological, mostly subjective, and embracing multiple truths. (p. 29)

In embracing these multiple truths, he suggests that students need to learn to be “cultural border crossers” (Aikenhead 1997), reminiscent of Anzaldúa’s Nepantleras.

I choose to talk about knowledge from the point of view of a Nepantlerx because it highlights metaphysics and the choice for persons to stay in tensions rather than choosing one view over the other. A critical theorist might suggest an omnipotent perspective from above, a single version of mathematics that would be necessarily less oppressive and best at addressing ethics. In contrast, a post-structural view might suggest a relativist position where there is no one truth and all possibilities are viable for addressing ethics. For me, neither of these options is productive, as each requires a form of collapsing under one umbrella. From the view of a Nepantlerx, one is always trying to find ways of staying in the tensions long enough to birth new knowledge. The value of Nepantla is reminding us to seek multiple realities and to hold those in view because they help us generate new knowledge.

Embracing Nepantla would mean allowing these differing views to remain separate but in relation. Anzaldúa refers to this state of interdependence and solidarity as nos/otras,[x] meaning us/them intertwined. [See Gutiérrez (2012) for an explanation of nos/otr@s as it relates to mathematics education.] Like Nepantla, mathematics is always in motion and embodying principles that could be considered contradictory. Mathematically, the relationship between abstraction and contextualization is an example, as the definition of each relies upon the other.

Mathematx

Combining the views of In Lak'ech, reciprocity, and Nepantla allows us to raise new questions about a vision of practicing mathematics that might move past previous notions of Western versus other mathematics, past an idea of mathematics as either oppressing or liberating, beyond a mathematics that is either discovered or invented, towards an idea that allows us to deal with today's complexity and uncertainties. Towards that end, I am calling for a radical reimagination of mathematics, a version that embraces the body, emotions, and harmony.

Seeking/Performing Patterns for Problem Solving and Joy

Mathematx is a way of seeking, acknowledging, and creating patterns for the purpose of solving problems (e.g., survival) and experiencing joy. Beginning with the principles of recognizing self and/in others, responsibility towards others, and valuing tensions, several things stand out as different from the typical way Western mathematics is conducted or experienced by students in school. First, although some mathematicians experience pleasure as a result of solving previously unsolved problems, that aspect of joy is often a very small percentage of the time and almost always absent from the "mathematical product" (e.g., new theorem, new proof) that is valued by the community. Yet, mathematics education researchers who study aesthetics highlight this domain as essential to human meaning making and to the insights that mathematicians develop (Sinclair 2009).

Aesthetics join emotion, pleasure, and understanding for humans as they relate to their world (Dewey 1934). For mathematicians, aesthetics may serve as a precursor for intuition, whereby they do not rely upon a sense of logic and deduction but upon some general sense of how things connect together (Burton 1999), often illuminating a unity of meanings and values. In this sense, intuition and wonder may lead to joy and discovery (Sinclair and Watson 2001). That is, we seek what is surprising and wonderful, yet events must fit into a broader scheme; the parts must fit with the whole (Gadanidis and Borba 2008). In fact, because humans have had to discern patterns in their world in order to survive, we may be predisposed to attend to just "enough complexity to engage the mind but…not overwhelm it with incomprehensible irregularity or diversity" (Sinclair 2009, p. 52). Although much of this intuitive/aesthetic work remains at the subconscious level for many mathematicians, mathematx is intricately tied to what is pleasing and rewarding in a connected way, not just a utilitarian or "problem solving" manner. This perspective is consistent with Boylan's (2016) call for putting passion and pleasure at the heart of mathematics education. For me, "pleasing" includes not just the playful way in which many "pure[xi]" mathematicians invent new workspaces by beginning with different axioms, (e.g., 8-dimensional space) but also how other persons perform mathematx for/with us. This version of play deviates from Bishop's definition surrounding games because play does not necessarily involve an organized game, but includes a kind of frivolous activity with value perhaps only for the one performing it.

Like plants, humans also have a way of expressing ourselves (our tastes, our values) and our sense of beauty through patterns (e.g., braiding hair, creating symmetry in our surroundings, walking, dancing, speaking, dressing, creating balance in a home). These patterns are both playful (useless) and purposeful (useful) at the same time because they have the potential to connect us with others. Reviewing the work of Dissanayake, Sinclair (2009) highlights that this form of expressing ourselves through aesthetics helps indicate that we are special. In terms of patterns, it might not be just regularity that matters for persons. Biologists have noted that the ability to embody opposites (Nepantla) is consistent with living systems that show simultaneous stability and plasticity, incomplete separation between internal and external topology, prolonged stages of criticality, and the co-existence of future and past (Soto et al. 2016; Longo and Montévil 2011; Montévil et al. 2016). Again, broadening our definitions of living beings may yield insights for mathematicians who seek to discern, appreciate, and reciprocate patterns.

Current versions of what count as "beautiful" in mathematics tend not to reflect the diversity in our world. Instead, they tend to relate to truth (Stewart 2007), implying universals rather than uniqueness/expression that would align with performance or a plurality of epistemologies. If we can recognize that cultural theses of modes of living are aesthetic choices (Popkewitz 2002; 2008) and some aesthetics are not superior to others, then the means for controlling or dominating is lessened. The opportunity to appreciate another's values is the embodiment of In Lak'ech. In other words, approaching life in this way of appreciating and looking for similarity is what helps us grow and also recognize difference. Ethics and aesthetics join in mathematics when we have guiding principles like In Lak'ech, reciprocity, and Nepantla.

Intervention in Reality

Second, whereas mathematics tends to be thought of as a noun (e.g., a body of knowledge, a science of patterns, a universal language), mathematx is performance and, therefore, a verb. Just as identity is not something that you are, but rather something you do (Butler 1999), mathematx emphasizes the guiding principles and the process as opposed to the product. Drawing upon the concept of reciprocity, mathematx is an intervention-in-reality (action) as opposed to a representation-in-reality (explanation) (Santos 2007). The starting point for Western mathematicians would be to begin with embracing the joy/emotions and seeking In Lak'ech, reciprocity, and looking for opportunities to be a Nepantlerx while doing mathematics. Let us consider an example. A common theme in combinatorics is to start with an object P, and define some sort of counting function to P, which makes sense for taking in positive values because it results in a polynomial. Then, negative values are substituted into the counting function and it is recognized as a new counting function for a different/new mathematical object. For mathematicians, this work is known as combinatorial reciprocity (Meléndez 2017). In fact, Beck and Sanyal (2017) ascribe animacy to the process by referring to it as moving from "your world" to "my world." The new counting function has offered something that the original counting function could not. Is the mathematician grateful for the offering of this new counting function? Is there some joy in noting that functions can give back to each other? How might that starting point extend to other forms of reciprocity in doing mathematics with other persons?

The idea of mathematx as verb is consistent with many Aboriginal languages that are largely verb-based and may relate to how persons practice mathematics (Lunney Borden 2011). Mathematx is an activity that cannot be extracted from the living being(s) in the process of solving problems and/or experiencing joy--the mathematxn. Although ethnomathematics tends to take into consideration the idea that different cultures do different mathematics, the unit of analysis normally remains at the level of the group and what they have produced, possibly promoting the unintended message that all members of that culture do the same things for the same purposes. Mathematx acknowledges this group relation, but recognizes the meaning that each person ascribes to what is being experienced.

The x at the end of the word signifies movement, an openness, the x being a variable that could be represented by anything. In this sense, mathematx is constantly evolving, depending upon what is represented with that x. This framing is consistent with the choice to use "x" as an ending (e.g., Latinx) to represent any gender performance instead of privileging a patriarchal view or ascribing to a binary of male/female.

I choose mathematx instead of mathematix in order to distinguish between the two when spoken aloud. In Nahuatl, the "x" is pronounced "sh." So, the word is pronounced mathematesh. The x is also political in the sense of Malcolm X, the human rights activist who took on the x to represent all of the unnamed ancestors and their cultures that had been lost through slavery. For me, mathematx is a political statement about reclaiming the persons who have been lost when humans remain at the center. As such, mathematx seeks to intervene in the status quo of mathematics.

Living Mathematics

The title of this article suggests a vision of living mathematx. What might it mean to live mathematx? Living mathematx means both that we live a version of mathematx as well as we are a living version of mathematx. This framing is consistent with Nahua metaphysics that suggests one is both <u>in</u> Nepantla and one <u>is</u> Nepantla. Living mathematx means moving through the world with other living beings, acknowledging, appreciating, and reciprocating the patterns produced. If we look to animals and plants for some insight, we see that Brassica oleracea (Romanesco cauliflower) performs itself in both utilitarian (compact) and non-utilitarian (pleasing) ways that may get us to pay attention to its form and to continue to cultivate it. On the one hand, Romanesco cauliflower performs a version of the "Fibonacci" sequence that maps onto Western mathematics, and the elegance of the pattern brings joy while at the same time solves problems of space. Yet, like all persons, every brassica oleracea, performs itself in a way, and over its lifetime, that shows variance and suggests a departure from a pre-determined set of possible outcomes programmed by genomes (Montévil et al. 2016). We might ask ourselves, why is a grove of trees, each with similar but not perfect versions of fractals more pleasing than a computer-generated version of a grove of trees that precisely follows expanding symmetry? Is there something more in our relation that triggers a sense of pleasure, appreciating the aesthetics that plants perform? Are we able to discern and appreciate asymmetry along with symmetry? And, in what way(s) might this relate to aesthetics, intuition, or insight? Are there patterns in the ways in which our pleasure is communicated back to plants, for example, through pheromones or other means we are not yet able to understand or describe?

Do other persons remind us of the importance of beauty in imperfection, of not relying upon a defined algorithm? That is, although they offer good approximations of such things as shorelines of oceans, fractals in Western mathematics do not map perfectly onto the universe around us. Moreover, not all symmetry is inherently beautiful or "natural." Marcelo Gleiser refers to this phenomenon as the aesthetics of the imperfect. He notes that while synthesizing amino acids in a laboratory setting, biologists achieve approximately 50 percent right-handed chiral[xii] formations and 50 percent left-handed formations. Yet, in living creatures, virtually all amino acids are left-handed. This asymmetry is critical for protein folding and reproduction. The same is true for the asymmetry of occurrence in matter and anti-matter in physics[xiii]. So, asymmetry, not just symmetry, may be a form of performance by living beings to which we need to pay greater attention. Perhaps this asymmetry has aspects of a pattern that are complex enough without being overwhelming to initiate surprise or wonder.

Can our older brothers and sisters in this universe (and others) teach us something based on how they have developed and organized themselves to relate with each other to please and solve problems? From a practical point of view, are there ways in which we can organize our living spaces to draw upon visions such as the Three Sisters and other geometric formations that our older brothers and sisters use? In some respects this idea of learning from our older brothers and sisters is not new. Researchers have begun to rely upon biomimicry, copying the forms observed in "nature," in order to solve complex problems of space, design, and efficiency. For example, termites have taught architects in Harare, Zimbabwe, how to erect buildings with patterns that create effective internal climate control systems; Kingfisher birds have taught engineers how to construct high speed trains that will move through the air with less noise; plants and insects are teaching aerospace engineers about miori folds in order to tightly package and then deploy enormous complex origami versions of sun shades to block the light and allow telescopes to take more accurate pictures; similar folds in the universe are helping physicists understand neighboring galaxies. However, all of this biomimicry is taking place in research labs, not in schools with students. We are missing an opportunity to expose students to plants, animals, and other persons as our teachers, and perhaps also our opportunity to reciprocate actions.

In terms of recognizing and performing patterns—living mathematx—marine creatures such as salmon, sea turtles, trout, and eels have the ability to read magnetic fields in the earth and use them in migration (Pennisi 2017). Animals such as bears, dear, elk, great apes, macaws, lizards, and fruit flies are able to read (communicate with) plants in order to self-medicate when they have diseases (Shurkin 2014) or develop high levels of toxins in their skin and use other chemical signals to communicate and ward off predators (Hagelin and Jones 2007). Several tree species such as oak, spruce, and beech are known to communicate among themselves and with each other in order to ward off disease, share resources, and protect each other (Wohlleben, 2016). Like Las Tres Hermanas (corn, beans, squash) mentioned earlier, many of our cousins seem to recognize/acknowledge patterns and create new ones while collaborating and valuing reciprocity. To date, many researchers rely upon Bishop's (1988) classification of six forms of mathematics: counting, locating, measuring, designing, playing, and explaining. I urge us to consider what forms of classification might we develop in looking to other-than-human persons and the ways in which they live mathematx in their local contexts? Which new forms of mathematics might arise?

From a philosophical perspective, perhaps it is neither that we have come to appreciate the "natural" patterns present in plants, animals, and rocks, as Platonists would have us believe (i.e., that they have taught us patterns that were programmed within them or that they developed), nor that we simply project our own aesthetics onto our living cousins (i.e., that we see the mathematics we want to see in our environment) as Realists would have us believe. More likely, our relations and the tensions between us provide the multiple lenses on reality and instability. We are constantly in motion like a Nepantlerx. This is consistent, though different, from Barad's (2001) notion of "intra-action." If, instead of perpetuating a human/non-human binary, we consider the shared consciousness between all living beings, the greater unity to which we belong, we are more likely to value mathematx for what it offers us. We can acknowledge both the potential for domination between living beings while also opening up the possibility of harmony and reciprocity in the practice of mathematics.

As we look for new structures and forms of mathematics to help solve the global crises we encounter as well as to experience joy, we might consider how other living beings might offer lessons and insights. We have developed new structures and physics concepts by studying intently such things as symmetry and conservation laws in the physical world. Even using a narrow definition of living beings, biologists have noted that all organisms (uni-cellular or multicellular) do not simply follow prescribed rules or programming. They develop their own norms/rules in a way that balance between plasticity and robustness; that is, they show spontaneous organization and variance that does not appear in physics (Soto et al. 2016). If we broaden our understanding of living beings beyond the organism, we might find even further insights.

Reflecting an Ecology of Knowledges

Building upon Andreotti, Ahenakew, and Cooper's epistemic plurality (2011) and Santos' (2007) call for a new ecology of knowledges, I suggest that mathematx guide our work in mathematics. Because mathematx acknowledges that all persons will seek, acknowledge, and create patterns differently in order to solve problems and experience joy, multiple knowledges are valued and sought. These multiple knowledges are important, given that all knowledge is partial and each offers us a different angle and understanding on the world. The goal is not to work towards a summative understanding, as if by simply adding the different knowledges we will have a complete or perfect view. Rather, our work is to locate ourselves in others and others in us, as we attempt to understand our world through patterns. Doing mathematics in this way offers us the opportunity to unlearn our epistemological arrogance. The concept of reciprocity draws upon complementarity in recognizing that different knowledges contribute something others do not. Mathematx nurtures a view of mathematics that always considers strengths and limitations for particular purposes. For example, we might ask ourselves: which forms of mathematics can our brothers/sisters perform for which we do not have a way to express? In looking to other persons, might we be more open to multiple versions of knowing that are constantly open to new axioms and even non-axiomatic mathematics?

While others have noted that Western mathematics—sometimes referred to as Platonist mathematics or European mathematics or European American mathematics—is in opposition to Indigenous mathematics, I am not seeing that mathematx would be in opposition; rather it would include Aboriginal mathematizing. In the same way that Latinx rejects the gender binary, mathematx rejects the epistemological binary. Mathematx allows for a variety of expressions without suggesting one is "normal," superior, or the reference point for erasing other epistemologies. However, mathematx is not everything and anything. It privileges a particular way of moving through the world that acknowledges and produces patterns that align with the collective consciousness and energy of the cosmos and respects other persons. Mathematx is less a way to describe how we currently do mathematics and more a goal for how to approach our relations with each other in the practice of mathematics. In this sense, mathematx is a quest for intersubjectivity and systems thinking, not unity.

Moreover, mathematx acknowledges Nepantla by underscoring the fact that there is no absolute universalism or absolute relativism. That is, there is no umbrella term under which all forms of mathematics can collapse and explain everything in reality. When we move from a global universal mathematics to a form of mathematx, whereby we acknowledge epistemological pluralism and are guided by first principles of In Lak'ech, reciprocity, and Nepantla, we are likely to see changes in not only mathematical activity (and products) but also in mathematxns.

Philosophers, sociologists, and anthropologists who study mathematics have long argued that "school mathematics" is but one small version of the many forms of mathematics practiced in the world and that such mathematics does not operate outside of individuals, morals, or politics (Brown 1994; Clarke 2001; Ernest 1994, 2000; Fitzsimons 2002; Restivo 1994; 2007; Turnbull 2000; Verran 2001). Often, in making these claims, researchers point to the field of ethnomathematics to highlight the fact that all cultures do mathematics in localized ways. In some respects, I am arguing for an extension of ethnomathematics to include animals, plants, rocks, bodies of water, and other persons. Mathematx is consistent with a focus on peace, education as relation, a recognition of the imprint of Western thought in dominant mathematics, and a language through which people could be more creative (D'Ambrosio 2007; Francois and Van Kerkhove 2010; Gerdes 1988; Powell and Frankenstein 1997). Even so, I choose mathematx as opposed to "ethnomathematics with the inclusion of other-than-human persons" because I aim to avoid some of the pitfalls of previous understandings and implementations of ethnomathematics (Cimen 2014; doCarmite and Pais 2009; Vithal and Skovsmose 1997). For example, I am not looking to use Western mathematics or a Platonist view as the standard by which we judge other persons to live mathematx or to suggest a kind of essentialization of humans (Gutiérrez 2000; Francois and Van Kerkhove 2010). Moreover, I do not wish for the knowledge of our older brothers and sisters to simply be acknowledged/sanctioned and shared (Mesquita and Restivo 2013); I want such knowledge to be valued and applied. Although D'Ambrosio broadened his definition of "ethno" to include "all culturally identifiable groups with their jargons, codes, symbols, myths, and even specific ways of reasoning and inferring" (p. 17, cited in Francois and Van Kerkhove), people have continued to think about ethnomathematics as practiced by ancient ethnic (non-Western or non-White) cultures[xiv] or collapsed it into a form of cultural appropriation. By introducing mathematx, I also seek to decenter the notion of "tics" (technologies), which, for me, do not capture the body/spirit (feminine) and the ways we move through the world in the same metaphysical manner (Haraway 1988; Harding 2008). Mathematx is more than explaining and understanding in order to survive (D'Ambrosio 1990); it attends to aesthetics and the body.

Implications for Teaching and Learning

Elsewhere, I have argued that the practice of school mathematics in the US regulates the child by privileging: algebra/calculus over geometry/topology/spatial reasoning; rule following over rule breaking; Western mathematics (culture free) over ethnomathematics (recognizing that even academic mathematicians are a culture); the "standard algorithm" over invented or international algorithms; abstraction over context ("just pretend this is real world"); mind over body; logic over intuition; and encouraging students to "critique the reasoning of others" over appreciating their reasoning (Gutiérrez, in preparation). Not only can these repeated practices over a lifetime serve to dehumanize students and teachers in classrooms, the narrative about mathematics being a pure discipline, reflective of the natural world around us, universal, with an almost unilaterally positive relationship to society's advancement, leaves many humans unable to challenge this narrative to consider other ways of doing mathematics. In this way, school mathematics comes to normalize and valorize particular practices and to make others seem deviant and in need of fixing (Skovsmose 1994; Walkerdine 1994). By continuing to privilege data analysis and probability over other kinds of spatial patterning, even if that data analysis concerns itself with issues such as climate change, we run the risk of limiting new ways of doing mathematics and our relationships to the practice.

In contrast, what might teaching and learning look life if mathematx were embraced? First, students need time to relate with other-than-human persons in order to develop a familiarity with the kinds of patterns that exist outside of themselves—things that are both another version of us and yet not exactly us—so they can provide mirrors onto ourselves and windows onto another's world. Rather than education happening within school walls, students might be asked to head outdoors. In lieu of a purely dominant mathematics curriculum (Gutiérrez 2002), students might be asked to investigate: How do we acknowledge, understand, and relate to the patterns in bird song? What are the patterns/signs/codes that allow some animals to relate to their plant relatives for the purpose of self-medication? What are some of the patterns that occur as insects package their wings and bodies? And, in what way(s) might those forms solve problems and bring joy? How do those packages of wings and bodies relate to other packages in humans, in other species, in the imagination? Where does the search for patterns fail to capture other meanings in these practices? These are all questions for which most teachers will not have answers. Therefore, different from the portrayal of the math teacher as the credentialed professional who has acquired the "knowledge base" and who is inserted into the child's life in a coercive relationship whose success is conditional upon pre-set performance measures and criteria, living mathematx would involve the passing of knowledge only when the knowledge receiver is ready and a relationship is formed between giver and receiver, as suggested earlier by Hatcher et al. (2009).

In some respects, seeking to understand how we and our older brothers and sisters live mathematx can serve as both a problem solving exercise (in mental manipulation, spatial reasoning, and other things that might map easily onto current forms of humans doing mathematics), but it is also likely to deviate from the language we have to understand or describe. In this way, students will be learning how to be open to other forms of being and for recognizing the tools necessary for reading and responding (reciprocity) to those forms and also being fully present in the beauty of such performances. Such an education would shift the dynamics from an objectifying description and problem-solving manner towards one that includes joy, respect for the person, and the desire to act (reciprocate) in a way that is responsive to the particular situation at hand, thereby changing the individual learner in the process. In the same way that we might see traditional mathematics classrooms move away from students being taught to "critique" the reasoning of other students, as is called for in the Common Core State Standards in Mathematics (National Governors' Association 2010) towards what I refer to as "appreciating" the reasoning of other students (i.e., being able to stand in their shoes), we might see that process occur across all persons.

Some researchers have started to bridge the gap between aesthetics and mathematics through the online game *Fold It* where players find pleasure in folding proteins in compact ways and earn game points (Cooper et al. 2010). The players' unique folds are analyzed by researchers who then apply puzzle solutions to real world problems in the medical industry. In fact, this form of crowd sourcing has developed insights and answers to problems concerning the AIDS epidemic that researchers and computer-generated approaches alone had failed to solve. Researchers involved in the project are studying the intuition of players and how they approach the folding process in order to improve algorithms generated by computers. This form of pleasure and "learning" occurs outside of the school walls. However, combining versions of exploring the world to relate with other persons and then playing such games may help us identify certain trends that would have been difficult using our eyes alone. That is, there may be ways in which relating with plants, animals, rocks, or other persons inspire us to develop intuition in approaching the visual display of computer-generated objects that can be both pleasing for us as well as build upon the mathematx that other persons live in order to generate biomedical solutions to health problems.

Learning through mathematx accedes that all knowledge is based on particular worldviews and ways of knowing that close down other possible choices; that is, knowledge is a political process, not a neutral product. Rather than mathematics being seen as the pursuit of truth in the sense of a unifying theory of reality (e.g., the unique solution to string theory) and, therefore, the means to control, learners embracing mathematx might come to see that the mathematics performed by humans is but one form that describes part of our world, but not all. Through living mathematx, teachers and students would practice walking alongside of other living beings, revising their understandings based upon their relations with them. In this sense, students would have opportunities to unlearn their epistemological arrogance. Teachers would focus upon helping create opportunities for learners to engage in an aesthetic experience—seeking surprise both in how similar something is, but also how it differs—to wonder about how other living beings seek, acknowledge, and perform patterns for their own survival and joy. Teachers might also encourage students to search for patterns that are felt/experienced (at the macro level), not just conceptually identified (at the micro level). What are the aesthetic preferences that help us define and understand the concept of pattern? Through mathematx, learners are likely to become more reflective about their learning and their relations in the world—what they know, what they do not know, as opposed to what can be known.

Because mathematx involves the Nepantla state of both/neither when discussing problem solving and joy, learners will need to become comfortable with such uncertainty. In other words, they will come to know and practice mathematics as neither purely problem solving, nor as purely joy, but also not both in a cumulative sense. Learning mathematics in this way means being able to, at times, acknowledge one side over the other, but always seeing the two in relation.

Teachers' roles would necessarily shift from telling/showing and towards living alongside of students and other persons. Teachers should be asking themselves, "Am I conducting mathematical activity with an eye towards reciprocity, Nepantla, In Lak'ech? Am I doing mathematics to see myself in others and others in myself, to give and to receive from my universe, to acknowledge multiple ways of knowing and multiple kinds of knowers?" Students would be learning to move through the world, appreciating, noting the forms, packages, and connections that plants, animals, rocks and other persons develop. In a sense, we are apprenticing learners to become "mathematxns" by providing guiding principles—In Lak'ech, Nepantla, and reciprocity. We are preparing them to look for what we already acknowledge/sanction as some humans doing mathematics with how other persons (human and other-than-human) live mathematx. In doing so, we must recognize that ignorance might not just be a lack of knowledge but an active refusal to know because it disrupts one's previous beliefs. If we start early with young learners, it may be easier to disrupt what humans have come to consider normal in the practice of mathematics. That is, like learning a new language, young students often are able to absorb new ideas and new ways of gaining knowledge.

Mathematx is not a rival body of formal knowledge to mathematics. Rather, mathematx is a worldview that surrounds and guides whatever it is that we are trying to accomplish mathematically. However, because of the performativity of mathematx, this new approach is likely to produce new structures and forms that academic mathematicians might acknowledge as new mathematics. Indigenous epistemologies value context and relationships, recognizing that our strength comes from understanding ourselves not with universal principles but in relation to particular lands and particular living beings. One could argue that the individual cannot be extracted from its environment and understood in any meaningful way. Biologists would agree, suggesting that because biological systems operate under different theoretical principles, a focus on living beings is likely to require different forms of mathematical modeling (Montévil, 2017). For example, breaking something down into its parts in order for study does not necessarily lead to anything meaningful about the results of a model when inserted back into its context. We saw this was the case with synthesized amino acids versus ones occurring in nature. So, our definition of a "useful mathematical model" may need to be reexamined when we include all living beings as performers of mathematx, including ones that would not be classified as organisms.

I am not suggesting that humans have gotten it all wrong and that by turning to other-than-human persons, we will get it right. My goal is not to get closer to some absolute truth about our world. Rather, learning with other persons opens the door for us to have different lenses for viewing and relating with our universe and others. And, in doing so, we have the opportunity to learn how different approaches (mathematics or mathematx) make im/possible certain forms of knowing the world, recognizing that all of these forms are provisional, local, and legitimate. Even so, given the history of particular knowledges, knowers, and ways of knowing that have dominated in our history with respect to mathematics, it is important to give greater focus to the ways other-than-human persons live mathematx.

I recognize the potential limitations of attempting to use a term like mathematx that is difficult to both say and spell, even if one understands conceptually what it can offer. The term ethnomathematics, even when being explicit that all cultural forms of mathematics are "ethno" has not prevented many researchers and teachers from continuing to use Western mathematics *in opposition to*, instead of *as a version of* ethnomathematics. That is, neither do we tend to refer to Western mathematics as such nor do we refer to other mathematics as Eastern, Mexican, Northern, or American. Ethnomathematics seems to encourage researchers and teachers to create a binary between Western and Indigenous, rather than recognizing a variety of forms, some with overlapping goals and principles. Moreover, ethnomathematics also has not been well incorporated into the school mathematics curriculum. So, some might wonder, what is to prevent the same phenomena with mathematx?

To avoid these potential pitfalls, I have suggested we expand our view to all living beings, thereby providing us with the ability to consider how some humans live mathematx differently from each other as well as from other persons, creating new lines of solidarity (In Lak'ech) or difference (and the need for reciprocity), or contradiction/tension (Nepantla). By expanding to other living beings, mathematx can avoid the trap of Western versus "other" mathematics and open the door for new categories to be drawn. For example, in what ways do humans live mathematx that are consistent or compatible with how trees live mathematx? And, how are individual humans affected by considering trees to be simultaneously another version of us (In Lak'ech) and not a version of us (Nepantla), but in need of our reciprocity? In what ways are we incompatible? What are the new knowledges and sensibilities we need to fully develop to live in harmony? Moreover, because mathematx is not a description of the world, but rather a set of first principles in doing mathematics, it differs from ethnomathematics in that it sets out a form of intervention.

Although the vision of living mathematx that I have outlined may sound outlandish, we need only remember Clarke's (1973) third law: "Any sufficiently advanced technology is indistinguishable from magic." In fact, I argue that mathematics as a field and as a human endeavor need only look to other sciences to see it is late to evolve. The field of physics used to promote the idea that there was a single time-space continuum. Then, Brian Greene (2011) introduced the concept of infinite parallel universes and physicists are now imagining how humans could participate in more than one space at one time. Moreover, the cosmologist Alexander Vilenkin has proposed a theory of our universe sitting within a bubble of other universes (Vilenkin and Tegmark 2016), the implication being that other universes may have different laws of physics. In a similar vein, I am suggesting that we may have different forms of mathematx in which we participate, but to which we are largely blind and numb. When we move [1]through the world seeking connections and reciprocity, our views of ourselves and of others change. I ask us to open our minds to envision how such a view could change the relationship between humans, mathematics, and this universe with/in which we currently live.

Endnotes

[i] I am grateful to Federico Ardila-Mantilla, Kimberly Seashore, Andrés Vindas Meléndez, and Diana Zambrano at San Francisco State University; and Brandon Singleton at the University of Georgia for providing helpful comments on an earlier version of this article.

[ii] I cite this article as 2010/2013 because it was published online through JRME in 2010 and some researchers began citing it as such then. It was not released in print until 2013, and some researchers have cited it as such since. Because the focus of the article is on a particular point in history, the work should reflect the earlier date.

[iii] My maternal grandmother was a woman of Rarámuri (Tarahumara) descent. My ancestors are located in the Copper Canyon region of Northwestern México.

[iv] Two-spirit is an Aboriginal term.

[v] I use Indigenous and Aboriginal interchangeably. US authors tend to use the term Indigenous, whereas authors from Canada, Australia, and New Zealand tend to use the term Aboriginal. In Canada, Aboriginal includes First Nations, Métis, and Inuit peoples.

[vi] I place Fibonacci in quotes to highlight the presence of settler colonialism. That is, although the Italian Leonardo Pisano (Fibonacci) receives credit for the pattern, many cultures and persons throughout the world, including Pingala in 200BC in India, had already known/performed the same pattern many years earlier. In fact, if humans are no longer the center, we might credit nautilus

pompilius (Nautilus shell), pinus coulteri (pinecone), or helianthus annus (sunflower) with the "discovery."

[vii] Conocimientos translates to "knowledges" in English.

[viii] Similar to the use of Chicanx, Nepantlerx indicates solidarity with people who identify as LGBTQIA2S. In the Spanish language, the –ero/-era ending of a word typically signifies "one who…" As such, a Nepantlerx is one who chooses to reside in Nepantla.

[ix] Anzaldúa's terms do not reflect the "x" because she was writing before such language was common. She used a version that privileges a feminist perspective and therefore ends in "a" instead of "o."

[x] Anzaldúa's terms do not reflect the "x" because she was writing before such language was common. She used a version that privileges a feminist perspective and therefore ends in "a."

[xi] I place pure in quotations to suggest that there is no such purity to mathematics. When we use terms like pure mathematics or fundamental mathematics, we are "othering" different forms of mathematics in ways that make them sound primitive or deviant. An Aboriginal stance would call into question whether any form of mathematics could be seen as pure, as it will always have a purpose and a grounding—cultural context—to start.

[xii] Chirality refers to the geometric structure of a molecule, in particular how four different entities connect to a carbon center. Like hands, chiral molecules cannot be superposed onto their mirror image.

[xiii] See, for example, Paul Dirac's prediction of anti-matter that contradicted classical quantum physics where systems were thought to only have positive energy.

[xiv] Noted exceptions include the work of Gelsa Knijnik (2011), who has chronicled the Peoples Land Movement in Brazil.

PSYCHOLOGY IN MATHEMATICS EDUCATION: PAST, PRESENT, AND FUTURE

Leslie P. Steffe
University of Georgia
lsteffe@uga.com

Starting with Woodworth and Thorndike's classical experiment published in 1901, major periods in mathematics education throughout 20th century and on into the current century are reviewed in terms of competing epistemological and psychological paradigms that were operating within as well as across the major periods. The periods were marked by attempts to make changes in school mathematics by adherents of the dominant paradigm. Regardless of what paradigm was dominant, the attempts essentially led to major disappointments or failures. What has been common across these attempts is the practice of basing mathematics curricula for children on the first-order mathematical knowledge of adults. I argue that rather than repeat such attempts to make wholesale changes, what is needed is to construct mathematics curricula for children that is based on the mathematics of children. Toward that end, I present several crucial radical constructivist research programs.

Keywords: Learning Trajectories, Research Methods, Cognition, Curriculum

> The accent must be on auto-regulation, on active assimilation – the accent must be on the activity of the subject. Failing this there is no possible didactic or pedagogy which significantly transforms the subject (Piaget, J., 1964).

Mathematics Education—1900-1950

Behaviorism and Faculty Psychology

The classical experiment. The classical experiment by Woodworth & Thorndike (1901) at the beginning of the 20th Century introduced the "scientific movement" in education and it was considered as the death knell of faculty psychology, the doctrine of "mental discipline" (e.g., Whipple, 1930; Thorndike, 1922). In faculty psychology, the mind was viewed as a collection of separate modules or faculties assigned to various mental tasks, such as reason, will, concentration, memory, or language and it was thought that training in one faculty would transfer to another. As a result of their experiment, Woodworth & Thorndike (1901) concluded that, "The improvement in any single mental function rarely brings about equal improvement in any other function, no matter how similar, for the working of every mental function-group is conditioned by the nature of the data in each particular case" (p. 250). The lack of transfer led Thorndike (1903) to develop his theory of identical elements: "The answer which I shall try to defend is that a change in one function alters any other only in so far as the two functions have as factors identical elements" (pp. 80-81). Once this idea was accepted, "arithmetic was on its way to being analyzed into elements so that the stimulus-response theories of Thorndike could be more readily applied" (Van Engen & Gibb, 1956, p. 1).

Cartesian epistemology. There was also a separation or duality between the mind and the body in faculty psychology in that it was thought that mental discipline of the intellect would lead to control of the will and emotions, a duality that has become known as "Descartes error" (Damasio, 1994, pp. 248)—"I think, therefore I am." It is interesting to me that this philosophical rationalism of faculty psychology was regarded as falsified by means of a "crucial experiment" that was conducted in the context of a competing paradigm, empiricism.[i] Although I don't wish to defend faculty psychology, in retrospect I believe that a basic reason why faculty psychology was abandoned transcended Woodworth and Thorndike's classic experiment. In empiricism, the doctrine that the world imprints itself on the mind, there is a duality that is similar to the mind-body duality between an endogenic (mind centered) view versus an exogenic (world centered) view (Konold & Johnson, 1991). This mind-reality duality in the main explains why faculty psychology was rejected and why empiricism was so widely embraced. In behaviorism, no explanation of mind was needed nor was it sought so there was already a major conflict in the two views of mind in faculty psychology and in the behaviorism of Woodworth and Thorndike[ii]. That is, there was already a paradigmatic rejection of faculty psychology by the empiricists and the classical experiment corroborated the philosophical rejection. Furthermore, in empiricism, something is true, "only if it corresponds to an independent, 'objective' reality" (von Glasersfeld, 1984. p. 20). So, the idea that the functioning of one faculty would be transferred to the functioning in another faculty would have to be validated by such functioning in objective reality, which is the crux of the classical experiment.

Behaviorism and Progressive Education

Progressive education. Although faculty psychology was abandoned as a psychological rationale in education, there was a competing paradigm to the scientific movement during the period of time that was known as Progressive Education. Under the leadership of John Dewey, the Progressive Educational Association was formed in 1919 and it served as a counterpoint to the scientific movement. Progressive Education promoted the idea of a child-centered education as well as other aspects of education.[iii] As early as 1902 John Dewey wrote;

> Abandon the notion of subject matter as something fixed and ready-made in itself, outside of the child's experience; cease thinking of the child's experience as also something as hard and fast; see it as something fluent, embryonic, vital; and we realize that the child and the curriculum are simply two limits which define a single process. Just as two points define a straight line, so the present standpoint of the child and the facts and truths of studies define instruction. (Dewey, 1902, p. 11)

This quotation might be interpreted as Dewey introducing a duality between the child and the subject matter. Dewey's (1902) distinction here is the subject matter as known by the scientist and the subject matter as known by the teacher.

> Every subject thus has two aspects: one for the scientist as a scientist; the other for the teacher as a teacher. These two aspects are in no sense opposed or conflicting. But neither are they immediately identical. (p. 22)

For Dewey (1902), subject matter for scientists represented a given body of truths, whereas for the teacher,

> He is concerned not with the subject matter as such, but with the subject matter as a related factor in a total and growing experience. Thus to see it is to psychologize it. (p. 23)

Two concepts of number. Dewey's emphasis on psychologizing subject matter was quite different than that of the behaviorists. The difference is well illustrated in how Dewey and Thorndike regarded number. For McLellan & Dewey (1895),

> Number is not a property of the objects which can be realized through the mere use of the senses, or impressed upon the mind by so-called external energies or attributes…In the simple recognition, for example, of three things as three the following intellectual operations are involved: *The recognition of the three objects as forming one connected whole or group*—that is, there must be a recognition of the *three* things as individuals, and of the *one*, the unity, the whole, made up of the three things. (p. 24)

So, Dewey was not an empiricist. Recognition is an indication of assimilation, which, for Piaget (1964), is the essential relation involved in learning. Recognizing the three things as individuals is the result of using an operation of the mind, the unitizing operation (von Glasersfeld, 1981), and recognizing the three things as the one, the unity, is the result of using the operation of uniting the three things into a composite unity. Unitizing sensory material from two or more sensory channels into experiential wholes stands in contrast to the assumption that the world imprints itself on the mind, an assumption on which Thorndike's psychology of number was based.

Thorndike (1922) identified three meanings of numbers—the series, collection, and ratio meanings—and he credited McLellan and Dewey for the ratio meaning. However, he made no attempt to engage in an analysis of the operations of the mind that produce these meanings. Of the collection meaning, he wrote:

> Or we may mean by knowledge of the meaning of numbers, knowledge that two fits a collection of two units, that three fits a collection of three units, and so on, each number being a name for a certain sized collection of discrete things, such as apples, pennies, boys, balls, fingers, and the other customary objects of enumeration in the primary school. (pp. 2-3)

As an empiricist, number was taken as a given in reality and imprinted itself on the mind through the senses. Rather than being concerned with the mathematical experience of the child, for Thorndike (1922), "The psychology of the elementary school subjects is concerned with the connections whereby a child is able to respond to the sight of printed words by thoughts of their meanings…" (p. xi).

Thorndike's influence. The influence that Thorndike had in mathematics education is illustrated in the twenty-ninth yearbook of the National Society for the Study of Education.

> Mainly, the main psychological basis is a behavioristic one, viewing skills and habits as fabrics of connections. This is in contrast, on the one hand, to the older structural psychology [faculty psychology][iv] which has still to make direct contributions to classroom procedure, and on the other hand, to the more recent Gestalt psychology, which, though promising, is not yet ready to function as a basis of elementary education. (Knight, 1930, p. 5)

Knight's attempt to separate the behaviorist approach to elementary education and that of the faculty psychologists was spurious because it is difficult to distinguish faculty psychology's educational model (mental discipline) and Knight's development of a behavioristic educational model. In faculty psychology, it was thought that the best way to strengthen the minds of younger students was through drill and repetition of what we might now call the basic skills in order to cultivate the memory[v], which is quite similar to Knight's interpretation of Thorndike's (1922) Psychology of Arithmetic. Thorndike thought that arithmetical knowledge should be treated as an organized interrelated system, whereas his students, of which Knight was one, focused on the mechanics of arithmetic (Van Engen & Gibb, p. 10). Knight also wrote of avoiding progressive education in the same introduction to the yearbook.

> Some readers may feel that the spirit of this Yearbook is too conservative, that it lacks a bold and daring spirit of progressiveness. There has been a conscious attempt to avoid the urging of any point of view not supported by considerable scientific fact. (Knight, 1930, p. 2)

A contentious relationship. The contentious relationship between progressive educators and educators who held the opinion that the function of the school was to train the working class, be they empiricist or faculty psychologists, appeared prior to the publication of the twenty-ninth yearbook. In 1918 Harold Rugg and John Clarke critically analyzed attempts to reconstruct ninth-grade mathematics and presented their own program in the last chapter of their study. "[T]he construction of a continuous mathematical course, worked out around two basic principles, one mathematical and the other psychological" (p. 176) was a major component of their program. They did cite a classic textbook series (Wentworth, Smith, & Brown, 1918) as an attempt to reconstruct ninth grade mathematics, but such texts were regarded as coming up short. In a perusal of the cited text I found that basic algebra was as formal, rule bound, and manipulative as one would expect in a text designed to train students in algebra.

The contentious relationship continued on after Rugg and Clarke's 1918 study, this time directed toward Harold Rugg's social study textbooks. Rugg eventually became one of a small group of progressive educators at Teachers College, Columbia University where he published a social study textbook in 1929 from a social-justice perspective titled, "Man and his changing society," that became widely used. Being a social studies textbook, it was appropriate that there was a focus on social problems in the Unites States and the author encouraged students to explore potential solutions. Rugg was eventually accused of socialism and conservative patriotic business groups who did not want school children raising questions about the capitalistic economic system censured his books.

> By the end of the decade Rugg's books and several others were condemned by the American Legion, the Advertising Federation of America, and the New York State Economic Council. In 1940, in a speech to the leaders of the oil industry, H.W. Prentis, the President of the National Association of Manufacturers (NAM), complained that public schools had been invaded by "creeping collectivism" through social science textbooks that undermined youths' beliefs in private enterprise.[vi]

Progressive education was repudiated and, during the decade of the 1950's, it disintegrated as an identifiable movement in education.[vii] Although the movement may have disintegrated, that doesn't mean that the involved principles died with it.

Mathematics Education 1950-1970: The Era of Modern Mathematics

After World War II, wide spread concern for the state of the education of scientists and engineers emerged when compared with that of the Russians. As a result, the mathematics community became integrally involved in the reeducation of college teachers of mathematics (Price, 1988). The concern soon shifted to the education of precollege mathematics (and science) teachers, especially after the Soviet Union launched Sputnik I in October of 1957. Buttressed by the National Science Foundation, a concerted effort was made by several mathematicians to upgrade the precollege mathematics curriculum in order to educate college capable students (CEEB, 1959; Price, 1988). Classical idealism (the doctrine that reality, or reality as we can know it, is fundamentally mental) replaced empiricism as the dominant philosophical position among the reformers and mathematics textbooks were written from the point of view of a mathematician's mathematics (e.g., Allendoerfer & Oakley, 1959; School Mathematics Study Group, 1965).

However, among the curriculum reformers the belief was, and it still is by most contemporary mathematicians, that mathematics is discovered rather than invented by human beings (Stolzenberg, 1984). So, despite a major shift from empiricism to idealism, Cartesian epistemology was still the prevailing epistemology of the curriculum developers and others primarily involved in the modern mathematics movement, including researchers in mathematics education. Behaviorism was rejected and problem solving along with learning by discovery became the major psychological emphases (Pólya, 1945, 1981) for which Wertheimer's[viii] (1945) work on productive thinking served as a basic psychological rationale. Wertheimer considered productive thinking, or the solving of problems, as based on insight and criticized reproductive thinking such as repetition, conditioning, and habits, all of which are emphasized in behaviorism.

Teaching Modern Mathematics

Interestingly enough, during the modern mathematics movement of the 1960's, mathematics teachers in the main did not change their traditional, behavioristic ways of teaching mathematics. There were at least three reasons for this state of affairs. First, mathematics teachers were not knowledgeable about what was purported to be the psychological emphases of the modern mathematics programs. Institutes for mathematics teachers were held, but the institutes did not offer courses on problem solving or learning by discovery. The primary emphasis in the institutes was on upgrading the mathematical preparation of mathematics teachers.[ix,x] Second, the modern curricula emphasized mathematical structure and the logical, deductive presentation of ideas rather than problem solving and learning by discovery.[xi] There were minimal attempts to psychologize the subject matter in these ways, which was a major oversight because of the influence textbooks have on the classroom teaching of mathematics. Finally, behaviorism is a common sense psychology. Although I would say that few mathematics teachers, including myself, had a working knowledge of Thorndike's psychology of arithmetic or algebra, or of behaviorism more generally, being held accountable for four or five classes of 25-35 students per class can easily lead a teacher to using common sense psychology in teaching without being reflectively aware of doing so. What I mean by a common sense psychology is amply demonstrated in the following citation from an introduction to Thorndike's psychology of algebra.

> Suffice it to say here that it emphasizes the dynamic aspect of the mind as a system of connections between situations and responses; treats learning as the formation of such connections or bonds or elementary habits; and finds that thought and reasoning—the so-called higher powers—are not forces opposing those habits but are those habits organized to work together and selectively. (Thorndike, Cobb, Orleans, Symonds, Wald, & Woodyard, 1926, p. v)

Piaget's Genetic Structures as a Psychological Rationale

It is very interesting that Piaget's genetic structures and stage theory of cognitive development served as a psychological rationale for the modern mathematics programs at the elementary school level (Bruner, 1960). This was primarily due to the logical-mathematical structural emphasis in the modern mathematics programs that left the programs without a psychological rationale. Piaget's *constructivism* did not serve as an epistemological basis for the modern mathematics programs nor was it even emphasized in a conference devoted to Piaget's work and the modern programs that was held at Cornell University in 1964 (cf. Ripple & Rockcastle, 1964). Instead, the interest was in Piaget's stage theory and his formalizations of the thinking of children within the stages as can be seen by Bruner's (1960) citation of Bärbel Inhelder, Piaget's close collaborator, in *The Process of Education*:

> Basic notions in these fields are perfectly accessible to children of seven to ten years of age, provided that they are divorced from their mathematical expressions and studied through material the child can handle himself. (p. 43)

Inhelder's idea was that children in the *concrete operational stage*[xii] were ready to learn, and indeed could learn, "basic notions in these fields". This idea served as the basis of Bruner's (1960) famous concept of the readiness to learn the basic structures of mathematics:

> Any subject can be taught effectively in some intellectually honest form to any child at any stage of development. (p. 33)

Bruner (1960), however, conflated basic structures of mathematics and Piaget's genetic structures when he referred to "less able students":

> Good teaching that emphasizes the structure of the subject is probably even more valuable for the less able students than for the gifted ones. (p. 9)

By "less able students," I take Bruner as referencing children in Piaget's preoperational stage, children who's thinking was not explained by Piaget's Grouping structures. In this quotation, he seemed caught in Cartesian anxiety.

> [Cartesian anxiety] is an anxiety that permeates all metaphysical and epistemological questions concerning the existence of a stable and reliable rock upon which we secure our thoughts and actions. As Bernstein explains: "Either there is some support for our being, a fixed foundation for our knowledge, or we cannot escape the forces of darkness that envelope us with madness, with intellectual and moral chaos (p. 18)." (Konold & Johnson, 1991, p. 2)

In spite of using Piaget's psychology as a rationale for the emphasis on mathematical structure, Piaget was considered to be an observer rather than a teacher, and the elasticity of the limits of children's minds was not considered as having been established:

> These reformers (and I speak now not only of SMSG) have been so successful in teaching relatively complex ideas to young children, and thus doing considerable violence to some old notions of readiness, that they have become highly optimistic about what mathematics can and should be taught in the early grades. (Kilpatrick, 1964, p. 129)

I had no problem with Kilpatrick's assertion for children who were in Piaget and Inhelder's more advanced concrete operational stage.[xiii] But I did not accept Bruner's famous hypothesis about the readiness to learn for the "less able" children nor did I accept Kilpatrick's assertion for children in Piaget's preoperational stage. Consequently, the way in which Piaget's grouping structures might be relevant in the mathematics education of children became a major problem for me soon after I earned my Ph.D. from the University of Wisconsin in 1966. At that point, research in mathematics education was still based in empiricism and to work scientifically meant to use experimental and statistical methods (Stanley & Campbell, 1963) in the test of hypotheses in a way that was quite similar to Thorndike and Woodworth's classical experiment.

Applying Piaget's Psychology

After joining the Department of Mathematics Education in 1967, I turned to working for a period of approximately eight years in an attempt to reject Bruner's famous hypothesis concerning the readiness to learn mathematics for children who were in Piaget's pre-operational stage. In this effort, I functioned as an experimental researcher with little awareness that Piaget (1980) rejected empiricism.

> Fifty years of experience has taught us that knowledge does not result from a mere recording of observations without a structuring activity on the part of the subject. (Piaget, 1980, p. 23)

My efforts were directed toward *applying* Piaget's psychology in the mathematics education of preoperational children in a "scientific" manner. Although I experimentally rejected Bruner's readiness hypothesis for these children (e.g., Steffe, 1966, 73), the children rather forcefully taught me that I had no insights into the psychology of their mathematical thinking (Steffe, 2012). I considered myself as doing pseudo-science and making only accretional progress if I was making any progress at all. The relationships with the mathematics students that I taught as a mathematics teacher was missing. That is, my contributions to the mathematical thinking and reasoning of the children who were my "subjects" in the experiments was not being realized.

So, rather than rely on Piaget's Grouping structures as a psychology of the child, I returned to my identity as a mathematics teacher and taught two classes of first-grade children over the course of a school year so the children could teach me how they think when engaging in mathematical activity (Steffe, Hirstein, & Spikes, 1976).[xiv] The involved children taught me that counting was their primary and spontaneous way of operating in discrete quantitative situations and that counting could have quite different meanings for different children. Piaget had not explained children's counting, so this finding corroborated abandoning attempts to *apply* Piaget's *psychology* in children's mathematical education. It also led to throwing off the straight jacket that controlled experimentation and statistical methodology had on my conception of doing science in mathematics education. In fact, it led to developing the teaching experiment as a method of doing research and using teaching as a method of scientific investigation (Cobb & Steffe, 1983; Steffe, 1983; Steffe & Thompson, 2000b; Steffe & Ulrich, 2013).

The shift to using teaching as a method of scientific investigation was a major shift in doing research and, to my knowledge, at the time it was unprecedented in the United States. I learned later that researchers in the Academy of Pedagogical Sciences in the USSR had already used versions of teaching experiment in their work (Kilpatrick & Wirszup, 1975–1978). Not only did their work provide academic respectability for what then was a major departure in the practice of research in mathematics education in the United States, it was also a departure in the goals of the research. In El'konin's (1967) assessment of Vygotsky's (1978) research, the essential function of a teaching experiment is the production of models of student thinking and changes in it.

> Unfortunately, it is still rare to meet with the interpretation of Vygotsky's research as modeling, rather than empirically studying, developmental processes. (El'konin 1967, p. 36)

So, the new problem that faced me was to construct explanations of the mental processes that are involved in children's counting and, further, to construct explanations of how children might construct those mental processes. I had constructed a typology of the units children create in counting that they taught me. However, I could not explain the processes that are involved in children's construction of these unit types other than Piaget's account of children's construction of what he called arithmetical units (Piaget & Szeminska, 1952). That is*, I realized that it was I who had to construct a psychology of the mathematical children that I taught rather than attempt to apply a psychology that had been constructed for a different purp*ose. That was a major breakthrough in my conception of what it meant to do research in mathematics education.

Mathematics Education 1970-2000: The New Progressive Educators

Interdisciplinary Research on Number

The modern mathematics era ended circa 1970 and behaviorism came roaring back into mathematics education. When von Glasersfeld and I started to work on the project, Interdisciplinary Research on Number (IRON), he had just published his manifesto on radical constructivism (von Glasersfeld, 1974) and it was his intention to start an epistemological revolution that would eliminate the duality between mind and reality in Cartesian epistemology. It was also his intention [and mine] to countermand the stranglehold that behaviorism once again had on mathematics education throughout 1970's and 1980's. Radical constructivism emerged as an epistemology in mathematics as well as in science education (e.g., Driver, 1995) throughout the 1980's and played a role similar to that of progressive education during the first one half of the century. But the role was essentially based on von Glasersfeld's (1989) first principle that, "knowledge is not passively received but actively built up by the cognizing subject" (p. 182) rather than on the research that we were doing in IRON. In fact, I frequently was told that joining radical constructivism was like joining a political party. Few progressive educators appreciated the implications von Glasersfeld's (1989) second principle that, "the function of cognition is adaptive, and serves in the organization of the experiential world, not the discovery of ontological reality" (p. 182), which was the "radical" part of radical constructivism that eliminated the Cartesian dualism between mind and reality (von Glasersfeld, 1974, 1984).

The Standards Movement and the "Math Wars"

Mathematics education was a conceptual wasteland during the 1970's, so it was no surprise that another crisis in education emerged that was marked by the publication of *A Nation at Risk* (National Commission on Excellence in Education, 1983). Influenced by this newly perceived crisis, the constructivist revolution, and the recommendation that problem solving be the focus of school mathematics in the 1980's (National Council of Teachers of Mathematics, 1980), the standards movement in mathematics education officially began in 1989 with the publication of the *Curriculum and Evaluation Standards for School Mathematics* (CESSM; National Council of Teachers of Mathematics, 1989). The influence of Cartesian epistemology was still strong among the progressive educators, so CESSM was a strange mixture of realism and constructivism in spite of the commission claiming a constructivist view of learning, where learning was thought to, "occur through active as well as passive involvement with mathematics" (CESSM, p. 9).

The National Science Foundation funded ten curriculum projects based on the CESSM that were published circa 2000, curricula that unfortunately became known as "constructivist curricula." The publication of these curricula extended the famous "math wars" between conservative mathematicians and progressive mathematics educators that erupted in California (cf. Klien, http://www.csun.edu/~vcmth00m/). The "math wars" had their origin in the 1985 *California Mathematics Framework* (California State Department of Education, 1985). This framework,

> [W]as considered a progressive document—an antecedent of the 1989 NCTM *Standards.* California's professional teacher organization, the California Mathematics Council, was one of the most progressive teacher organizations in the country, and one of the most enthusiastic adopters of the spirit of the 1989 *Standards.* When the next adoption cycle came, the 1992 *California Mathematics Framework* (California State Department of Education, 1992) "pushed the envelope" a good deal further: it emphasized reform, focusing on "mathematical power" and collaborative and independent student work while de-emphasizing traditional skills and algorithms. (Schoenfeld, 2007)

The attempts of the constructivist curricula writers to focus on student work were realized in part through their social agenda, "Mathematics for All," and concomitantly, how they regarded mathematics learning and teaching. In this agenda, it was assumed that all students could learn the mathematics specified in the content standards of CESSM.

> If all students do not have an opportunity to learn this mathematics, we face the danger of creating an intellectual elite and a polarized society. The image of a society in which a few have the mathematical knowledge needed for the control of economic and scientific developments is not consistent either with the values of a just democratic system or with its economic needs. (CESSM, 1989, p. 9)

The social agenda of the writers of the so-called constructivist curricula was based on social constructivism (Bauersfeld, 1995, 1996; Cobb & Yackel, 1996, Voight, 1989). The orientation that shaped the social agenda and the recommendations for teaching is cogently caught in a comment made by Bauersfeld (1995) that, "We can understand the development of mathematizing in the classroom 'as the interactive constitution of a social practice'" (p. 150). This sociological emphasis is compatible with von Glasersfeld's (1989) first principle of radical constructivism if "interactively" is included in "actively." It doesn't, however, take into account von Glasersfeld's (1989) second principle. The reason is that, although interaction is a fundamental assumption in radical constructivism, there are two types of interaction: within subject and between subject interaction (Steffe & Thompson, 2000a). The social constructivists emphasize between subject interaction and make few attempts to model what might go on inside of the heads of children, which is where learning and development take place.

The social agenda served to exacerbate the dissatisfaction the mathematical critics had with the "constructivist" curricula.

> [T]here is a unifying ideology behind "whole math." It is advertised as math for all students, as opposed to only white males. But the word all is a code for minority students and women (though presumably not Asians). In 1996, while he was president of NCTM, Jack Price articulated this view in direct terms on a radio show in San Diego: "What we have now is nostalgia math. It is the mathematics that we have always had, that is good for the most part for the relatively-high socioeconomic anglo male, and that we have a great deal of research that has been done showing that women, for example, and minority groups do not learn the same way. They have the capability, certainly, of learning, but they don't. The teaching strategies that you use with them are different from those that we have been able to use in the past when ... we weren't expected to graduate a lot of people, and most of those who did graduate and go on to college were the anglo males." (Klein, 2000)

Klein went on to say that; "I reject the notion that skin color or gender determines whether students learn inductively as opposed to deductively and whether they should be taught the standard operations of arithmetic and essential components of algebra" (Klein, 2000). So, not only did Klein critique the standards in CESSM and the mathematics that was involved in the "constructivist" curricula, he was also a critic of how teaching was conceptualized and practiced. Essentially, the "math wars" were reminiscent of the contentious relationship between conservative patriotic business groups and progressive educators concerning Rugg's social science textbooks.

Mathematics Education 2000 and Forward: Outcome-Based Education

Klein's rejection of the standards and the social agenda of the constructivist curricula writers foreshadowed the mission of the Common Core State Standards for Mathematics (CCSSM) (National Governors Association for Best Practices and Council of Chief State School Officers, 2010). The release of the CCSSM helped thaw the "math wars" (Lobato, 2014; Norton, 2014) primarily, in my view, because of the presence of more rigorous curriculum standards. We find the following statement in the introduction to CCSSM.

> The standards are designed to be robust and relevant to the real world, reflecting the knowledge and skills that our young people need for success in college and careers. With American students fully prepared for the future, our communities will be best positioned to compete successfully in the global economy. The Common Core State Standards provide a consistent, clear understanding of what students are expected to learn, so teachers and parents know what they need to do to help them (CCSSM, 2010, Introduction).

The CCSSM, similar to the CEEB in 1969, was designed primarily for college bound students.[xv] It has carried the emphasis on outcome-based education forward to the present time, whose beginning was marked in mathematics education by the publication of the CESSM in 1989. It might seem surprising that I would say that CESSM ushered in outcome-based education given that it also was an impetus of the constructivist curricula that was so severely criticized in the "math wars". However, one of the main criticisms of the "constructivist" curricula and CESSM by the mathematicians was that the involved standards were weak, not that there were not any standards.

Outcome-based education is based on Cartesian epistemology with its requirement that something is true only if it corresponds to an independent, objective reality, where the standards constitute that objective reality. The neo-behaviorism of outcome-based education along with the national emphasis on standards-based education by the No Child Left Behind Act of 2001 has had the effect of standardizing precollege mathematics education. For example, students are required to take standardized test throughout their years in school[xvi] and these tests are used in evaluating teachers, a practice that has become known as Value Added Measures [VAM's] of teacher performance. This surge of neo-behaviorism in mathematics education during the first years of the 21st century is exemplified in the report of the National Mathematics Advisory Panel (2008) with its emphasis on *rigorous scientific research*. The research conducted in IRON concerning children's number sequences and fraction schemes and how they are used in the construction of adding, subtracting, multiplying, and dividing schemes that has been published in books and various articles (e.g., Steffe, von Glasersfeld, Richards, & Cobb, 1983; Steffe & Cobb, 1988; Steffe, 1992; Steffe & Olive, 2010) was not even mentioned in that report. So, obviously, the authors of the report did not consider that research as scientific research if they considered it at all.

Given the ubiquity of the influence of outcome-based education, one might think that there should be another major effort by progressive educators to countermand that influence similar to the era of the modern mathematics programs or to the era of the constructivist curricula. While that may be of critical importance given the current state of mathematics education in precollege education, essentially the attempted wholesale changes in mathematics education that were made following national reports were abandoned after the changes led to major disappointments and failures. If this history can be used to predict what might happen if another round of national reform in mathematics education is attempted, a strong argument can be made that what is needed is to construct mathematics curricula *for* children that is based on the mathematics *of* children rather than continue on with the historical practice of basing mathematics curricula for children on the first-order mathematical knowledge of adults. Simply put, if lasting progress in mathematics education is to be made, researchers must establish the construction of mathematics curricula for children as an academic field. I think of constructing mathematics curricula for children that is based on the mathematics of children as a result of intensive and longish periods of teacher/researcher interactions with children. Toward that end, I present several radical constructivist research programs that are tailored toward constructing mathematics curricula for children that emerge from the work in IRON. Before presenting the programs, I present several basic concepts that I feel will help understand the research programs.

Radical Constructivist Research Programs

Basis Concepts

First- and second-order models. I understand *children's mathematics* as a result of maturation coupled with what children have constructed as a result of interacting in their social-cultural milieu in all of its aspects. The assumption that children construct mathematical knowledge is an assumption of an observer.[xvii] Children's mathematics is thought of as first-order knowledge, which are, "the hypothetical models that the observed subject constructs to order, comprehend, and control his or her own experience (Steffe, et al., 1983, p. xvi). An observer psychologizes children's mathematics by constructing second-order models, which are, "the hypothetical models observers may construct of the subject's knowledge in order to explain their observations (i.e., their experience) of the subject's states and activities" (Steffe et. al. 1983, p. xvi). The second-order models are referred to as the *mathematics of children* and the children's first-order models are referred to as *children's mathematics.*[xviii] The concept of children's mathematics is based on the belief that mathematics is a product of the functioning of human intelligence (Piaget, 1980). The mathematics of children, which is an explanation of children's mathematics, is a legitimate mathematics to the extent that teachers/researchers can find rational grounds to explain what children say and do.

Epistemological analysis and conceptual analysis. Conceptual analysis is the method by which the second-order models that constitute the mathematics of children are produced. Conceptual analysis is an analysis of mental operations. In explaining conceptual analysis, von Glasersfeld (1995) drew from his experience with Silvio Ceccato's Italian Operational School, whose goal was to, "reduce all linguistic meaning, not to other words, but to 'mental operations'" (p. 6). The main goal of conceptual analysis is defined by a question from Ceccato's group: "What mental operations must be carried out to see the presented situation in the particular way one is seeing it?" (p. 78). Thompson & Saldanha (2000) reformulated the goal in a way that is more relevant to constructing second-order models of children's language and actions. Their goal is to describe, "conceptual operations that, were people to have them, might result in them thinking the way they evidently do" (p. 315). Although I have extensively engaged in conceptual analysis in the construction of the mathematics of children, I know of no papers that have been written that address the problem of how one might creatively use the analytical tools that are available in radical constructivism in conceptual analysis of children's mathematical concepts and operations.

When conceptual analysis is used in the construction of second-order models, I refer to it as a second-order conceptual analysis. Thompson & Saldanha (2000) included what I refer to as first-order conceptual analysis in their discussion of epistemological analysis, that is, an analysis of one's own mathematical concepts and operations (cf. Thompson, 2008). According to Thompson & Saldanha (2000), epistemological analysis, "is used to model what might be called systems of ideas, like systems of ideas composing concepts of numeration systems, functions and rate of change, or even larger systems like those expressed in quantitative reasoning" (p. 316). First-order conceptual analysis is inextricably involved in second-order conceptual analysis of children's mathematical language and actions. Thompson & Saldanha (2000) also included a teacher/researcher analyzing their own concepts and operations relative to children's concepts and operations in interactive mathematical communication. This kind of analysis involves the teacher/researcher operating as Maturana's (1978) second-order observer; that is, an "observer's ability through second-order consensuality to operate as external to the situation in which he or she is, and thus be observer of his or hers circumstance as an observer (p. 61).

In the following quotation, if "intentionally isomorphic" is interpreted as imputing operations to a mathematically operating child, what I said about making explanations is similar to Maturana's second part of the scientific method.

> As scientists, we want to provide explanations for the phenomena we observe. That is, we want to propose conceptual or concrete systems that can be deemed to be intentionally isomorphic to (models of) the systems that generate the observed phenomena. In fact, an explanation is always an intended reproduction or reformulation of a system or phenomenon. (Maturana, 1978. p. 30).

Maturana's second part of the scientific method emphasized second-order conceptual analysis and his first part emphasized first-order conceptual analysis, which was, "observation of a phenomenon that, henceforth, is taken as a problem to be explained" (Maturana, 1978, p. 29). Of the observer, he commented,

> Yet we are seldom aware that an observation is the realization of a series of operations that entail an observer as a system with properties that allow him or her to perform these operations, and, hence, that the properties of the observer, by specifying the operations that he or she can perform determine the observer's domain of possible observations. (Maturana, 1978, p. 30)

Like Maturana, I take the subject dependent nature of science in mathematics education as a starting point. But I expand on it in two ways. First, the primary reason for engaging children as a teacher/researcher is to allow children to teach one how and in what ways they operate mathematically and, as commented by Thompson & Saldanha, to *create* operations that if a child had those operations, the child would operate as observed. Second, as a teacher/researcher kind of scientist, my *contributions* to children's ways and means of operating mathematically by teaching them is a constitutive part of a conceptual analysis of children's mathematical language and actions. In the words of Steier (1995);

> Approaches to inquiry … have centered on the idea of worlds being constructed … by inquirers who are simultaneously participants in those same worlds. (p. 70)

This understanding of the subject dependent nature of science in mathematics education provides researchers with the power to create images of unrealized possibilities in the mathematics education of children. But these possibilities are subject to the constraints of children as self-organizing systems—the mind organizes the world by organizing itself (Piaget, 1935/71).

Learning and development. A central goal that runs throughout each research program is to learn how to operationalize children's mathematics learning and development as spontaneous processes in mathematics teaching. A virtue of teaching that is focused on constructive itineraries of children's mathematics in which the teacher/researcher is a participant is that it allows the teacher/researcher to become aware of children's constructive processes, which are understood as the construction of schemes and the accommodations that children make in them (cf. von Glasersfeld, 1980). Because of continual interaction with children, a teacher/researcher is likely to observe at least the results of those critical moments when restructuring is indicated by changes in children's operations and anticipation (Tzur, 2014). Major restructuring of mathematical schemes is compatible with a vital part of Vygotsky's (1978) emphasis on studying the influence of learning on development.

Unlike Vygotsky, however, I regard both learning and development in the context of accommodations that children make in their schemes (Steffe, 1991b). But there is a difference in the two kinds of accommodations. Learning is captured by the functional accommodations that occur in a scheme in the context of the scheme being used, whereas development is captured by metamorphic accommodations that occur independently in no particular application of a scheme. A metamorphosis of a scheme is thought to be the result of autoregulation of the process of interiorizing the scheme (cf. Simon, Saldanha, McClintock, Akar, Watanabe, & Zembat, 2010, for a related view).

Learning and development are not spontaneous in the sense that the provocations that occasion them might be intentional on the part of the teacher/researcher. In children's frames of reference, though, the processes involved are essentially outside of their awareness. This is indicated by the observation that what children learn or develop often is not what was intended by the teacher/researcher. It also is indicated when a child learns or develops when a teacher/researcher has no such intention. Even in those cases where children learn what a teacher/researcher might intend, the event that constitutes learning arises not because of the teacher's actions. Rather, teaching actions only occasion children's learning (Kieren, 1994). Learning as well as development arises as an independent contribution of the interacting children. So, although I do not use "spontaneous" in the context of learning and development to indicate the absence of elements with which children interact, I do use the term to refer to the non-causality of teaching actions, to the self-regulation of the children when interacting, to a lack of awareness of the learning process, and to its unpredictability. Because of these factors, I regard learning and development as spontaneous processes in children's frame of reference.

Trajectories of the constructive activity of children. The construction of trajectories of children's learning and development is one of the most daunting but urgent problems facing mathematics education today. It is also one of the most exciting problems because it is here that we can construct an understanding of how teacher/researchers can profitably affect children's mathematics (Steffe, 2004). By building an understanding of children's mathematical concepts and operations and how a teacher/researcher can engage children to bring forth changes in those concepts and operations, a vision of children's mathematics education can emerge in which children engage in productive mathematical learning and development and teacher/researchers engage in productive mathematical teaching. The principle of self-reflexivity[xix] compels teacher/researchers to consider their own knowledge of children's mathematics, including accommodations in it, as constantly being constructed as they interact with children as the children construct mathematical knowledge. Through the construction of trajectories of children's learning and development that are coproduced by children and teacher/researchers, it is possible to construct trajectories that include an account of teacher/researchers' ways and means of acting and operating relative to children's ways and means of acting and operating (Ellis, 2014). Such an account entails the teacher/researcher operating as a second-order observer.

A trajectory of children's learning and development includes a model of the children's initial concepts and operations, an account of children's constraints and necessary errors, an account of the observable changes in children's concepts and operations as a result of their interactive mathematical activity in situations that are used by a teacher/researcher when interacting with children, an account of the situations relative to a teacher/researcher's models of the involved children's mathematics and the teacher/researcher's goals and intentions, and an account of the involved mathematical interactions. A similar historical account of what transpires in between observed changes is critical not only to understand the changes, but also to provide estimates of the length and the nature of the plateaus in children's mathematical learning and/or development.

Trajectories of the constructive activity of children are third-order models that include the second-order models that constitute the mathematics of children, the first-order models of the teacher/researcher, and relationships between them. In the following research programs that I present, I assume that the models that constitute the mathematics of children produced by IRON will be used at least as starting places in the construction of the trajectories. Because of the nature of the trajectories, I will refer to them as mathematics curricula for children throughout the rest of the paper (Steffe, 2007). Concentrating on constructing mathematics curricula for children does not exclude research programs that center on teacher/researchers working with classroom teachers of children.[xx,xxi] In fact, each stated research program can be reformulated so that it is a research program that involves teacher/researchers working with classroom teachers of children.

The First Research Program

The first research program is to construct mathematics curricula for children who enter their first grade as counters of perceptual unit items over the course of their first eight years in school.[xxii]

The second-order models that were constructed in IRON concerning children's number sequences and how the number sequences are used in the construction of adding, subtracting, multiplying, and dividing schemes have been published in books and various articles (e.g., Steffe, et. al., 1983; Steffe & Cobb, 1988; Steffe, 1992; Steffe & Olive, 2010). Ulrich (2015-16) has published two very readable papers that provide an introduction to the units, schemes, and operations that were constructed in IRON as well as to some of the work that has extended the basic work (e.g., Hackenberg, 2013; Hackenberg & Lee, 2015; Hackenberg & Tillema, 2009; Hunt, Tzur, &

Westenskow, 2016; Norton & Wilkins, 2013; Tillema, 2013; Ulrich, 2012). To start, I provide a brief summary of the first two stages in the construction of children's number sequences.

The first stage is a sensory-motor or pre-numerical stage that comprises pre-counters, counters of perceptual unit items (CPUI), and counters of figurative unit items (CFUI). Counters of perceptual unit items are restricted to counting items that are in their perceptual field, such as the toys in their toy box, their steps, their heartbeats, or the chimes of a Grandfather clock. For example, an interviewer covered six of nine marbles with his hand and asked Brenda, a six-year-old child, to count all the marbles. Brenda first counted the interviewer's five fingers and then counted the three visible marbles. The interviewer pointed out that he had six marbles beneath his hand and Brenda replied, "I don't see no six!" (Steffe, & Cobb, 1988, p. 23)

Counters of figurative unit items might attempt to count the items in a closed container when told that there are, say, seven items in the container, by touching the container where they believe items might be hidden in synchrony with uttering number words. Because they concentrate on generating images of the items they are counting, they can easily become lost in counting and stop fortuitously. Counting figurative unit items is a step in interiorizing the countable items, which produces abstract unit items (Steffe et.al, 1983). If the child also interiorizes the acts of counting, I mark this monumental event by referring to it as the stage of the initial number sequence (INS). *Spontaneously* counting-on is the indication of the INS (Steffe, & Cobb 1988).

To illustrate some of the constraints that I experienced when teaching CPUI, I recount my experience teaching three such children at the start of their first grade in school. I taught them approximately 60 times in teaching episodes over their first two school years to explore their progress in the construction of counting-on (Steffe, & Cobb, 1988). Although these children also participated in their regular mathematics classrooms, they did not spontaneously count-on in spite of my best efforts to provoke it and, presumably, the best efforts of their teachers. It wasn't until their 3rd Grade that at least one of them had constructed counting-on. Based on my experience in working in teaching experiments and teacher education at UGA and data that were supplied to me by Professor Bob Wright of Southern Cross University, Australia, who started the Mathematical Recovery Program (Wright, Martland, & Stafford, 2000; Wright, Stewart, Stafford, & Cain, 1998), I estimate that 40% of entering first graders in the United States are CPUI. Of this estimate, Professor Wright commented that, "I think that is a good estimate for the number in the perceptual stage or lower, that is the children who can't yet count perceptual items. I think the percentage would be lower in Australia and New Zealand, say about 30%" (Personal Communication).

Of the 40% who enter the 1st Grade as CPUI, I expect that a majority of them to construct counting-on during their 3rd Grade [Wright estimated that from 5 to 8% might not be counting-on by the 3rd Grade]. From that point on the relative percentages are not certain, but because of the length of time and the great difficulties we had in teaching experiments in engendering progress beyond counting on (Biddlecomb, 2002, Hackenberg, 2005; Tillema, 2007), my best estimate is that approximately 30% of the children entering the 6th Grade will be only able to count-on. And those who are at that stage will remain there until their 8th Grade. Wright's estimate was, "that about 30% of kids entering the 6th Grade in the US will only be able to count-on" (Personal Communication).

I consider this program as the most important research program in mathematics education today. My appeal to those who choose to work in such an intractable but crucial research program is to learn how to teach these children in such a way that they do not lose confidence. My practitioner's maxim is that children are never wrong; even children who are CPUI. An adult can easily induce "mistakes" in these children, but my basic and pervasive assumption is that children are rational beings and our responsibility is to find ways of acting and interacting that are not only harmonious with their ways and means of operating, but will also affect them in productive ways. It is crucial to re-establish the NCTM's vision of mathematics for all.

The Second Research Program

The second research program is to construct quantitative mathematics curricula for children who enter their first grade as CFUI or children who can only count-on (1) in the construction of operative measuring schemes, and (2) in the construction of adding and subtracting schemes as reorganizations of their operative measuring schemes during their first two grades in school.

Children who enter their first grade as CFUI have a quite different constructive trajectory than those who enter as CPUI. It is possible for CFUI to construct the INS by means of a metamorphic accommodation by the end of their first grade in school (Steffe & Cobb, 1988, pp. 308ff). By the end of the second grade, it is possible for their INS to undergo another metamorphic accommodation in the construction of the explicitly nested number sequence (ENS), which is indicated when children spontaneously count-up-to (Steffe, 1992, 94: Steffe & Cobb, 1988).

There are three principal *operations* of the ENS that were not available to children who have constructed only the INS. The first is that units of one have been constructed as *iterable* units; for example, at noon a grandfather clock strikes one twelve times in contrast to simply making 12 chimes. The second is that any initial segment of a (finite) number sequence can be disembedded—"lifted"— from the complete sequence without destroying the sequence.[xxiii] The remainder of the initial segment in the sequence can be also disembedded from the sequence and the numerosity of the remainder can be found by counting its elements starting with "one." This way of counting is referred to as *the recursive property* of the ENS in that children can take the number sequence as its own input (Steffe & Cobb, 1988). That is, children who have constructed the ENS can willfully create their own countable items using elements of their number sequence and count these elements using the same number sequence that was used to create the countable items. It is as if the child has two number sequences "side by side," one to use to create countable items and the other to count the countable items. ENS children have more "mathematical power" than do INS children, to borrow a phrase from the California Mathematics Framework. So, there are three distinct stages in children's construction of their number sequences entering their first grade in school; CPUI, CFUI and the INS, and the ENS. There is a more advanced number sequence that only rarely can be observed that is referred to as the generalized number sequence (GNS; Ulrich, 2014, 2016)

My best estimate is that children who enter their first grade as CFUI or who can only count-on comprise 45% of the first-grade population. Table 1 contains my best estimates of the percent of children who enter their first grade in each of the three number sequence types. The question of whether stage shifts can be engendered by means of specialized interactions has been

Table 1: Number Sequence Type Across Grades for Children Who Enter their First Grade Counting-on (INS) or as CFUI.

Grade/N Seq.	CFUI or INS	ENS	GNS
First	≈ 45 Percent	≈ 10 to 15 Percent	≈ 0 to 5 Percent
Second	≈ 30 Percent	≈ 25 to 30 Percent	≈ 0 to 5 Percent
Third	≈ 5 Percent	≈ 45 to 50 Percent	≈ 0 to 10 Percent

worked on by Norton and Boyce with an *eleven-year old* child (2015). These authors did demonstrate that by working intensively with the child individually in 14 teaching sessions, he did make progress in reasoning from one level of units (INS) to two levels of units (ENS). The authors note, however, that,

> Cody did not seem able to coordinate units in continuous contexts in the same way he could in discrete contexts…We conjecture that that limitation is due to the lack of physical referents for the embedded units within composite units that are continuous. For example, a tablespoon contains three teaspoons, but these three units are not as evident within the tablespoon as they would be with three chips within a cup. Rather, students have to produce the units within a continuous composite unit through some kind of segmenting or partitioning activity (Steffe, 1991a), which involves breaking down the composite unit. (Norton & Boyce, 2015, p. 229)

Children who have constructed the ENS and, hence, two levels of units, do use their number concepts spontaneously in partitioning continuous units. So, there is always an issue of the generality of the learning process when the situations used in the teaching experiment are with only one type of quantity. According to some authors, a fundamental question that pervades mathematics education today is whether mathematical thinking begins with counting or with comparisons of quantity (Sophian, 2007). Based on the work of Davydov (1975) and influenced by Doughtery (2004), Sophian (2007) commented that, "The most fundamental idea I have derived from those papers is the idea that mathematical thinking begins, not with counting, but with comparisons between quantities, in particular the identification of equality and inequality relationships" (p. xiv). This notion of quantity is based on Davydov's (1975) formal definition that a quantity is any set for the elements of which criteria of comparison have been established. However, establishing the quantitative property of a composite unit called its numerosity and the quantitative property of a continuous item called its length precedes a need for comparing the numerosity of two collections or the length of two continuous items (Steffe, 1991a). So, it's not a matter that mathematics begins with comparisons between quantities be they discrete or continuous. Rather, one might say that mathematics begins with establishing the quantitative properties of objects (Steffe, 1991a). This fits with Thompson's (1994) notion of a quantity as, "composed of an object, a quality of that object, an appropriate unit or dimension, and a process by which to assign a numerical value to the quality" (p. 184). This idea of quantity, both discrete and continuous, leads to the following reorganization hypothesis.

> *Reorganization Hypothesis*: Operative measuring schemes and their use in constructing adding and subtracting schemes can emerge as reorganizations of children's INS.[xxiv]

In this hypothesis, the main goal is for children to use their INS in measuring activity in order to transform the measuring activity, such as described in CCSSM standard 1.MD.2 stated below, into operative measuring schemes and to what Thompson, Carlson, Byerley, & Hatfield, (2014) referred to as additive measurement.

> Express the length of an object as a whole number of length units, by laying multiple copies of a shorter object (the length unit) end to end; understand that the length measurement of an object is the number of same-size length units that span it with no gaps or overlaps. Limit to contexts where the object being measured is spanned by a whole number of length units with no gaps or overlaps.

It is important to note that this CCSSM standard is written in such a way that emphasizes the activity of measuring. After actually measuring linear objects to establish how to measure and the units used in measuring, INS children can engage in *operational* measuring activity such as finding the length of a 64-inch string after it is increased by seven inches. If operational measuring is generalized across other quantities such as time, money, temperature, weight, etc., children can construct operational measuring schemes that they could use as if they were using the INS in discrete quantitative situations. They could also be asked to find, say, how many tablespoons of powder could be made from nine teaspoons of powder to engender the construction of composite units—or units of units—which, at this point, I consider as essential in engendering a metamorphosis of the "INS measuring schemes." Furthermore, in the case of discrete quantity, *children construct adding and subtracting schemes as reorganizations of their number sequences* (Steffe, 2003). So, by the children using their INS in the construction of operative measuring schemes, they can in turn use their measuring schemes in the construction of operative adding and subtracting schemes across different quantitative contexts. My hypothesis is that if a stage shift is observed from an INS to an ENS measuring scheme in the case of one type of quantity, a corresponding stage shift will be observed in all of the measuring schemes that the INS was used in establishing. Such a constructive generalization would lead to considerable mathematical power of the children, to borrow a phrase from the California standards.

For children who are CFUI, engaging in measuring activity that includes counting activity extends the goals, situations, activities, and results of their figurative counting schemes. Similar to the INS children who use their counting schemes in measuring activity, the effects of the CFUI using their figurative counting schemes in measuring activity is yet to be determined. Still, it is possible that their measuring activity could serve in engendering metamorphic accommodations like that which produces the INS (cf. Steffe, & Cobb, 1988, pp. 306 ff) if for no other reason than a teacher/researcher could capitalize on children's need to measure things in such a way that provokes monitoring re-presentations of measuring activity.

The Third Research Program

> *The third research program is to construct quantitative mathematics curricula for ENS[xxv] children in the construction of extensive quantitative measuring schemes and their use in constructing adding, subtracting, multiplying, dividing, and numeration schemes in which strategic reasoning and relationships between quantities are of primary importance.*

I agree with Smith & Thompson (2007) that an emphasis on quantitative reasoning needs to begin early on in children's mathematics education and that building quantitative reasoning skills for the majority of students is not a one or two-year program. Their paper concerned how a shift in current school curricula could emphasize quantitative reasoning, whereas my emphasis is on constructing a quantitative mathematics for children based on abstractions from actually teaching children to establish learning trajectories in the sense that Ellis (2014) explained. In this context, it is critical to understand what schemes can be considered as extensive quantitative schemes, which I refer to as genuine measuring schemes. Rather than think of extensive quantities as substances as would be the case when considering 5/4 as referring to a point on the number line, von Glasersfeld & Richards (1983) pointed out that Gauss focused on extensive quantities as relations.

> To forestall the idea that the extensive quantities he is referring to are a matter of inches or degrees, Gauss hastens to add that mathematics does not deal with quantities as such, but rather with relations between quantities. These relations he calls "arithmetical" and in arithmetic, he explains, quantities are always defined by how many times a known quantity (the unit), or an aliquot part of it, must be repeated in order to obtain a quantity equal to the one that is to be defined, and that is to say, one expresses it by means of a number" (pp. 58-59).

The ENS is the first numerical counting scheme that qualifies as an extensive quantitative scheme in that any number such as 50 can be conceived of as one fifty times as well as 50 ones. The other operations of the ENS are also critical in constituting this scheme as an extensive discrete quantitative measuring scheme. So, by viewing the construction of measuring schemes more generally as reorganizations of the operations that produce the ENS, the hypothesis is that the measuring schemes will emerge as extensive quantitative schemes.

The Fourth Research Program

> *The fourth research program is to construct quantitative mathematics curricula for children in (1) the construction of quantitative measuring schemes as reorganizations of their fraction schemes,*[xxvi] *and (2) the construction of multiplicative and additive measuring schemes as reorganizations of their fraction schemes.*

A reorganization hypothesis that was fundamental in the work of IRON that centered on children's construction of fraction schemes was that *children's fraction schemes can emerge as accommodations in their numerical counting schemes.* The fraction schemes that emerged were of a different genre than the number sequences that were used in their construction primarily because children used their number sequences (or concepts) in partitioning in their construction of fraction schemes.[xxvii] Two basic fraction schemes that emerged were the partitive and the iterative fraction schemes.

The partitive fraction scheme. When ENS children use their number concepts in partitioning, they establish an equi-partitioning scheme (Steffe & Olive, 2010, p. 75ff). For example, when the number concept five is used in partitioning a candy bar, say, an estimate can be made of where to mark off one of five equal parts. Once a mark is made, the child can disembed the marked part (mentally or physically), use it in iterating to make five equal parts, and mentally compare the five parts to the original bar to test if the five parts together are equivalent to the original bar. If a child considers that the disembedded part is one out of five equal parts, or a fifth of the candy bar, this produces the first genuine fraction scheme that is referred to as the partitive fraction scheme (PFS; Tzur, 1999).

The iterative fraction scheme and fractional numbers. For children who have constructed the ENS and the PFS, it would seem that the CCSSM Standard 4.a under Number and Operations—Fractions would be appropriate for these children.

> Understand a fraction a/b as a multiple of $1/b$. For example, use a visual fraction model to represent 5/4 as the product 5×(1/4), recording the conclusion by the equation 5/4 = 5×(1/4).

This standard was meant to illustrate how *multiplying a fraction by a whole number* might be modeled by a mathematics teacher in a straightforward way. But it doesn't explain the operations that are involved in children constructing fractions as *fractional numbers*. There is a scheme in the fractional knowledge of children, the *iterative fraction scheme* (IFS), where the fraction 5/4 is constituted as a fractional number; as five times one fourth of the candy bar (Steffe, & Olive, 2010, p. 333ff). The structure of the "candy bar" produced consists of a unit of units of units. That is, as a composite unit containing a composite unit comprised by 4/4 of the candy bar and one more partitive unit fraction. Once constructed, children can use the scheme to produce fractional connected number sequences {1/4, 2/4, 3/4, 4/4, 5/4, 6/4, …} that are constructive generalizations of their explicitly nested number sequence (Steffe, & Olive, 2010, p. 333ff) . This is the first fraction scheme that can be judged as an *extensive quantitative scheme*. The PFS constructed using the ENS is still constrained to the fractional whole. The construction of fractional numbers is not in the zone of potential construction of the children who have constructed the PFS in any short-term sense because it involves a stage shift from two to three levels of units coordination.

The splitting scheme. The splitting scheme, which is a reorganization of the equi-partitioning scheme, is used in the construction of fractional numbers. The splitting scheme is indicated when children can mentally produce a hypothetical stick that can be iterated seven times when given a stick and told that the given stick is seven times longer than their stick and are asked to make their stick. After the splitting scheme is constructed, if a child mentally splits a stick into, say, 48 parts, the child knows that one of the parts would be one forty-eighth of the whole stick because the whole stick is 48 times as long as the part. The result of the scheme is an inverse multiplicative relation between the part and the partitioned whole in the sense that Gauss specified extensive quantitative relations (cf. also Thompson, & Saldana, 2003).

Assessments of fifth through eighth grade children. With this brief introduction to the PFS and the IFS, I now turn to assessments of fifth, sixth, seventh, and eighth grade children concerning these schemes. Norton & Wilkins (2009) found that only 34% of the fifth graders and 35% of the sixth graders in their sample could engage in splitting, which is an indication of the presence of the operations that produce three levels of units[xxviii]. Of those same children, only 14% and 20%, respectively, provided some indication of having constructed the iterative fraction scheme.[xxix] In other assessments, Norton & Wilkins (2010) found that only 13% of their seventh grade sample and 19% of their eighth grade sample could produce the fractional whole when given, say, a stick partitioned into three parts and told that it was three sevenths of a candy bar and asked to draw the whole candy bar, which I consider as an assessment of fractional numbers.[xxx] In their earlier study Norton & Wilkins (2009) reported similar percentages for their fifth and sixth grade samples (14% and 18%). These data are consistent with an analysis of the percentages of children at one, two, and three levels of units that I present in Table 2 in which Norton's and Wilkins' data are included.

Table 2: Estimated Percent of Children at Each Level of Units by Grade

Grade/Level	One Level	Two Levels	Three Levels	IFS
Third	45	45	10	
Fifth	35	40	25 (34%)[NW]	(14%)[NW]
Sixth	30	30	40 (35%)[NW]	(18%)[NW]
Seventh				(13%)[NW]
Eighth				(18%)[NW]

It is especially disconcerting that only approximately 15.5% of Norton & Wilkins' seventh and eighth grade sample indicated that they had constructed a fraction as a multiplicative concept. It's disconcerting because, based on my own estimates, at least 40% of this sample should be able to construct a fraction as a multiplicative concept; that is, they should have been able to construct the IFS. But this expectation is tempered by the realization that the children in the fractions project constructed the iterative fraction scheme by working with us in teaching experiments. The fraction standards of the CCSSM are stated by grade level and as such underestimate what children who have constructed three levels of units can accomplish. On the other hand, children who have constructed two levels of units are constrained to constructing the PFS, a scheme that children use to construct proper fractions. What this means is that approximately 45% of the third-grade population, 40% of the fourth grade population, and 30% of the sixth grade population are able to construct partitive fractions, but not fractional numbers. When combined with the children who have constructed only one level of units throughout these three grade levels, we see that approximately only 15% of the third graders, 25% of the fourth graders, and 40 percent of the sixth graders will be able to construct the IFS and engage in producing fractional numbers.

Recommendations of the NMAP. Children's construction of fractions as well as the teaching of fractions must be changed. In the report of the National Mathematics Advisory Panel (2008), the following comment was made.

> Difficulty with learning fractions is pervasive, and is an obstacle to further progress in mathematics and other domains dependent on mathematics including algebra. … Conceptual and procedural knowledge about fractions with magnitudes less than 1 do not necessarily transfer to fractions with magnitudes greater than 1. Therefore, understanding of fractions with magnitudes in each range needs to be taught directly and the relation between them discussed. (p. 28)

Apparently, the authors of this report believed that fractions (proper and improper) can be taught directly to children regardless of the levels of units the children have constructed. The report of the panel, as I interpret it, exemplifies an empiricist as well as a neo-behavioristic agenda in the teaching of mathematics in precollege education that harks back to Thorndike's influence on the teaching of mathematics during the first one-half of the last century. Still, I do agree with the writers of the report concerning the pervasive difficulty that the learning of fractions presents to schoolboys and schoolgirls and also to the pervasive difficulty that the teaching of fractions presents to their mathematics teachers. Resorting to direct teaching in an attempt, for example, to raise children who have constructed only the PFS to the IFS could be interpreted as a more or less empirical enterprise and as generating a whole industry of empirical research on mathematical learning, to paraphrase Michael Cole's (2004) comments concerning the training studies of the 1960's that were conducted to prove Piaget wrong. In contrast, for the children who have constructed at least the partitive fraction scheme, my hypothesis is that quantitative measuring schemes can emerge as reorganizations of children's fraction schemes.

This hypothesis is similar to the hypotheses in the second and third research programs that additive measuring schemes can be constructed as reorganizations of children's number sequences. It is quite different, however, in that partitioning is a fundamental operation in the construction of the measuring schemes, which opens the way for children to construct measuring schemes involving two levels of units; for example, meters and centimeters, minutes and seconds, pounds and ounces, weeks and days, etc. Measuring systems in multiple levels of units might still be problematic. It is especially crucial to investigate possible changes that indicate *fundamental* transitions between reasoning with two levels of units and three levels of units induced in the construction of quantitative measuring schemes and their use in the construction of multiplicative and additive measuring schemes.

The Fifth Research Program

> *The fifth research program is to construct quantitative mathematics curricula for children in their construction of the rational numbers of arithmetic and the rational numbers, and the schemes and operations entailed in and by these constructions.*

Fractional numbers are a major achievement of children who can use three levels of units as assimilating operations, but fractional numbers are not equivalent to the Rational Numbers of Arithmetic nor to the Rational Numbers. Constructing the rational numbers of arithmetic involves the operations that generate the generalized number sequence (cf. Ulrich, 2014, p. 256). To exemplify those operations, an eight-year old child, Nathan, was presented with copies of a string of three toys and a string of four toys and asked to make 24 toys. Nathan reasoned out loud as follows,

> Three and four is seven; three sevens is 21, so three more to make 24. That's four threes and three fours! (Steffe & Olive, 2010, p. 278)

In solving the task, Nathan integrated a unit of three and a unit of four into a unit of seven, iterated the unit of seven three times to produce 21, increased 21 by three to produce 24, disunited 21 into three threes and three fours, integrated the additional three with the three threes, and produced four threes and three fours. These operations are operations of a GNS. In a GNS, any composite unit can be taken as the basic unit of the sequence in such a way that the composite unit implies the sequence just as the unit of one implies the ENS. Similar to the ENS, in the GNS a child can establish two number sequences "side by side", a sequence of units of three and a sequence of units of four and combine the basic units of each sequence together to produce another sequence of units of seven. What this amounts to is the coordination of two three-levels of unit structures.

The rational numbers of arithmetic can be regarded as those operations that can be used to transform a given fraction into another given fraction; that is, the operations that are involved in quotitive fraction division. Quotitive fraction division involves the coordination of two three-levels of units structures; units within units within units. For example, consider a case where a child is given a segment that is said to be 1/5 of a unit segment and another segment that is said to be 1/3 of the same unit segment, and asked to use the 1/3-segment to produce the 1/5-segment. If the child partitions the 1/3-segment into five parts, takes one of these parts as a 1/15-segment and iterates this segment three times to produce the 1/5-segment, and if the child abstracts the operations as 3/5 of 1/3, then 3/5 is referred to as a rational number of arithmetic. After operating, I would also want to know if the child knows that 3/5 of the 1/3-segment is the 1/5 segment without actually taking 3/5 of the 1/3-segment. I would also want to know if the child can engage in reciprocal reasoning and understand that 5/3 of the 1/5-segment is the 1/3-segment (Hackenberg, 2010, 2014; Thompson & Saldanha, 2003; Thomson, et. al., 2014).[xxxi] The child is aware of the operations needed, not only to reconstruct the unit whole from any one of its parts, as in the case of fractional numbers, but also to produce any fraction of the unit whole starting with any other fraction, which are the operations involved in quotitive fraction division. (cf. Olive, 1999, for an interpretation of the schemes and operations involved in the production of the rational numbers of arithmetic). My hypothesis is that construction of the rational numbers of arithmetic entails a metamorphic accommodation relative to fractional numbers, and learning how to engender this accommodation and the constructive possibilities it entails is included in the first part of the fifth research program.

One might think that the distinction between the rational numbers of arithmetic and the rational numbers is "simply" that the latter involve negative as well as positive rational numbers of arithmetic. But that is not the case at all. My hypothesis is that a scheme of recursive distributive partitioning operations is involved in constructing rational numbers. In general, distributive partitioning operations are those operations that allow a student to share n units among m people and interpret one share as *n*/*m* of one unit and as 1/*m* of all *n* units (Liss, 2015; Steffe, Liss, & Lee, 2014; Lamon, 1996). Distributive partition operations are involved in what Thompson et al. (2014) referred to as "Wildi Magnitudes". The power of Wildi's definition of magnitude is that it makes explicit the fact that, "the magnitude of a quantity is invariant with respect to a change of unit" (Thompson, et. al., 2014, p. 4). So, if a quantity measures 22 inches, and if there are 12 inches/foot, then the quantity also measures 22inches/(12 inches/foot), whose transformation into 22*(1/12 foot) or 22/12 feet involves rational number of arithmetic operations. It also involves use of a scheme of recursive distributive partitioning operations because, according to Thompson (2014), "When a person *anticipates* that any measurement of Q[xxxii] with respect to an appropriate unit can be expressed in *any other* (emphases added) appropriate unit by some conversion without changing Q's magnitude, she possesses Wilde's meaning of magnitude" (p. 4)

When the scheme of recursive distributive partitioning operations can be used to produce what I would consider an equivalence class of fractional numbers, I would judge that the child has constructed a rational number.[xxxiii] I hypothesize that the construction of the rational numbers constitutes a stage shift relative to the rational numbers of arithmetic, and learning how to engender this stage shift and the constructive possibilities it entails is included in the second part of the fifth research program. The scheme of recursive distributive partitioning operations that is involved in the construction of rational numbers is also involved in the construction of intensive quantity (Liss, 2015; Steffe, et al., 2014). The main difference is that intensive quantity involves relative magnitude, which means that a quantity is measured using a quantity of a different nature (Thompson, et al., 2014). In the case of rational numbers, a quantity is measured using a unit quantity of the same nature as the quantity to be measured.

The Sixth Research Program

> *The sixth research program is to construct quantitative mathematics curricula for children in their construction of integers and rational numbers as measures of change in an unsigned quantity, where "unsigned" refers to the magnitude of the quantity, and operations with them.*

Based on work by Thompson & Dreyfus (1988), Ulrich (2014) defined an integer as a measure of change in an unsigned quantity, where "unsigned" refers to the magnitude of the quantity. Concerning integer addition, Ulrich (2014) commented that,

> Unlike in unsigned addition, in which the second addend can have a different quality than the first addend, the addends in this case need to be of the same type in the mind of the student. Depending on the relative magnitudes, the sum could be a subsequence of either addend. … I hypothesize that a student will need to have constructed the GNS in order to conceptualize addition in this way, precisely because both addends need to be reified composite units (which seems to correspond to iterability and the ability to disembed while maintaining a nested relationship) so that the sum can be disembedded from either addend (p. 256).

Ulrich's hypothesis concerning the operations that are needed to construct integer addition leaves open the question of the operations that are needed to construct the concept of an integer other than her comment concerning "reified composite units." I interpret the meaning of a "reified composite unit" in terms of Thompson's (1994) hypothesis that, "an integer is a reflectively abstracted constant numerical difference" (p. 192). So, Ulrich's hypothesis concerning the operations needed to construct integer addition also pertains to the construction of the concept of integers. Although it might seem unusual that the operations needed to construct integers are two steps beyond the operations that are needed to construct the natural numbers of the ENS as extensive quantities, all of the operations of the ENS have to be reorganized and extended to produce an integer as a difference of two such natural numbers. That is, as a reflectively abstracted concept, an integer is the difference of any two signed quantities *a and b,* denoted by $a - b$, such that $a - b$ is a constant number of units between *a* and *b* in the direction from *b* to *a.* This concept of an integer is crucial in algebraic reasoning and should not be finessed by using the sum of a and the additive inverse of b as the definition of a difference $a - b$ like it is done in CCSSM.

I extend this way of regarding integers to the construction of signed rational numbers, where rational numbers are regarded as magnitudes in the way that I regard them in the above text. Based on my experience teaching middle school children in teaching experiments as well as teaching prospective middle school mathematics teachers, finding sums and differences of signed quantities whose magnitudes are rational numbers will require at least a constructive generalization of integer operations. Furthermore, although the product and quotients of signed quantities are rarely considered in studies of children's mathematics, they are fundamental as preparation for more general algebraic reasoning and involve constructive generalizations of rational number of arithmetic operations. Constructive trajectories also need to be established in which students establish the laws of signs for products as a logical necessity as well as patterns of reasoning that might be recognized as distributive, associative, and commutative reasoning.

Finally, because of the preponderance of children who are yet to construct the rational numbers of arithmetic or even fractional numbers in the middle school and beyond, it is essential to explore what a quantitative mathematics curricula involving signed quantities might look like for children who have constructed only three levels of units. This problem is especially acute for children who have constructed only two levels of units.

The Seventh Research Program

The seventh research program is to construct quantitative algebraic curricula for children in the construction of basic algebraic knowing.

The first aspect of the program is to learn the operations that are involved in children's construction of combinatorial reasoning. My hypothesis is that the concept of natural number variable is essential. Even children who can reason with three levels of units make extensive lists when finding the possible outcomes of two or more events that occur together rather than reason with compositions of natural number variables (Panapoi, 2013). Further, my hypothesis is that the multiplicative principal of combinatoiral reasoning and the dimensionality involved in spatial coordinate systems (Lee, 2017) both involve recursively coordinating two three levels of units structures. Lockwood (2015), in her work with college students, and Panapoi (2013) and Tillema (2007, 2013, 2014), in their work with middle grade students of differing levels of units, have made substantial progress in this program. But extensions of their work are needed to establish mathematics curricula for children involving combinatorial reasoning across differing levels of units.

The second part of this research program is to extend the fifth and sixth research programs to working with operations on quantities of unknown measurements, which could be considered as "generalized arithmetic." An extensive quantitative unknown refers to the potential result of measuring a *fixed* but unknown extensive quantity before actually measuring it (Liss, 2015, p.30). An intensive quantitative unknown refers to the potential result of enacting the operations that produce a fixed but unknown equivalent ratio. The production of such a ratio implies the availability of the operations needed to produce an equivalent ratio and, thus, a proportional relationship (Liss, 2015, pp. 31-32). Hackenberg (2005, 2010, 2013, 2014), Hackenberg & Tillema (2009), Hackenberg & Lee (2015), and Liss (2015) have made substantial progress in this program by working with students of differening levels of units. An extension of this work is needed so that quantitative algebraic curricula for children are established across differing levels of units.

The third part of this research program is highly related to the second part. It is to construct quantitative algebraic curricula for children concerning the construction of the basic rate scheme and its use in the construction of linear functions. Given two co-varying quantities, I consider a rate as the result of enacting the operations that produce a ratio equivalent to a unit ratio at any but no particular time (Steffe, et al., 2014, p. 52). The basic rate scheme can be considered as a metamorphosis of intensive quantitative unknowns and proportional reasoning. One might consider the result of enacting a rate formally as an equivalence class of ratios, but that doesn't say anything about the involved metamorphic accommodation that produces rate. Toward that end, Thompson's (1994) commented that, "A rate is a reflectively abstracted constant ratio, in the same sense that an integer is a reflectively abstracted constant numerical difference" (p. 192). Although I agree with this way of thinking about a rate, it too doesn't specify the operations that children use to produce the reflective abstraction. There are various studies that contribute to understanding such mental operations (Ellis, Özgüra, Kulowa, Williams, & Amidonba, 2015; Hackenberg, 2010; Hackenberg & Lee, 2014; Johnson, 2012, 2014; Liss, 2015; Moore, 2014, Thompson, 1994; Tillema, 2013). But how teacher/researchers might provoke such a reflective abstraction is a fundamental problem in establishing quantitative algebraic curricula for children across differing levels of units.

Endnotes

[i] I surmise that, in part, it was because of what was considered as sufficient to falsify a theory during that period of time. According to Lakatos (1970) all justificationists, "whether the intellectualists and empiricists, agreed that a 'hard fact' may disprove a universal theory" (p. 94).

[ii] Thorndike considered himself a connectionist, which I regard as a form of behaviorism, but not radical behaviorism.

[iii] There was also an emphasis on social interaction, active citizen participation in all spheres of life, and democratization of public education.

[iv] Comment in brackets is added to the quotation.

[v] (http://www.eds-resources.com/facultytheory.htm)

[vi] (http://schugurensky.faculty.asu.edu/moments/1938rugg.html)

[vii] (http://www.uvm.edu/~dewey/articles/proged.htm)

[viii] Wertheimer was one of the three founders of Gestalt psychology along with Kurt Koffka and Wolfgang Köhler.

[ix] I attended a sequential summer institute for secondary school mathematics teachers during the summers of 1961, 62, and 63 at Kansas State Teachers College, Emporia, Kansas. There were no courses on teaching via problem solving that emphasized discovery learning by students although we did solve a lot of mathematical problems!

[x] James W. Wilson offered a course on problem solving for MEd and Ph.D. students at the University of Georgia for many years.

[xi] There were modern programs that did emphasize experiential learning of mathematics (Davis, 1990).

[xii] Piaget's grouping structures served as an abstracted model of the reasoning of children in what Piaget called the concrete operational stage.

[xiii] Piaget thought that the construction of the length unit was more advanced than the construction of the arithmetical unit.

[xiv] I am indebted to Dr. Larry Hatfield for his colleagueship and insight that led us to teach 1st and 2nd grade children in order to learn children's thinking.

[xv] A mathematician writer of the content standards told me that the standards are designed so that students can take college mathematics courses.

[xvi] In some cases, students can opt out of taking these tests.

[xvii] In constructivist research, Maturana's concept of the observer is essential. According to Maturana (1978), "Everything said is said by an observer to another observer who can be himself or herself" (p. 31).

[xviii] "Students" can be substituted for "children". I use "children" throughout the paper to be consistent.

[xix] Self-reflexivity involves applying one's epistemological tenets first and foremost to oneself.

[xx] Cf. Student-Adaptive Pedagogy for Elementary Teachers: Promoting Multiplicative and Fractional Reasoning to Improve Students' Preparedness for Middle School Mathematics, Dr. Ron Tzur, Principal Investigator.

[xxi] Cf. AIMS Center for Math and Science Education

[xxii] Cf. the work of Dr. Robert Wright's US Math Recovery Council.

[xxiii] Twenty-nine, say, can be disembedded from fifty while leaving it "in" fifty.

[xxiv] In stating this hypothesis, I assume that in the case of continuous quantity, children will primarily use units like inches, pounds, etc., in segmenting.

[xxv] This research program is not restricted to six-year-old children.

[xxvi] Cf. Hackenberg, Norton, & Wright (2016) for an excellent start on this problem.

[xxvii] A number concept such as five is a composite unit containing five arithmetical unit items containing records of counting "1, 2, 3, 4, 5."

[xxviii] Hackenberg (2007) found that some children who constructed only two levels of units could engage in splitting.

[xxix] These authors referred to this scheme as the generalized measurement scheme for fractions (GMSF).

[xxx] These authors referred to this scheme as the measurement scheme for proper fractions (MSPF).

[xxxi] Reciprocal reasoning of the kind Thompson, et al. (2014) identified involves coordinating two three-levels of units structures.

[xxxii] Q is taken as 22 inches in length.

[xxxiii] I did not observe a child construct what might be called an equivalence class of fractions even in the case of the GNS children (Steffe, & Olive, p. 337ff)

THREE FACETS OF EQUITY IN STEFFE'S RESEARCH PROGRAMS

Erik Tillema
Indiana University, IUPUI
etillema@iupui.edu

Amy Hackenberg
Indiana University, Bloomington
ahackenb@indiana.edu

The NCTM research committee made a recent, urgent call for mathematics education researchers to "examine and deeply reflect on our research practices through an equity lens." With this in mind, we use this paper to reflect on the ways in which Steffe's work has contributed to three facets of equity. We also suggest opportunities for researchers working within this framework to deepen their commitments to issues of equity.

Keywords: Equity and Diversity, Cognition, Learning Theory

The percentages that Steffe (2017) gives in his plenary paper are alarming because they indicate that current standards, and curricular materials based on these standards, are insufficient for a large percentage of students in grades K-8. For example, a majority of students entering 6th grade are not structuring number and quantity in ways that are required for the significant multiplicative reasoning that is the target of most middle school mathematics standards and curricular materials (e.g., developing proportional reasoning, an understanding of rates, etc.). For us, this phenomenon is fundamentally an issue of equity: As it stands, current standards and curricular materials are inequitable if they do not meet the learning needs of a significant number of elementary and middle school students.[i]

So, we take this opportunity to discuss Steffe's research in relation to the NCTM Research Committee's recent, urgent call for mathematics education researchers to "examine and deeply reflect on our research practices with an equity lens" (Aguirre et al., 2017, p. 125). We start with the important caveat that Steffe has not explicitly analyzed the ways in which race, culture, ethnicity, gender, and socio-economic status impact learning opportunities for students in school mathematics either at a broad level or in his specific interactions with students. This caveat may lead some mathematics education researchers to simply dismiss Steffe's work; after all, isn't this omission simply another way of saying that Steffe has studied mathematics teaching and learning using a colorblind framing that does not account for contextual or cultural factors in the teaching and learning process? We think that this conclusion is far too dismissive given Steffe's: a) profound commitment to unpacking what he terms students' mathematics; b) his drive to work with cognitively diverse students over long periods of time to learn this mathematics; and c) his repeated pushes to interrupt dominant discourses about what mathematicians, mathematics education researchers, and curriculum writers think should constitute school mathematics (e.g., Steffe, 1992, 1994; Steffe & Olive, 2010). We see this paper, then, as an opportunity to reflect on the ways that Steffe's research addresses facets of equity, as well as a space to call for researchers using similar frameworks to deepen their commitment to issues of equity in the context of critiques of de-contextualized and/or colorblind framings of mathematics teaching and learning (e.g., Martin, Gholsson, & Leonard, 2010; Martin, 2009).

In our view, Steffe's research addresses at least three critical facets of equity: positionality and power relations, what counts as mathematics, and access and achievement. We start with an overview of how Steffe's research addresses these facets of equity. Then we provide data excerpts to illustrate each facet of equity. The excerpts are of middle school students who have interiorized one level of unit because their mathematical ways of operating are rarely reflected in current curricula and standards.

Three Facets of Equity

Positionality and Power Relations

In sociology, *positionality* refers to the "occupation or adoption of a particular position in relation to others, usually with reference to issues of culture, [race], ethnicity, or gender" (Oxford Dictionary on-line). Those who articulate their positionality are articulating their stance or viewpoint on themselves, others, and interaction between people, often with respect to societal identifiers. In his research, Steffe articulates his stance on himself as a teacher/researcher and on those with whom he interacts (students). This stance starts with self-reflexivity, which is a version of Gutiérrez's mirror test (2016): "The principle of self-reflexivity compels teacher/researchers to consider their own knowledge of children's mathematics, including accommodations in it, as constantly being constructed as they interact with children as the children construct mathematical knowledge," where "Self-reflexivity involves applying one's epistemological tenets first and foremost to oneself" (2017).

Although this positionality does not address culture, race, ethnicity, or gender, we argue that it does address relations of power between a teacher and students. As Cobb (2007) points out, Steffe's research paradigm is an actor-oriented perspective, concerned with "small scale" human interactions that are useful (although not sufficient) for instructional design at the classroom level, not an observer-oriented "large scale" view of societal structures that focuses on how people participate (or are barred from participating) in cultural practices. So, the power that Steffe addresses has to do with power relations in student-teacher relationships. Although some may see that as a limited view of power from the perspective of social science more broadly (e.g., Foucault), it nevertheless bears directly on the idea that power is intertwined with knowledge and that those in power (including mathematics education researchers) are those who determine what we count as knowledge.

Steffe's orientation is that his own mathematics (his own first-order knowledge) is insufficient to understand children's mathematics (their first-order knowledge). For example, Steffe states: "I usually find it inappropriate to attribute even my most fundamental mathematical concepts and operations to children" (2010b, p. 17). Instead of doing that, he positions students as rational mathematical thinkers who have mathematical knowledge to which he does not have direct access. Steffe positions himself, as a teacher/researcher, as someone who must learn from children "how and in what ways they operate mathematically" (2017) and who must *"create* operations that if a child had those operations, the child would operate as observed" (2017). This statement is a statement about making a second-order model of a student's thinking (the mathematics of students), which he views as mathematical knowledge—as legitimate mathematics. Indeed, for Steffe, second-order knowledge is social knowledge co-constructed by him and children (2010b). Thus, the students with whom he interacts have power to determine what we count as knowledge—in fact, students are primary in his student-teacher relationships because he could not learn students' mathematics (i.e., create the mathematics of students) without interacting with them. This stance positions students as the generators of knowledge.

What Counts as Mathematics

There are numerous examples of the creation of second-order knowledge in Steffe's research, starting with the five counting sequences that model how children undergo significant reorganizations in creating and structuring units and quantity in their construction of what we call whole numbers (e.g., Steffe & Cobb, 1988; Steffe, von Glasersfeld, Richards, & Cobb, 1983). In this paper we give an example of fractional knowledge that Steffe learned from students: the partitive fraction scheme (Steffe, 2002, 2010a). Often standards documents and curricular materials define fractions as parts out of wholes (e.g., 4/5 is four parts out of five parts) or as multiples of unit fractions (e.g., 4/5 is 4 × 1/5) (CCSSM, 2010). These definitions do not reflect students' ways and means of operating as they construct fractional knowledge because they omit a lot and, as Steffe (2017) points out, they may ask students to conceive of fractions in ways that are not within their current possibilities in the near term (cf. Norton & Boyce, 2013).

Students who have interiorized only two levels of units have the potential to construct partitive fraction schemes (Steffe, 2010a). Students who construct this scheme create fractions from iterating (repeating) a unit fraction some number of times. So, for example, if asked to draw 4/5 of a granola bar they partition the bar into five equal parts and then take one of those parts four times. This activity looks like these students see 4/5 as 4 × 1/5—they are repeating 1/5 four times, after all. However, the 4-part bar that is the result of their activity is, *for them*, four parts out of five parts—it has a part-whole meaning. So, when these students are asked to draw 7/5 of a granola bar, they will often object that doing so does not make sense because you can't take seven parts out of five (Olive & Steffe, 2001). Constructing partitive fractions is an advance over fractions conceived of only as parts in relation to wholes. However, students who have constructed only partitive fraction schemes do not yet see fractions as consisting of sequences of fractional numbers (e.g., 1/5, 2/5, 3/5, 4/5, 5/5, 6/5, 7/5, etc.), as Steffe (2017) points out. In addition, students who have constructed partitive fraction schemes have just begun to think of fractions as measurable extents—they have not completed this process (Steffe & Olive, 2010).

Yet rather than position students who have constructed partitive fraction schemes as deficient or behind, Steffe argues that these students' mathematics is a legitimate mathematics that should be the basis for developing curricula and instruction in schools. That is, he states: "rather than assume a God-like stance regarding 'school mathematics,' I assume that I must intensively interact with my students to learn what their mathematics might be before I can begin to think about what 'school mathematics' might be" (1992, p. 261). He critiques school mathematics texts—even reform texts—as being based on the writers' first-order knowledge of school mathematics. This phenomenon

> "places the mathematics of schooling outside of the minds of the students who are to learn it and is manifest in the univocal expression of concepts like multiplication and division. One searches the school mathematics books in vain for a mathematics of children, and school mathematics is taken to be the way it is rather than the way students make it to be" (1992, p. 260).

So, Steffe views school mathematics—mathematical knowledge—as something that should be squarely based on students' mathematical ideas.

Access and Achievement

In our view, developing curricular tasks and instructional materials for students who have constructed partitive fraction schemes is about the issue of access. Gutiérrez (2009) characterizes *access* to be about

> the resources that students have available to them to participate in mathematics, including such things as: quality mathematics teachers, adequate technology and supplies in the classroom, a rigorous curriculum, a classroom environment that invites participation, and infrastructure for learning outside of class hours (p. 5).

She characterizes *achievement* as about student outcomes, including "participation in a given class, course taking patterns, standardized test scores, and participation in the math pipeline (e.g., majoring in mathematics in college, having a math-based career)" (p. 5). She positions access and achievement at the ends of the "dominant" axis, and power and identity at the ends of the "critical" axis in her framework on equity.

Steffe's research does not directly address some items in Gutiérrez's (2009) list of resources for access, such as adequate technology and supplies in the classroom, or infrastructure for learning outside of class hours. However, Steffe's research is about increasing access to mathematical ideas and participation because it redefines what is being accessed. Rather than position mathematics as something outside of the minds of students to be accessed, he positions mathematics as being created by students, and so it is something that they have access to already, in a sense. Thus, his job as a teacher/researcher to facilitate this access is to create second-order models of students' ways of operating that allow him (and others who work in a similar vein) to interact with students so that their mathematics can surface and so that they can build on their ways of thinking from wherever they are. And, further, his job is to create learning trajectories, which he refers to as third-order models (2017), as curricula that would constitute school mathematics. Steffe's call to base school mathematics on the mathematics of students means students' achievement is defined as making progress from where they are—as learning.

Three Examples

In this section we illustrate each aspect of equity with data of student-teacher interactions. We aim to paint a picture of what student-teacher interactions based on models of students looks like, because we argue that, done well, these interactions open significant opportunities for participation and learning. Although this statement is true for all students, it is striking for those who have interiorized only one level of unit in middle school, because these students' ways of thinking are typically not reflected in or addressed by school mathematics (e.g., Hackenberg, 2013). So, all three examples in this section are of students who have interiorized one level of unit.

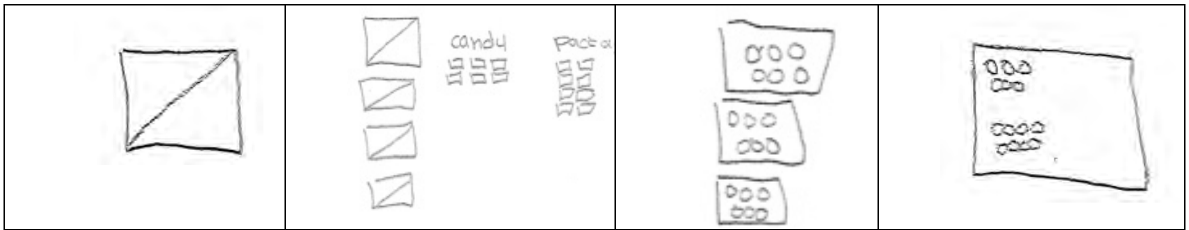
Here we present a few aspects of our second-order models of these students to help readers interpret the data: Students who have interiorized one level of unit view numbers as composite units (units of units)—e.g., 5 is five 1s and also one 5. However, for these students there is not a multiplicative relationship between the units of 1 and composite units. In addition, these students have yet to construct disembedding operations, whereby they can lift part of a number out of the number and not destroy the number, e.g., take 10 out of 14 while keeping 14 intact. Since these students cannot yet disembed, they don't reason strategically when combining numbers additively. For example, to determine 14 + 18, they typically count on by 1s from one of the numbers. In contrast, students who have constructed disembedding operations can separate 14 into 10 and 2 and 2, combine one 2 with the 18 to make 20, and then add on the 10 and 2 to get 32. This strategic additive reasoning is not in the province of students who have interiorized one level of unit. To make assessments of students' levels of units, we often use problems that involve embedded units, as we demonstrate next.

Power and Positionality: Hal Coordinating one Level of Unit

We examine Hal's response to the *Candy Factory Problem* to show what it looks like when a 7th grade student has interiorized only one level of unit. We then analyze how the teacher positioned himself in relation to Hal and the impact of this positionality on power dynamics in a student-teacher relationship.

> *Candy Factory Problem:* A candy factory puts 6 candies in each package, puts 8 packages in each box, and puts 4 boxes in each crate. Make a picture to show the number of candies in one crate.

Data Excerpt 1: Hal solves the *Candy Factory Problem*.[ii]
[The teacher reads the problem to Hal. Hal draws Figure 1a.]



(a)	(b)	(c)	(d)

Figure 1. Hal's response to the *Candy Factory Problem*.

T: Okay. What do you got there?
H: A crate.
T: And can you, like, the candies…so it says 6 candies in each package, puts 8 packages in each box, and puts 4 boxes in each crate. So can you draw what would be inside the crate? [Hal draws Figure 1b.] So these are your six candies, eight packages, and four crates [points to each part of Figure 1b]? [Hal nods.]
….
[The teacher asks Hal to re-read the question. The teacher then asks Hal to draw a single package containing six candies. The teacher asks Hal to draw a second package, and then a third package (Figure 1c).]
T: How many packages does it say would be in one box?
H: Eight.
T: Yeah. So could you draw everything that would be in one box?
H: Six candies and eight packages [draws Figure 1d.]
….
[The teacher returns to asking Hal to draw a fourth package with six candies in it, adding on to Figure 1c. He then asks Hal how many total candies there would be if he had a fifth package.]
H: Thirty.
T: Thirty? Okay. How did you know it was 30?
H: Because 5 times 6 is 30.

This excerpt illustrates that Hal initially did not consider candies, packages, or boxes to be contained in a crate—he drew a single crate (Figure 1a). He subsequently drew the candies and packages outside of the original crate, re-interpreted the one crate as a box, and drew three more boxes (Figure 1b). These drawings provide indication that he assimilated the situation using a single level of unit (e.g., a crate or a box or a package or a candy). With support from the teacher/researcher, Hal established a drawing where candies were contained within packages (Figure 1c). However, this structure seemed ephemeral for him because when the teacher asked him to use it to show "everything that would be in one box," he drew six candies and eight packages, separately, inside of the box (Figure 1d). Doing so indicates that he did not use a two-levels-of-units structure, a package containing six candies, when he created his box.

Interestingly, the last part of the excerpt demonstrates that Hal could use multiplication facts to solve problems—in fact, later in the interview it was evident that he knew and could use many multiplication facts, which is not atypical for middle grades students, even those that are coordinating solely one level of unit (Norton & Boyce, 2015). However, this phenomenon does not mean that "knowing multiplication facts" for students like Hal results from the structure and imagery that is typically assumed when students use such facts.

Galindo, E., & Newton, J., (Eds.). (2017). *Proceedings of the 39th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* Indianapolis, IN: Hoosier Association of Mathematics Teacher Educators.

We contend that middle grades students like Hal are often silenced or invisible in the classroom; they are often positioned as deficient and behind. In fact, even for the teacher/researcher (who was an experienced middle school teacher), Hal's response to this problem was surprising, and it took significant adjustment on his part in order to be responsive to Hal in the moment. Ultimately the teacher/researcher abandoned the original problem as it was stated in favor of presenting problems that were related but did not involve all of the levels of units as the original problem. The teacher/researcher did so because he interpreted his primary goal of interacting with Hal to be to learn Hal's mathematics. This goal, when taken seriously, can be quite humbling, because even an experienced teacher can quickly realize the insufficiency of his or her own mathematical thinking in bringing forth productive mathematical reasoning on the part of the student. So, positioning oneself as Steffe (2017) does is not at all a simple challenge for mathematics education researchers.

Indeed, we think such an orientation needs to be learned anew in each student-teacher interaction in order for mathematics education researchers and teachers to avoid positioning themselves in a "God-like" role. When a teacher ceases to position themselves as learner (for example, by assuming they know what a student should learn prior to interacting with a student), they reify their prior knowledge as the knowledge to be learned rather than entering interactions openly. Notably, however, this does not mean that teachers or researchers should enter interactions with students unprepared, but rather with a genuine openness to students' contributions to these interactions. In the interaction with Hal, it would have been possible to simply "coach" him through creating a representation for solving the problem where the teacher would have learned very little about the structure Hal attributed to the situation. We have witnessed many middle school students who have interiorized one level of unit experience this kind of coaching in schools.

Expanding What Counts as Mathematics: Kianna solves the Coordinate Points Problem

We turn now to a second 7^{th} grade student who was part of the same study, and who had also interiorized one level of unit, to examine how she worked through and solved the *Coordinate Points Problem*.

Coordinate Points Problem. You have number cards that have the numbers 1 through 8 on them. You draw a card, replace it, and draw a second card to create a coordinate point (e.g., 1, 2).

a. How many coordinate points could you make? Represent these points as an array.
b. Suppose you added one additional number card that has the number 9 on it. How many *new* coordinate points could you make?

In typical curricula this problem could be considered to be about "finding the difference of two squares"—the difference between 8^2 and 9^2. Successive iterations of this problem (e.g., starting at 9 and adding the 10 card) could open the possibility for students to consider that the difference between two squares is non-constant, and that the difference of these differences is constant (it is 2). We suggest that seeing the task as univocally about "finding the difference of squares" elides students' mathematics. We use data from Kianna to illustrate what a different characterization affords in terms of seeing what the challenges and successes were for a student who has interiorized one level of unit, and how in turn this characterization serves to expand what counts as mathematics.

We anticipated that, for Kianna, creating pairs and taking them as countable items would be a challenge. Therefore, we asked her to list aloud the new pairs as she was creating them and to keep track of how many pairs she had created. Kianna started the problem by listing aloud the new coordinate points, putting up a finger of her left hand each time she said a new coordinate point and reusing the fingers of her left hand once she had used all five of them. Then the teacher/researcher asked her how many she had created. Kianna seemed uncertain. She listed several calculations that she appeared to think were relevant (e.g., 9 + 9 and 9 × 9). Instead of asking her to compute, the teacher/researcher responded as follows.

Data Excerpt 2: Kianna solves the *Coordinate Points Problem*.

T: You want to just say them out loud again? You had a pretty cool method before. You want to just keep using that?

K [smiles]: Yeah. Okay. So, one nine, two nine, three nine, four nine, five nine [puts up a finger of her left hand each time she says a coordinate point until all five fingers on her left hand are raised], six nine [she begins to reuse the fingers of her left hand each time she says a coordinate point], seven nine, eight nine, nine...[is about to say nine-nine, but stops herself]. I mean, one nine [re-states one-nine instead of saying nine-one], two nine [finishes using the fingers on her left hand a second time], three nine, four nine, five nine, six nine, seven nine [finishes using the fingers on her left had a third time], eight nine, nine nine [puts up the thumb and index finger of her left hand]. That's twelve new ones. Yeah, that's twelve.

T: Twelve? Let's try one more time.

K: Ah. Okay. [Smiles broadly].

T: Do you want to try one more time?

K [emphatically]: Yeah.

T: Okay. You're so close.

K: Okay. One nine, two nine, three nine, four nine, five nine, six nine, seven nine, eight nine, one nine, two nine, three nine, four nine, five nine, six nine [is keeping track on her left hand in a similar manner as the previous attempt]... I said that wrong [realizing she has said one nine, two nine, instead of nine one, nine two, etc.]. Okay. One nine, two nine, three nine, four nine, five nine, six nine, seven nine, eight nine, nine one, nine two, nine three, nine four, nine five, nine six, nine seven, nine eight, nine nine [keeps track in a similar manner on her left hand as previously]. It would be eighteen?

T: Eighteen. You're so close.

W: How'd you get eighteen?

K: I was trying to count them on my fingers. I have a problem when I go past fifteen.

T: You're doing great.

W: Can I ask a quick question?

K: Yeah.

W: How many past fifteen did you get?

K: I think I got two more.

W: Okay. So, what's two more than fifteen?

K: Seventeen.

W: Yeah.

For Kianna, solving the problem appeared to be both challenging and satisfying. Kianna often said she did not like mathematics because she could not "see" herself in her mathematics classes. Her attitude about the interview, however, differed significantly from that: She smiled throughout, acknowledged and accepted the challenges presented to her, and successfully solved problems that were hard for her. We argue that this was possible because the teacher/researcher planned activity for her based on the mathematics of students who have interiorized one level of unit and can make two levels of units in activity, and he used this model as a basis for being responsive to her in the moment. For example, he asked Kianna to verbally list the pairs, which meant he supported her to produce pairs in her activity. He planned this activity for her because creating a pair (coordinate point) in activity is similar to creating a two-levels-of-units structure in activity: Both involve counting two units as a single unit (Tillema, 2013).

After watching Kianna make two attempts at enumerating the pairs, and arriving at 12 and then 18 pairs, the witness-researcher suspected that she was having difficulty coordinating the number of times she had counted by five on her left hand (three) with the number of left over fingers she had (two). Her response of 12 likely stemmed from a lack of differentiation of the number of times she had used all the fingers on her left hand and the two remaining fingers she used—when she reviewed her activity, she equated the two remaining fingers with the number of times she had used all of the fingers on her hand (two): Two hands and two leftover fingers would give 12. Her response of 18 likely stemmed from a similar lack of differentiation, except that in this response she seemed to substitute the three times she used her hand for the number of leftover fingers; three hands and three leftover fingers would give 18. The witness-researcher interacted responsively with her, assuming that this might be the conflation that she was making and so supported her to review the number of leftover fingers she had beyond 15 to determine she had counted 17 coordinate points.

Kianna's response of 17 coordinate points is numerically equivalent to the difference between 9^2 and 8^2. However, we think that claiming that she found the difference of two squares does not match well with Kianna's mathematics. In fact, we think it conflates the mathematics of the observer with the mathematics of a student by failing to differentiate between the two.

Instead, we think that Kianna's problem entailed creating and counting pairs that contained nine in either the first or second position, where her counting activity involved coordinating the number of times she used the five fingers on her left hand (three) with the number of leftover fingers she had on her left hand at the end of her count (two). There was not evidence that she established in a single structure the total number of pairs that could be created with nine number cards (9^2), the number of pairs that could be created with eight number cards (8^2), and the 17 newly created pairs that had the number nine in either the first or second position. Coordinating these three quantities in a single structure could be initial evidence for considering a students' mathematics to be compatible with something that might be called "finding the difference of two squares." Even though Kianna did not do this, her way of operating was fundamentally interesting to us and to her, involved challenging mathematics for her, and imbued her with a sense of mathematical power—she was a participant in producing the solution to what she considered a challenging problem.

Access and Achievement: Alyssa's Work on Symbolizing her Reasoning

We now turn to an example from a different study within a 5-year project to investigate how to differentiate instruction for middle school mathematics students, as well as relationships between students' rational number knowledge and algebraic reasoning. The current phase of the project involves the second author in co-teaching 25-30 day classroom units with a classroom teacher in which the teacher and project team design to differentiate instruction. In the first of these classroom design experiments, the 20-student 8th grade pre-algebra class consisted of five students who had interiorized one level of unit, 13 students who had interiorized two levels of units, and two students who had interiorized three levels of units. The focus of the instruction was equivalence in algebraic contexts, following the *Say It With Symbols* unit from the 3rd edition of the Connected Mathematics Project (Lappan et al., 2014).

One of the students who had interiorized only one level of unit, Alyssa, struggled with most of the ideas in the unit. For example, in class on Day 7 students were learning to factor expressions based on "reversing" the Distributive Property. To factor $6 + 2x$ Alyssa wrote $3(2 + x)$. Even after two conversations between the second author and Alyssa's group about what products they were aiming for, Alyssa still wrote $3(2 + x)$ while her groupmates had expressions like $2(3 + x)$. Later, on Day 14 students were solving an equation to find the break-even point in a situation that involved a school group selling boxes of greeting cards. Because Alyssa and another group mate were struggling to solve the equation, the second author worked with them on understanding the situation—finding the profit when different amounts of boxes were sold: 1, 5, 10, and 20. After seeing that all of these amounts resulted in losing money, the group mate was ready to increase the number of boxes to find the break-even point, but Alyssa suggested that they try 3 boxes or 15 boxes. In general, keeping track of the multiple quantities involved in determining profit (number of boxes, revenue, expenses) was challenging for Alyssa.

During a mid-unit interview, the second author posed to Alyssa a question similar to one worked on in class about developing an expression for the amount of money a swimmer raised in a swim-a-thon, where each sponsor gave the swimmer \$10 to start and \$2 per lap. There were 15 sponsors. Alyssa wrote "$10 + 2x + 15$," where x was the number of laps. Her rationale was that the swimmer was getting more, so "then you're adding, is what I thought." When asked how much money one sponsor gave the swimmer, Alyssa suggested "$10 \times 15 + 2x$", She explained as follows: "the 15 is how many sponsors and then they start with \$10 so I did 10 times 15 to give the amount of money that she's getting." She added the $2x$ because "for every lap they're giving her more money." But then she was concerned about the \$150 because it seemed like too much money from one sponsor. So, although she had just identified the 150 as coming from 15 sponsors, she then thought it was from just one.

With questioning support similar to what we have shown in the prior two data excerpts, Alyssa developed correct numerical responses for the swimmer swimming 4 laps with 1 sponsor and then 2 sponsors. However, she appeared to be "in" the activity of reasoning through these specific outcomes and did not stand above them in order to abstract a structure that she could represent algebraically. The second author expected this phenomenon, to some degree, based on her second-order model of students like Alyssa working on algebraic problems (Hackenberg, 2013). So, the second author drew from evolving second-order knowledge of Alyssa's ways of thinking that opened possibilities for Alyssa to be mathematically active—i.e., to access her mathematical ways of thinking in the context of the problem, and thereby to participate mathematically. In contrast, in math class Alyssa often followed along with the responses of group mates and did not seem mathematically active. In other words, she often did not seem to access her mathematical ways of thinking.

Interestingly, like Kianna, Alyssa appeared to find the interview pleasing in that in the school days that followed she asked the second author why her math class couldn't be like the interview because what they were doing in math class did not make sense to her, implying that the interview was sensible and even enjoyable. So, in the interaction during the interview, Alyssa appeared to experience herself as capable of doing mathematics in a way that she did not regularly experience in mathematics classrooms. Her comments and demeanor further support the claim that in the interview she had access to mathematical activity in a way that was pleasing and unusual for her.

If the second author had had more time with Alyssa on the swim-a-thon problem (e.g., if the problem were a classroom task), she would have continued to work with numerical examples for the amount of money earned in swimming 4 laps with different numbers of sponsors to learn whether Alyssa could abstract a pattern from her activity that she could represent algebraically. Exploring these possibilities with Alyssa would have promoted Alyssa's achievement in the sense of learning. If Alyssa's classroom tasks were designed similarly to this task, how would her access to mathematical activity and her mathematical achievement, or learning, change? We can't say for sure, of course. However, students who tend to feel like mathematics makes sense and who feel that their ideas are valued are certainly more likely to participate regularly and actively, in comparison with students who generally feel that they don't understand in mathematics classrooms, which was the case for Alyssa. Being active mathematically is certainly necessary for learning and achievement more generally, although it does not guarantee any particular learning or achievement.

Concluding Remarks

We have aimed to show how Steffe's research programs address three aspects of equity: positionality and power relations in student-teacher relationships, what counts as mathematics, and access and achievement. In doing so, we have seen how intertwined these three aspects are—it is hard to draw a boundary between them, because each mutually influences the other. For example, by positioning students as the generators of mathematical knowledge, Steffe expands what counts as mathematical knowledge: Students' mathematics counts as mathematics, or rather, the mathematics of students, since that is what he creates based on his interactions with students. Steffe advocates that this mathematics become the basis for curricular design, which has implications for access in the sense of how mathematically active a student might be in their classroom interactions with a teacher, and achievement in the sense that this helps to re-define what success might look like in mathematics classrooms.

We do note that, throughout his work, Steffe focuses on cognitive diversity. Over the course of his career he has worked with students from diverse backgrounds including different racial, cultural, ethnic, gender, and socio-economic backgrounds. Thus the participants in his studies have been diverse in these ways, but this has not been the focus of his analyses. We see this observation as an opportunity for researchers working within this tradition to continue to expand their analytic lens. We see at least three promising possibilities for such an expansion: a) explicit analyses of student-teacher interactions that account for how race, culture, ethnicity, gender, or socio-economic status impact the mathematics that a teacher-researcher is able to bring forth in interactions with students; b) design or teaching experiments that embed the goal of making second order models of students mathematics in situations that address a substantial social issue; and c) explicit attempts, based on second order models of students' mathematics, to influence policy discussions.

To examine what letter *b* might look like, we highlight one of our current graduate students who has used Steffe's framework as a basis for selecting students into a design experiment in which he created mathematical problems that opened the way for students to consider racial bias in jury selection (Gatza, in press). Gatza is working to unpack how, for example, different students' understanding of randomness or a limiting process (including differences based on level of units coordination) impact how they reason about issues of racial bias, and in turn how their understanding of issues of racial bias impact their understanding of randomness or a limiting process (in ways that may not strictly be accounted for based on differences in units coordination). We see unpacking these complex relationships as one avenue for researchers working in this tradition to deepen their commitments to issues of equity.

Endnotes

[i] Steffe (2017) might say that this statement is true for all students because standards and curricular materials under-challenge students who have interiorized three levels of units.

[ii] In the data excerpts, T stands for teacher/researcher, H for Hal, K for Kianna, and W for witness-researcher. Comments enclosed in brackets describe students' nonverbal action or interaction from the teacher/researcher's perspective. Ellipses (…) indicate a sentence or idea that seems to trail off. Four periods (….) denote omitted dialogue.

ELEMENTARY MATHEMATICS SPECIALISTS: ENSURING THE INTERSECTION OF RESEARCH AND PRACTICE[i]

Maggie B. McGatha
University of Louisville
maggie.mcgatha@louisville.edu

This paper provides a historical overview of the role and impact of elementary mathematics specialists as well as current implications and opportunities for the field. Furthermore, suggestions are offered for the mathematics education field for ensuring the intersection of practice and research.

Keywords: Teacher Education-Inservice/Professional Development, Teacher Knowledge, Elementary School Education

Historical Background

Over the years, many groups and leaders have seen the need for supporting teachers of elementary mathematics. In 1981, the National Council of Teachers of Mathematics (NCTM) Board of Directors recommended that state certification agencies offer teaching credentials for elementary school teachers that included mathematics specialist endorsements. The intent of this recommendation was to prepare elementary teachers to assume the primary responsibility of teaching mathematics, typically in the intermediate grades. At that time, certification boards across the country did not positively respond to this suggestion by creating mathematics specialist endorsements (Dossey, 1984). Since that time, a number of recommendations for the use of elementary mathematics specialists (EMSs) have emerged (see Figure 1).

Year	Recommendation
1981	The National Council of Teachers of Mathematics (NCTM) Board of Directors recommends that state certification agencies offer teaching credentials for elementary school teachers that include mathematics specialist endorsements.
1983	The National Science Board Commission on Precollege Education in Mathematics, Science and Technology recommends mathematics specialists in grades 4-6 in *Educating Americans for the 21st Century.*
1984	An article in *The Arithmetic Teacher* by John Dossey, entitled *Elementary School Mathematics Specialists: Where Are They?* discusses the importance of mathematics specialists in the elementary school.
1989	The National Research Council in *Everybody Counts* recommends that states alter certification requirements to encourage the use of mathematics specialists in elementary schools.
2000	*The Principles and Standards for School Mathematics* (NCTM) discusses the importance for mathematics teacher-leaders and specialists especially in grades 3-5.
2001	The National Research Council in *Adding It Up* recommends that mathematics specialists should be available in every elementary school.
2001	*The Mathematical Education of Teachers* (CBMS) calls for mathematics specialists starting at the fifth grade.

2003	Johnny Lott's Presidential Message entitled *The Time Has Come for Pre-K-5 Mathematics Specialists* advocates for mathematics specialists at the elementary level.
2003	An article in *Teaching Children Mathematics* by Reys and Fennel, entitled *Who Should Lead Mathematics Instruction at the Elementary Level? A Case for Mathematics Specialists* makes the case for mathematics specialists using both models.
2003	NCTM and the National Council for Accreditation of Teacher Education (NCATE) release standards for Elementary Mathematics Specialists programs.
2006	Francis (Skip) Fennell's Presidential Message entitled *We Need Elementary Mathematics Specialists NOW* outlines the need for mathematics specialists/leaders.
2008	The National Mathematics Advisory Panel (NMAP) releases their report in which they call for research to be conducted on the use of mathematics specialists in elementary schools.
2009	NCTM Research Brief describes 9 research studies focused on mathematics specialists and coaches and calls for additional research.
2010	Association of Mathematics Teachers Educators (AMTE) releases *Standards for Elementary Mathematics Specialists* which outlines program standards for teacher credentialing and degree programs. Revised in 2013.
2010	AMTE, Association of State Supervisors of Mathematics (ASSM), National Council of Supervisors of Mathematics (NCSM), NCTM joint position statement recommends that every elementary school should have access to an EMS.
2012	Conference Board of Mathematical Sciences (CBMS) *The Mathematical Education of Teachers II* outlines the increased use of EMSs.
2012	NCTM/CAEP *Standards for Elementary Mathematics Specialists* (Advanced Preparation) are released.
2013	Linda Gojak's Presidential Message entitled, *It's Elementary: Rethinking the Role of the Elementary Classroom Teacher,* advocates for mathematics coaches and specialists at the elementary level.
2015	Updated NCTM Research Brief describes 24 research studies focused on mathematics coaches and calls for additional research.
2017	AMTE releases the 2nd book in their Professional Development Series, *Elementary Mathematics Specialists: Developing, Refining, and Examining Programs that Support Mathematics Teaching and Learning*

Figure 1. Recommendations for Mathematics Specialists and Coaches. Adapted from Fennell, F. S. (2017). We need elementary mathematics specialists now: A historical perspective and next steps. In M. B. McGatha & N. R. Rigelman, (Eds.). *Elementary mathematics specialists: Developing, refining, and examining programs that support mathematics teaching and learning.* Charlotte, NC: Information Age Publishing. Reprinted with permission.

Although these recommendations use the term *mathematics specialist*, they describe models that include working with students, teachers, or both. Some of the recommendations distinguish between the models by using different titles and others do not. In fact, the title of these teacher leaders varies from state to state and even from district to district. In an effort to provide some clarity on these titles, my colleague and I (McGatha & Rigelman, 2017) offered a general overview of the work in which these teacher leaders engage and suggested some common language that could be used in referring to these positions (see Figure 2).

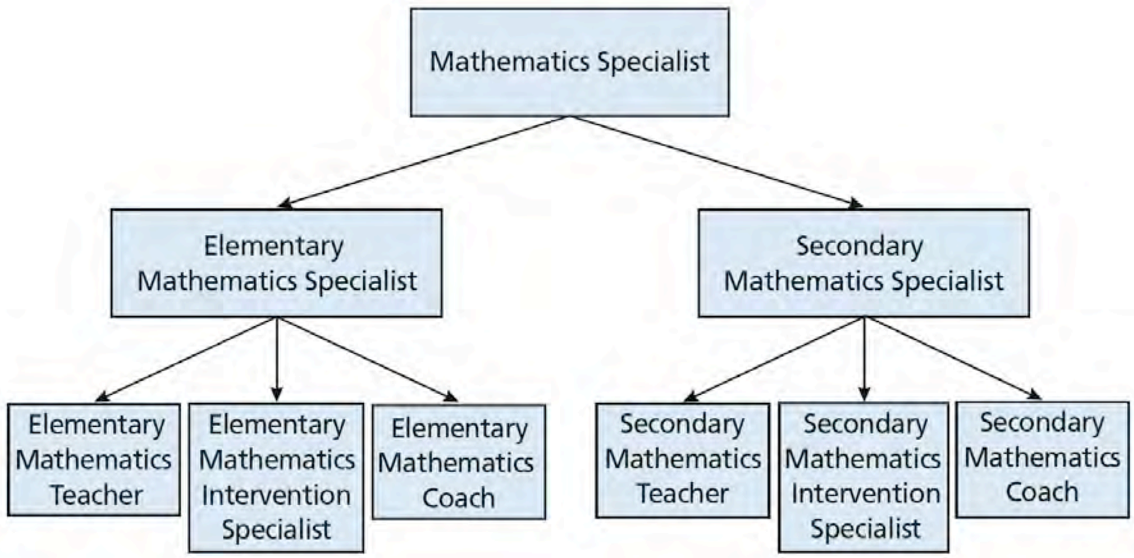

Figure 2. Mathematics Specialists' Titles. Source: McGatha, M. B. & Rigelman, N. R. (2017). Introduction. In M. B. McGatha & N. R. Rigelman (Eds.). Elementary mathematics specialists: Developing, refining, and examining programs that support mathematics teaching and learning. Charlotte, NC: Information Age Publishing. Reprinted with permission. Copyright IAP. All rights reserved.

The titles under EMS and Secondary Mathematics Specialist (SMS) describe the major roles in which these teacher leaders engage: (a) mathematics teacher, a professional who teaches mathematics to students; (b) mathematics intervention specialist, a professional who works with students in "pull out" or "push in" intervention programs; and (c) mathematics coach, a professional who works primarily with teachers (McGatha & Rigelman, 2017).

Regardless of the title used to describe these teacher leaders as indicated in Figures 1 and 2, the mathematics education community has recognized a need for mathematics specialists at the elementary level for over 35 years. These recommendations stimulated several initiatives in schools and districts across the country.

Practice: What is Happening in the Field?

In 1988, ExxonMobil launched the *K-5 Mathematics Specialist Program* in which grants were given to 120 districts across the country to train and place mathematics specialists in elementary schools. However, the model in this program was actually the mathematics coach model since teachers were trained to be "proactive resources for other teachers, administrators, and parents" (ExxonMobile, n.d.). This corporate-based program was one of the first large-scale mathematics coaching initiatives in the United States. The state of Virginia took advantage of the ExxonMobile grants and became an early leader in supporting the work of EMSs. Various stakeholders and organizations in that state began work as early as 1992 and that work still continues today (http://www.vacms.org). More recently, the Elementary Mathematics Specialists & Teacher Leaders project (ems&tl), supported by the Brookhill Institute of Mathematics, was created in 2009 to support a core group of EMSs in Maryland. The project studies the impact of mathematics specialists and also hosts a nationally recognized clearinghouse (www.mathspecialists.org). Other large scale projects (e.g., Mathematics Coaching Project, Examining Mathematics Coaching Project) have, and continue to, support EMSs. This is in addition to the many district-based programs that exist across the US.

Another important aspect of work in the field, focuses on the ongoing support of the three national mathematics education professional organizations (AMTE, NCSM, NCTM). Arbaugh, Mills, and Briars (2017) outlined this important work and presented a representative list of activities from each organization (see Figure 3).

With the increased attention on EMSs and projects to support their work, AMTE felt it was important to address credentialing and degree programs for these mathematics professionals. In 2010, AMTE released *Standards for Elementary Mathematics Specialists: A Reference for Teacher Credentialing and Degree Programs.* When the standards were published, there were only nine states that had a credential for EMSs while nearly every state has a credential for reading specialists. Currently, 20 states have some sort of credential for EMSs. While this growth is impressive in just seven years, we need every state to support the credentialing of EMSs.

Unfortunately, the number of schools or districts that have implemented mathematics coaching or specialist programs is unknown because a comprehensive national survey of such programs does not exist (National Mathematics Advisory Panel, 2008). However, the number of large-scale projects and the work of professional organizations as described above clearly indicate a growing focus on EMSs. Since 2000 the number of sessions on mathematics coaching and specialists at the annual conferences for AMTE, NCSM, and NCTM has steadily increased. In addition, other anecdotal evidence provides insights into the growing popularity of mathematics coaches and specialists. For example, a search on the Internet for “mathematics coach” produced 21,900 hits in 2008 and 26,600,000 in 2017 and “mathematics specialist” produced 17,000 hits in 2008 and 615,000 in 2017. While the exact number of schools and districts using mathematics specialists or coaches is unknown, it is clear that these programs have become a preferred professional development strategy to improve the teaching and learning of mathematics. It is critically important that we research what is happening in the field to verify the impact of EMSs.

Research: What is Happening in the Field?

When the first NCTM research brief on mathematics specialists was published in 2009, there were only nine studies included in the report. Research in this area quickly gained prominence and there were 24 research studies included in the 2015 research brief. And, the research continues. The research included in this brief overview (2002-2017) has either been published in an educational journal, edited book, or presented at a research conference so it has undergone some sort of peer-review process. Additional research has been conducted and can be found in evaluation reports, program review documents, and dissertations.

Specialists as Mathematics Teachers

There are currently very few studies on EMSs working as MTs. McGrath and Rust (2002) studied the effectiveness of departmentalized mathematics at the elementary level. The study compared gain scores in achievement test data from students in self-contained classrooms and departmentalized classrooms in grades 5 and 6. For the mathematics subtest of the achievement data, there were no significant differences in student achievement data gain scores between departmentalized and self-contained classes. However, Gerretson, Bosnick, and Schofield (2008) found that using MTs at the elementary school level allowed teachers more time to effectively plan lessons and focus their professional development (PD). In addition, teachers in this study reported gains in student achievement as a result of using MTs. Nickerson (2010) also noted that achievement gains were greater in treatment schools with MTs as compared to control schools without MTs. The MTs in this study noted significant changes to students' persistence in solving mathematics tasks and increased interest in mathematics. Nickerson noted changes in MTs' instructional practice towards an inquiry-based approach, but pointed out that this took time.

More recently, Markworth (2017), examined the various content specialization models of MTs involved in team teaching within seven school districts. Similar to the Gerretson, Bosnick, and Schofield study (2008), the MTs acknowledged affordances to the content specialization models such as having more time to focus on fewer content areas, which allowed for more in-depth study and focused PD. The MTs believed this supported them in providing higher quality instruction. MTs also pointed out that sharing the responsibility for teaching was beneficial to students. Constraints to the model are also described including (a) scheduling issues not present when teaching in a self-contained class and (b) isolation can occur if there is only one content area teacher per grade level.

Specialists as Mathematics Coaches

The majority of the research on EMSs focuses on MCs. These studies answer three main questions: (*a*) How do coaches interact with teachers? (*b*) What knowledge do coaches need? and (*c*) What is the impact of mathematics coaching?

How Do Coaches Interact with Teachers? The answer to this question varies greatly because districts and schools are still trying to figure this out. Several studies have focused on this question in order to support schools in understanding the most beneficial coaching practices. The research focuses on coaching practice in one-on-one settings (one coach and one teacher) and group settings (one coach and multiple teachers).

Studies that reported on coaching in one-on-one settings, in general, have identified similar ways of interacting with teachers that fell along a continuum from *more-directive* to *less-directive.* While each study used different language to describe the ways of interacting, they all focused on similar ideas. On the *more-directive* end of the continuum, the coach shared knowledge by (*a*) modeling lessons, (*b*) telling teachers what to do, or (*c*) providing resources for teachers (Becker, 2001; Chavl et al. 2010; Polly, 2012). Toward the middle of the continuum, coaching interactions focused on collaborative activities such as co-teaching, co-planning, and providing support during teaching (Becker, 2001; Chavl et al. 2010; Gibbons & Cobb, 2017; McGatha, 2008; Polly, 2012; Race, Ho, & Bower, 2002). At the *less-directive* end of the continuum, the coach supported teachers in becoming reflective practitioners. Activities on this end of the continuum included collecting data from observed lessons, providing feedback, and engaging teachers in thoughtful reflections (Becker, 2001; Bruce & Ross, 2008; Chavl et al., 2010; Gibbons & Cobb, 2017; Harrison, Higgins, Zollinger, Brosnan, & Erchick, 2011; McGatha, 2008; Olson & Barrett, 2004; Olson, 2005; Polly, 2012; Race, Ho, & Bower, 2002). While all of these coaching interactions serve useful purposes, activities on the *less-directive* end of the continuum seem to be more powerful in supporting teachers in changing their instructional practice.

A second aspect of coaching practice is coaching in group settings, such as a coach working with grade-level teams or professional learning communities. Gibbons and Cobb (2017) identified potential group coaching practices from the research on professional development and teacher learning that included (*a*) doing mathematics, (*b*) analyzing student work, (*c*) analyzing classroom video, and (*d*) rehearsing high-leverage practices. They point out that these practices can serve as a beginning framework, but additional research is needed to understand the usefulness of these practices in group settings. Baker, Bailey, Larsen and Galanti (2017) used the potential coaching activities identified by Gibbons and Cobb (2017) as a framework to identify high-leverage coaching practices across other coaching studies. Baker et al. (2017) suggested that even though the practices were not identified in many of the coaching studies, it did not invalidate the list. They agreed with Gibbons and Cobb (2017) that more research is needed in this area.

A few studies have focused on group coaching situations. In these settings, it is important to have regularly scheduled meetings in order to build continuity and maintain momentum (Gibbons, Garrison, & Cobb, 2011). In addition, it is critical to focus group meetings on issues of practice such as student learning and best teaching practices. (Alloway & Jilk, 2010; Obara & Sloan, 2009; Gibbons, Garrison, & Cobb, 2011). Beyond regularly scheduled meetings, Gibbons (2017) reported on the use of math labs (similar to lesson study) as a coaching structure to support the collective learning of a group of teachers.

What Knowledge Do Coaches Need? The *Standards for Elementary Mathematics Specialists* (AMTE, 2010, 2013) offer detailed descriptions of three broad areas of knowledge necessary for mathematics coaches and specialists: (*a*) content knowledge for teaching mathematics, (*b*) pedagogical content knowledge for teaching mathematics, and (*c*) leadership knowledge and skills

(p. 4). Researchers generally agree that these three areas of knowledge are important. However, the research focuses more explicitly on the third category of leadership knowledge and skills.

Sutton, Burroughs, and Yopp (2011) outlined eight domains of mathematics coaching knowledge: "Assessment, Communication, Leadership, Relationships, Student Learning, Teacher Development, Teacher Learning, and Teacher Practice" (p. 16). At first glance, many of these domains seem aligned with the AMTE categories; however, the detailed descriptions reveal more focused attention on supporting *teacher* learning, which falls into the AMTE category of leadership knowledge and skills. Several research studies help to further define specific ways coaches can support teachers. For example, it is important for coaches to understand trajectories of teachers' development so they can offer differentiated experiences for teachers (Baldinger, 2014; Gibbons & Cobb, 2016; Sutton, Burroughs & Yopp, 2011) and create long-term goals for teachers' development (Gibbons & Cobb, 2016). Coaches should have a deep knowledge of instructional practice and theory so they can support teachers in (*a*) assessing their own practice (Gibbons & Cobb, 2016) and (*b*) making connections between theory and practice (Alloway & Jilk, 2010; Sutton, Burroughs, & Yopp, 2011). Campbell and Malkus (2013) reiterated the importance of adequate preparation for coaches to make sure they possess the knowledge necessary to be effective coaches.

What Is the Impact of Mathematics Coaching? Two major areas are discussed in the research concerning the impact of mathematics coaching: improving teacher instructional practice and improving student achievement. Teacher instructional practice is defined broadly to focus on best practices in teaching as described in NCTM documents (1991, 2007). Of course, each study reports on particular aspects of teacher instructional practice.

Across all the instructional practice studies, researchers saw improvements (in varying degrees) in teacher instructional practice including increases in teacher questioning (Polly, 2012; Race, Ho, & Bower, 2002); student engagement (Balfanz, MacIver, & Byrnes, 2006; Race, Ho, & Bower, 2002); and teaching for understanding (Becker & Pence, 2003; Bruce & Ross, 2008; Burroughs, E., Yopp, D., Sutton, J., & Greenwood, M, 2017; Neuberger, 2012). Increases were also noted in particular instructional formats such as cooperative learning (Balfanz, MacIver, & Byrnes, 2006; Becker & Pence, 2003); classroom discourse (Balfanz, MacIver, & Byrnes, 2006; Neuberger, 2012; Race, Ho, & Bower, 2002); and technology (Becker & Pence, 2003). Two studies in this category differed from the others in that their findings did not fall into the categories described above but were more focused on specific instructional practices. Rudd, Lambert, Satterwhite, and Smith (2009) focused on one particular instructional practice, teacher's use of math-mediated language in their lessons. After the professional development and coaching sessions, researchers saw an increase in teacher's use of math-mediated language. Krupa and Confrey (2010) noted increases in (*a*) effective use of class time, (*b*) accurate delivery of content, and (*c*) frequent use of formative assessment as a result of teachers working with coaches.

Seven studies looked at the impact of mathematics coaching on student achievement. In varying degrees and with a variety of methods, all the studies reported increases in student achievement. At the elementary and middle school levels, studies show that coaching positively impacted student achievement on state-level assessments during the first and second years of a coaching program (Conaim, 2010; Zolligner, Brosnan, Erchick, & Bao, 2010). Additional studies at the elementary and middle school levels focused on student achievement impact after four years of a coaching program and showed even stronger results (Balfanz, MacIver, & Byrnes, 2006; Brosnan & Erchick, 2010; Campbell, Griffin, & Malkus, 2017; Campbell & Malkus, 2011). Findings from these longer studies indicate that, in order to significantly impact student achievement, coaches needed both experience and sufficient time to interact with teachers. There is only one study conducted at the high school level (Alloway & Jilk, 2010) and it was not specifically designed to study student achievement; however, its authors noted that pass rates in algebra and geometry classes increased from 40% to

70% after the implementation of coaching. As we move forward in the field, it is imperative to ensure the intersection of practice and research.

Ensuring the Intersection of Practice and Research

Probably the most important way to ensure the intersection of EMS practice and research is to collaborate, collaborate, collaborate! We must emphasize the importance of ongoing research to identify best practices in the field that are making a difference in teacher practice and student achievement. We really can't describe research-based practices in the field quite yet. We need more research!

I propose four suggestions to support the field in ensuring the intersection of EMS practice and research:

1. *Identify districts using EMSs.* As noted above, the number of districts using EMSs is unknown because a comprehensive national survey of such programs does not exist. Such a survey needs to happen! Once we know where programs exist, we can encourage districts to share their successes and challenges to support other EMSs through conference presentations and articles in practitioner journals. In addition, we can support districts in conducting research on their EMS programs to inform the field.
2. *Provide adequate preparation and ongoing support for EMSs*. As noted throughout this paper, there are many initiatives focused on supporting EMSs in the field. These efforts need to continue and new initiatives need to emerge. There is an abundance of anecdotal evidence of districts utilizing EMSs without providing them any professional development or ongoing support. Research has shown that adequate preparation and ongoing professional development can positively impact student achievement (Campbell & Malkus, 2013).
3. *Increase the number of states with EMS certifications/endorsements.* As noted previously, there are currently only 20 states that offer an EMS certification/endorsement. As the number of states offering an EMS credential increases, we will see more EMSs in the field supporting the teaching and learning of mathematics. Receiving a credential should require some level of preparation which aligns with suggestion #2. And, of course, more well-prepared EMSs in the field will increase the research possibilities.
4. *Establish working groups focused on EMS research.* There are relatively few researchers focused on EMSs. They need opportunities to collaborate with other like-minded researchers to reflect on their practice and explore future research opportunities. A few such groups have emerged but we need more attention on focusing the EMS research agenda. Relatedly, two EMS research conferences have occurred recently (AMTE in 2015 and the Virginia Mathematics Specialist Initiative in 2016). Such conferences are another opportunity for researchers to share their work and form collaborations. Because the audience is relatively small, these conferences are not that expensive and funding is available to support these efforts. The research that emerges from these collaborations will provide insights for EMSs in the field.

It is exciting to be involved in an area of practice and research that is still emerging and growing! We have opportunities to influence the field in multiple ways. We also still have many challenges facing us. As we continue to find ways to ensure the intersection of practice and research, we will move the field forward in positive ways.

A FRAMEWORK TO GUIDE THE DEVELOPMENT OF A TEACHING MATHEMATICS WITH TECHNOLOGY MASSIVE OPEN ONLINE COURSE FOR EDUCATORS (MOOC-ED)

Karen F. Hollebrands
North Carolina State University
kfholleb@ncsu.edu

Mathematics teacher educators face a challenge of preparing teachers to use technology that is rapidly changing and easily available. Teachers have access to thousands of digital tools to use with students and need guidance about how to critically choose and use tools to support students' mathematics learning. Research provides guidance to teachers about what features to look for in a technology tool and suggestions are offered about how mathematics teacher educators and researchers can support teachers in using technology to teach mathematics.

Keywords: Technology, Teacher Education-Preservice, Teacher Education-Inservice/Professional Development

Introduction

Technology is an essential component of today's workplace and a ubiquitous part of our society. 82% of high school students and 68% of middle school students have access to smart phones. 75% of these students would like to use their devices to support learning (Speak Up, 2014). Students report that using technology better engages them in learning. Parents state that the use of technology will better prepare their children for the workforce of tomorrow. While researchers have evidence to show the positive impacts the use of technology can have in classrooms, and while there are increasing numbers of freely accessible digital tools available to use, teachers' incorporation of technology has been slow.

We know technology, like any tool, must be selected and used carefully. Mathematics teachers have access to more open-access digital resources than ever before. While ten or twenty years ago, teachers were creators of activities, today, teachers search, find, select, and often modify activities they find using Google, Pinterest, or the Blogosphere. In addition, many teachers have access to digital resources that accompany their curricula. With so many activities easily available, many teachers have become curators rather than creators of digital resources. As teachers gather materials together to present to students, they need guidance to assure that what they have selected will meet the needs of their students and will achieve their learning goals. Teacher educators face a tremendous challenge in preparing teachers to use digital technology that is rapidly changing to support students' mathematics learning. For example, the resources available today may be different tomorrow. Research can provide guidance and advice to assist teachers in using technology in the mathematics classroom.

In this paper, a framework developed to guide the design of a Teaching Mathematics with Technology massive open online course for educators (MOOC-Ed) will be shared along with questions that teachers can consider when making decisions about using technology to teach mathematics.

Guiding Framework

The Didactic Triangle.

A framework was created to guide the development of a MOOC to support teachers in using technology to teach mathematics. The foundation of this framework is the didactic triangle. The didactic triangle is a representation that has been used by several researchers (e.g., Brousseau, 1997;

Freudenthal, 1991; Steinbring, 2005) to describe interactions that occur among a teacher, his or her students, and the content that is being taught. These interactions can be described in terms of pedagogical activities the teacher uses to engage students in learning content – in this case, mathematics. It is important to note that mathematics refers to mathematical topics like algebra, geometry, measurement, statistics, probability, and number, and also the mathematical processes students use when engaging with mathematics. These mathematical processes and practices include using representations, making connections, communicating reasoning, creating and critiquing arguments, attending to precision, solving problems, and mathematical modeling (NCTM, 2000, 2014; National Governors Association Center for Best Practices, Council of Chief State School Officers, 2010)

Within the didactic triangle many interactions take place. For the purpose of designing our MOOC, we focus on those interactions that are planned and used by the teacher. These include (but are not limited to) pedagogical activities related to 1) the selection and implementation of mathematical tasks, 2) questions teachers pose to push student thinking or probe their understanding, 3) the facilitation of mathematical discussions, and 4) assessment of student learning. We depict these four pedagogical activities at the center of our didactic triangle (See Figure 1).

Figure 1. A sample of activities that take place among students, teachers, and mathematics.

Although not explicitly mentioned, we acknowledge that there are many factors that influence classroom interactions such as classroom culture, norms, attitudes, and beliefs. These all influence the enactment of the pedagogical activities we have placed at the center of the triangle. We depict the addition of technology to the classroom by adding a vertex to expand the didactic triangle and create the didactic tetrahedron.

The Didactic Tetrahedron

To make explicit how one considers the role of technology among interactions with students, a teacher, and mathematics, the didactic triangle was extended by Tall (1986), and more recently by Olive et al. (2010) and Ruthven (2012). We can depict this influence by expanding our didactic triangle to create a didactic tetrahedron with technology as the fourth vertex (See Figure 2). Olive et al. state "the introduction of technology into the didactic situation could have a transforming effect on the didactical situation that is better represented by a didactic tetrahedron, the four vertices indicating interactions among Teacher, Student and Mathematical Knowledge, mediated by Technology" (p. 168).

It is important to define what we mean by technology. For some, technology is any object or tool that allows a user to accomplish a task. Others restrict the use of the term technology to refer to electronic or digital technology. Some researchers make distinctions between artifacts, tools, and instruments. According to Monaghan "an artefact is a material object, usually something that is made by humans for a specific purpose, e.g. a pencil. An artefact becomes a tool when it is used by an agent, usually a person, to do something" (Monaghan, Trouche, & Borwein, 2016, p.6). On the other hand, Trouche discusses the process that is involved in an artefact becoming an instrument. He states, "when an artefact has been appropriated by a user, I will name instrument the mixed entity composed of the artefact and the associated knowledge… a tool is a thing somewhere on the way from artefact to instrument" (ibid, p.8). In this paper technology will be used synonymously with tools as defined by Monaghan.

Figure 2. The didactic tetrahedron which includes technology.

When adding technology to mathematical pedagogical activities it is important for teachers to think about how the use of technology influences representations of mathematics and how the use of technology influences pedagogy.

The Influence of Technology on Representations of Mathematics

Mathematics is abstract and it is only through its representations to which we have access to it. Technology offers new and different representations for students and teachers to interact with and use. For teachers, we emphasize that when evaluating technology there are three important factors to consider (See Figure 3). In particular, it is important to determine if the representations technology offers, determine whether it has mathematical fidelity, and consider if technology will be used with students as an amplifier or as a reorganizer (Pea, 1985, 1987).

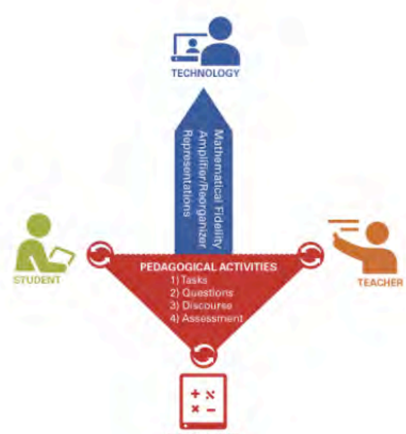

Figure 3. Three factors for teachers to consider when evaluating technology.

Mathematical Fidelity. When choosing technology to use in the classroom, teachers need to make sure that what is represented in the tools are accurate representations of the mathematics. Dick refers to this as, "mathematical fidelity" (Zbiek, Heid, Blume, & Dick, 2007). To illustrate, consider the sketch shown below that was created to show how to compute the slope of a line.

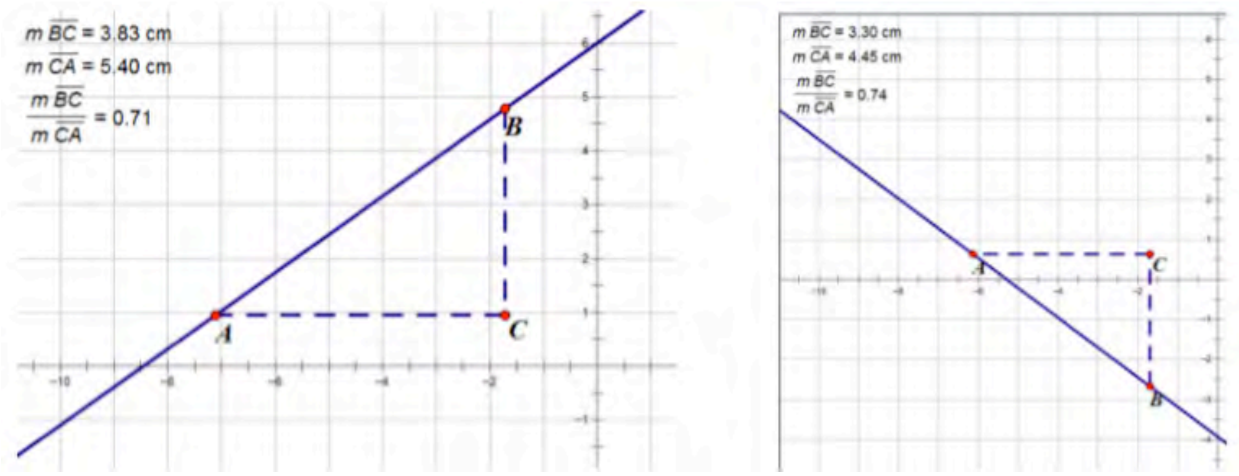

Figure 4. An example of a technology-based activity without fidelity.

Notice that the length of segment *BC* and segment *AC* are used to calculate the ratio of the "rise" to the "run." Segment lengths are always positive and this becomes problematic when the line has negative slope. In this case, the technology calculated the ratio, but cannot account for the negative slope – thus, the calculated ratio is not mathematically correct. The sketch is not faithful to the mathematics and thus lacks mathematical fidelity. It is important for teachers to select tools to use with students that have mathematical fidelity. In addition, teachers should also consider how students will interact with the technology.

Amplifier/Reorganizer. Pea (1985, 1987) used the metaphors of amplifier and reorganizer to describe how technology might be used. As an amplifier, technology performs many of the same actions that could be completed by hand, just more precisely, quickly, and efficiently. The question that is answered using by-hand methods or using technology is relatively unchanged. For example, students might be asked to create a table of values for the function with rule $f(x) = 3x+5$. This could be produced by hand or by using a spreadsheet. The results would be generated more quickly and accurately with the spreadsheet. As a reorganizer, technology changes the way students think about a question or mathematical idea. For example, a student may be provided with the graph of the function with rule $f(x) = 3x+5$ that is linked with a table of values and sliders that dynamically change the values of the slope and y-intercept parameters. By allowing the technology to quickly produce the graph and table, questions can be posed to shift a student's focus from producing the representations to conjecturing and reasoning about how changes in the parameters are related to changes in the graph and table.

When technology is used as a reorganizer, questions can be posed that align with and take advantage of the representations and actions afforded by the tools. Many technology tools that support mathematics learning provide multiple representations of mathematical objects (e.g., numeric, graphic, symbolic, pictorial) and allow the user to interact with the technology to dynamically adjust one representation and see the changes in other representations. This dynamic linking can influence how students reason with and make connections among different representations of mathematics (Kaput, 1987).

Representations. The use of multiple representations to support students' mathematical thinking has long been recognized as an important pedagogical activity (e.g., Kaput, 1992; NCTM 2000, 2014). Research suggests that the use of multiple representations can assist students in developing deeper understandings of mathematics and become more flexible problem solvers (Ainsworth, 1999). NCTM (2014) claims, "Effective teaching of mathematics engages students in making connections among mathematical representations to deepen understanding of mathematics concepts and procedures and as tools for problem solving" (p. 24). When one thinks about representations of mathematics, symbols, graphs, and tables often come to mind. Mathematical representations can also include pictures, diagrams, contexts, verbal descriptions, and physical objects. There are many ways to represent mathematical ideas.

Technology tools provide students with easy access to representations and these technology-based representations are often linked. That is, a change in one representation results in a change in other representations. For example, changing the function rule $f(x)=2x+1$ to $f(x)=3x+1$ can result in a corresponding change in its graph. From these interactions, students can better understand slope. However, it is important that the production of multiple representations is not the sole focus of an activity. Rather, multiple representations can be the centerpiece of productive mathematics discussions and making connections within and among different representations an important cognitive activity (NCTM, 2014).

With these important features of technology described, we created questions that teachers might consider when selecting tools to use in the mathematics classroom that are shown in Figure 5.

Technology-Mathematics	*Mathematical Fidelity*. Is the technology tool a faithful and true representation of the mathematics students are to learn? (Dick, 2008) *Amplifier/Reorganizer*. Does the technology allow the teacher and/or student to do the same work more effectively, efficiently, and quickly (amplifier)? Does the technology change the way the student and/or teacher thinks about mathematical ideas (reorganizer)? (Pea, 1985) *Representations.* How does the technology represent the mathematics? Does it provide linked representations for students to use? (Goldin & Kaput, 1996)

Figure 5. Questions teachers may consider when evaluating interactions between mathematics and technology.

The Influence of Technology on Pedagogy

Just as technology can influence the mathematical representations students interact with, it can also impact pedagogy. It is important for the teacher to be aware of the opportunities technology allows and consider how it influences the four pedagogical activities involved in 1) designing tasks, 2) posing questions, 3) facilitating discourse, and 4) assessing student learning.

Researchers have described tasks in terms of their cognitive demand (Henningsen & Stein, 1997) and mathematical richness. Technology can have an influence on both the richness of a task and its cognitive demand. A mathematically-rich task in a paper-and-pencil environment may be a completely different activity when students have access to technology tools. Consider the task of constructing an equilateral triangle. Doing so on paper with compass and straight-edge requires different thinking than doing so with a dynamic geometry program. Similarly solving a question such as the following requires different thinking if solved using paper and pencil or solved using a dynamic geometry program.

1. In the coordinate plane, line p has slope 8 and y-intercept $(0,5)$. Line r is the result of dilating line p by a factor of 3 with center $(0,3)$. What is the slope and y-intercept of line r?

A. Line r has slope 5 and y-intercept $(0,2)$.

B. Line r has slope 8 and y-intercept $(0,5)$.

C. Line r has slope 8 and y-intercept $(0,9)$.

D. Line r has slope 11 and y-intercept $(0,8)$.

Figure 6. A technology inactive question from https://parcc.pearson.com/resources/Practice-Tests/TBAD/Geo/PC1105806_GeoTB_PT.pdf

If the question is answered using paper and pencil, a student may plot $f(x)=8x+5$. They may then plot the point (0,3). They may determine the distance between (0,5) and (0,3) to be two and then multiply this distance by three to determine that (0,9) is the image of (0,5) under the dilation. This may be repeated for another point to find line *r* or a student may recall that the slope is invariant under dilation. Using a dynamic geometry program, students need to enact technological procedures, plotting a line, plotting a point, and performing dilation. The thinking needed is different given the different tools students have available for them to use. Thus, when teachers have access to technology, they need to think carefully about the tasks and questions they will pose and the thinking required of students when technology is used. Dick and Hollebrands (2011) stress the importance of questions in the context of technology by stating: "The value of technology to the teacher lies not so much in the answers technology provides but rather in the questions it affords. Indeed, "what questions could I ask that I could not ask before?" is the ruler by which we should judge what technology buys us as teachers of mathematics" (p. xvi).

Technology also allows teachers new tools to use when leading mathematical discussions. Collaborative tools such as Google Docs, Sheets, or Slides allow multiple students to share and discuss their work with the whole class. Mathematics specific technology tools like the TI-Navigator and Desmos allow the teacher to monitor and share student work. Orchestrating discussions using these types of tools requires teachers to focus on their mathematical goals and consider ways that they can reach them by selecting and sequencing students' work to assist them in making connections (Smith & Stein, 2011).

Finally, assessment in mathematics classrooms can look very different when teachers are using technology. Game-like assessment tools like Kahoot! Quizlet and Quizzies can be motivating for students and can provide feedback to teachers about what students know. Diagnostic assessments tied to learning trajectories can provide teachers with information about what students know or do not know and make informed decisions about what to do next to advance students' learning.

We present these as questions a teacher may consider when using technology in the mathematics classroom (See Figure 7).

In addition to considering how technology can influence mathematics and pedagogy there are ways in which technology interacts with the teachers and students that we highlight in our MOOC. These are described in the following sections.

Technology -Teacher Edge. Technology is used by teachers and students in the classroom in a variety of ways. Walk into any classroom and you may find teachers using a document camera, interactive white board, and a laptop equipped with a wide array of software applications. Dick and Hollebrands (2011) use the constructs of conveyance and mathematical action technology to assist teachers in making distinctions among the different technology they have available to use in the classroom.

Type of Technology. Conveyance technologies are used to "transmit and/or receive information" and are not math specific. These include presentation technology (PowerPoint, document cameras, interactive boards, projectors), communication technology (social media), collaboration technology (Google Docs), and assessment technology (clickers, educational games). Even though these technologies are not mathematics specific they can still have a significant impact on a mathematics classroom by providing opportunities for students to consider and critique each other's solutions and justifications.

Pedagogical Activities	**Questions to Consider**
Designing Tasks	What is the cognitive demand of this technology-based task? (Stein & Smith, 1998) How will the student interact with the task and technology? How does technology enhance student learning? What learning goals would be best served by this task? How might I prepare students to engage productively in this task?
Questions	What new questions does this technology allow me to ask? In what ways can I ask questions that will advance student thinking and probe what students are learning? What opportunities does the technology allow for students to pose their own mathematical questions? How might a structure my classes to help students feel comfortable generating and posing their own questions and responding to questions that other students generate?
Discourse	Does the technology allow for different solutions and/or different solution strategies? What would make a discussion of technology-based tasks productive? How can I use technology to facilitate a productive mathematics discussion?
Assessment	What type of feedback does the technology provide to the student? How can I build self-assessment into the tasks? How can I leverage the technology to determine what students are learning? How can I use the technology to assess what the students have learned?

Figure 7. Questions a teacher can consider when examining the effects of technology on pedagogy.

Mathematical action technologies are tools, software, and applets that can "perform mathematical tasks and/or respond to the user's actions in mathematically defined ways" (Dick & Hollebrands, 2011, p. xii). These technologies include: graphing calculators, computer algebra systems, and dynamic mathematical environments (GeoGebra, the Geometer's Sketchpad, Fathom, TinkerPlots). Often these technologies are used to perform computations, graph functions, plot data, and construct geometric figures. However, mathematical action technologies can also be used to allow students access to approaches and tasks that would not be possible without technology. Here technology can be used to develop students' mathematical understanding and support students as they explore patterns. Mathematical action technologies can also offer opportunities for teachers to pose questions and tasks that could not be asked in non-technological environment (Zbiek, Heid, Blume, & Dick, 2007). For example, in a dynamic geometry environment, a teacher can ask students to explore how a particular quadrilateral behaves when one of its vertices is dragged. This question is one that cannot be posed in a paper-pencil environment. Guiding questions a teacher can consider when selecting and evaluating technology tools are included in Figure 8.

Technology Consideration	**Issues to Consider and Questions to Pose**
Technology-Teacher	Conveyance/Mathematical Action Technology. Will the technology be used for the teacher to convey information to students (e.g., power point, internet)? Will the technology be used to allow students to perform mathematical actions? (Dick & Hollebrands, 2011) Is the technology readily available for the teacher? Is the learning curve minimal for the teacher?

Figure 8. Questions a teacher can consider when selecting technology tools.

Technology-Student Edge. When making a decision about whether to use a particular technology tool, thinking about how students interact with the technology is especially important (See Figure 9).

Figure 9. The edges of the tetrahedron.

Mathematical action technology often include mathematical representations students can directly manipulate. Direct manipulation allows users to use a mouse or their finger to interact directly with the representation of the mathematical object. The way that the object moves is continuous. There is no lag between the user's own movement and that of the object in the environment. The way that the objects respond is determined by mathematical rules. Thus, through direct interactions the student can observe and infer mathematical properties and theorems. This is one important feature that makes technology tools different from non-technology tools such as base-10 blocks or a ruler. By interacting with technology, students can learn mathematical rules and properties. Conveyance technology tools, on the other hand, typically do not offer mathematics representations and can sometimes be challenging for students to enter mathematics notation. However, these conveyance technologies can be designed by the teacher to provide students with feedback that they can use to gauge their learning and mathematical understanding. Some questions teachers may want to consider when thinking about students' interactions with technology are included in Figure 10.

Technology-Student	Interaction. How does the student interact with the technology? Is the technology available? Is the technology learning curve minimal or steep? Feedback. What types of feedback does the technology provide to students when they are interacting with it?

Figure 10. Questions teachers can consider related to the ways students interact with technology and the feedback it provides.

Conclusion

While technology is rapidly changing and evolving, there are general questions teachers can contemplate when making decisions about whether to select and use a particular technology tool. Teachers should consider whether the technology they are selecting to use is a conveyance or mathematical action technology. They should evaluate the types of representations the technology offers and determine whether those representations are faithful to the mathematics students are learning. They should also assess whether the technology is used to amplify or reorganize students' thinking. How technology effects the design of tasks, questions that can be posed, facilitation of discourse, and assessment of student learning should also be considered. Finally the ways students can interact with the technology and the feedback it provides to support students' mathematics learning should be taken into consideration.

Acknowledgments

The design, implementation, and research of MOOC-Ed courses at North Carolina State University is partially funded by the William and Flora Hewlett Foundation. Any opinions, findings, and recommendations expressed are those of the authors, and do not necessarily reflect the views of the Hewlett Foundation. Thank you to Hollylynne Lee and Gemma Mojica for their contributions in course design and to Tom Dick, Janet Bowers, Pam Buffington, and M. Kathleen Heid for their feedback on the development of a framework for the course.

DIGITAL TECHNOLOGIES IN MATHEMATICS CLASSROOMS: BARRIERS, LESSONS AND FOCUS ON TEACHERS

Ana Isabel Sacristán
Center for Research and Advanced Studies (CINVESTAV), Mexico
asacrist@cinvestav.mx

In this paper, drawing from data from several experiences and studies in which I have been involved in Mexico, I reflect on the constraints and inertia of classroom cultures, and the barriers to successful, meaningful and transformative technology integration in mathematics classroom. I focus on teachers as key players for this integration, calling for more teacher involvement in both professional development, and as co-constructors and collaborators in the design of technological implementations and resources.

Keywords: Technology, Teacher Education-In Service/Professional Development

Classroom Cultures, Teachers and Technologies

Throughout his career, Seymour Papert, a pioneer advocate of digital technologies for changing learning, criticized the way in which school systems constrain knowledge and learning. At the ICMI Study 17 study conference in 2006, in the final talk of his life (Papert, 2006), Papert denounced that educational systems ration every aspect by dividing learning into school grades, "cutting up the knowledge into the subjects" and ordering it; with schools being dictated by graphocentrism—i.e. by paper-and-pencil technology—and new technologies being used only to implement what was there before the newer technologies. He ridiculed that situation by saying: "We'd never have had airplanes...if we had constrained the new transportation to follow the schedules of the sailboats and the horse-drawn carriages; but that's what we are doing in our schools" (Papert, 2006).

Before delving into the issues of the constraints—or what I call the inertia—of educational systems, let us look at some evidence on how digital technologies and tools (DT) have been used and are being used in schools, using data from several studies carried out in Mexico over a decade, and from the research literature.

Uses of Digital Technologies in Classrooms in Mexico and Elsewhere

In a survey carried out in Latin-America in 2006 and reported in Julie et al. (2010), it was found that the most predominantly-used software in mathematics classrooms were software for word processing (Word, LaTex, PDF) and presentation (PowerPoint) – not mathematical tools, but communication ones. Other studies in Mexico at middle-school (Rodríguez-Vidal & Sacristán, 2011) and high-school levels (Miranda & Sacristán, 2012, 2016) showed similar results, with few teachers using technology in classrooms, and of those who did, for simply presenting information, projecting videos, plotting graphs or checking results produced in paper-and-pencil, with very rare use of technology by students. In those studies, the access to technology in classrooms was scarce.

Despite technology becoming more accessible in some schools, this year (2017), Luc Trouche and I visited a high-school in Mexico where we again observed a teacher using technology in a similar way: to simply project static function graphs using GeoGebra, completely omitting any of the dynamic and experimental possibilities (and main purposes) of such a "Dynamic" Geometry environments (DGEs). (In Sacristán, 2011, we also reported on a case where the teacher failed to transmit the dynamic function of a DGE, and students simply used the software for drawing static figures.) Furthermore, the 2017 teacher did not encourage—in fact, *dis*couraged—students from using technological tools in the classroom (interestingly, however, a couple of students ignored the teacher's recommendations, and did use a tablet to reproduce some of the functions demonstrated by the teacher).

Although in more developed countries, technological tools in the classrooms are becoming increasingly ubiquitous, the use of DT is not so different. For example, in the UK, a report edited by Clark-Wilson, Oldknow and Sutherland (2011), cites other reports that conclude that, despite considerable investment in DT in schools, these are underused within in secondary mathematics classrooms and, if used, their potential is generally underexploited. The report also points to classroom evidence suggesting that the use of DT has had emphasis

> on teacher-led use, using mainly presentational software such as PowerPoint and interactive whiteboard software. Revision software and online content services are also used, with the focus being on the computer teaching mathematics alongside practice exercises. Where digital mathematical tools such as graphing calculators, dynamic geometry, and spreadsheets are used, these are conceived primarily as presentational, visual and computational aids rather than as instruments to facilitate mathematical thinking and reasoning. (Clark-Wilson, Oldknow and Sutherland, 2011, p. 19)

On his part, Trouche (2016), while pointing to a lack of research at a large-scale for analyzing the real integration of technology in mathematics classrooms, reports that, in general, integration remains local with a huge difference between schools and teachers. It is also mostly teacher-centered (at least in the cases of England and France), with sometimes teachers showing students the use of the technology, or being unable to analyze the effects of the technology being used. Monaghan hypothesizes that, in the case of England, the increased teacher-centered use of DT in class in classrooms could be due to the increase of interactive whiteboards (IWBs) with "a very large proportion of the use of IWBs is teacher use of IWBs with PowerPoint (rather than interactive mathematics software) and the result is 'teacher demonstration,'" perhaps pointing to students "not being granted wide access to tools to explore mathematical relationships" (Monaghan, Trouche & Borwein, 2016, p. 388). I argue that teacher demonstration is due also to the inertia of old school practices and cultures that are teacher-centered, particularly in countries where this model is still prevalent, such as Mexico.

I summarized these observed predominant uses in classrooms of technology in Sacristán (2011; in press), as being for:

- Presentation or demonstration (e.g. PowerPoint, projecting graphs, videos, etc.)
- Easier visualization
- Easier, faster computation and accuracy
- Saving time (time optimization)
- Checking paper-and-pencil task results
- Information
- Student's revision, exercises or "drill and practice" through interactive, or online resources (such as pointed by Clark-Wilson, Oldknow & Sutherland, 2011, above)
- Communication (e.g. using email or Internet for sending homework)

With many times:

- Little innovation (doing, as Papert criticized, the same or similar tasks as with paper-and-pencil)
- A lack a sense or understanding of didactical and mathematical purposes for the use of digital tools in their classrooms; leading to technocentrism (showing or teaching about the tool itself—see Brennan, 2015—rather than using the tool for mathematical purposes)

- Ignoring the purpose or potential of the tools (e.g. no dragging or dynamism using DGE, as narrated above), indicating, again, the influence of graphocentrism
- Unlinked to other resources (Monaghan & Trouche, 2017)

Thus, when we look at the evidence of how digital technologies are used in schools, we see that in fact they are used in the direction that Papert (2006) claimed: to teach and serve the old (e.g. serve existing curricula), with much of their potential ignored.

On the other hand, the research literature is full of successful innovative practices with technology at experimental scale. But many authors, and at different education levels (see also, Clark-Wilson, Oldknow & Sutherland, 2011; Artigue, 2012), point to how

> despite over 20 years of research and curriculum development concerning the use of technology in mathematics classrooms, there has been relatively little impact on students' experiences of learning mathematics in the transformative way that was initially anticipated. (Clark-Wilson, Robutti & Sinclair, 2014, p.1)

In Sacristán (in press), I reflected on the gap between research results and what happens in classroom practices. Clark-Wilson, Robutti & Sinclair (2014) indicate that a response to this has been increasing research on the role of the teacher; and that will be the theme of the last section of this paper. But I will focus now on the reasons, such as different types of obstacles and barriers, impeding more meaningful technology integration in schools and practice.

Difficulties and Challenges for the Integration of DT for Math Learning in Classrooms

Between 1997 and 2006, a government-sponsored national program in Mexico called EMAT (Teaching Mathematics with Technology) was put into practice for gradual implementation of expressive computational tools, together with a pedagogical model, in the middle-school mathematics classrooms (see Sacristán & Rojano, 2009). We learned a lot from that program in terms of issues that emerge when attempting large-scale massive implementation of technologies in schools (even when carefully designed and planned through the expertise of an international team of mathematics education researchers, as was EMAT). Difficulties and obstacles were encountered at different levels: (a) the teacher, student and classroom level; (b) the school level; (c) the local authorities level; and (d) the national government level; and of different kinds related to:

- *changes in classrooms practices and cultures*: both teachers and students were unaccustomed to working in a more exploratory, student-centered, setting, and teachers had difficulties in adapting to the *proposed* pedagogical model
- *integration of technological tasks with the established curriculum*
- *time issues*: time (or lack of) for preparing the technology-based tasks, and for their implementation
- (teachers') *content knowledge of mathematics*: the use of technology made teachers aware of their deficiencies of their mathematical content knowledge, leading to two types of consequences: (i) some teachers did not want to continue working with technology; or (ii) in other cases, it *motivated* and helped teachers improve their content knowledge.
- *professional development* and support in terms of the tools – which was usually insufficient and without *continuity*
- *teachers and students' attitudes, beliefs and confidence* with regards to the use of the technological tools and programs: these have been shown to have an impact on students' learning with the tools (Sacristán, 2005). As we put it in Sacristán and Rojano (2009, p.213): "Putting it bluntly, 'good teachers' achieve good results: they are able to take

advantage of the *technological* tools and their students benefit from those experiences; but less experienced, poorly trained teachers, or simply teachers who dislike the technological tools, do not do so well."
- *technical difficulties*
- *administrative and bureaucratic issues, policies and political issues*, including lack of communication between the different levels of authorities. It is also worth noting that the program was discontinued in 2006 due simply to a change in government (change in policy). It did survive at some local levels, mainly in places where there would be some form of local support, such as a self-appointed regional coordinator.

In other studies (e.g. Sacristán, Sandoval & Gil, 2011; Miranda & Sacristán, 2016), there were similar findings pointing to reasons that impede the integration by teachers of DT. Among these: difficulties in accepting changes (even when they recognize possible benefits of DT) with many of them continuing doing the same as before; fears (e.g. of losing control of the class, of showing mathematical and technical deficiencies); difficulties in understanding how to integrate technologies in terms of the mathematical aims; lack of adequate infrastructure; and lack of time.

These difficulties are similar to those mentioned in the BECTA (2004) review on barriers to the uptake of information and communication technologies (ICT) by teachers. That report categorizes barriers (e.g. lack of access to resources—including lack of hardware, inappropriate organization, poor quality software—lack of time, lack of effective training, technical problems, lack of confidence, resistance to change and negative attitudes, no perception of benefits) into school-level barriers and teacher-level barriers, which can be external and internal barriers. Likewise, Clark-Wilson, Oldknow and Sutherland (2011, p. 20), cite a report from the UK's National Centre for Excellence in Teaching Mathematics where mathematics teachers' concerns about the use of DT are listed as related to:

- a lack of confidence with digital technologies;
- fears about resolving problems with the technology;
- fears about knowing less than their learners;
- access to digital technologies;
- inappropriate training;
- lack of time for preparation;
- a lack of awareness of how technology might support learning;
- not having technology use clearly embedded into schemes of work,

and include among the barriers to the more student-centered use of DT:

- an inadequate guidance concerning the use of technological tools in curriculum documentation;
- assessment practices;
- and "a perception that digital technologies are an add-on to doing and learning mathematics".

To these we can add the current overload of information and availability of resources of varying quality that are available to teachers through the Internet.

From Challenges to Trends and Lessons

The *NMC Horizon Reports* (www.nmc.org) takes a look every year (since 2012) at technology adoption, at both K-12 and higher education, enlisting (six for each) (i) key trends accelerating technology adoption, (ii) significant challenges impeding technology adoption, and (iii) developments in technology, poised to impact teaching, learning, and creative inquiry.

Among the trends that are identified in several of the reports (Johnson et al., 2015; Adams Becker et al., 2017; NMC/CoSN, 2017) that will be having an impact—in the short, mid and long terms—on technology adoption, are: an increasing use of collaborative learning approaches and of blended learning; a shift from students as consumers to creators and the recent push for coding literacy; the rise of STEAM learning, which seeks to engage students in interdisciplinary learning breaking down traditional barriers between different classes and subjects—one of the criticisms raised by Papert (2006), cited at the beginning of this paper; a rethinking of how schools work, shifting to deeper learning approaches (e.g. project-based learning, etc.) and a redesigning of learning spaces.

At the same time, one of the challenges that the *NMC Horizon Reports* consider difficult (even "wicked" at higher education level), is the changing role of teachers and educators, whose

> primary responsibilities are shifting from providing expert-level knowledge to constructing learning environments that help students gain 21st century skills including creative inquiry … acting as guides and mentors, … providing opportunities for students to direct their own learning trajectories. (NMC/CoSN, 2017, p. 7)

The nine years of EMAT led us to identify some of the key factors for success and for transforming school practices and teacher's roles, such as: adequate planning, gradual implementation, continuous professional development and support, and enough time (years) for assimilation and integration (Sacristán & Rojano, 2009). In relation to the latter, we found that even the most enthusiastic, committed towards the program, and supported teachers, needed at least three years in order to appropriate themselves of the tools and pedagogical ideas. But those who did became very successful in the future, continuing using the resources from the program for many years on their own, even until even this day. In fact, during the writing of this paper, I received an out-of-the-blue call from one of the teachers with whom I worked during the EMAT program. She told me of the limited resources in the school where she now works, in a very low-income area, but how, by implementing the EMAT materials in the last few years (more than a decade after they were developed), student achievement and assessments had improved dramatically, and she had even won two prizes for her work (one of them for her students' explorations with Logo of the four-color theorem). This case shows an appropriation by the teacher of the resources, tools and pedagogical ideas.

It is thus clear that the key player for successful implementations of technology-centered educational innovations is the teacher.

> the role of the teacher is very important, and his/her beliefs, insecurities and lack of mathematical and technical preparation affect the possible impact that the use in the classroom of these technologies can have on students' learning and even attitudes. The need for careful, considered and continuous work with teachers is thus extremely important. A priority in this kind of work should be the integration of digital technologies with the work that teachers are required to do, to take them into account at all steps of the implementation process, and to assist them in developing pedagogical strategies. (Julie et al., 2010, p.380)

With respect to the latter, I would like to reflect briefly on policy aspects and the changing role of teachers in the design of technological implementations.

A Reflection on Policies for Technology Integration, Societal Changes and Teachers

The EMAT program was a top-down design: a policy-driven decision that attempted to achieve technology integration in mathematics teaching and learning, and teachers were not involved in its design. It may have succeeded in small scales, but for an innovative educational program to catch on, it cannot be only about policy-driven implementations, no matter how carefully and well designed it is. For appropriation by teachers of new resources and pedagogical ideas, it may be a prerequisite to involve teachers in the design from the beginning, not just as participants, but as co-creators. In fact, rather than a technologically-driven model of technology integration, Hennessy, Ruthven, and Brindley (2005) point to the importance of teacher involvement, although also influenced by the teachers' working contexts, for effecting classroom change. Furthermore,

> approaches with the most potential to bring about genuine improvement in learning mathematics are those that resonate with teachers—with their interests, beliefs, emotions, knowledge, and practice. (Kieran, Krainer, & Shaughnessy, 2013, p. 364)

But involving and engaging teachers in the design of technological implementations is only one part of what is needed. There are dialectical forces at play here. On the one-hand, top-down policies do generate part of the change: they can initiate it and sow seeds of transformation (as in the case of teachers from EMAT, who 15 years later, continue working and transforming classrooms with what they learned); even if, as an imposition, it is unlikely it will resonate with the majority of teachers. On the other hand, changes that take place in society due, for instance, to technological advances—such as the trends mentioned in the NMC reports above—also influence policies. In any case, professional development and support is needed. In Trouche, Drijvers, Gueudet, and Sacristán (2013), we discussed the above and said:

> Merely providing access to technology is not enough for promoting educational change; support for teachers' professional development is a necessary precondition for a thoughtful and fruitful integration of technology. […] Policy shifts do not fall out of the blue, but reflect or intend to support underlying views on learning, and are mediated by new paradigms of teaching and learning. (Trouche et al., 2013, p. 756)

The issue of professional development was also touched upon in the NMC reports, in relation to the changing role of teachers:

> The evolving expectations also change the ways teachers engage in their own continuing professional development, much of which involves social media, collaboration with other educators both inside and outside their schools, and online tools and resources. Pre-service teacher training programs are also challenged to equip educators with digital competencies amid other professional requirements (NMC/CoSN, 2017, p. 7)

I will now focus on teachers as the core of the efforts for improving meaningful technology-integration and promoting changes in classroom cultures.

Improving Technology Integration in Math Classrooms: Focus on Teachers

Based on what was said in the previous sections, this focus on teachers has two aspects: (i) professional development, and (ii) enhancing teachers' involvement in generating changes, resources and decision-making.

I will begin by drawing from two experiences of in-service professional development programs of which I was part of, both of which emphasized self-reflection by teachers.

Two Experiences of Reflective Professional Development Programs for In-Service Teachers

As the EMAT experience taught us, there is a need to strengthen the mathematical content knowledge of teachers in our country, so the training and self-reflection processes in both programs addressed three aspects: the technological, mathematical and pedagogical.

Experience 1. From 2005-2010, I participated in a long-term professional development program for a small group of six in-service teachers in Mexico. As described in Sacristán, Sandoval and Gil (2011), our approach was for teachers to reflect on the changes in their practice through both training and classroom implementation of DT, document their findings and present them in seminar sessions to their fellow participants and the tutors. For this, we developed a professional development model (Fig. 1), based on works (e.g. Artzt and Armour-Thomas, 1999) that provide models in which teachers reflect on their instructional practice. In the pedagogical design of our model, we considered teaching as a constructive process that requires reorganizing and reinterpreting the subject matter and the practice as a result of experience (Thompson, 1992); and that the knowledge that is derived from social interactions in a (real-life) context is more valuable and significant for the teacher (Liu & Huang, 2005).

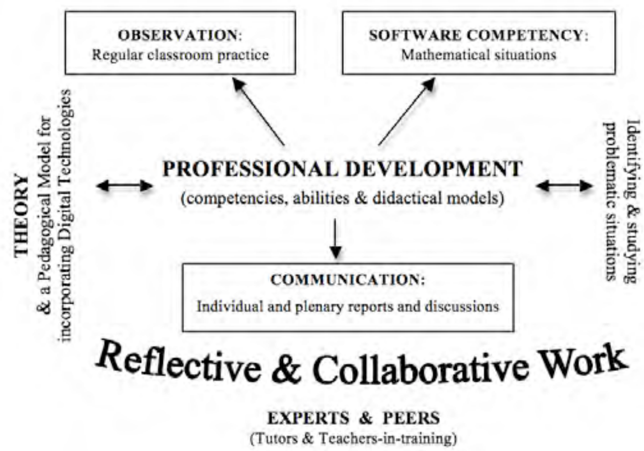

Figure 1. The professional development model described by Sacristán, Sandoval & Gil (2011).

In our program, teachers were involved in: (a) training and development of abilities, for the use of DT in the classroom (mainly Spreadsheets, Dynamic Geometry, CAS and Logo, as well as some applets); (b) the design and planning of teaching strategies and activities that integrate DT; and (c) engaging in observation and reflection-on-action (Bjuland, 2004) of the changes in their own teaching practice with the new tools. The participants also studied and discussed theoretical frameworks and pedagogical models for a meaningful incorporation of DT into the (mathematics) classroom. In parallel, the participants attempted to incorporate DT, as well as the pedagogical models studied, into their real-life classroom activities, analyzing and reflecting upon the potentials, limitations and changes brought forth by this incorporation of DT into their own practice, and that of their colleagues, from various perspectives. These activities and model are schematized in Figure 1. This experience, even though it was a top-down initiative, gave the participants the opportunity to reflect upon and share their personal experiences with the other participants. We consider that the diverse elements of the development model—training, continuous support, processes of reflection, self-observation, and promoting equally the technological, mathematical and pedagogical aspects—were significant for helping generate changes in the participants' professional practices, and enabled them to construct didactic strategies for the use of DT, more in accordance with the specific needs of their students and/or of other teachers. Half of them even appropriated themselves of our model's ideas, for peer training, designing and implementing a training program for other teachers and colleagues.

All six participants considered the educational system as very rooted in traditional ways and difficult to change; but they perceived a change from a technical and presentation use of DT, to more mathematically-centered uses, both in themselves, and in some of those they trained.

Experience 2. In 2009-2011, as described in Parada, Sacristán & Pluvinage (2013), we used a theoretical and methodological model called the Reflection-and-Action (R-&-A) Model, for promoting reflective processes—as a complement to professional development, and for strengthening the teachers' mathematical content knowledge—in two communities of practice (CoP) of mathematics educators (in-service teachers and researchers) in Mexico: one with 46 members; another with 125 members, which met through internet forums and periodically in person. The R-&-A model centered on a mathematical activity that was reflected upon before, during and after a teaching experience, i.e., through three reflective processes: (a) reflection-for-action; (b) reflection-in-action; and (c) reflection-on-the-action. The reflections that emerged enhanced teachers' mathematical content knowledge related to the specific activities, and also helped them recognize the need to adapt methodological and didactic resources, such as DT, to the purposes and characteristics of each student group.

Teachers as Active Collaborators in Meaningful Technology Integration

In the above section, I presented professional development experiences that promote teacher reflections and collaborations. The first one, though successful, was not a teacher initiative. The second one, included a researcher as mediator who proposed and coordinated the mathematical reflective processes. I believe that in order to generate change, teacher involvement and collaboration with researchers needs to take place in a way that makes teachers feel they are decision-makers. I consider this crucial in terms of motivation, beliefs, and overcoming affective apprehensions – which we have seen are areas that can be important barriers to integration and sustainability. Sustainable CoPs or networks involving both researchers and teachers are important and ICT makes it possible to share, discuss and remix resources online. A useful example from which we can draw lessons, is that of Sésamath (http://www.sesamath.net/) in France (see Trouche et al., 2013), which emerged as a bottom-up approach where mathematics teachers started to share and design resources and software. A bit over ten years ago Sésamath started to collaborate with researchers (Trouche et al., 2013). The quality of the resources at the beginning may not have been so good but through the sharing between teachers, and collaboration with researchers, these were greatly improved (Monaghan & Trouche, 2017).

> Explaining the reasons for the success of *Sesamath* requires specific research. The existence in France of the IREMs (Institutes for Research on Mathematics Education), a national network that involves many mathematics teachers, has played an important role. A similar project could perhaps not succeed in countries were such a network, linked with mathematics education, did not exist. (Trouche et al., 2013, p.772)

Concluding Remarks

In this paper I began by quoting Papert (2006) and his criticism of educational systems as a way of introducing the issue of the difficulties of creating meaningful change and technology-integration in classrooms, and the inertia of the classroom and the paper-and-pencil cultures that limit change. This was then expanded in listing some of the barriers identified from decades of research, to that change and integration. After a brief excursion into some of the lessons learned from technological and educational trends, I focused on the teacher as the key player for successful and transformative technology-integration and argued in favor of promoting models of collaboration (such as CoPs and networks) between teachers, researchers and policy-makers that both enhance teachers' professional development, empower them and provide a means for sharing, discussing and improving resources and their implementations, as well as overcoming some of the detected barriers. But one of those barriers is time: educational systems need also change (perhaps pushed by the trends of society) in a way that makes them more flexible for allowing teachers more time to engage in collaboration and innovation.

There are some other aspects that I did not cover in this paper, and that are worth reflecting upon. For instance, what role do MOOCs have, or will have, both in terms of changing the role of teachers and of technology for teaching and learning mathematics; as well as for teachers' professional development? Or are they a way of up-scaling current educational practices without truly innovating them?

CROSSROAD BLUES

Nathalie Sinclair
Simon Fraser University
nathsinc@sfu.ca

In this paper I take up the questions posed by the conference organisers with respect to what we have learned and where we are going in technology-based research in mathematics education research. I begin by troubling the metaphors of crossroads and intersections and argue—through a wide range of considerations in relation to past research, to theory development, to teaching practices, to assessment and curriculum design and to concerns around access and equity—that there may be more fruitful metaphors for understanding our past and imagining our future.

Keywords: Technology, Learning Theory, Equity and Diversity

The metaphors of 'crossroads' and 'intersections' that were chosen for this conference are worth dwelling upon, in relation to research on the use of digital technologies. Crossroads are often used symbolically in literature, drawing on Sophocles' work *Oedipus*, to indicate a crucial moment of choice. In Oedipus there were three possible roads to follow, perhaps evoking past, present and future. But Sophocles' idea of choice may be less about making an independent decision, than about following the roads that have been carved by destiny: Oedipus was always going to end up killing his father. The invitation of the conference organisers to think in terms of crossroads provoked for me some questions about whether we really are at a decision point with numerous options available and whether one choice might be inevitable. The metaphor of intersections, which is similar in some ways, also has more mathematical connotations, ones that evoke significant ideas in geometry, especially around whether lines will intersect, how many times they will intersect and what it means to not intersect at all—all these questions being beautifully perturbed by moving to dimensions beyond the plane. But what could it be, in the context of research on technology in mathematics education, that could be seen as a crossroad or an intersection?

In considering this question, I was reminded of the work of the anthropologist Tim Ingold (2007), whose book *Lines: A brief history* traces the way in which the very idea of *line* functions metaphorically in Western society. He argues that it is so deep and entrenched that we can often find ourselves using it to describe a wide range of phenomena—often using words such as trajectories, paths, roads, trails, courses, routes—that might not actually be so linear or straight or one-dimensional. In his book, Ingold distinguishes two ways of thinking lines: as transporting and as wayfaring. In the former, we might think of getting from point A to point B and the line is the journey that gets us there. In the latter, the line is what one makes as one moves; there is no path independent of the travelling. Transposed to a theory of learning, the former would tend to conceive of learning as a sequence of journeys one might make from one concept to the next; the latter would focus on the act of tracing, on the direction that is taken and the new territory being explored. The former involves reaching successive destinations while the latter involves creating paths. Whereas crossroads and intersections, at least in my own imagery of them, have the past, the present and the future already laid out—you can go this way or that—I wonder whether it is possible to dwell in the present and so withhold the temptation to pre-determine a destination, let alone the journey that will take us there. Getting off the plane, we might even be able to think of creating paths that loop around like a Mobius strip or fan out into a surface or sprout into 17 dimensions, only four of which we might actually be able to see. As with most of our thinking around education, such an approach, which embraces multiplicity, indeterminacy and nonsense, may be the best way to handle the complexity of digital technology use in mathematics education.

Galindo, E., & Newton, J., (Eds.). (2017). *Proceedings of the 39th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* Indianapolis, IN: Hoosier Association of Mathematics Teacher Educators.

In what follows, I have attempted to address the questions and prompts offered by the conference organisers, not in a way that is exhaustive, but that is opportunistic—drawing on my own research and research interests in technology. I will try to keep the provocation of anti-crosswords alive throughout, inviting readers to think less in terms of the image in Figure 1a and more in terms of the image in Figure 1b, which is a replica of the cover of Ingold's book.

Figure 1. From transporting (intersections and crossroads) to wayfaring.

What we Have Learned from the Routes we Have Traversed

One way of seeing research in mathematics education is as an activity that enables us to answer questions, question such as: Should digital technologies be used in mathematics classroom? When is one technology better than another? What does a given technology change the way students learn? Another way of seeing research in mathematics education is as a practice of posing new questions, perhaps transforming the questions we started with so that they better respond to the complexities of the mathematics classroom. In this second kind of practice, the questions shift: new paths are created. Researchers have realised that the first question listed above, for example, depends less on empirical evidence than on assumptions about the goals of mathematics education. The second question may shift if one realizes that each technology might produce a different mathematical conception, in which case deciding on which is the best depends on many factors, ranging from aesthetic choices in mathematics to considerations of what might be evaluated on standardised tests. The third question listed above will also morph as researchers begin to appreciate that the student-technology dyad is a reductive focus, and that the role of the teacher, of the curriculum and of the classroom environment are also significant factors in what is learned.

To answer the question of what we have learned, it thus seems reasonable to consider how our questions have changed over the past few decades of research on the use of technology in mathematics education. I turn to the recently published *Second Handbook of Research on the Psychology of Mathematics Education* (Gutiérrez et al., 2016), which contains a chapter on technology (Sinclair & Yerushalmy, 2016) that considers the research published in the PME proceedings from 2006-2016. This is just one source—other Handbooks could also have been considered—but I have chosen it because it is international and because it explicitly compared research over the past decade with research conducted over the previous decade, which was reported in the first *Handbook of Research on the Psychology of Mathematics Education*, which was published in 2006.

The authors of the technology chapter report that while the 2006 Handbook had been structured into different topic areas (geometry, arithmetic and algebra), the research over the past decade was less amenable to such a categorization, in part because the research was *less explicitly concerned* with particular mathematical concepts. Instead, the primary concerns were theory, the role of the teacher, new technologies and the design of tasks and assessment. The authors found that while the majority of papers in PME proceedings were related to the use of well-known digital technologies such as dynamic geometry environments, computer algebra systems, graphing calculators and spreadsheets, these papers were less focused on the question of 'do they work?' than on questions such as: how do teachers integrate them? How might suitable tasks be designed for the use of a given technology? How might new theories help us understand the role that technologies play in teachers' and students' mathematical activity? Indeed, with respect to the first question, the authors remark on the attention not only to the teacher's role in using a given technology in the classroom, but to the challenge of orchestrating several types of resources: "Technology has opened up new challenges for teaching, not only in terms of their knowledge and beliefs, but also in terms of the complexities of integrating different kinds of resources" (p. 236). The shifting emphasis from the learner to the teacher can also be seen in the recently published edited collection entitled *The mathematics teacher in the digital age* (Clark-Wilson et al., 2014). This book was heavily oriented towards theory and professional development, but marked by a near absence of focus on mathematics. These new strands of research become entangled with prior foci of interest.

An entire section of the chapter is devoted to theorising. The authors cite Drijvers, Kieran and Mariotti's (2009) "plea for the development of integrative theoretical frameworks that allow for the articulation of different theoretical perspectives" (p. 89), especially ones that can extend and refine the two dominant theories found in European research: instrumentation theory and the theory of semiotic mediation. Sinclair and Yerushalmy report that while these two theories, which attend explicitly to the use of digital tools, were predominant, several other theoretical perspectives were used in the PME proceedings over the last decade, many of them *not* specifically attending to digital tools. The authors write that,

> With respect to the papers that do draw on theories, there has been significant development over the past decade, which suggests that the field of mathematics education related to digital technology has certainly matured; it has evolved from being an "experimentation niche" and has become an established domain of research that now carries a more solid message for the future (p. 251).

The authors go on to identify two issues related to theory use: first, they argue that theories related to the use of digital technologies need to be better coordinated with more general and established theories; second, while there has been a burgeoning of theory use and development, the concomitant development of associated methodologies has not kept pace. The idea of better coordination might imply some kind of intersections with other theories, but the simple crossing of one theory with another rarely does justice to the epistemological, ontological and axiological commitments of each.

One thing that we can say about "what we have learned from the routes we have traversed" is that the use of new theories has enabled us to ask different, more refined questions about the use of technology mathematical teaching and learning. For example, instead of asking "did the students learn fractions better?" an instrumental genesis approach might focus more on the new schemes that the students developed in using a given technology to work with fractions; a semiotic mediation approach might focus on the particular gestures that students made while using a technology and how they were transformed into mathematical signs by the classroom teacher. In both cases, there is not a revisiting of the initial question, but a re-layering of it. These questions focus less on the determining whether digital technologies should be used or whether they work better than other resources; they instead take technology use as a given and investigate the complex and often unexpected effects on how learners move their bodies, how mathematical concepts seem to arise and crystallise in new ways and how aspects of classroom activity, such as language use, student agency and material arrangements (of furniture, devices, bodies) change as well.

One final note on what we have learned relates to the evolution of research identified by Sinclair and Yerushalmy from the study of the use of "second wave technologies" [i], which are open in the sense that they do not contain embedded tasks, to an interest in *task embedded* digital technologies, "which direct the actions and uses to more specific purposes" and *evaluative* digital technologies, which "provide feedback on students' responses and actions" (p. 252). The inclusion of tasks and evaluative features may improve accessibility for teachers in that it takes care of some of the decisions that teachers would have to make with more open technologies such as identify and choosing problems and assessing student learning. Of course, the streamlining of open digital technologies may also have an adverse effect on classroom use, inasmuch as openness has often been taken as crucial for encouraging curiosity, expressiveness and agency. Nonetheless, we see in this evolution a complexifying of technology in which it is not simply the hardware/software device with strict boundaries, but instead a more amorphous entity that includes its associated tasks and modes of use. The question is less about technology A then it is about technology A using task B in setting C.

Addressing Issues of Access and Equity within Mathematics Education Today

For the most part, at least according to reports in the literature, the long-standing challenge of access—that is, whether students and teachers have access to computers and to software—is no longer the main hurdle in digital technology integration. Not only have computers become more common in classrooms, but many schools have embraced tablets; furthermore, the trend towards free software (including free versions of software programs that were originally licensed) has removed some hurdles for teachers, especially teachers in developing countries[ii].

As intimated above, the greater hurdle for technology integration relates to teaching practices, to curriculum and to assessment—and, in a sense to access to professional development (see Clark-Wilson et al., 2014). In terms of equity, there have been two main, different approaches to supporting diverse learners' needs through the use of technology. These seem to entail quite different understandings of what certain learners need in order to have more mathematical success. The development of new digital technologies addressing equity has focused mainly on students diagnosed with learning disabilities (MLDs), as well as deaf and blind students[iii]. In the area of the MLDs, for example, there have been several software programs created to help struggling children improve their number sense. These tend to be focussed on particular aspects of number and designed as *instructive*[iv] environment, which provide instant evaluative feedback and tend to target procedural skills. Such programmes aim primarily to address the deficits of the children; equity thus identifies the problem as belonging to the learner (rather than to the mathematics, the environment, etc.). Unfortunately, despite some promising results (Butterworth & Laurillard, 2010), researchers such as Goodwin and Highfield (2013) have shown that children working with the instructive digital technology were more focussed on receiving positive feedback than on discussing or reflecting on the embedded mathematical concept.

A different approach has been taken up by researchers in Brazil (see Fernandes et al., 2011; 2013; Santos, et al., 2013), who have studied the use of digital technologies in inclusive classrooms (that may include deaf, blind, seeing and hearing students), and have developed more *manipulative* technologies. Their design and research process seeks to identify different ways of interacting with mathematics that may help all learners, and not just those diagnosed with disabilities. Such work requires re-thinking mathematics (as something that can be heard, for example, instead of seen through symbols or graphs) instead of merely simplifying traditional mathematics or breaking it down into steps. Their approach to equity identifies the problem as belonging less to the learner than to the mathematics (or the ways it is taught). A similar approach was taken in the study reported by Cohen et al. (2017), which involved the use of the *manipulative*, mutitouch iPad app *TouchCounts* with grade 1 children identified as low-achievers in the mathematics classroom. The app, which enables tangible, visual, aural and symbolic modes of interaction, was used both in the whole classroom situation, but also in a smaller group setting with the identified children. The use of fingers, which enabled these children to improve their subitising and awareness of place value, was also helpful for the other children in the classroom.

Returning to the metaphors of crossroads, it seems that one image that drives the choice of technology used with MLDs is that the children cannot take one road, so they must take the other, thereby setting off a chain of entailments about two kinds of mathematics, two kinds of learners, two kinds of technology. Such an approach fails to consider the extent to which the traditional technology of mathematics (paper and pencil) is implicated in the very nature of school mathematics and the possibility that new technologies may change what school mathematics looks (and sounds and feels) like, and what mathematical actions might be valued in the classroom.

Barriers within Research Traditions, Educational Policy, and Teaching Practice that Impede Researchers', Students' and Teachers' Success

In the first section, I identified the recent burgeoning of theory that was evident in the last 10 years of research published in the PME proceedings, as well as the current tendency for digital technology-specific theories to be isolated from other theories in mathematics education. A similar phenomenon—the segregating of technology and non-technology research—can also be seen in peer-reviewed journal publication. This is evident when comparing articles published in JRME, FLM and ESM (three of the top-ranked, long-standing international journals in mathematics education). As Table 1 shows, there are relatively few articles that focus explicitly on the teaching and learning of mathematics using digital technology. The frequency of publication seems to be quite stable when comparing articles published in 1996, 2006 and 2016.

One reason for this low frequency is the fact that there are several journals in which authors can choose to publish their work, journals where technology is an explicit focus (for example, IJCML (now TKL), DEME, IJMTL, CJMSTE). Publications in these 'technology journals' may not be in conversation with publications in journals such as JRME, FLM and ESM, thus leading to a group of theories that specialise in the use of technology and another group of theories that more or less ignore issues relating to technology[v]. This has been partially true for the influential learning trajectory research, which though tending to a more Vygotskian perspective, which recognises the central importance of language and tools in learning, continues to identify and disseminate trajectories that do not specify the use of digital technologies. If technologies were used in any of the tasks studied by researchers, it is assumed that the stepping stones from one concept to another could be made *no matter what* technology is used—but the default technology is almost always paper and pencil. This point of view contradicts the Vygotskian premise, but also reifies a certain vision of mathematics teaching and learning that makes it more difficult for digital technologies to be taken up more widely—and thus contributing to the continued debate around "the basics" (see Roth, 2008).

Table 1: Comparison of Articles Focused on the Use of Digital Technology Across Journals

	JRME		FLM		ESM	
	Technology	Total	Technology	Total	Technology	Total
2016	1	12	1	29	3	61
2006	0	13	2	31	0	50
1996	0	23	1	23	2	32
Total	1	48	4	83	5	143
	2%		5%		3%	

The ignoring of technology has also tended to occur in the areas of curriculum design and assessment (some of which is based on learning trajectory research). While standards in most countries may have language that includes reference to the importance of technology, the actual concepts that are listed, and the order in which they are listed, are determined in a way that is absolutely independent of any particular digital technology. For example, in the area of geometry, which is my research focus, a curriculum or textbook that asks students to engage in geometric construction by drawing shapes that have numerically determined side lengths and angle measures is anti-dynamic[vi]. This after two decades of research showing the pedagogical benefits of using dynamic geometry environments in the teacher and learning of geometry.

Lines can be dangerous. Lines can begin as imaginary paths to be followed, but once carved, they can become troughs that are hard to escape. Research in the use of digital technologies can sometimes reinforce troughs, when it focuses more on how technologies make concepts more efficient or quick to learn, rather than underscoring the sometimes unexpected conceptual shifts that innovative digital technologies can occasion.

The issue of assessment may be particularly important in high school and undergraduate contexts, where the use of digital technology on tests is often disallowed, meaning that students may be learning with a given technology but are being assessed as if that technology was a disposable scaffold to learning. Sangwin et al. (2010) argue, "if a teacher encourages students to make extensive use of tools in a course but does not allow their use on the end-of-course test, are students being given the opportunity to show what they learned with the use of such tools?" (p. 229). The issue is complex, however: in a study of secondary school teachers in Canada, Venturini (2015) found that teachers were reluctant to use digital technology assessment tasks because they were concerned that the students would learn as they used the digital technology, which was seen to contradict the purpose of assessment.

In terms of teaching practices and teachers' success, there has certainly been a dearth of research in this area. As Sinclair and Yerushalmy write, "Compared with research on student learning with technology, research on the teacher has not been as well developed" (p. 260). Nascent theory development began with the framework of TPACK, which describes the different types of knowledge that teachers may use in their teaching practices, adding technology to the well-known pedagogical and content knowledge aspects. As a theory, it is rather limited. More recently, theories that provide a more analytic lens on the role of the teacher in teaching with digital technology have been developed, based on theories of instrumental genesis (such as instrumental orchestration). Ruthven (2014) has also proposed a framework for analysing the teaching expertise that underpins successful use of digital technology in the mathematics classroom. His framework highlights the tensions that arise for teachers when trying to integrate technology, that relate to the lack of articulation between digital technologies and other resources such as textbooks, curricula and assessment. Worth studying would be situations in which this articulation has been attempted (perhaps with a high-quality e-textbook (see Pepin et al, 2015) or with trajectories that have been elaborated using digital technologies).

Laying the Groundwork for Future Crossroads or Intersections Among Theory, Research, and Practice

When thinking about future crossroads or intersections, two recent, related developments in educational research come to mind, both of which are highly relevant to technology. One is the association of mathematics with computational thinking (CT) and the other is the emergence of the idea of STEM. Both developments have received substantial funding over the past decade (and have given rise to specialized conferences, journals and special issues) and will likely shape future discussions around the role of technology in mathematics education. In both cases, the role of technology shifts quite significantly from the way it has been conceived in research over the past two decades. Before commenting on whether or not we are at a crossroads, I would like to look more closely at each new development in turn.

In the case of CT, the research initiatives most closely associated with mathematics education have involved studying the use of computer programming as a means to support mathematical learning, much in the tradition of Papert (1980). For example, Benton et al. (2017) as well as Gadanidis et al. (2016) explore the use of Scratch programming in relation to concepts that are recognizably mathematical (e.g., angle, binomial theorem). In these two cases, the digital technology in question is one that was not designed specifically for the teaching and learning of mathematics, and that entails practices and values that are specific to the domain of computer science.

In the case of STEM, the nature of the "T" seems to be less precise than in CT, involving not so much the use of programming (or coding), but instead the use of digital tools. For example, in the STEM videos published by the Teaching Channel[vii], students use scientific tools such as digital thermometers or calculators as well as simulations (a programme for building and testing rollercoaster). In these cases, the technology is not vectored towards the learning of mathematics, but rather to the completion of what is essentially a science or engineering project. Whereas the CT connection privileges computer programming as the primary mode of engagement with digital technology, the STEM agglomeration features the use of digital technologies that are oriented towards their pragmatic value rather than their epistemic value (see Artigue, 2002 for a discussion of the distinction between these two values).

I bring up these two examples because of the stress they will likely place on the way digital technologies are used and researched in mathematics education. They displace technology from being constitutive of mathematics (à la Rotman, 2008), which may result either in the displacement of technology to something you do in your CT lesson, not in mathematics, or in the isolating of technology as one element in a STEM fruit salad of disciplines that shares little disciplinary value with mathematics. Again, a crossroads view of things encourages us to think about choices, about going this way or that. But, at this moment in time, what we may need more of is attending to the multiple threads in which mathematics education is entangled and how the choices that seem on offer are already the consequence of a set of assumptions and commitments—and to think, what could things look like before the crossroads?

Acknowledgments

Thanks to David Pimm for his reactions to the first draft and his gentle way of elbowing me off the road. Thanks also to Sheree Rodney for collecting the data used in Table 1.

Endnotes

[i] Sinclair and Jackiw (2005) describe three ways of technology evolution in mathematics education. The first wave focused on learners' interactions with technology (such as Papert's research with Logo); the second wave shifted from programming languages to technologies that were more transparently related to the school mathematics curriculum, such as graphing calculators, computer algebra systems and dynamic geometry environments; the third wave was concerned with technologies that attended to the social context of the mathematics classroom.

[ii] But this should not necessarily be seen as a positive development for mathematics education. Paying software programmes were maintained and came along with teacher support and, frequently, curriculum materials; they could be expected to be developed by professional software designers, and to last for long periods of time.

[iii] As far as I am aware, there are very few examples of digital technologies that have been designed for other groups of students who have been identified as under-achieving, based on gender,

race or socio-economic status. One exception, which dates back to the 1990s, was Klawe's E-GEMS project (see Inkpen et al., 1995), which was targeted specifically for girls. A small number of researchers have also explored the use of digital technologies with bilingual learners, who also face particular challenges in the mathematics classroom (see Ng, 2016).

[iv] Goodwin and Highfield (2013) distinguish three types of digital technologies: instructive, manipulable and constructive. Sinclair and Baccaglini-Frank (2014) describe each as follows:

> Instructive digital technologies tend to promote procedural learning, relying on evaluative feedback and repetitive interactions with imposed representations. Manipulable digital technologies enable the imposed representations to be manipulated so as to engage students in discovery and experimentation. […] Finally, constructive digital technologies are ones in which learners create their own representations, which are often the goal of the activity, thereby promoting mathematical modeling and what Noss and Hoyles (1996) characterize as expressive uses of technology. Goodwin and Highfield argue that while instructive technologies may be well-suited for procedural learning, manipulable and constructive technologies better support conceptual learning.

[v] That is it possible to do this strikes me as quite interesting, but coherent with the view that mathematics—and thus the learning of mathematics—can be separated from its technologies.

[vi] And example of this can be found in the New York State Common Core Mathematics Curriculum.

[vii] See, for example: https://www.teachingchannel.org/videos/teaching-stem-strategies and https://www.teachingchannel.org/videos/stem-lesson-ideas-heat-loss-project. An analysis of these STEM videos is currently in preparation (Bakos et al, in preparation).

This paper is part of a three-year inquiry that supports and investigates the work of groups of mathematics teacher educators using technological tools to design and implement multimedia practice-based teacher education curriculum materials. This paper describes the kinds of activities, interactions, and tools used by mathematics teacher educators to engage in such work. Using Engeström's Activity Theory as a framework, we organize our observations of the groups' work sessions, noting differences across the groups' objectives and ways of organizing the division of labor and tools for engaging in the work. Our results suggest the activity of collective curriculum development amongst teacher educators can take on at least three distinct types of interactions. We present these types of interactions as "caricatures" (Lambdin & Preston, 1995), using data from all of the groups to represent composite descriptions.

Keywords: Curriculum, Instructional Activities and Practices, Teacher Education-Preservice, Teacher Education-Inservice/Professional Development, Technology

Introduction

We share data from an ongoing NSF project that engages groups of mathematics teacher educators in collective work using technological tools to design and implement online practice-based teacher education curriculum materials. The work within that project can be broadly framed as part of the larger efforts to reimagine mathematics teacher education through the development of a common curriculum (Ball and Forzani, 2011) centered on practice-based experiences for enabling novices to learn to teach *in, from*, and *for* practice (Lampert, 2010). The efforts to reimagine mathematics teacher education may tread some of the same terrain as the well-studied efforts to reform K-12 mathematics through the design of better curriculum (e.g. Lappan & Phillips, 2009) and professional development for supporting teachers to use those materials (Remillard, Herbel-Eisenmann, & Lloyd, 2009). Both efforts attempt to address deficiencies in the current systems by reimagining, in some measure, what happens in instructional settings (whether in K-12 or higher education); and both treat curriculum as a lever to do that.

To understand how teacher educators may use the curriculum of teacher education to make teacher education practice-based, it is useful to consider the different ways in which teachers use curriculum in K-12 settings: While there is a tradition in which curriculum developers create materials, teach them to teachers, and then teachers implement them with fidelity as a goal, that is by no means the only use. Reviewing the literature of curriculum use studies, Remillard (2005) describes three kinds curriculum use studies and their corresponding perspectives. The first set of studies takes the perspective of curriculum as a "fixed entity" and takes for granted that the teacher serves as a "conduit for the curriculum". The second set of studies takes the perspective of the curriculum as a more or less stable starting point from to which the teacher makes adaptations in ways that may be more or less faithful to the curriculum design. The third set of studies takes the perspective that the teacher is positioned as an active interpreter of the written curriculum and "author" of the enacted curriculum (Doyle,1992). Ball and Cohen (1996) suggests a reconceptualization of curriculum as a site first for teacher learning and then a resource for student learning. This suggestion fits well into this third perspective as such an approach gives teachers an opportunity to work collaboratively with curricula materials in order to decide how they will use them to solve the problems of improvement.

In this paper, we aim to describe and explain how groups of teacher educators organize their collective work around the task of designing and implementing technology-mediated practice-based curricular materials for teacher education. Research on curriculum use suggests that there could be a host of ways that the field addresses the larger problems of developing common practice-based curricular materials for teacher education; and each of these approaches comes with different kinds of affordances and constraints for the work at hand. We wonder about the various ways in which mathematics teacher educators might elect to organize themselves around the task of developing technology-mediated practice-based teacher education materials and what sort of affordances and constraints can be found across the variety of organizational choices. In this paper, we describe and explain three ways in which 12 groups of mathematics teacher educators engaged in the activity of collectively developing and using technology-mediated practice-based materials for teacher education. To do this, we use methods from activity theory, noting differences across the groups' objectives, division of labor, and tool usage. To illustrate these differences, we borrow a practice from Lambdin and Preston (1995, p. 130) and create "caricatures" of groups to describe these differences, where a caricature represents a composite description by combining information from all 12 groups.

Methods

Setting

In this paper, we present our findings regarding the types of interactions between 12 Fellows and their Inquiry Group Members (IGMs) across a two-and-a-half year timeframe from May, 2014 to November, 2016. The Fellows come from research institutions (Doctoral institutions with the moderate, higher, and highest levels of research activity) and serve in a variety of positions (Assistant, Associate Professor, and Full Professor as well as Lecturers). Next, each Fellow formed their own inquiry group that included one to seven members from a variety of institutions and geographic locations. The Fellows assembled inquiry groups for the purposes of developing technology-mediated mathematics teacher education curriculum materials.

To develop these materials, the Fellows and their Inquiry Group Members had access to the tools and capabilities within the Lesson*Sketch* platform (www.lessonsketch.org). Lesson*Sketch* provides teacher educators with a suite of online tools for composing and interacting with multimedia representations of practice. ***Depict*** offers users a drag-and-drop environment allowing users to easily represent scenes from a classroom in the form of a storyboard. ***Annotate*** allows users to make time-stamped comments on a variety of media files, such as video, audio, or storyboards. ***Plan*** offers users a drag-and-drop environment for authoring agendas for interactive experiences for clients, integrating multimedia tools for both producing and interacting with representations of practice with more traditional course planning tools such as multiple choice and open-ended question generators. In addition to those tools, Lesson*Sketch* also has accompanying capabilities for enabling users to manage and study client interactions with the experiences. One such capability is the ***Experience Manager*** that allows users to distribute online experiences to clients by either assigning the experience directly to clients in Lesson*Sketch* or by providing them with an access code or an email link. The second capability, ***Reports,*** allows users to collect data about clients' activities within such experiences, including both user contributions (such as responses to questions or pins on a video) and behaviors (such as time spent on an activity).

For the first year of the project, the Fellows worked on drafting an instructional module(s) for one of their own courses. The Fellows' modules (like the Fellows' teaching assignments) were

Galindo, E., & Newton, J., (Eds.). (2017). *Proceedings of the 39th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* Indianapolis, IN: Hoosier Association of Mathematics Teacher Educators.

varied, with some designed for pure mathematics coursework, others for mathematics methods coursework, and still others for general education coursework. During the first year, the Fellows met together with the project group for two face-to-face meetings and participated in monthly online meetings across the year to check in with one another. During the second year of the project, the Fellows recruited Inquiry Group Members to help implement and/or construct modules. During this time the Inquiry Group Members met together with their Fellow and with the project team for face-to-face for work sessions on three occasions and held their own meetings throughout the year (either virtually or face-to-face on their own schedule). The Fellows continued to meet virtually, with one another, every month.

Data Collection

We collected a variety of data to document the ways inquiry groups organized themselves to collectively develop and/or enact curricular materials. For this research, we documented each group's work in several ways. During the year one face-to-face meetings, we observed the Fellows' interactions with one another and the project staff, collecting audio recordings of whole group discussions and taking field notes during their work sessions. During the year two face-to-face meetings, we observed the Fellow's interactions with the Inquiry Group Members and with project staff, taking field notes about the ideas exchanged and the roles various group members were taking on. Across both years, we conducted and recorded monthly interviews with Fellows using video conferencing software, to support their progress. In the Fall of 2016, we surveyed Inquiry Group Members using adapted versions of the Concerns Based Adoption Model (George, Hall, & Stiegelbauer, 2006) and Team Climate (Anderson & West, 1998) Surveys. We used this survey to investigate the group distinctions as well as some of our observations about differences in possible group characteristics (state of the modules when the IGM joined the group, agency, similarity of professional goals) more thoroughly. We used Inquiry Group Members' responses to the survey to verify the nature of each group's activity (e.g., whether or not the primary activity and ways of working—*implementation, collective construction,* or *independent construction*—we had observed were compatible with the primary activity and ways of working the group members identified) as well as to confirm some key characteristics that were difficult to fully perceive from observation alone. Lastly, we collected system-use data to understand whether and how different groups used the various tools and capabilities within the Lesson*Sketch* platform.

Data Analysis

To begin describing the inquiry group interactions in a systematic way, we analyzed the data using Engeström's (1987) activity theory, and its related mediational triangle (Figure 1). Activity theory was developed to model goal- (or object-) oriented behavior as activity systems, accounting for the collective nature of human activities as interactions between distinct elements.

While all the inquiry groups could be described as comprising the same type of *subjects* (mathematics teacher educators) working on behalf of the same type of *community* (fellow mathematics teacher educators) for the same *outcome* (namely educating future or current mathematics teachers), our observations of their activities suggested several important differences across groups within the *object*, *division of labor*, *rules*, and *tool* components of the mediational triangle. First, we noticed differences in "what" the inquiry groups were collectively focused on doing together, that is a difference in the groups' *objects (or goals)*. Avowedly what they all had to do related to an instructional module. Groups seemed to primarily be focused either on constructing modules (either collectively or individually) or implementing a module created by the Fellow or some other group member. Based on these differences, we categorized the groups' activity systems according to one of two objects: *construction* or *implementation.*

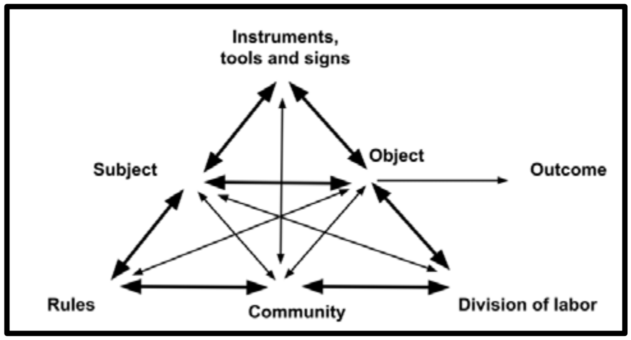

Figure 1. Engeström's mediational triangle (Engeström, 1987)**.**

Second, while all of the groups with an *implementation* objective seemed to use the same *division of labor*, namely the Fellow played the role of "curriculum writer" while the Inquiry Group Members implemented that curriculum in their own settings, we noticed differences in how those groups with *construction* objectives divided the labor. Some of those groups took on the task of constructing a module(s) in such as way that the Fellow and the Inquiry Group Members worked together to develop a single set of materials; other groups took on the work so that the Fellow played the role of "lead innovator"—developing his or her materials first—and the Inquiry Group Members each followed suit by patterning their own materials after the Fellow's work, but not necessarily in ways that would allow for the materials to be implemented together. Based on these differences in the *division of labor* we categorized the construction groups into two different types: *collective construction* or *independent construction*.

Third, we noticed some important broad similarities in the ways the tools mediated the work of the Fellows and Inquiry Group Members. To begin, the ***Depict***, ***Annotate,*** and ***Plan*** tools were primarily used for their authoring capabilities. While the ***Plan*** tool was created for authoring experiences, there are many other ways in which ***Depict*** and ***Annotate*** could be used. While the ***Depict*** tool can be used to author content for experiences (e.g., develop storyboards for students to interact with), it can also be used to provide feedback to students' contributions (e.g., to provide a visual interpretation of a student's vague narrative account of a classroom event and ask whether it happened in that way). Similarly, while the ***Annotate*** tool can be used to author content for experiences (e.g., identify moments of a video for students to comment on), it can also be used to provide feedback to students about their contributions within an experience. For the most part, however, we observed the Fellows and their Inquiry Group Members using ***Depict*** and ***Annotate*** to *author module content*. Thus, for the purposes of this work, we classified the use of ***Depict***, ***Annotate,*** and ***Plan*** as mediating primarily the authoring of modules; while the capabilities within ***Experience Manager*** mediating the *distribution of modules for review* prior to implementation as well as *distribution of modules for implementation* with students; and the capabilities of ***Report*** for *analyzing aspects of the module use*.

Finally we noticed some important differences across groups in terms of the ways in which they used the different capabilities (*Authoring* Modules, *Review* and *Distribution* Modules for Implementation*,* and *Analyzing* Module Use*)* in the Lesson*Sketch* system to mediate their collective work. We suspected that there would be meaningful differences in the ways in which these groups used the tools and capabilities to mediate their collective work, but since much of their tool usage happened when we were not directly observing them we could not be certain which tools and capabilities they were accessing without a closer examination of system data.

Results and Discussion

In this section, we present our overall findings by developing caricatures or composites of the Inquiry Groups' work based on their group structure, the conditions that seemed to characterize the group's activity system, and the ways in which the tools and capabilities afforded by the Lesson*Sketch* platform seemed to mediate that activity. By taking the inquiry group to represent the unit of analysis, we emphasize that the caricatures do not reflect the work of individuals but the larger activity system. The caricatures were created during the data analysis process as opposed to being a priori to the analysis.

The categorization of the groups or subgroups as engaged in *implementation, collective construction,* or *independent construction* activities came fairly easily from the observations as described above. Our observations were confirmed in the survey responses from the Inquiry Group Members. Those working in *implementation* groups describing their work primarily in terms of *using*, *piloting*, or *suggesting revisions* to the module created by the Fellow and those in the *construction* groups describing their work primarily in terms of *building*, *designing*, or *creating* module(s). Inquiry Group Members engaged in *independent construction* activities indicated relatively more concern about the personal consequences of the project including logistics and the time involved in the activities of the project than those engaged in *collective construction* activities. To represent these composites in more memorable ways, we use the metaphor of different ways of having a dinner party: (1) Hosting; (2) Potluck; (3) Cooking Club.

Hosting. One way to organize a dinner party is for the host to prepare a single meal for the guests. While customs may differ, this kind of organization usually calls for the bulk of the meal preparation to take place prior to guests' arrival. Similarly, those groups with an *implementation* objective commenced after the Fellow had drafted a version of the module that was ready for distribution and the primary focus of the group was to implement a common set of teacher education modules. These groups tended to be large (~5 members) and the members held similar professional goals, usually in the form of a common course or a common approach to teacher education. Coming back to the metaphor of a host preparing a meal for guests, the host needs to consider ahead of time the match between the dish prepared and the kinds of foods the guests are accustomed to eating. The host could ensure this match by preparing a dish common enough to be palatable to all of the guests or by selecting guests amenable to the kind of dish that will be served. We see evidence of the Fellows in these groups using both strategies, both designing the module around common themes in the field as well as identifying Inquiry Group Members according to similar perspectives on teacher education. Once these groups gathered, their activities were highly structured, with the Fellow providing the module, the Inquiry Group Members enacting it with their students and providing data back to the group to inform the Fellow's revision of the module. These clearly defined roles seemed to come with fairly hierarchical structures that positioned the Inquiry Group Members to enact the module without revisions, as to provide the cleanest data back to the Fellow. While some exceptions were made, these negotiations happened privately between the Fellow and the individual Inquiry Group Member. This kind of hierarchical structure guiding the *division of labor* is somewhat unsurprising if one considers the metaphor of a host preparing a single meal for many guests. Modifications to the meal just prior to the serving could be quite difficult for a host to accommodate and such modifications could jeopardize the more primary activities of the evening, such as sharing a meal together or gathering feedback about a dish. The kinds of comments Inquiry Group Members made following implementation of a module were summative—focused tweaking small elements of the module. Again, in light of the metaphor, this is perhaps unsurprising given the kinds of access guests at a dinner party have to the actual production of the meal. The structure of this type of Group could be observed in the use of the technological tools, the Fellows in these groups (compared with Fellows from the other two groups), were the heaviest users of the *review, distribution,* and *analysis* tools; while their Inquiry Group Members (compared with Inquiry Group Members from the other two composites), tended not to use many tools.

Potluck. A second way to organize a dinner party is for everyone to bring a single dish to share with others at the host's home and collectively the individual contributions make up the meal, sometimes called a potluck. Those groups engaged in an *independent construction* activity, commenced after the Fellow had drafted a version of the module and the focus of these groups' activity was on both providing feedback on the Fellow's modules and using the Fellow's module as inspiration for each member to make their own. These groups also tended to be large (~5 members) and its members held different professional goals; some joining because the work might offer research opportunities while other members joining to learn how to use technology to construct materials for their own courses. Like the *Potluck* model for dinner parties, these groups handled their collective work by dividing and conquering, with members carrying out their roles in fairly disconnected ways, working parallel to or in tandem to one another's efforts sometimes unaware of the various work of other members. Unlike the *Hosting* model for organizing dinner parties, *Potluck* models do not require a host to ensure that the prepared dishes match the kind of foods guests might be interested in consuming. For one, a guest's own dish can provide some assurance for such a match, but also the wide variety of dishes to choose from ensures that guests will find something they are amenable to eating. Similarly, the Fellows in these groups were not observed needing to make any sort of accommodations or negotiations regarding implementation of modules, nor did the group make any sort of official bid that any materials would be implemented, leaving it mostly up to the Inquiry Group Members to decide what, if anything, they would like to try out in their own contexts. That said, like the participants at a potluck who sometimes seek out recipes for particular dishes brought by guests, Inquiry Group Members' knowledge was seen to be a resource for offering ideas for their own module and revisions for the Fellow's module. Both the Fellows and their Inquiry Group Members were the heaviest users of the authoring capabilities (when compared with their counterparts across the other two groups).

Cooking Club. A third way to organize a dinner party is for guests and host to plan and cook a meal together as with cooking clubs or progressive dinners. Distinct from the *Hosting* or *Potluck* models for organizing a dinner party, the *Cooking Club* model for dinner party organization does not require for the bulk of meal preparation to happen prior to commencing the activity. Instead, the host takes on the responsibility to send invitations or perhaps make provisions for supplies for the meal; and the guests for such events arrive with anticipation for taking part in the cooking. Similarly, groups engaged in *collective construction* activities commenced at a time when the module was still in the form of a vision and not yet drafted in any concrete way and the primary focus of the group was to create a common set of teacher education modules. These groups tended to be smaller (1 to 3 members) and members held similar professional goals usually in the form of a common course or a common approach to teacher education. Unlike the *Hosting* model for organizing dinner parties, *Cooking Club* models do not place exclusive responsibility on the host for ensuring that the prepared meal matches the kind of foods guests might be interested in consuming, because the decision on the meal to be prepared is shared by the group. Similarly, the Fellows in these groups were not observed needing to make any sort of accommodations or negotiations regarding the eventual implementation of the collectively developed module. Perhaps like a *Cooking Club* that has been gathering for some time, these groups' exchanges were characterized by an insider language, where group members seemed to have a shared understanding for the meaning and value of particular constructs (making it sometimes difficult for an outsider, such as the researchers, to follow the conversations). This way of using language seemed to, at least in some ways, make the Inquiry Group Members' knowledge readily accessible for use by the group to design and revise the materials. The activity of *collectively constructing* modules seemed to promote the sharing of practical knowledge within these groups that would often times move fluidly between bursts of creation followed by more theoretical conversations. We liken this kind of sharing of knowledge through collective action to the gathering of individuals around a counter to collectively dice a meal's ingredients and who may learn simply by carrying out the practice of dicing near others who are also dicing, but might also stop to clarify the distinctions between the practices of chopping, dicing, and mincing. The Fellows in these groups, while not the highest users in any of the categories of *authoring*, *reviewing, distributing*, or *analyzing*, these Fellows maintain fairly high uses across all capabilities; while their Inquiry Group Members were the only frequent users of the *reviewing* capabilities (compared with Inquiry Group Members from the other two composites), they were also users of all capabilities.

Significance of the Research

In the above findings, we presented three different caricatures representing the ways in which we observed teacher educators organize themselves around the activity of constructing mathematics teacher education curriculum materials. In the presentation of these three caricatures, we see two important differences between the larger body of literature on curriculum use and this work. The first difference stems from the fact that these groups were designing digital materials that can be easily edited which is distinct from the more canonical use of curriculum in which materials are less amenable to such edits. Related to this difference, we take as critical the finding regarding the ways in which the digital tools seemed to mediate various kinds of activities related to the design and use of online curriculum material. The second difference stems from the fact that these groups were comprised of teacher educators, rather than K-12 teachers. Distinct from K-12 curriculum use, we note that the "status" of curricular materials in this project is far from "fixed". The mathematics teacher educators featured worked closely (or perhaps they were themselves) with curriculum writers. Related to this difference, we take as critical the finding that teacher educators not officially "charged" with the writing of the materials (as was the case for the Inquiry Group Members) can be positioned in very different ways within the work of developing and implementing curricular materials for teacher education. Perhaps most importantly, we see this work as laying the groundwork to begin asking questions about what each of these various models of activity affords to the work of designing and implementing teacher education with digital curricular materials.

This study examines the perceptions of the Standards for Mathematical Practice (SMPs) held by 34 middle school mathematics teachers (MSMTs) as evidenced by their interactions with seven lessons drawn from thinking device (TD) and delivery mechanism (DM) curriculum types. MSMTs' perceptions of the SMPs consistent with their wording in the Common Core State Standards for Mathematics (CCSSM) included a flexible definition of precision beyond calculation. However, MSMTs also possessed a number of perceptions of the SMPs that were at odds with the wording of these standards in the CCSSM. For instance, they considered a curriculum resource's imperative for students to use a tool to be an indication of SMP 5. MSMTs whose district-adopted curriculum was categorized as TD had significantly less invalid SMP justifications than teachers using DM curricula t(34) = 2.41, p = .022.

Keywords: Curriculum, Standards, Middle School Education, Instructional Activities and Practices

The majority of students in the US are situated within educational systems linked to the Common Core State Standards for Mathematics (CCSSM). As we enter the seventh year of CCSSM implementation we find ourselves at an educational crossroads. These crossroads consist of reflecting on what we have learned thus far with regard to CCSSM implementation and determining where we need to go from here to realize these ambitious standards. CCSSM research has investigated the standards themselves (Schmidt & Houang, 2012), examined elementary level mathematics textbooks' alignment to the CCSSM, ascertained teachers' perceptions of the CCSSM (Davis et al., 2014), and described ways that teachers make the Standards for Mathematical Practice (SMPs) explicit to students during classroom instruction (Selling, 2016).

Opfer, Kaufman, and Thomas (2016) investigated the perceptions of a nationally representative sample of K-12 public school teachers in the US and found that teachers reported spending less time on SMP 7 (structure) or SMP 3 (constructing arguments) than other SMPs. In contrast, other research (Davis et al., under review) suggests that teachers consider the SMPs to be components of each lesson that they construct. Opfer and colleagues also found that teachers at the elementary level were more likely to misunderstand SMP 4 (modeling) than secondary teachers. Heck and colleagues (2011) noted that a group of mathematics educators and policy researchers they surveyed were concerned about the separation of the SMPs from content in the CCSSM as well as a lack of clear descriptions of what a trajectory in learning SMPs might look like across grades. An important component that is missing from this research involving teachers' perceptions of the CCSSM is the mediating presence of their district-adopted curricular resources. Mathematics teachers frequently use textbooks (Banilower et al., 2013) and other research that we have completed as part of our larger study suggests that teachers interpret textbook materials vis-à-vis the CCSSM (Roth McDuffie et al., 2017). Given this setting, we were especially interested in the perceptions of teachers using different types of curricula as textbooks that have been referred to as standards-based were created from documents that contained processes similar to the SMP. Hence, this study was designed to answer two research questions.

1. What perceptions do a group of middle school mathematics teachers (MSMTs) hold with regard to the SMPs as revealed through their work with two types of curricular resources?
2. How do the SMP perceptions of a group of MSMTs differ by district-adopted curriculum type?

Frameworks

Teachers' Interactions with Curricular Resources

We take the perspective that teachers' curriculum use involves what Remillard (2005) describes as participation with the textbook. That is, we consider teachers to be active interpreters of their curricular resources. Moreover, we consider these interpretations to be governed by teachers' personal resources (e.g., beliefs), the contexts in which they work, orientation, professional identity, students, and curriculum (Stein, Remillard, & Smith, 2007). Additionally, teachers themselves are transformed by their work with curricular resources (Remillard). We situate teachers' work with their curricular resources within Stein and colleagues temporal phases of curriculum use. In particular we use their terminology *intended curriculum* to denote the lesson plans that teachers create from their curricular resources or *written curriculum*. We consider curricular resources to encompass all of the materials associated with a program (e.g., assessment resources) in print or digital forms.

Types of Curriculum Programs

In earlier work (Choppin, McDuffie, Drake, & Davis, 2015) we conceptualized curricular resources based upon monologic and dialogic communication functions. Curricula were categorized as following a *delivery mechanism* (DM) if they serve a monologic function where content is viewed from the perspective of an expert and delivered to novices. Curricula were categorized as *thinking device* (TD) if they serve a dialogic function where the goal involves soliciting the thinking of novices and using this knowledge to move novices towards more complex thinking levels. We use the terminology *TD teachers* and *DM teachers* to denote teachers whose districts have adopted TD curricula types and DM curricula types, respectively, and we place the curriculum type after the teacher's pseudonym in the results section.

Methods

This study is a component of a larger study examining how MSMTs interact with their curricular resources in the context of the CCSSM. This component of the larger study used staged lesson plans (SLPs) to reveal MSMTs' interactions with their curricular resources vis-à-vis the CCSSM. In an SLP, teachers who have used one type of curricular resource for at least one year were given one week to create an intended curriculum from a different type of curricular resource. The SLP was designed to reveal how MSMTs used their district-adopted curricular resources by asking them to plan from a different type of curriculum resource. During the SLPs MSMTs were asked a series of questions involving the CCSSM content standards and SMPs, the SLP curricular resources as well as the district-adopted curricular resources, and the intended curriculum. Participants were purposefully drawn from school districts that had adopted both TD and DM curricula in print and digital forms from both rural and urban middle school settings. A total of 62 different MSMTs working in four different CCSSM states completed 75 SLPs in two waves during the 2013-2014 and 2014-2015 school years. In the initial wave of SLPs, MSMTs were asked to create an intended curriculum from a SLP curriculum resource that was of a different type than the district-adopted curricular resource. In the second wave of SLPs, a selection of MSMTs was asked to create an intended curriculum from three different lessons from a TD curriculum (described in more detail below). All teachers were asked which SMPs were addressed in the respective intended curricula that they created from these curricular resources. However, only 34 of these teachers were asked specifically to point out in their intended or written curricula where SMPs occurred. The 37 SLPs completed by these teachers form the data set at the center of this study. A total of 21 and 13 MSMTs had been using a DM and TD curriculum for at least one year, respectively.

SLP Curricular Resources

The curricular resources used in the SLPs were drawn from three different curriculum resources, two of which were considered to be TD, and one DM. The two categorized as TD were *Connected Mathematics 3* (CM) (Lappan, Fey, Fitzgerald, Friel, & Phillips, 2014) and *College Preparatory Mathematics* (CPM) (Kysh, Dietiker, Sallee, Hamada, & Hoey, 2013). The DM curriculum was *Glencoe Mathematics* (Glencoe) (Carter, Cuevas, Day, & Malloy, 2013). MSMTs who taught grades 6 were provided with a lesson involving proportional reasoning: (Glencoe – P) (Carter et al., 2013, pgs. 14-27); (CM – P) (Lappan et al., 2014, pgs. 18-23); *Core Connections: Course 1* (CPM1) (Kysh, Dietiker, Sallee, Hamada, & Hoey, 2013a, pgs. 224-227); or *Connections Course 2* (CPM2) (Kysh, Dietiker, Sallee, Hamada, & Hoey, 2013b, pgs. 743-745). MSMT who taught grade 8 were provided with a lesson involving linear functions (Glencoe – LF) (Carter et al., 2013, pgs. 267-277); (CM – LF) (Lappan et al., 2014, pgs. 5-11); or *Core Connections Course 3* (CPM3) (Kysh, Dietiker, Sallee, Hamada, & Hoey, 2013c, pgs. 308-311). We chose roughly equal numbers of grade 7 teachers to work with proportional reasoning and linear functions lessons. For each SLP curricular resource, MSMTs were provided with the student textbook, lesson planning resources, unit planning resources, assessment resources, and a copy of the CCSSM. The number of MSMTs working with each SLP curriculum resource by district-adopted curriculum type appears in Table 1.

Table 1: Participants by Curriculum Type and SLP Curriculum Resource

	District-Adopted Curriculum Resource	
SLP Curriculum Resource	DM	TD
Glencoe – P	–	3
Glencoe – LF	–	5
CM – P	9	–
CM – LF	11	–
CPM1	2	–
CPM2	–	4
CPM3	1	2

Analysis

The data in this study were analyzed through iterative cycles (Miles, Huberman, & Saldaña, 2014). In an initial cycle of analysis we coded data with a variety of broad codes connected to a larger project. In this study, we focused on data coded as 01-MP (mathematical practices), 0-Curric (descriptions of intended curricula or written curricula), and 04-Adapting (adaptations made to the written curricula). Data coded as 01-MP were subsequently coded for each of the SMPs based upon a word or words associated with that SMP. For example, the word *persevere* led us to categorize these data as SMP 1. Interview excerpts including language that was ambiguous (e.g., explore) or potentially could pertain to more than one of the SMPs (e.g., explain) was excluded from analysis. Next, a combination of in-vivo and descriptive coding was used on data associated with each SMP. Last, we examined the codes within each SMP for themes shedding light on MSMTs' perceptions. We determined the validity of each MSMT's justification for the presence of a SMP in the curricular resources or intended curriculum by comparing the teacher's justification to the written description for each of the SMPs in the CCSSM using techniques similar to Opfer and colleagues (2016) as well as our own previous work (Davis et al., under review) in excerpts coded as 0-Curric. Data coded as 04-Adapting were used to better understand the adaptations made with respect to the SMPs. Our analyses of the written description of the SMPs in the CCSSM led to the identification of SMP 1 and SMP 3 in both the CM – P and CM – LF SLP materials and we calculated the percentage of DM teachers who identified these SMPs in these materials. As the number of invalid SMP justifications made by the 34 teachers in our study met the assumptions of an independent samples *t*-test we used a two-tailed test to examine the significance of the differences in invalid justifications between TD and DM teachers with an alpha level of .05. Additionally, we calculated the percentage of valid SMPs out of the total SMPs noted for DM and TD teachers.

Results

SMP Perceptions of MSMTs Regardless of Curriculum Type

A common theme running through the majority of MSMTs' responses in the first SMP was multiple approaches. MSMTs perceived that both perseverance and sense making required multiple approaches. Additionally, the majority of teachers noted that problems that required students to make sense of them and preserve in solving them were complex in some way. As Davidson (TD) put it in her SLP, "If they're going to persevere in solving something, it better be something that is going to challenge their thinking in some way."

Only six teachers (all DM) mentioned that their SLP curricular resources contained components of SMP 2. A common theme among responses with regard to this SMP was real-world contexts. That is, some teachers stated that for this SMP to be present students needed to consider the mathematics embedded in a real-world situation. Contextualization and decontextualization were both mentioned by MSMTs in reference to SMP 2.

For many MSMTs, SMP 3 embodied the development of arguments and the careful examination of the arguments produced by others. Instead of arguments, however, MSMTs often stated that students would "discuss," "share," or come to a "consensus" about different ways to solve a problem such as determining which mixture was "most orangey" in the CM – P lesson.

Three of the SLP curricular resources (Glencoe – LF, CM – LF, and CPM3) specifically directed students to create tables, graphs, and equations for a variety of real-world contexts involving linear functions. An example of one set of questions from CM – LF appears below.

Name	Walking Rate
Alana	1 meter per second
Gilberto	2 meters per second
Leanne	2.5 meters per second

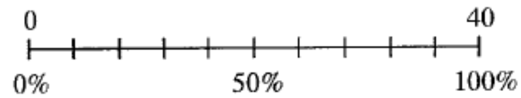
A. 1. Make a table showing the distance walked by each student for the first ten seconds. How does the walking rate affect the data?
2. Graph the time and distance on the same coordinate axes. Use a different color for each student's data. How does the walking rate affect the graph?
3. Write an equation that gives the relationship between the time t and the distance d walked for each student. How is the walking rate represented in the equation?
(Lappan et al., 2014, pgs. 6-7).

MSMTs considered questions in the textbook lessons such as the one above to be instances of SMP 4. Christiansen (DM) justified the presence of mathematical modeling in the set of questions above in the following way: “They’re making a table as a model. They’re making a graph to model the situation. They’re also going to be asked to write an equation for each situation. That would be a type of model.”

None of the MSMT discussed other aspects of modeling such as moving from the mathematical model back to the real-world context or the assumptions that needed to be made in creating the mathematical model for some real-world situation. For Dietrich (DM) and other MSMTs the presence of what they deemed to be a real-world situation was a necessary and sufficient condition for SMP 4 to occur in the lesson.

Consider the problem appearing in the CPM1 (p. 226) curricular resource.

> With your team, you will use the percent ruler shown at right to examine a sample of 40 raisins and peanuts.



> Copy the percent ruler onto your paper. Then use it to determine how many raisins would make 50% of the sample. How many raisins are in 10% of the sample? (Kysh et al., 2013a, p. 226).

MSMTs in our study felt that imperatives asking students to use such tools in the curricular resources was evidence that students were gaining proficiency with SMP 5 as seen in Tyler’s (DM) statement: “You have to use appropriate tools strategically in this one because you’re working with a percent ruler.” Other teachers pointed to the use of tools such as graphing calculators to check their work in creating the graph by hand. Thus, for these teachers they considered such tools as being used strategically by students. Other teachers considered the open-ended use of tools to be a prerequisite for the presence of SMP 5 in curricular resources.

Despite previous research suggesting that many teachers feel that SMP 6 appears in each mathematics lesson they prepare (Davis et al., under review) only 15 out of 34 MSMTs listed SMP 6 as appearing in the SLP curricular resources they were given or their intended curricula. Altogether MSMTs’ mentioned precision with regard to communication, accuracy, measurements, labels, reading/creating graphs, calculations, and gathering data.

Several MSMTs described the presence of SMP 7 in their SLP curricular resources. For instance, Dietrich (DM) wanted to draw students’ attentions to the structure of percent being compared to 100 in the CPM1 lesson. Similar to the CCSSM architects, MSMTs connected structure with pattern identification (SMP 8). This is perhaps best seen in Christiansen’s (DM) examination of the CM – LF curricular resource where she perceived the curricular resources as providing opportunities for students to identify the structure of constant slope within a linear function as embodied in tables, graphs, and equations.

SMP 8 expects students to look for and express regularity in repeated reasoning. MSMTs noted that students would have opportunities to identify the y-intercept and slope of linear functions appearing in tables, graphs, and equations either in the written or intended curriculum.

SMPs Perceptions by MSMTs’ District-Adopted Curriculum

We found that 63% of SMP justifications made by teachers using a DM curriculum type and 85% of SMP justifications made by teachers using a TD curriculum type were valid. There was a statistically significant difference in the number of invalid SMP justifications for TD and DM curriculum types $t(34) = 2.41$, $p = .022$. Regardless of curriculum type MSMTs struggled with correctly justifying SMP 4 and SMP 5. For TD teachers these were the only two SMPs in which they had incorrect justifications. In SMP 1, DM teachers only drew attention to making sense of problems and not to perseverance. Several DM teachers confused complexity with abstraction in SMP 2. For instance, one of the lessons (CM – P) asked students to determine which of four different orange juice mixtures was most orangey and least orangey. Martin (DM) stated that this problem involved SMP 2 and justified the practice in this way, "For number two, with reasoning abstractly and quantitatively, now we're getting into, are they going to think outside the box on certain things as far as 'How am I going to get to what's most orangey or least orangey?'" Interestingly, none of the TD teachers identified SMP 2 in the SLP curricular resources. In SMP 3, DM teachers described checking answers for correctness as an engagement in the development of an argument. Both TD and DM teachers incorrectly justified SMP 4. TD teachers focused on the presence of multiple representations of a function (e.g., graph), but did not connect these to real-world contexts. DM teachers' incorrect justifications in SMP 4 involve the presence of multiple representations or a real-world context. DM and TD teachers both incorrectly asserted that the presence of tools such as a table was evidence of SMP 5. In SMP 6, one DM teacher (Shaw) stated that when students were learning a new method for solving a problem, students did not need to be precise in their work. In SMP 7 and 8 there was not sufficient detail to determine the validity of the justifications of the same two DM teachers (Cartwright and Tyler). Additionally, only 45% of the DM teachers identified SMP 1 and only 35% of DM teachers identified SMP 3 across the CM – P and CM – LF lessons.

A total of eight TD MSMTs were engaged in an SLP for the Glencoe – P or Glencoe – LF lessons. In all of these cases, the teachers saw no indication of the SMPs in the lessons. Granville (TD) summed up her evaluation of the Glencoe – P materials in the following way, "I mean what they say is that the aspects of mathematical thinking, practices 1, 3, and 4 are emphasized in every lesson. I just had a really hard time imagining the way this seemed to play out that they were doing any kind of engaging in any of the practices." Consequently, all eight of the teachers made significant adaptations to their DM curricular resources. The eight TD teachers began their intended curricula by taking problems from the DM curricular resource that were presented as being solved in one way (e.g., table) and providing them to students without an expected solution method. They felt that without presenting a particular method, these problems better embodied SMP 1 as they were less leading, more investigative and would be complex for students to solve. These TD teachers also provided students with a variety of different tools for students to use to solve these problems, which they felt was better connected to SMP 5 due to the fact that students had to choose which tool they would use to solve the problem. Another common theme in the intended curricula among these teachers was the use of cooperative groups whereby students would be expected to solve the problems together and engage in argumentation as they justified their solution methods, thereby engaging in SMP 3.

Discussion and Implications

This study examined a group of MSMTs' perceptions of the eight SMPs as well as how those perceptions differ by MSMTs' district-adopted curriculum type. On the one hand, our findings suggest that the MSMTs we sampled are able to correctly identify SMPs 1, 2, 3, 6, 7, and 8 in a variety of curricular resources or their intended curricula. On the other hand, MSMTs' perceptions about SMPs 4 and 5 were problematic. Teachers using both DM and TD curriculum types did not identify the connection between a real-world context and the mathematical representation or the need to translate from the mathematical representation back to the real-world context. They also did not mention other aspects of modeling such as determining what aspects of the real-world situation should be included in the model and which should be discarded. The MSMTs we interviewed tended to focus on just one action associated with modeling. In SMP 5, MSMTs considered the mere presence of a tool such as a percent ruler to be sufficient for students to gain proficiency with this practice. That is, they were concerned less about what tools were appropriate for a given situation and what it meant to use those tools strategically.

We assert that MSMTs' difficulties with SMP 4 and 5 are connected to the issue of learning trajectories involving these practices. It is not only important to determine what a particular SMP looks like at a particular grade level (Heck et al., 2011), it is important to understand what types of knowledge and skills comprise an SMP, when those should best be taught, how those skills are sequenced, and what curricular resources embodying these activities look like. For example, we would expect that an initial step in developing competency in SMP 5 would involve understanding how to use particular tools. However, as several MSMTs in our study noted in their intended curricula, students need to be asked to complete tasks where they must choose which tool is best suited for the task and justify that use of tools. As we stand at these CCSSM educational crossroads, an important next step in supporting teachers in bringing these standards to life involves providing professional development for teachers in these two SMPs, articulating a set of competencies associated with these skills, and developing curricular resources that embody these skills set within a reasoned trajectory.

We found that the DM teachers in our sample were less successful in identifying SMPs in their curricular resources or their intended curricula than the TD teachers we interviewed. This suggests that the understanding of SMPs exhibited by the DM teachers in our sample is different from the understanding of the SMPs held by TD teachers we interviewed. Consequently, we would expect that DM teachers' classrooms would provide fewer opportunities for students to engage in the SMPs for two reasons. First, DM teachers may experience difficulty in ascertaining when these practices occur in their curricular resources. Second, as the TD teachers demonstrated when they engaged with DM curricular resources, these materials may simply not provide students with many opportunities to engage in the SMPs.

TD teachers engaged in SLPs involving DM curricular resources demonstrated that invigorating these materials with SMPs is not an easy task. In the eight cases where TD teachers were engaged in this work, their intended curricula bore only a slight resemblance to the DM curricular resources from which they were drawn. If educational policy advocates wish to take the development of students' SMP proficiency seriously or as the CCSSM implores, connect content to the SMPs, our study suggests that not all types of curricular resources are created equal. Indeed, bringing the SMPs to life in the classroom may require that we seriously consider the adoption of TD curriculum resources and the concomitant professional development they require as we reflect on our location at the CCSSM crossroads and where we go from here.

As part of a larger study, we report findings on teachers' use of the Common Core State Standards for Mathematics (CCSSM) and teacher resources (TR) that were included with teachers' published curriculum programs. We analyzed 147 lesson planning interviews with 20 middle school teachers to understand how teachers interpreted and enacted the CCSSM while working with their curriculum materials. We investigated teachers' noticing of CCSSM and features of TR in planning lessons. Regardless of curriculum, teachers perceived that the lessons were designed to address the CCSSM. Findings for patterns among curriculum type, teacher orientation, and teachers' noticing are presented. Implications for curricular policy and design are discussed.

Keywords: Curriculum, Curriculum Analysis, Instructional Activities and Practices, Middle School Education.

The purpose of this study was to explore patterns related to teachers' orientations to instruction (Remillard & Bryans, 2004), teachers' uses of district-adopted curriculum programs (i.e., *the designated curriculum* [Remillard & Heck, 2014]), and specific curricular features teachers noticed (Jacobs et al. 2010, 2011) as they used teacher resources to plan lessons (i.e., *the intended curriculum*). These lessons – and the designated curriculum – were ostensibly aligned with the Common Core State Standards for Mathematics (CCSSM) (i.e., *the official curriculum*) (Remillard & Heck, 2014). The CCSSM (CCSSI, 2010) were initially adopted by 45 states plus the District of Columbia, and, despite a rollback in some states, the CCSSM or CCSSM-based standards are still in place in most states. Thus, the CCSSM-adopting states share a relatively common articulation of content and the progression of content across the grades. This provides researchers an opportunity to consider how districts and teachers interpret standards and to understand the role of curriculum materials in the process of enacting those standards.

When asked to compare the CCSSM with prior standards, teachers interpreted the CCSSM as requiring a greater emphasis on problem solving, discovery, communication, and conceptually-driven instruction (Roth McDuffie et al., 2015). Although teachers expressed a relatively strong view of these CCSSM features, prior research on teachers' enactments of similar recommendations in the National Council of Teachers of Mathematics Standards documents (NCTM 1989) showed that even reform-minded teachers did not tend to implement the recommendations beyond superficial features (Coburn et al., 2016; Spillane & Zeuli, 1999).

Framework

Our framework draws on three complementary perspectives: orientations toward teaching and learning mathematics, teachers' professional noticing, and types of curriculum programs. Each perspective is described briefly below (also see Roth McDuffie et al., 2017).

Orientations toward Teaching and Learning Mathematics

We see teachers as designers as they work with and enact curriculum across a range of classrooms contexts (Brown, 2009; Remillard & Heck, 2014). Productive enactments and adaptations of curriculum materials, desired outcomes of the design process, are responsive to local contexts and involve teachers noticing students' mathematical thinking in relation to curriculum resources (Choppin, 2011). However, most adaptations of high cognitive demand tasks cause the cognitive demand to decline to procedural routines (Stein et al., 1996). Thus, how teachers use materials can limit learning opportunities for students; however, others have pointed as well to curriculum materials as limiting factors (Stein et al., 1996). Thus, *which* curriculum materials are designated for use and *how* teachers enact materials can both affect student learning and achievement (Stein et al., 2007; Tarr et al., 2008). In regard to teachers' use of materials, teachers' orientations toward curriculum materials influence how the materials are enacted (Remillard & Bryans, 2004). Remillard and Bryans describe teachers' *orientation toward curriculum materials* and its relationship to learning as,

> A set of perspectives and dispositions about mathematics, teaching, learning, and curriculum that together influence how a teacher engages and interacts with a particular set of curriculum materials and consequently the curriculum enacted in the classroom and the subsequent opportunities for student and teacher learning. (p. 364)

To classify teachers' orientations, we turned to Munter, Stein, and Smith's (2015) two instructional models of instruction, *dialogic* and *direct*. Munter and colleagues' characterizations of primary instructional patterns in US mathematics classrooms represent a consensus view from a group of expert stakeholders, and they describe nine characteristics associated with each model. *Dialogic instruction* entails teachers providing students with opportunities to: wrestle with big ideas, assert and justify claims, and engage in carefully designed, high cognitive demand tasks (cf., Stein et al. 1996). Teachers engage in practices including orchestrating rich class discussions, introducing representations that can be used repeatedly in different situations, and sequencing activities in ways that position students as autonomous learners (Munter et al., 2015). Dialogic instruction is consistent with visions for effective teaching and learning espoused by NCTM (NCTM, 2014) and seminal research in mathematics education (e.g., NRC, 2005; Stein et al., 2007). Although both dialogic and direct instruction reflect a commitment to students' understanding of mathematics, *direct instruction* aligns with an acquisition approach (Sfard, 1998). Teachers maintain primary intellectual authority (along with the textbook) by: presenting an objective for a lesson, demonstrating how to complete problems, scaffolding students' practice, and evaluating to correct students. To engage students, teachers maintain a brisk pace, invite unison responses, and praise correct responses (Munter et al., 2015).

Given that meaningful and authentic problem solving, sense-making, and explaining and justifying solutions are emphasized in the CCSSM's Standards for Mathematical Practice (MPs), then it seems that the CCSSM align with a dialogic model. Yet, the CCSSM are ambivalent on pedagogical approaches (McCallum, 2012). On one hand, the MPs align with the characteristics and goals of dialogic instruction; on the other hand, due to the major gaps in empirically developed learning trajectories in key middle grade topics (Daro, Mosher, & Corcoran, 2011), the middle grade content standards are based on the logic of the discipline as much as they are framed by developmental and reasoning-focused approaches. Thus, the CCSSM leave room for teachers to attend to, interpret, and enact the content standards and MPs in various ways.

In contextualizing research on teaching in a broader system, we turned to Remillard and Heck's (2014) model describing a system for curriculum policy, design, and enactment, as described above, with a focus on: *official curriculum* (e.g., CCSSM and/or other policy documents); the *designated* *curriculum* (plans and curriculum materials authorized by local educational authorities) and *teacher-intended curriculum* (interpretations and decisions in planning). We considered how teachers used and worked between the CCSSM as an official curriculum and their designated curriculum to develop teacher-intended curriculum.

Teacher Noticing in Teaching and Learning Mathematics

An emerging body of research on mathematics teachers' *noticing* supported us in studying how teachers construct an intended curriculum and then enact curriculum (Jacobs et al., 2010, 2011; Mason, 2011). Although researchers have framed noticing in slightly different ways, a commonality is that noticing involves not only the attention that teachers give to classroom actions and interactions, but also teachers' reflections, reasoning, decisions and actions. Jacobs and colleagues defined *professional noticing of children's mathematics thinking* as consisting of a set of three interrelated skills: attending, interpreting, and deciding how to respond (Jacobs et al., 2010, 2011). Jacobs and colleagues argued that *deciding to respond* should be included as part of noticing because it is linked to the other skills of professional noticing (attending and interpreting) "during teachers' in-the-moment decision making." Jacobs and colleagues (2011) view the three skills of attending, interpreting, and deciding to respond as "inextricably intertwined" (p. 99), and we share this view. In forming our analytical framework to investigate teachers' work with curriculum, we adapted research on teacher noticing (Jacobs et al., 2010, 2011) to include curriculum as an object of noticing. Other researchers independently have begun to use a framing of curricular noticing in studying prospective teachers as they learn to work with curriculum materials (*c.f.,* Males et al., 2015).

Types of Curricular Programs

We conceptualize curricula according to monologic and dialogic communication functions (Wertsch & Toma, 1995). We characterize curriculum programs as *delivery mechanism* (DM), if they are designed from the monologic function, in that the content is developed from the perspective of expert performance, to be delivered to novices. In contrast, *Thinking Device* (TD) curriculum programs emphasize the dialogic function so that the primary goal is to elicit student thinking and to provoke interactions that generate understanding. In previous work for the larger study, the curriculum programs used by the participating teachers were analyzed and classified according to these two types (Choppin et al., 2016). The above perspectives framed the study and served as the foundation for our analytic frameworks, as described in the next section.

Methods

From our larger data set, we purposefully selected 20 teachers using four different curriculum programs, with two TD programs and two DM programs. We applied qualitative methods of analytic induction and constant comparison (Bogdan & Biklen, 2007; Miles, Huberman, & Saldaña, 2014) to identify patterns and themes regarding teachers' use of the CCSSM and the teacher resources (TR) that are provided in teachers' designated curriculum materials in planning lessons. The research questions driving the study were: (1) In planning lessons, what do teachers notice in CCSSM and in TR?; and (2) How do types of curriculum materials and teachers' orientations relate to teachers' noticing during planning?

Data Sources

From our larger project data, we selected four districts with curriculum programs of different types. From these districts, we selected 20 teachers who participated for at least one year, so that we had a representation of each of the middle grades (grades 6 to 8) and teaching experience (from first-year to over 20 years). All participating districts and teachers stated that they were implementing the CCSSM in their instruction. Data sources included 147 interviews: pre- and post-lesson interviews that focused on teachers' planning with their designated TR, and interviews as teachers planned a lesson with materials that were different from their designated curriculum (using contrasting resources). We collected data over three academic years from Fall 2012 (start of Year 1) to Spring 2015 (end of Year 3), and districts participated in either two or three years of the project, with three to four interviews conducted each year with each teacher participant (see Table 1). The classification shown for each curriculum is based on prior analysis (Choppin et al., 2016).

Table 1: Teachers, Designated Curricula, and Curriculum Type

District	Teachers (with # of Interviews per Teacher)	Designated Curriculum Program (by Year of Study)	Curriculum Type
Anna	Anderson (6), Cartwright (3), Dietrich (7), Martin (3), Shaw (6)	Digits (Fennell, 2010) (Y2, Y3)	DM
Chester	Allen (9), Granville (6), Menard (7), Pless (11)	Connect Mathematics Project (CMP, Lappan et al., 2014), CMP2 (Y1), CMP3 (Y2,Y3)	TD
Denton	Amedon (4), Blackburn (12), Gagnon (10), Gates (9), Hastings (7), Leonard (12), Sprague (6)	Glencoe (Carter et al., 2013) (Y1, Y2), CMP3 (Y3)	DM (Y1, Y2) TD (Y3)
Sanders	Boris (8), Gryder (6), Pearle (8), Ross (7)	CPM Mathematics (Kysh et al., 2013), (Y2, Y3)	TD

Data Analysis

We analyzed data through iterative cycles (Miles, Huberman, & Saldaña, 2014). Initially, using qualitative data analysis software, we coded data with a set of broad codes related to the larger project. For this study, we focused on data coded as "teacher resources" and "planning." We then ran reports to gather all data with these codes for the 20 teachers. We conducted finer level coding of these reports for instances of: (1) evidence of dialogic or direct orientations, applying Munter et al.'s (2014) nine characteristics; and (2) curricular noticing of the CCSSM (e.g., content standards, mathematical practices) and features of the TR (e.g., lesson structure, suggested questions, example problems, student approaches). We generated analytic memos for the participants to describe patterns and conjectures and compile data associated with these patterns. To examine patterns across participants, we created a matrix with rows for each participant and columns for foci of noticing and orientations, as described in the codes above. Within each cell we recorded findings for each teacher and then examined patterns and differences by curriculum program and by curriculum type.

Results

We categorized teachers into one of four categories based on teachers' designated materials and orientations evidenced in planning (see Table 2). For a few teachers, identifying orientation was not as clear as for most. For example, Pearle predominately demonstrated a dialogic orientation when she explained that she focused on "big problems and not just your memorization or your simple computation, like the math that I grew up [doing]" and on writing to support thinking. However, Pearle planned to introduce new vocabulary by presenting it to students at the beginning of the lesson (a direct orientation). In these cases, we classified based on the predominant orientation, with no more than one characteristic aligning with the other orientation. Teachers' orientations were consistent in planning with both their designated materials and with the contrasting materials provided in the interview. We identified two primary patterns for orientation and type of designated materials: TD materials paired with dialogic orientations and DM materials paired with direct orientations. That is, for 17 of the 20 teachers, their orientations aligned with the design of their designated curriculum materials. For the remaining three teachers (who demonstrated a direct orientation and were using TD materials), they had previously used Glencoe (DM) and were in the first year of using CMP3 (TD). Their comments and planning indicated that they noticed ways CMP3 was different from Glencoe, but they continued to remain at the center of the lesson, hold authority for content, and prioritize procedures. For example, Gates stated, "I'm …struggling with [CMP because] kids do not get to the standard algorithm…As I say to [my students], I need you to do 145 divided by 7 and just do it with the old standard [algorithm.]"

Table 2: Teachers Categorized by Orientation and Their Designated Curriculum

District	Thinking Device Materials (TD)	Delivery Mechanism Materials (DM)
Dialogic	Allen, Amedon, Boris, Granville, Gryder, Leonard*, Menard, Pearle, Pless, Sprague* (10 Teachers)	(0 Teachers)
Direct	Gagnon*, Gates*, Hastings* (3 Teachers)	Anderson, Blackburn, Cartwright, Dietrich, Gagnon*, Gates*, Hastings*, Leonard*, Martin, Shaw, Sprague* (11 Teachers)

*Note: Denton teachers changed from Glencoe to CMP during the study. Teachers marked with an * appear in two categories, based on the materials they used that year.

Next, we analyzed patterns for curricular noticing in teachers' planning with their designated TR and with contrasting materials (see Table 3). Within each cell, italicized phrases are the topics of noticing, and text that follows represents the primary and consistent themes for each form of curricular noticing (i.e., how teachers attended, interpreted, and decided to respond) within that category. As much as possible, we incorporated teachers' phrasing and terms to represent the theme (e.g., "big ideas", "key questions", "investigations", "inquiry-based", "talk through", "key steps"). In three of the four categories, teachers interpreted the TR as aligning with CCSSM; however, teachers with a dialogic orientation interpreted DM materials as not addressing the CCSSM. These teachers were planning with contrasting TR (Glencoe), rather than their designated TR (CMP3). Thus, all teachers viewed their designated TR as aligned with CCSSM, and yet their interpretations and decisions with the CCSSM and TR in lesson planning varied, as shown in the other cells.

As an example, Allen (dialogic orientation) evidenced her noticing of *CMP3*'s TR features and planned to provide an initial, informal exposure to ratio as a way to develop understanding:

> [I want students to] understand what the numbers are, what they're there for, what they're being used as.…Do they know [what each part of the ratio refers to]?….I always feel like the [first] investigation, it's really just that informal exposure….I think being able to recognize different types of comparisons, what they might look like, how you might get them, I'm just kind of starting to set the stage for [understanding that] isn't [just one] type of comparison.

In contrast, Gates (direct orientation) noticed *Glencoe's* TR features by focusing on the steps she planned to demonstrate and how students will practice these steps.

> For example, 2+y=3, we all use the strategy of bringing down a railroad track and then doing whatever you do to the side…. So I have a process where I usually have them do a few problems with me,…and if I feel like they're okay, I have them do a few problems with a partner, and then if they're doing well, … I let [students work] independent[ly].

Table 3: Noticing Patterns in Planning with Designated vs. Contrasting Curriculum

Teacher Orientation	Curriculum Type	
	Thinking Device Materials (TD)	Delivery Mechanism Materials (DM)
Dialogic Teachers	*CCSSM and TR Alignment*: Interpreted materials as aligned with CCSSM	*CCSSM and TR alignment*: Interpreted materials as not aligned with CCSSM
	MPs: Attended to MPs in CCSSM and decided to feature these through open problems and investigations.	*MPs*: Attended to lack of focus on MPs, interpreted as limiting students' opportunity to learn, and decided not to not use or substantially adapt TR.
	TR Feature, Problems and Homework: Attended to and worked problems as students might to anticipate their thinking, strategies, and confusions (interpreting and deciding). Selected problems to align with big and with MPs (interpreting and responding).	*TR Feature, Problems and Homework*: Attended to problems and homework, interpreted as focused on skills and as not deep enough to induce reasoning, conjectures, and explaining. Decided to adapt or replace or only use in limited ways for practice.
	TR Feature, Lesson and Participation Structures: Attended to Launch-Explore-Summary (L-E-S) structure. For each phase considered key questions and approaches to engage students in productive struggle, communicating, and justifying (interpreted). Decided to launch the lesson with key questions and contexts, how to use cooperative groups, and how to facilitate a summary discussion.	*TR Feature, Lesson and Participation Structures*: Attended to the role the curriculum materials and the teacher played in presenting ("telling") students what steps to use to solve problems, with time for students to practice similar problems. Interpreted the heavy focus on whole group and practice as limiting students' development of understandings and engagement in MPs. Decided to substantially adapt or replace approaches from TR.
Direct Teachers	*CCSSM and TR alignment*: Interpreted materials as aligned with CCSSM	*CCSSM and TR alignment*: Interpreted materials as aligned with CCSSM
	MPs: Attended to MPs, interpreted as different from designated materials, decided not to use the TR approaches related to mathematical practices due to perceived time needed and/or needing to cover "basics" first.	*MPs*: If attended to CCSSM, attended to content standards (not MPs), interpreted as topics to be covered, and decided to cover standards by following TR (showing procedures and providing time for practice).
	TR Features Problems and Homework: Attended to inquiry-based approaches, interpreted as "overwhelming" for planning and students, and decided problems were beyond their students' capabilities. Decided to adapt or replace with practice problems.	*TR Feature, Problems and Homework*: Attended to problem sets as a first-step in planning, selected problems based to match students' current skills and to practice new content (interpreting and deciding).
	TR Features, Lesson and Participation Structures: Attended to the L-E-S	*TR Features, Lesson and Participation Structures*: Attended to examples to

	structure. Interpreted that students need more direct instruction and practice, viewed investigations as too challenging for students and requiring too much time. Decided to scaffold and model problems first and supplement to ensure that students had skills, procedures, and practice needed before attempting investigations.	model and problems to assign for individual seatwork and/or homework. Decided on examples, what to model, how to talk through the problem solving process, key steps to emphasize, and key cautions to share. Decided on errors to look for when students were practicing problems and ways to correct or prevent these errors.

Discussion and Implications

A growing body of evidence indicates that characteristics of curriculum impact teaching and learning (e.g., Stein, Remillard, & Smith, 2007; Tarr et al., 2008). Indeed, we found that teachers' orientations matched the type of curriculum they were using in most cases. For the three teachers whose direct orientation was different from the approach of their TD materials, they attended to differences in the curriculum approaches, but then discussed how they were "struggling" to plan lessons as TR suggested, and often supplemented with practice problems from past DM resources. This pattern and other findings above indicate that a TD curriculum can support teachers' dialogic orientations in planning and incorporating CCSSM (and especially the MPs). However, similar to past reform efforts, the CCSSM and curriculum materials can be interpreted and enacted in multiple ways (Coburn, Hill, & Spillane, 2016; Remillard, 2005; Spillane & Zueli, 1999). Teachers also might attend to differences and then decide to plan based on their past practices or past materials. Teachers need support (e.g., professional development, coaching) and time to enact TD lessons in ways that are consistent with goals for dialogic instruction. This study is a next step in understanding specific ways teachers notice and interact with different types of TR and with CCSSM. This can inform both curriculum developers in designing curriculum and teacher educators in preparing teachers to enact ambitious practices.

THE CHANGING EXPECTATIONS FOR THE READING OF GEOMETRIC DIAGRAMS

Leslie Dietiker

Students studying geometry at the secondary level are expected to read diagrams in different ways than those in elementary school. In this paper, we present an analysis of the changes in diagrammatic expectations by comparing the geometric diagrams found in Grade 1 U.S. textbooks with those in U.S. high school geometry textbooks. This work included developing and using a coding scheme that recognizes dimensions of reading a diagram geometrically, including the type of object represented, use of deduction, use of mental redrawing, interpretation of markings, and the necessity of the diagram. The way in which elementary and secondary students are expected to interpret diagrams was shown to change along several of these dimensions, posing potential learning barriers for students. We end our paper with a discussion of what our results mean for the learning of geometry.

Keywords: Curriculum, Geometry and Geometrical and Spatial Thinking, Elementary School Education, High School Education

An identical task with the same geometric diagram can be found at different grade levels with different expectations for interpreting the diagram (Dietiker & Brakoniecki, 2014). For example, in elementary school, a diagram of a quadrilateral with 4 apparent right angles is supposed to be identified as a rectangle, whereas in high school, the same diagram is expected to be interpreted as a quadrilateral that is not necessarily a rectangle. How are students expected to read information from geometric diagrams in mathematical tasks, specifically those found in textbooks? And how might these expectations change? In a study of the expectations of textbooks with respect to how students read geometric diagrams, Dietiker and Brakoniecki (2014) expand on Pimm's (1995) notion of *reading geometrically* and propose multiple dimensions of reading geometric diagrams. These dimensions, gleaned from analyzing the geometric tasks in multiple elementary and secondary textbooks (including traditional and reform curricula from multiple countries), represent distinct aspects of geometric diagrams that students are expected to pay attention to and interpret as they negotiate the meanings of mathematical tasks.

In this present paper, we report on our continuing analysis of textbooks to reveal how the expectation of diagrammatic reading changes as students progress through school. In particular, we compared the geometric diagrams found in Grade 1 U.S. textbooks with the diagrams of U.S. high school geometry textbooks in order to learn how different the expectations are. This work included developing and using a coding scheme that recognizes the dimensions of reading geometrically, which are described in detail in this paper.

We end our paper with a discussion of what our results mean for the mathematical learning of geometry. With evidence that students are expected to develop sophisticated ways to negotiate meaning from diagrams, we argue that within each of these dimensions, educators can craft opportunities for students to develop strategies for reading geometric diagrams to ease the transition from elementary to secondary school.

Framework

This study examines the mathematical content with regard to geometric diagrams within the *textbook curriculum*. The textbook curriculum is specifically limited to comprehensive written curricular materials that are published for use by teachers and students. Although the textbook curriculum has an impact on curriculum as enacted in classrooms, this analysis is limited to the content as it is interpreted by readers (i.e., the researchers) of the texts. For this study, *problems* include all textbook prompts (whether interrogatives or not), such as tasks, activities, and questions for which an expected response from a student is provided in the teacher edition, although withheld from students. Thus, worked examples (i.e., tasks that are completely solved within the student text materials) are not framed as problems.

An *expectation* of a problem is framed as a limiting condition with regard to a student's response of a question or task. For example, if an assumption from a diagram is necessary (such as interpreting an unmarked angle in a geometric diagram as a right angle) to get the expected answer provided in the textbook, then we argue that this assumption is a *diagrammatic expectation*. In any geometric diagram, there are many potential assumptions that could be made. We limit our definition of expectations to those that are required based on the given answers in the teacher textbook.

Methods

In order to learn how the expectations for reading geometric diagrams differ from elementary to high school, the teacher and student materials from four U.S. textbook series were selected for analysis, including two from first grade and two from high school. These grade levels were selected in order to demonstrate the change in expectations of diagram interpretation that students experience. The two elementary textbooks include the University of Illinois at Chicago's *Math Trailblazers* (2008, "MT") and the University of Chicago's *Everyday Mathematics* (2007, "EM"). Within these textbooks, we considered diagrams in the problems in all chapters focused on geometry, including topics such as shapes, volume, and symmetry. The two high school textbooks include the *CME Project Geometry* (2009, "CME") and *Prentice Hall Mathematics Geometry* (2004, "PH"). In these textbooks, we analyzed all diagrams for problems and questions in Chapter 1 in order to learn about the assumed expectations of geometric reading at the start of a formal geometry course in high school. In all textbook portions that were analyzed, we eliminated from analysis any problems for which the teacher edition listed an incorrect answer.

Due to the fact that the purpose of this work is to establish the expectations for how students interact with diagrams, only the diagrams that are part of a student task were analyzed. This does not include diagrams included in exposition or in worked examples, as students do not have to interpret or make decisions about these diagrams. Additionally, because we did not have the assessment materials for all four curricula, we restricted our analysis to lesson materials focused on learning new content.

Methods of Analysis

To describe the reading expectations of the geometric diagrams, we developed five overarching codes. The first describes how the reader is expected to interpret the diagram *as* something (e.g., a real life object or a representation of a set of objects). When analyzing our interpretation of geometric diagrams *as* something, we recognized multiple distinguishable characteristics that became sub-codes. Some tasks included geometric diagrams that were meant to be interpreted *as drawn* (as indicated in the task statement and answer). For example, a task that asks a reader to measure the diagram to make statements about the geometric object is expecting this reader to interact with the diagram as the geometric object under study. Another example is a task in which a student is expected to indicate (by drawing) a line of symmetry for a geometric object depicted in a diagram.

In analyzing those tasks that require a reader to interpret the geometric diagram as drawn, we recognized that some require an assumption of either a metrical or topological relationship condition by the reader. For these tasks, there is a positive consequence for making assumptions based on the diagram, and having skepticism toward the diagram is disadvantageous. For example, in the task shown in Figure 1, a reader needs to assume that points E, C, and B are collinear in order to get these answers (displayed in pink) correct.

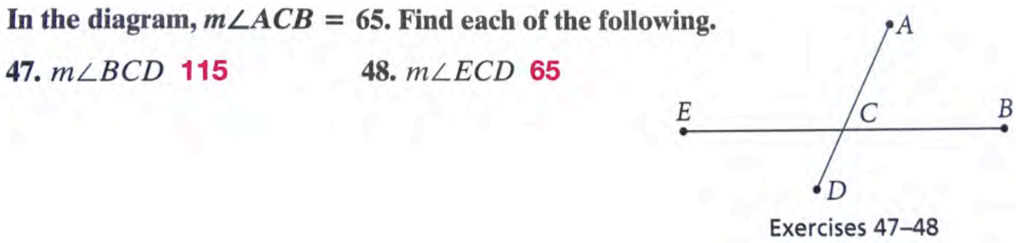

Figure 1. An example of *As Drawn With Necessary Assumption* from PH (2004, P. 31).

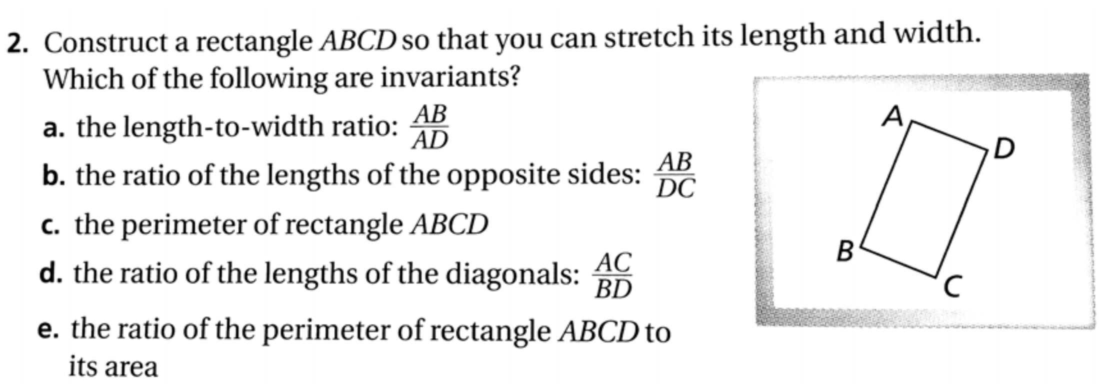
However, not all geometric diagrams are positioned by the text to be taken as drawn. Others are positioned in such a way that they are *representations* of an abstract geometric object (or a set of objects) and thus, a student is expected to <u>not</u> make assumptions of the geometric object based on the diagram. In these cases, a reader may be expected to read the diagram as a representation of a particular geometric abstraction when given a diagram that is not necessarily accurate. For example, for the diagram in Figure 2, which accompanies a prompt for students to determine the largest rectangle in the image, a reader would have a negative consequence if they assumed the angles of the rectangular characters were as depicted (which are not drawn as right angles because of the 3D orientation).

Figure 2. Example of *Representing with Assumptions* from MT (2008, p. 187).

Reading as *representing* also includes geometric diagrams that represent multiple geometric objects (read as a generality). That is, in some tasks, a reader is expected to recognize that a geometric diagram is a single representation of a *multiplicity*. Along with these, we note that some of these require a reader to make at least one additional assumption. The geometric diagram in the task in Figure 3 is an example of a diagram representing a multiplicity since a reader is expected to interpret the diagram as one of many.



2. Construct a rectangle *ABCD* so that you can stretch its length and width. Which of the following are invariants?

a. the length-to-width ratio: $\frac{AB}{AD}$

b. the ratio of the lengths of the opposite sides: $\frac{AB}{DC}$

c. the perimeter of rectangle *ABCD*

d. the ratio of the lengths of the diagonals: $\frac{AC}{BD}$

e. the ratio of the perimeter of rectangle *ABCD* to its area

Figure 3. Example of *Representing as Multiple* from CME (2009, p. 54).

Other tasks do not explicitly include what we commonly consider to be geometric diagrams, but instead include an image of a real world object (such as the soda can in Figure 4) with the expectation that it will be *interpreted as a geometric object* (i.e., a cylinder).

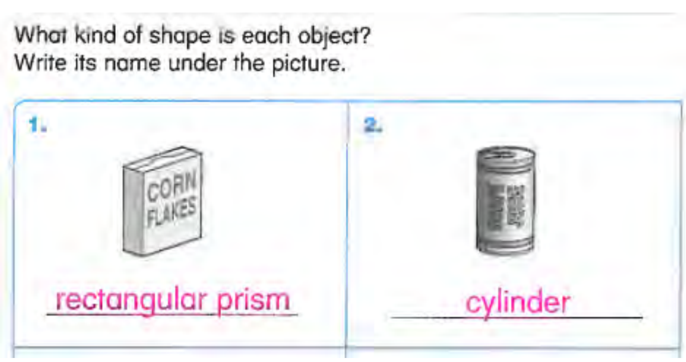


Figure 4. Example of *Real World Object* from EM (2007, p. 147).

Beyond the representations of geometric objects, we identified some geometric diagrams that are *not* representations of geometric objects. Some of these contain information that renders a geometric object as impossible or contradictory. For example, if a diagram of a triangle were marked with angle measures that do not sum to 180°, we interpreted that diagram as a *misrepresentation*. In addition, we coded geometric diagrams for which there is no expectation that a reader interprets the objects as geometric as *non-geometric*. For example, in a pattern problem with a string of triangles and squares, the students are not expected to interpret the objects as geometric. In fact, the use of the geometric shapes could easily be replaced with diagrams of flowers and firetrucks with no effect on the task.

The sub-codes for distinguishing how an object in a problem is to be interpreted and their interrelationships are represented in Figure 5.

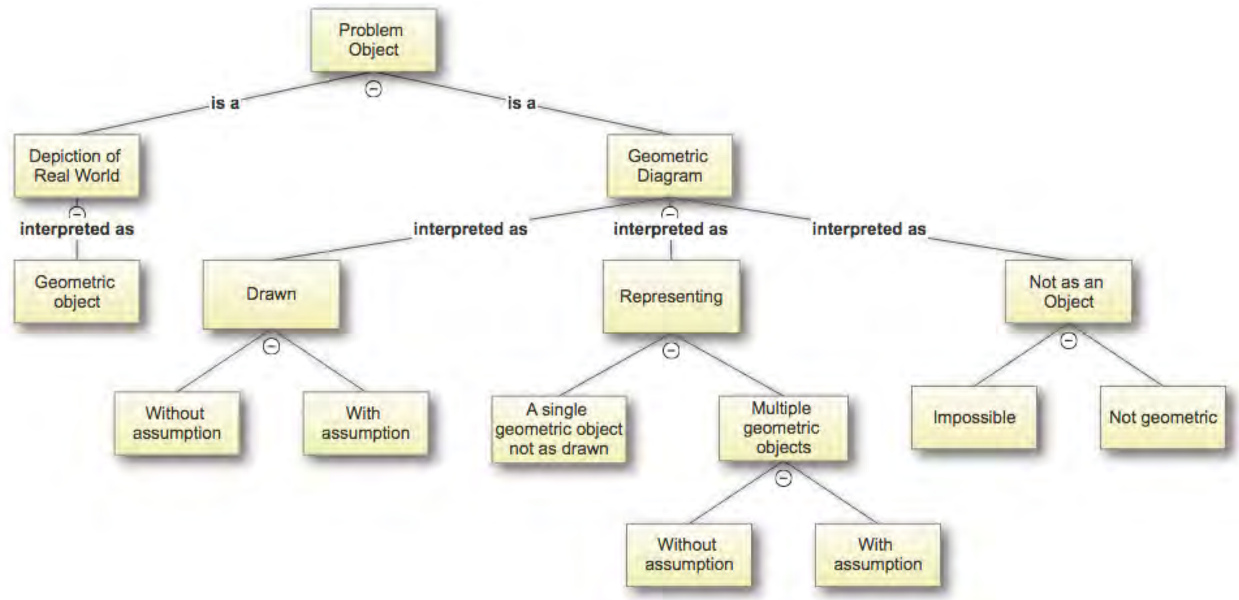

Figure 5. Diagram of sub-codes and their interrelationships for *Interpreting as*.

In addition to coding for the interpretation of the diagram, we coded four other dimensions of reading geometrically: whether *deductive reasoning* from the diagram is required to solve the task, whether the reader needs to *mentally redraw* the diagram to answer the task, whether the reader needs to *interpret conventional mathematical markings* to solve the task (e.g., reading the labels for the points in Figure 1), and whether *reading the diagram* is necessary to answer the task (e.g., the diagram in Figure 3 is supplementary while that in Figure 1 is necessary to solve the task).

Using this coding scheme, the three researchers analyzed each diagram from the selected portions of textbooks for the expectations of reading geometrically. These researchers include two mathematics educators and one doctoral student, of which two have high school teaching experience and one has extensive textbook design experience. Each code represents a consensus of all three researchers.

We suspected that there was a relationship between the intended grade of the textbook (elementary or secondary) and the various categories described above (the expected interpretation of the geometric object, whether deduction was necessary, whether mental redrawing was necessary, whether markings needed to be interpreted, and whether the diagram was necessary to the problem at all). To test the grade level's independence on each of these categories, we performed a Fisher's Exact Test (Fisher, 1922) between each grade level category and each of the above listed task categories to test the hypothesis that each of these categories was independent of the grade level of the textbook. Observed differences were statistically significant for $p < 0.01$.

Findings

The frequency of each type of diagrammatic expectation for textbooks of each grade level is reflected in Table 1.

When comparing how the textbooks expect students to *interpret as*, there was a statistically significant difference between the distribution of categories for elementary and high school texts ($p<0.001$). This enables us to assume that there is some dependence between the grade level of the textbook and the method of interpreting the diagram as an object. While the Fisher Exactness Tests indicates a likely dependence between categories, it does not identify specifically where the dependence exists. Thus, what follows is a summary of the more striking differences found in our coding results, highlighting where these differences likely exist.

Table 1: Frequency of Geometric Diagram Expectations

Task Expectation	Sub-Code	Elementary (n=61)	Secondary (n=156)	Fisher Exact P
Interpreting as	Real world as geometric object	5 (8.2%)	10 (6.4%)	0.000*
	Drawn	10 (16.4%)	51 (32.7%)	
	Drawn with assumption	36 (59.0%)	35 (22.4%)	
	Representation of single object	1 (1.7%)	4 (2.6%)	
	Representation of multiple	0 (0.0%)	45 (28.9%)	
	Representation with assumption	1 (1.7%)	6 (3.9%)	
	Impossible/contradictory	0 (0.0%)	1 (0.6%)	
	Non-geometric	8 (13.1%)	4 (2.6%)	
Using deduction	Required	0 (0.0%)	7 (4.5%)	0.195
	Not required	61 (100.0%)	149 (95.5%)	
Mentally redrawing	Required	0 (0.0%)	16 (10.3%)	0.007*
	Not required	61 (100.0%)	140 (89.7%)	
Interpreting conventional markings	Necessary	0 (0.0%)	81 (51.9%)	0.000*
	Supplementary	0 (0.0%)	26 (16.7%)	
	No markings	61 (100.0%)	49 (31.4%)	
Reading the diagram	Necessary	59 (96.7%)	123 (78.9%)	
	Supplementary	2 (3.3%)	33 (21.2%)	0.001*

Note. *Significant to $p < .01$.

Among the 61 diagrams of the elementary school textbooks and the 156 diagrams in the secondary textbooks, the most commonly expected interpretation of elementary textbook diagrams was *as drawn with assumptions*, with 59% of the diagrams in elementary. This means that a majority of the diagrams in elementary textbooks require students to interact with the diagram as the geometric object and that the student needs to make assumptions about measurements (such as a perceived right angle or a relationship between lengths) or properties (such as whether sides are parallel) based on how the diagram looks. Interestingly, high school textbooks also contain diagrams with this expectation, although they occur less frequently (22.4%). Instead, the most common expectation in the secondary diagrams is to interpret a diagram *as drawn* but without assumptions, which occurs in 32.7% of that grade level's diagrams, in contrast to 16.4%, as found in elementary textbooks.

Another noticeable difference between the grade levels' expected interpretations of diagrams was found for diagrams that *represent multiple* objects. No elementary school problems required students to interpret a diagram as a representation of multiple objects. In contrast, this was the second most frequently expected interpretation of the secondary diagrams, required for 45 (28.9%) of them. This suggests that high school texts expect students to know how to interpret a geometric object in a diagram as a general (rather than particular) representation at the start of a formal geometry course.

The geometric diagrams that *did not require the interpretation as a geometric object* were more found more often in elementary textbooks (13%) than secondary textbooks (3%). In addition, although there were relatively few instances of interpreting a diagram as *a single representation* overall, with only 5 diagrams in total, this occurred more often in the secondary textbooks (4). Although we expected to find more instances of diagrams depicting *real world* objects as geometric objects in elementary textbooks, the frequency of these diagrams was surprisingly similar in both grade levels (8.2% in elementary, compared to 6.4% in secondary).

Among the other categories of analysis, several also showed significant differences between elementary and secondary problems. A statistically significant difference was found when considering whether or not the diagrams needed to be *mentally redrawn* to solve the task ($p<0.01$). In the elementary textbooks, this expectation was not found. However, of the diagrams in the secondary textbooks, approximately 10% required a reader to visually manipulate a geometric object in order to solve the problem. Examples of these problems included tasks that require students to visualize what would happen to a geometry object if a vertex were dragged or how a diagram might change if a particular edge varied in length.

Another statistically significant difference was found when we compared the need to *interpret markings* of elementary diagrams versus those in high school diagrams ($p<0.001$). In the two elementary school textbooks, not a single diagram included any markings (right angle, congruent segment length, point name marking, etc.). This is in contrast to the high school textbooks' diagrams, of which almost two-thirds (68.6%) contain conventional markings. Of these, the majority required the interpretation of markings to solve the task (75.7% of those with markings, or 51.9% of all secondary diagrams). The remaining 16.7% of the secondary diagrams that contained conventional markings included a text prompt that supplied the information conveyed by these markings, rendering the markings in the diagram supplementary.

Lastly, we found a statistically significant difference ($p<0.001$) between the grade levels as to whether a student is expected to *read a diagram*. The diagrams in the elementary textbooks were almost always necessary to solve the task (96.7% of the time), in contrast to the high school texts which more frequently included diagrams that were supplementary to the task (21.2% of the time).

In contrast to the statistical differences described above, there was not a significant difference between the elementary and secondary diagrams regarding *using deduction* to solve a problem based on a diagram. None of the diagrams in the elementary textbooks require deduction and less than 5% of the diagrams in the high school tasks do so. In the elementary texts and opening chapters of the high school texts, it is almost never necessary for students to deduce a piece of information about a diagram which then needs to be used to learn additional information about that same geometric object.

Discussion and Implications

In this paper, we provide evidence that at some point in the transition from elementary school to the beginning of high school, there is a shift in expectations of how students are expected to read diagrams. As they start school, students are typically expected to make geometric assumptions based on how a diagram appears without being explicitly told about relationships that are necessary to solve a problem. By the time these students enter high school, they are expected to be able to reason about an object using only the information they are explicitly told and to not make assumptions based on how a diagram appears. This change in geometric interpretation of a diagram is consistent with van Hiele's (1959) description of sophistication of geometric understanding; younger children are expected to interpret geometric diagrams as a whole and only later begin to recognize the properties of geometric objects and their interrelationships. If a student does not recognize that a right angle is a property of a square, for instance, then marking right angles of diagrams of squares is pointless. Thus, it is sensible that textbooks for young children would contain the expectation that geometric diagrams be interpreted based on features as drawn (i.e., it looks like a square, therefore it must be a square).

However, we found it surprising that high school students are still expected to interpret geometric diagrams as drawn. Since high school geometry includes formal proofs, for which students are typically expected to reason only from given statements, it appears that students are expected to recognize and distinguish when they are able to make assumptions based on a diagram and when they are not. Even when students are not expected to assume metrical properties (e.g., an angle is a right angle just because it looks like a right angle), the students are expected to assume topological properties (e.g., if it looks like the figure is closed, it is). We wonder how students learn to distinguish when it is "okay" to make assumptions from diagrams and when it is not.

Interestingly, there was one aspect of reasoning with geometric diagrams that was not shown to be statistically significantly different from elementary to high school, which was whether diagrams required deductive reasoning. We expect that had we analyzed subsequent chapters in the high school textbooks, especially chapters in which students are asked to prove properties of geometric figures, that there would be more diagrams that require students to deduce new information about a geometric object from a diagram. Thus, based on this analysis, this shift may occur within the geometry course in high school.

Among all these dimensions in which reasoning about diagrams is expected to change, we wonder how aware curriculum authors and teachers are of these changes, and in what ways (if at all) these changes are communicated to students. We suspect that some of students' difficulty with geometry may be at least partly due to an inability to successfully navigate the implicit expectations of reading of geometric diagrams and we believe that helping students recognize the multiple roles that diagrams can play in geometry and mathematics is critical for their success.

martinez@math.uic.edu

Alison Castro-Superfine
University of Illinois at Chicago
amcastro@uic.edu

Research on learning trajectories in mathematics has grown considerably over the past decade. In this paper, we contribute to this body of research and present a curriculum-based hypothetical learning trajectory for middle school algebra. In doing so, we make the visible the process by which we developed this initial hypothetical learning trajectory, highlighting the considerations, decisions, and challenges we faced as part of this work.

Keywords: Learning Trajectories, Algebra, Curriculum Analysis

Background

Learning Trajectories in School Mathematics

A variety of definitions of the LT construct exist in the research literature, with substantial differences in focus and intent (see e.g., Clements & Sarama, 2004; Corcoran, Mosher, & Rogat, 2009; Confrey, 2008; Simon, 1995). According to the Consortium for Policy Research in Education (CPRE) Report on Learning Progressions for Mathematics (Daro et al., 2011), LTs are empirically grounded and testable hypotheses about how, with appropriate instruction, students' understanding of, and ability to use, core concepts and explanations and related practices grow and become more sophisticated over time (National Research Council, 2009). These hypotheses describe the pathways students are likely to follow to develop mastery of core concepts. Specifically, in our work we ascribe to the definition of LT proposed by Confrey et al. (2008): A researcher-conjectured, empirically-supported description of the ordered network of experiences a student encounters through instruction (i.e., activities, tasks, tools, forms of interaction and methods of evaluation), in order to move from informal ideas, through successive refinements of representations, articulation, and reflection, towards increasingly complex concepts over time. We further ascribe to the idea of a conceptual corridor (Confrey et al., 2009), which incorporates the possibility of multiple pathways toward learning, as well as attention to the landmarks and obstacles that students typically encounter along those pathways.

Approaches to Learning Trajectory Development in Mathematics

In the mathematics education community, LT researchers differ in how they conceptualize LTs, including the grain size of descriptions of levels of student thinking, how students move among the levels, and ways in which LTs are validated (Confrey, Maloney, Nguyen & Rupp, 2014). Such conceptual differences also include different approaches to LT development. For example, Clements and Sarama (2014) begin with mathematical goals or big ideas that are derived from both empirical research and expertise from mathematicians. From the mathematical goals, they develop cognitive models of student thinking based on theoretical and empirical models, and then move to developing tasks that are designed to promote student learning at different levels. Similarly, Lehrer, Kim, Ayers and Wilson (2014) begin with descriptions of student thinking that are based on empirical studies, extant research and mathematical expertise, which are coordinated into different levels of knowledge. From these descriptions, Lehrer et al. (2014) develop means of supporting changes among knowledge levels, to support student thinking, including instructional activities. Still, Confrey et al. (2014) begin with a synthesis of relevant research together with clinical interviews with students and teaching experiments in classrooms. While such approaches offer different insights into pathways of student thinking, such approaches often do not include the tools and resources teachers use everyday to plan for and enact instruction, such as curriculum materials, as a central component of the LT conceptualization. Indeed, teachers regularly use curriculum materials to determine the mathematics they are going to teach, which has considerable implications for pathways of student thinking.

An Alternative Approach to Learning Trajectory Development

In our work as part of the iFAST Project, we use mathematics curriculum materials as the starting point for articulating a hypothetical LT. Briefly, the iFAST Project is a multi-year project focused on articulating LTs in middle school algebra to inform the design of LT-based professional development for teachers. Thus, two main components of our work on the project involves understanding students' learning pathways within middle school algebra, and enhancing teachers' understanding of LTs to inform their use of effective assessment practices in the classroom. A central premise underlying our work is that high quality formative assessment practices depend on teachers having a clear sense of learning goals, student LTs, criteria for locating students along the trajectories, sharing this information with students, and using it to inform instructional decisions.

The development of proficiency in algebra holds a unique role in students' success in mathematics, serving as a gatekeeper to more advanced mathematics and affecting mathematics achievement in high school and beyond. The Common Core State Standards for Mathematics has reconfigured the sequencing of algebra content across grade levels, introducing it in Grades 6 and 7 with a major focus in Grade 8, and calls for students to learn algebra earlier and to more advanced levels than has traditionally been the case. As a result, whether or not middle school mathematics teachers are teaching a course designated as Algebra 1, they are being held accountable for all students' learning of rigorous content related to strands in algebraic functions and equation-solving. In the iFAST Project, our learning trajectory work is centered on linear functions and linear equations topics in middle school algebra.

We focus on the Connected Mathematics Project 3 (CMP3) curriculum as it is widely used and the treatment of linear functions and equations topics is consistent with other functions-based curricula in the U.S. As our main focus is understanding students' learning pathways within CMP3, we needed first to generate a map tracing the hypothetical learning opportunities of algebra concepts embedded in the curriculum. Of course, this is only a hypothetical description as the actual learning opportunities students encounter are mediated by multiple other factors (e.g., school, teacher, implementation, etc.). Thus, our approach stands in contrast with other approaches in least two ways: it is specific to CMP3 and we generated a hypothetical learning map first. In the sections that follow, we describe the process we developed to generate such a map and make visible the process by which we developed a curriculum-based hypothetical LT for middle school algebra.

Articulating a Hypothetical Learning Trajectory

Initial Considerations

As we embarked on understanding what students seem to learn and what are the remaining obstacles, the need to understand what learning pathway was intended for students to follow in the curriculum became evident. In order to map the opportunities provided by the curriculum to learn about specific algebra concepts we had to devise a process to understand and represent them. We wanted to produce a map of such opportunities as presented in the curriculum, thus we decided to start working with the unit goals provided by the curriculum materials.

Our initial intent was to map all linear functions and equations related topics within CMP3. This task proved to be too ambitious. As such, we narrowed our focus to what we considered to be a high leverage topic within the linear functions and equations domain. We focus on the transition from proportional to non-proportional linear functions, with a particular emphasis on rule writing. Thus, we selected units (i.e., focus units) that focus on proportionality, functions, proportional functions and linear functions. Within CMP3, we selected the following units: Grade 6 – Comparing Bits and Pieces, Grade 6 – Variables and Patterns, Grade 7 – Comparing and Scaling, Grade 7, Moving Straight Ahead, Grade 8 – Thinking with Mathematical Models, and Grade 8 – Say It With Symbols.

The first challenge we faced in creating this map was to come up with a useful grain size to describe the new content that students were offered an opportunity to learn about. We first considered working directly with the goals corresponding to focus units, but a map spanning across Grades 6-8 turned out to be too busy and difficult to be used by other researchers and teachers. Therefore, we decided to group unit goals that could be linked by a common mathematical theme.

Generating a Curricular Map

This following process is presented in a distilled way but it took several attempts for it to emerge to address limitations and implement desired improvements. We will try to note some of these back and forth in the process of coming up with the final process of clustering. The first challenge we faced in creating this map was to come up with a useful grain size to describe the new content that students were offered an opportunity to learn about. We first considered working directly with the goals corresponding to focus units but a map spanning throughout the three years grades 6-8 turned out to be too busy and difficult to be used by other researchers and teachers. Therefore, we decided to group unit goals that could be linked by a common theme. We referred to this process as "clustering". A preceding crucial step was to assign to each lesson problem unit goals.

Clustering process. One focus unit at a time, three researchers first independently clustered goals into clusters; second, researchers identified discrepancies and discussed the clusters by looking both at the representative lesson problems and the goals as stated in the curriculum until an agreement was reached. We iterated this process throughout all focus units.

External validation of clustering process. Once the researchers had completed the clustering process for all focus units, we convened a group of external reviewers (comprised of mathematics education researchers with familiarity with algebra and CMP) who conducted an external validation of the clustering process. This work entailed: (1) assessing the relationship between lesson problems and assigned goals, (2) assessing how the goals were group together forming a cluster, and (3) assessing whether the lesson problems selected were considered representative. External reviewers agreed with most of our work, they provided some minor suggestions for us to consider. One of the main contributions of this round of feedback pushed our team to think about the representative problems in two different lights. One as an exemplary lesson problem where students have the opportunity to learn and laser in a concept vs. lesson problems that would afford the most learning opportunities in the limited time an after-school professional development workshop affords, for example.

Connecting Clusters Across Grade Levels

Thus far in the process, we had goals, clusters and representative lesson problems at the unit level without an explicit connection across units and grades. In connecting the clusters among themselves two unforeseen processes unfolded: (1) in order to be able to express successive refinement in a trajectory we found it necessary to refine the language of the cluster, and (2) we revised some of the clusters and re-grouped them. Several elements were used in coming up with the curricular map across grades. The main organizing element is time, clusters are organized in columns according to a specific grade moving from 6th grade on the left to 8th grade on the right. Within a specific column (grade), we followed the order of the units chronologically according to the curriculum. To organize clusters and decide how they relate to each other we made decisions by looking at the representative problems, the goals and clusters; we pay specific attention to successive refinement of a same concept.

Discussion & Conclusion

Generating a curriculum based hypothetical trajectories map was a necessary step in our approach, as we set out to describe students' levels of understanding on proportional and linear functions taking into account what learning opportunities were provided by the curriculum chosen by the district. We think that this might provide a more nuanced picture as it not only takes into account the common core standards and extant research but also the opportunities students had to learn from the chosen curriculum. The ultimate goal of the project is to generate a CMP3 curricular map with levels of understanding (i.e., ranging for most proficient to incorrect) for each cluster. We have designed a set of three instruments to do this: end of unit assessments, end of year assessment, and a pre and post-assessment. These instruments differ on multiple aspects from each other (e.g., constructed response/multiple choice, content specific/non-specific to a unit/grade, etc.) but a detailed description of those exceeds the scope of this paper. By putting in relation the CMP3 HLT Map together with the multiple data sources we will be able to identify, describe and illustrate both levels of understanding as expected by the layout of the curriculum as well as "out of trajectory" levels of learning. The "out of the trajectory" learning might occur given the spiral nature of cmp3 where concepts are revisited at several later instances across those three years. In putting forward this process, we hope other researchers can replicate it by researchers to generate a map for other curriculums.

In this research report, we examine the perceptions that parents have regarding the use of multiple strategies in their children's classrooms, and then align their perspectives with the research literature. The themes of adaptivity and flexibility of strategies, conceptual and procedural knowledge, disposition and identity, implementation of multiple strategies, and the lack of effectiveness for all students were found in the literature as well as within the parent comments. Some of the parents produced counter-examples from the literature based on their experiences with their own children. By understanding the varying notions that parents (and the literature) have about the use of multiple strategies in mathematics, we can begin to create a way to have productive conversations with parents about curriculum reform.

Keywords: Curriculum, Elementary School Education, Number Concepts and Operations, Problem Solving

Introduction

> But the fact is there isn't great research behind it. And the other fact is that … students who are coming out of learning these strategies—the math scores have weakened. Because I'm all for doing a different strategy if you have proof that that strategy is even better than what we've been doing all along. However, at the end of the day the scores indicate that, no, it hasn't been the best approach to teaching math.

The comment above describes a tension expressed by many parents regarding current pedagogical practices that emphasize multiple strategies for problem solving and computation. The general curriculum expectations are for students to have opportunities to develop procedural flexibility and conceptual understanding through the process of selecting and using appropriate strategies in novel situations (e.g., National Council of Teachers of Mathematics, 2000).

The benefits of a multiple strategy approach have often not been accessible to or understood by parents. While parents, such as the mother quoted above, may reject that this pedagogical approach is best, the literature itself is not universally supportive of multiple strategies. In this paper, we investigate parents' perceptions of the value of alternative strategies in supporting children's learning of mathematics and how these perceptions are aligned with research. Our ultimate goal in doing this analysis is to identify fruitful ways to engage in productive conversations about mathematics curriculum reform with parents.

This report relates to the conference theme of research "as an intersection" by creating a path for researchers, teachers, and parents to be on the same road or conversation. It also addresses the conference theme of research "as a barrier" by examining the discourse used by parents surrounding the use of multiple strategies in mathematics classrooms and the impacts that these perceptions have on the parents' thoughts and feelings about how their children are learning.

Theoretical Framework

Within the literature, the rationale for teaching students multiple strategies is multifold. First, it has long been believed that such an approach supports the development of strategy adaptivity; that is, the ability to flexibly and creatively apply or generate an appropriate solution strategy to solve a given mathematics problem (Hatano, 1982). Second, teaching students multiple strategies is intended to enhance conceptual and procedural knowledge of number (Rittle-Johnson & Schneider, 2014). An awareness of various solution strategies is often associated with deeper conceptual understanding of how these strategies are used (e.g., Verschaffel et al., 2009). Also, students who develop and use procedures flexibly are more capable of using and adapting existing procedures when faced with unfamiliar problems (e.g., Blote et al., 2001). A third rationale in the literature is that multiple strategies cultivate appropriate attitudes towards math. This potential influence on disposition has, for example, been documented in Boaler and Selling's (2017) longitudinal study of two contrasting mathematics teaching practices (project-based vs. traditional) and their impact on students' identity and expertise in mathematics during their adulthood.

Is teaching multiple strategies feasible and valuable for all students? First, some research studies suggest that a multiple strategies approach may exacerbate the difficulties of low achieving students. Poorer working memory or other learning difficulties suggest that the goal of developing student adaptivity might be of limited value. Auer, Hickendorff, and Putten (2016) found that "lower ability students made counter-adaptive choices between the two strategies" by choosing a strategy that led to inaccuracies (p. 52). Second, exposing students to multiple strategies early may promote positive dispositions, but delaying exposure to multiple strategies may lead to greater adaptivity (Rittle-Johnson & Schneider, 2014). Their study indicated that flexibility in use of procedures was higher than the students in the delayed-exposure condition. Third, as Silver et al. (2005) note, although it is well accepted that students need experiences solving problems in more than one way, it is difficult to operationalize. The possible obstacles math teachers face include the actual and perceived limitations in teachers' mathematical knowledge, limited instructional time, restrictive conceptions of student ability, and a lack of opportunity to develop instructional routines related to teaching multiple solutions.

The parents in our study expressed a range of benefits and also disadvantages of their own and their children's experiences with a multiple strategies pedagogy. Parent perspectives are important because their involvement in children's educational experiences has far-reaching benefits such as improving achievement, increasing motivation, and reducing anxiety (Pattall, Cooper, & Robinson, 2008). Understanding parent perspectives and how they are or are not aligned to research allow researchers and teacher educators to refrain from dismissing criticisms as obstacles, and reconsider the validity of parent perspectives—even if they are based on a sample size of 1: their child.

Mode of Inquiry

Forty parents from urban and rural communities participated in our study. They completed a demographic questionnaire and participated in one of ten focus groups taking place in their respective communities. Focus groups, each approximately two hours long, were used as generative sites of data collection with the knowledge that differing parent perspectives required participants to explain their perspective to others, thus allowing us to notice differences in their experiences. The focus groups were structured to prompt parents to address their observations of their child's learning and the curriculum; compare their own mathematics schooling with their children's; describe their interactions when helping their child with mathematics at home; provide expectations about their child's mathematics learning; and describe communication received with the school and teacher about mathematics curriculum. Follow-up interviews were conducted with a subset of the parents

(15) in the focus groups to allow them to expand on and further clarify their comments from the focus group.

A common topic of discussion identified in the focus groups were parents' perceptions related to multiple strategies and alternative algorithms (see McGarvey & McFeetors, 2016). In the focus groups and interviews, the parent participants referred to a multiple strategies approach over 400 times. In this paper, we focus specifically on this large sample of comments using a thematic analysis (Braun & Clarke, 2006) of the focus group data using individual utterances as a unit of analysis. Through a constant comparative approach in sorting statements made by the parents in the focus groups, we identified key assertions in relation to the participants' perceptions of the role of multiple strategies in their children's learning of problem solving and computation. In the results, we explicate the ways in which parents make sense of alternative algorithms in their children's learning.

Findings

In Table 1, we highlight the range of themes we identified related to parents' perspectives of multiple strategies along with sample comments.

Table 1: Parent Perspectives on Multiple Strategies

Theme	**Assertions from Parents**
Adaptivity and flexibility of strategies	The answer is because once problems get more complicated, you might not know them at first sight. So you have to learn all the different strategies, that's why I think they teach all the different strategies because once it's more complex, it's like algebra and things like that. You need to know different ways to get the answers, ways that makes sense to you. Wouldn't you rather be really good at one than kind of mediocre at five?
Conceptual and procedural knowledge	They wanted them to understand the concept of all of the strategies and then pick the ones that worked better for them.
Disposition and identity	My middle son with ADHD has his problems. He would never be able to memorize …. It takes him a little while because he's slower and needs to focus, but he can use the strategies that he likes, which is not the standard algorithm, but he can figure it out. If she has to use the 15 different methods, then she sort of spirals out [of control].
Implementation of multiple strategies	There's this disconnect that they [teachers] think that they have to teach all of those ways and they [children] have to do them all of those ways. And we have to give it to them over and over and over again. Even if it doesn't work for them. I wish the teacher had had a better answer to that question. And I wish the teacher had known why she was teaching it those ways. I don't know if she knows.
Not effective for all	You have all of these strategies and you know having your child draw 90

students (both low and high achieving)	ticks on, you know paper, that's where you're wasting your children's time … in four or five different strategies you never allow them to master a particular method. She's not a drawer, she hates art. We were focusing more time on drawing pizza cones and all these things that had to do for these worksheets that were coming home, and coming up with a strategy name, that we weren't actually doing math. If there's, you know, 75% of children learn the best how we learned it growing up, why change it? And if those 25% or 20% or 15 or 10% are having troubles, then let's implement those strategies for those children instead of for broad all.

Conclusion

We note that parents did not necessarily view a multiple strategies approach from only one perspective. Instead, they often included multiple perspectives within one statement. In addition, although we provided here both the benefits and challenges to a multiple strategies approach as described in the literature, parents often provided counter-examples based on their perspectives that are important not to ignore.

ANALYSIS OF MATHEMATICS CURRICULUM MATERIALS TO ASCERTAIN STUDENTS' POTENTIAL TO DEVELOP AGENCY, AUTONOMY AND IDENTITY

Kwame Yankson
University of Michigan
yankson@umich.edu

This brief research report outlines a study of College Preparatory Mathematics (CPM) student curriculum materials to determine how language features of mathematical tasks position students to develop aspects of agency, autonomy and identity as learners of mathematics. I make a case for why I think these three attributes are important for mathematics learning, and I use analytic tools from Systemic Functional Linguistics to explore opportunities students have to develop agency, autonomy and identity when working on mathematical tasks in CPM textbooks.

Keywords: Curriculum Analysis, Middle School Education

Purpose of Study

The study investigates ways that language used in selected College Preparatory Mathematics (hereafter, CPM) mathematical tasks positions students to experience aspects of autonomy, agency and a sense of identity as learners and doers of mathematics. Agency, autonomy and identity are important because research (e.g. Lester & Cai, 2016) seems to indicate that students should be given more opportunities to rely more on themselves as they work on challenging mathematical tasks. Challenging mathematical tasks often have a high level of cognitive demand (Stein et al., 2000) and are often non-routine. Whether students of mathematics operate individually or with other learners in groups as they work to solve non-routine problems during lessons, it can be argued that they are required to assume greater control of the problem-solving process, independent of their teacher. By taking greater control of their learning, students are in essence being autonomous and engaging in agentic learning. I am interested in the CPM curriculum because it is an instance of problem-based or problem-centered learning. This form of learning often involves learning mathematics by working on complex and open-ended problems which are typically ill-structured so as to allow for several possible approaches and answers (Hmelo-Silver, 2004). Problem-based learning can provide learners of mathematics with opportunities to develop agency, autonomy and identity as doers of mathematics. Studying language used in mathematical tasks in CPM textbooks can inform research on how students are positioned to develop agency, autonomy and identity as learners of mathematics when engaged in problem-based or problem-centered learning.

The following research question guides my analysis of CPM curriculum materials:

> In what ways are language features of mathematical tasks in CPM student textbooks likely to support the development of aspects of students' agency, autonomy and identity?

Theoretical Framework

Agency is the first component of my theoretical framework. Lipponen and Kumplainen (2011) state that "agency can be defined as the capacity to initiate purposeful action that implies will, autonomy, freedom, and choice" (p. 812). There is an action component to agency, which may be afforded or constrained by conditions determining an individual's ability to act. Cobb et al. (2009) further distinguish agency into conceptual and disciplinary varieties. Learners experience conceptual agency when they are allowed to come up with their own methods and understandings during learning while they experience disciplinary agency when they are able to engage in mathematical work that involves known procedures.

Autonomy is the second component of my theoretical framework. It can be thought of as “a capacity to take control of one’s own learning” (Benson, 2011, p.58). For Benson, control refers to control of cognitive processes, of learning content and of learning management. In my analysis of mathematical tasks from CPM curriculum materials, my focus is primarily on the capacity for students to take control of cognitive processes either as they work individually or collaboratively in groups. Taking control of cognitive processes depends on affordances and constraints determined by language choices used to guide students’ to work on mathematical tasks. As these affordances and constraints also determine the capacity to act, the notions of agency and autonomy are intimately intertwined. The difference between these two concepts is quite subtle as to make the two terms have practically one and the same meaning. According to Benson (2007), “…agency can perhaps be viewed as a point of origin for the development of autonomy, while identity may be viewed as one of its more important outcomes.” (p. 30).

The third component of my theoretical framework is the notion of identity. Cobb et al. (2009) differentiate between students’ normative identity and students’ personal identities. They define normative identity as “both the general and the specifically mathematical obligations that delineate the role of an effective student in a particular classroom” (p. 43). The normative identity can be shared across students with different personal identities. For my conceptual framework, I am primarily interested in opportunities indicated in mathematics texts for students to develop normative identity as doers of mathematics.

Methods

Data consists of selected mathematical tasks for classwork from the most recent versions of student texts for the Core Connections (CC) Integrated I, II, & III CPM curriculum materials that address the subject of functions and graphs. Functions and graphs are a ubiquitous topic in mathematics, encountered by students over multiple years. Learners of mathematics see functions and graphs in numerous ways across the mathematics curriculum of high school, and this topic has importance in the future study of mathematics at the college level and beyond. As such, if functions and graphs are taught and learned in a way that can promote students’ agency and autonomy then as students encounter functions and graphs again in the study of higher mathematics, they could activate and draw on their developed ability to be agentic and autonomous. The CC Integrated textbooks are designed to have each chapter include a number of sections. Each section encompasses several lessons. For instance, chapter one of CC Integrated I, ‘Functions’, is organized into three sections, all of which deal with the topic of functions.

This brief research report analyzes instances of communication and interaction between textbook authors and readers. These communications and interactions can be seen as forms of guidance transferred from the textbook writers to students when directing students on how to work on mathematical tasks. The guidance takes the form of textbook writers giving some information or demanding some action of readers. Information given may be in the form of mathematics theorems, definitions or some other form of theory. Information given may also be in the form of statements of particular affordances or constraints of a mathematics task. Information demanded may be in the form of answer responses required of students.

These forms of exchange (giving or demanding) are represented grammatically by three kinds of clause moods: declaratives (usually statements), interrogatives (usually questions) and imperatives (usually commands) made on the part of the textbook writers. Zolkower & Shreyar (2007) define a clause as “the smallest possible group of words within a text that has meaning” (p. 182). Clauses as instances of communication serve as the unit of analysis for this study. In particular, I am interested in analyzing imperative clauses appearing in mathematical tasks. They are an aspect of the interpersonal meta-function, an aspect of Systemic Functional Linguistics which involves interactions (Thompson, 2013). In this case, the interactions are between textbook authors and students. Imperative clauses task students to take various actions. In these actions, there can be opportunities for students to experience agency and autonomy in their learning. I analyze two kinds of imperative clauses: inclusive and exclusive (Herbel-Eisenmann, 2007). Inclusive imperatives can position students as thinkers and demand that students' responses reflect their thinking. These imperatives feature verbs such as "explain", "describe", "justify", and "predict". They can be found in the following typical example clauses taken directly from CPM textbook data "explain how you found your answer", "describe additional features in your own words", and "be ready to justify your statements". Exclusive imperatives on the other hand direct students to carry out actions that tend to be less about what students think and more about executing actions related to established mathematics procedures. Examples of verbs found in exclusive imperative clauses are "calculate", "draw", "make", "use", "plot", and "write". Some example clauses from CPM textbook data are "use your calculator", "draw a slope triangle", "sketch the graph of $h(x) = (x + 3)^2 + 4$", "make a table" and "write an equation".

Through the study of imperative clauses, it is possible to point out opportunities for agency and autonomy students are given to rely on their own thinking and creative resources as doers of mathematics. The degree to which students are directed through inclusive imperatives versus exclusive ones can also shed light on how textbooks position students to develop identities as mathematics thinkers.

Results

The following results are based on analysis of clauses in 245 mathematical tasks from 57 lessons on functions across the three textbooks.

Table 1: Verbs in Inclusive and Exclusive Imperatives

Inclusive imperatives	Frequency	Exclusive imperatives	Frequency
Explain	56	Write	47
Describe	23	Use	33
Justify	19	Sketch	29
Predict	6	Draw	23
		Graph/Plot	17
		Label	15
		Solve	10
		Calculate	9
		Make	9
Totals	**104**		**192**

Discussion

The results in Table 1 generally align with those obtained for inclusive and exclusive imperatives in Herbel-Eisenmann (2007). The results show that the CPM texts feature both inclusive and exclusive imperatives. Table 1 shows a wider spread and more instances of exclusive imperatives than of the inclusive kind. For the analyzed CPM mathematical tasks, it may be inferred from these results that students are being positioned by the text in these mathematical tasks to carry out a greater variety of actions that pertain to established procedures in mathematics. On the other hand, the relatively high incidence of the verb "explain" shown in Table 1 draws attention to inclusive imperatives. "Explain", and other verbs such as "describe", "justify" and "predict", all of which featured in analyzed inclusive imperatives can give opportunities for students to develop conceptual agency, autonomy and their normative identity as they engage in thinking about and doing mathematics while working on mathematical tasks during lesson time. As such, this finding emerging from analyzed inclusive clauses can be seen as a language feature of mathematical tasks on functions in CPM student textbooks that positions students to express their conceptual agency, autonomy in their thinking and which can subsequently influence students' development of normative identity as a doer of mathematics.

CONCEPTUAL DEFICITS IN CURRICULAR INTRODUCTIONS TO MULTIPLICATION

John P. Smith III
Michigan State University
jsmith@msu.edu

This paper presents evidence that the U.S. curricular introduction to multiplication, and more broadly, "multiplicative relationships," is fundamentally additive and therefore conceptually deficient. Conceptualizing multiplication as the replication of equal-size groups of discrete objects and repeated addition provides insufficient support for understanding the full range of multiplicative relationships, numerically and quantitatively. The additive approach fails to extend sensibly to (a) many multiplicative situations (e.g., Cartesian product, area and volume measure, and scaling) and (b) the multiplication and division of fractions, decimals, and integers. The paper summarizes evidence from three levels of curriculum: The Common Core, elementary mathematics curricula, and mathematics texts for elementary teachers. The analysis points to the need for innovative curriculum development to support multiplicative thinking.

Keywords: Curriculum Analysis, Number Concepts and Operations, Elementary School Education

Research Objective

This analysis was undertaken to carefully examine how U.S. mathematics curricula introduce the operation of multiplication in the elementary grades. Specifically, it examined how elementary mathematics curricula—at three different levels of articulation—align with or depart from additive conceptions of multiplication. Quantitatively, additive conceptions focus on situations with equal-sized groups of discrete (countable) objects. Numerically, multiplication is presented as repeated addition. Such introductions create challenges for teachers and students when later work in mathematics and science presents situations and multiplication and division in non-whole number systems that are difficult to understand in additive terms (Davis & Simmt, 2006). If additive conceptions are currently dominant, new curricular approaches will be needed to provide more flexible and extendable foundations for teaching and learning multiplicative relationships. This study was motivated by a prior study of U.S. curricular presentations of area measurement that revealed a gap between additive, array-based conceptions and the multiplicative combination of length and width (Smith, Males, & Gonulates, 2016).

Theoretical Perspective

The analysis was guided by three perspectives: (1) the conceptual analysis of multiplicative situations, (2) Thompson's theory of quantitative reasoning, and (3) a general orientation toward learning as a constructive process. Following Vergnaud's (1983) analysis of the "multiplicative conceptual field," researchers have offered different typologies of multiplicative situations that are conceptually distinct and not easily reduced one to another. Greer's (1992) influential analysis identifies four: equal groups, area, multiplicative comparison, and Cartesian product. Understanding multiplication requires seeing how the operation applies differently to each type.

Situations, typically presented in curricula as "word problems," are structured by quantities and quantitative relationships (Thompson, 1994). Quantities are measurable attributes of objects or relationships. The theory of quantitative reasoning (QR) distinguishes discrete from continuous quantities, additive from multiplicative relationships, and operations of comparison from combination. For example, rectangular area can be seen either in additive terms as a discrete collection of squares and in continuous terms as the multiplicative combination of length and width.

QR emphasizes that mathematical thinking depends as much on the quantitative understanding of situations as on the numerical procedures used to compute numerical values.

If understanding multiplication involves both quantitative and numerical insights and if different types of situations relate discrete and continuous quantities in different multiplicative ways, then learning necessarily involves significant conceptual growth and change. If learning is a constructive process, students' initial understandings of multiplication must eventually adapt to and accommodate the wider range of situations, quantities, and multiplicative relationships. Initial conceptual foundations must be rich and flexible enough to accommodate that growth.

Method

The analysis examined three nested levels of elementary mathematics curricula. First, all content standards that referred to multiplication in *the Common Core State Standards for Mathematics* (*CCSSM*) (NGA & CCSSO, 2010) were located and analyzed, with special attention to grades 2 to 5. The analysis also examined the relevant passages of three *CCSSM* progressions documents. Second, grade 2 through 5 student and teacher materials in three elementary textbook series were analyzed: *Everyday Mathematics*, 4th edition (The University of Chicago School Mathematics Project, 2016) ("*EM4*"); *Engage New York* (New York State Department of Education, n.d.) (*"ENY"*) and *enVisionMATH Common Core* (2012) ("*enVision*"). Each was written or revised after the publication of the *CCSSM.* Third, four mathematics textbooks written for pre-service teachers and selected based on colleagues' recommendations were analyzed; the lead authors were Bassarear (2012), Beckmann (2014), Billstein (2013), and Sowder (2012). All parts of each text that dealt with multiplication and division and multiplicative situations were analyzed. At each curricular level, the analysis focused on: (a) the first multiplicative situation (or meaning) presented, (b) the presence or absence of an explicit definition of multiplication, (c) the relative frequency of discrete and continuous quantities in problems, and (d) the treatment of other types of multiplicative situations (after the first). The author carried the analysis.

Results

Multiplication in the *CCSSM*

The *CCSSM* presents three types of multiplicative situations in grades 3 through 5 (equal-groups, area, and comparison), with strong emphasis on equal-sized groups and discrete quantity. Rectangular area is presented as a type of discrete array (where the objects are squares). Multiplicative comparison is presented and then extended to scaling, in both cases as a numerical operation. Cartesian products are never mentioned. Overall, the meaning of multiplication is anchored in equal-sized groups of discrete objects. Area and volume measures are counts of squares and cubes, not the multiplicative combinations of lengths.

The *CCSSM* does not explicitly define multiplication but does explicit tie the meaning of multiplication to groups of discrete quantities, "Interpret products of whole numbers, e.g., interpret 5 x 7 as the total number of objects in 5 groups of 7 objects each" (Standard 1 3.OA). Area measure is linked to discrete arrays; "area involves arrays that have been pushed together" (*CCSSM*, Table 2, p. 89). The *CCSSM* does not describe area as a continuous quantity—the amount of space enclosed in a boundary. Multiplicative comparison is introduced in Grade 4 in numerical terms, "Interpret a multiplication equation as a comparison, e.g., interpret 35 = 5 x 7 as a statement that 35 is 5 times as many as 7 and 7 times as many as 5" (Standard 1, 4.OA). Numerical multiplication is extended to fractions and decimals in grade 5.

Galindo, E., & Newton, J., (Eds.). (2017). *Proceedings of the 39th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* Indianapolis, IN: Hoosier Association of Mathematics Teacher Educators.

Multiplication in Three Elementary Curricula

All three textbook series follow the *CCSSM's* presentation of multiplication relatively closely. But *ENY's* treatment of multiplicative content is extremely close to the *CCSSM*, so the analysis above applies equally and directly to that series. Counts of *ENY* word problems show much greater attention to discrete than continuous quantities.

enVision's presentation also emphasizes equal groups and illustrates numerical products as repeated sums of the same addend. Topic 4 in grade 3 concerns "Meanings for multiplication." Lesson 1, "Multiplication as repeated addition," states that multiplication "is an operation that gives you the total number when you join equal groups" (p. 101). Lesson 2 adds that "multiplication can also be used to find the total in an array" (p. 103). Lesson 4 introduces multiplicative comparison, but only for discrete quantities ("times as many"). Word problems in Topic 4 exclusively involve discrete quantities. In Topic 6, Cartesian products of two small sets of objects are represented as arrays. Topic 14 ("Area") defines area measure as "the number of square units needed to cover a region" (p. 342)—explicitly a discrete meaning. Grade 4 continues the focus on repeated addition of equal groups of discrete objects, reminding students to use their addition knowledge, "You have learned addition facts. Now you will use them to help you learn to multiply" (p. 6).

EM4 lays the foundation for multiplication in grade 2. Unit 8, "Geometry and Arrays," focuses on equal group situations and arrays, which are closely linked. After students partition rectangles into squares, teachers are directed to explain multiplication as an operation that involves "finding the number of objects in equal groups or rows" and that "an array is one way to represent equal groups" (Teacher Lesson Guide [TLG], p. 739). The text also states to teachers that "[u]sing equal groups language helps children build the conceptual foundation for multiplication (TLG, p. 746). All quantities in Unit 8 are discrete. In grade 3, Unit 1 focuses on numerical methods for finding products in equal groups situations and emphasizes skip counting and repeated addition. Unit 4 on area measure moves quickly from counting individual squares in rectangles to multiplying the number of squares in each row by the number of rows. Despite some efforts to move beyond rectangular area as pushed-together arrays, *EM4's* focus in grades 2 and 3 is on equal groups, arrays, and discrete quantity. The series introduces multiplicative comparison in grade 4 and scaling in grade 5, but never presents Cartesian products.

Multiplication in Elementary Pre-Service Texts

Three of the four texts explicitly define multiplication. Billstein and Bassarear define multiplication in numerical terms as repeated addition; Beckmann does so as the replication of equal groups. Sowder does not provide a definition but initially "views" multiplication as repeated addition. Beckmann presents all of Greer's four types of situations and adds arrays of discrete quantities. Her text interprets all five types as equal groups of discrete quantities. For example, the elements of Cartesian products are presented in an ordered list and then arranged into equal groups. Billstein presents three of Greer's types, excluding only comparison. Sowder excludes equal groups and adds an "operator view"—the only text to do so. Bassarear presents only Cartesian product and comparison.

All four texts explicitly acknowledge some concern with repeated addition. Beckmann admits that groups are not always salient in multiplicative situations; Bassarear states that pre-service teachers should look for other models when situations don't fit repeated addition well. Billstein states that repeated addition can lead to "misunderstanding," so other models should be introduced. Sowder indicates that the sole focus on repeated addition will limit children's thinking and could lead to the misconception that multiplication makes numbers bigger.

All texts extend multiplication to non-whole numbers in different ways. Billstein and Beckmann extend their definitions to integers and fractions (via repeated addition and equal groups respectively) but abandon them for decimals. Sowder and Bassarear use repeated addition for most cases of integers but shift to “area models” for fractions and decimals (Bassarear) or fractions alone (Sowder). Sowder treats decimals as whole numbers. In each text, the authors’ additive conceptions fail to extend to decimal multiplication or to some cases of integer multiplication, but these limitations are not addressed. Overall, despite variation and stated concerns, three of the four texts explicitly define multiplication as repeated addition or the replication of equal groups. Only one (Sowder) moves away from an additive conception.

Discussion

These results show remarkable consistency in how multiplication is introduced and developed in U.S. elementary mathematics curricula. The clear focus is on equal groups of discrete objects and repeated addition as the means of computing numerical products. But the foundation of equal groups does not generally extend to the multiplication of non-whole numbers and is a poor fit to important types of multiplicative situations. Introducing multiplication via equal-sized groups of discrete objects eases the task of initial teaching and learning, but it does so at substantial cost to later learning. We need innovative curriculum development work to articulate essentially multiplicative approaches to the operation of multiplication and the nature of multiplicative relationships beginning in the elementary years.

DISCOURSE ANALYSIS OF A SOUTH AFRICAN OPENLY LICENSED MATHEMATICS TEXTBOOK

Elizabeth Kersey
Purdue University
ekersey@purdue.edu

South African curriculum reform efforts have focused on making education more equitable. One way to measure this goal is to examine the voice of a curriculum. Thus, I use a discourse analytic framework to evaluate selected chapters from the textbook Everything Maths for Grade 12. The textbook provides access into the standard language of academic mathematics, but is not entirely consistent with the ontology of mathematics described in South African national curriculum documents. The role of the reader is more often that of a scribbler than a thinker. The textbook could be improved by adopting a more personal tone and requiring a deeper level of thought.

Keywords: Curriculum Analysis, High School Education, Equity and Diversity, Classroom Discourse

Mathematics curricula may not be sufficient to ensure equitable education without trained teachers to enact that curriculum, but it is a good place to start (Boaler, 2002). Mary Schleppegrell (2012) discusses how discourse analysis can help us to understand equity issues in mathematics classrooms. Of particular focus is how participants are positioned with respect to authority. For instance, when the author(s) tell the reader what they found in a previous exploration, this can be read as an attempt to control the reader's thinking (Herbel-Eisenmann, 2007). By presenting results from a discourse analysis of a South African textbook, I show how it contributes to and detracts from an equitable classroom, and the extent to which it is aligned with statements about mathematics and equity in national curriculum documents.

Social Justice and National Curriculum Documents

The Curriculum and Assessment Policy (CAPS; DoBE, 2011) is the national curriculum document that governs the textbook under review in this study. It contains explicit discussions of social justice issues. CAPS (DoBE, 2011) states one of its goals as "to promote accessibility of Mathematical content to all learners" (p. 8) and that students should "participate as responsible citizens in the life of local, national and global communities" (p. 9).

CAPS (DoBE, 2011) describes mathematics as follows:

> Mathematics is a language that makes use of symbols and notations for describing numerical, geometric and graphical relationships. It is a human activity that involves observing, representing and investigating patterns and qualitative relationships in physical and social phenomena and between mathematical objects themselves.

The description of mathematics as a human activity makes it appropriate to deploy a discourse analysis to analyze how well the textbook developed to suit these goals meets these aims and promotes the ideals of equity and social justice found throughout this document. In particular, the textbook should represent mathematics as an evolving human endeavor, position students as capable of mathematical reasoning, and not position itself as an infallible authority.

Discourse Analytic Framework

The discourse analytic framework used for this study was developed by Morgan (1996) and based on the linguistic work of Halliday (1978). The framework was operationalized by Herbel-Eisenmann (2007). This framework considers three functions of the text: the interpersonal, ideational, and textual features (Halliday, 1978). The interpersonal function is the focus of this analysis. It involves looking at how personal relationships are established in a text and where power is situated in those relationships (Morgan, 1996).

One way this framework is operationalized is by looking at any personal (first- or second-person) pronouns in the text (Herbel-Eisenmann, 2007). Using first-person pronouns acknowledges the existence of the authors (although the use of *we* can serve several functions; see Pimm, 1987), while using second-person pronouns acknowledges the existence of the readers. Another way the interpersonal function is analyzed is by looking at the questions and imperatives used in addressing the reader (Herbel-Eisenmann, 2007). The imperatives are classified as either inclusive or exclusive. Rotman (1988) defines the inclusive imperatives ("'consider', 'define', 'prove' and their synonyms", p. 9) as those which draw the speaker into the text and demand cognitive engagement. Exclusive imperatives, which Rotman (1988) classifies as all other mathematical verbs, are those that ask the reader to perform actions that are already meaningful in the shared world of the text. This would include situations such as asking the reader to solve an equation for an unknown variable.

Methods

Background of the Textbooks

For this study, the material for analysis was the South African Grade 12 *Everything Maths* (Siyavula, 2014) textbook from the *Everything Maths & Science* series, which grew out of a prior openly licensed textbook series called *Free High School Science Texts* (FHSST; 2008). Siyavula is a technology company focused on "building an integrated learning experience, drawing on the benefits of open content and adaptive practice for mastery in Maths and Science" (Siyavula, 2015).

Textbook Selection

This textbook series was chosen because it provides a much needed resource – free science and mathematics textbooks – to many schools that would otherwise lack this resource. It is available in both English and Afrikaans. The English texts are the ones analyzed here. The chapters analyzed are those on Finance, Trigonometry, and Euclidean Geometry. Finance was chosen because of its focus on applications, particularly applications that may well be relevant to students' lives. Trigonometry was chosen because of its flexibility – it can be used for rote calculations, for proofs, and for applications. Euclidean Geometry was chosen as the most likely chapter where students would be expected to write proofs and/or explain their answers. These were chosen because proofs and applications contain the most words, and thus the most material for discourse analysis. Additionally, since the type of imperatives is included in the analysis, those chapters with proofs should contain the largest sample of inclusive imperatives.

Analysis

The Finance, Trigonometry, and Euclidean Geometry chapters of the Grade 12 *Everything Maths* text (Siyavula, 2014) were analyzed using the framework developed by Herbel-Eisenmann (2007). This involved examining the voice of the texts using personal pronouns (e.g., I, we, you), and questions and imperatives. Specifically, the analysis included identifying personal pronoun usage (first and second person, singular and plural) and the number of questions and inclusive and exclusive imperatives. Inclusive imperatives are those that ask a reader to think more deeply about a concept and construct their own meaning, while exclusive imperatives ask a reader to execute a specific task in a well-defined manner.

Results

Counting by sentences, the Finance chapter comprised 37% of the text analyzed, the Euclidean Geometry chapter 31%, and the Trigonometry chapter 32%. The exercises constitute the largest portion, with 43.3%. The exposition and worked examples are then similar in size, with 26.9% and 29.8% of the text, respectively. These proportions should be kept in mind when reviewing the rest of the results, as these unequal proportions mean that not every section is weighted evenly.

Pronouns

Table 1: Personal Pronoun Usage in *Everything Maths Grade 12*

Section of Text	1st person singular	1st person plural	2nd person
Exposition	4	65	29
Worked Examples	0	64	0
Exercises	0	2	2
Total	4	131	31

The *Everything Maths* chapters chosen for analysis contain 168 total personal pronouns (see Table 1). Of these, 74 are in the Finance chapter and 70 are from the Trigonometry chapter, with only 22 (all first-person plural) from the Euclidean Geometry chapter. All of the first-person singular pronouns are in the Finance chapter. The majority (59%) of the personal pronouns are concentrated in the exposition, but the exposition only represents 30% of the text, making this tendency more pronounced. The exercises contain a scant 2% of the personal pronouns.

Imperatives

Table 2: Questions and Imperatives in *Everything Maths Grade 12*

Section of Text	Questions	Exclusive Imperatives	Inclusive Imperatives
Exposition	9	28	3
Worked Examples	7	165	30
Exercises	54	171	61
Total	70	364	94

The *Everything Maths* selections contain about six and a half times as many imperatives as questions (see Table 2). There are not quite four times as many exclusive imperatives as inclusive imperatives. The majority of the questions are from the Finance chapter, while the majority of the inclusive imperatives are from the Trigonometry and Euclidean Geometry chapters. The Trigonometry chapter has almost as many exclusive imperatives as the other two chapters combined. The questions and imperatives are concentrated in the worked examples and exercises, with 38% of them in the worked examples (30% of the total sentences) and 54% in the exercises (43% of the total sentences). Only 8% of the questions and imperatives are found in the exposition (27% of the total sentences).

Discussion

Pronouns

The most consistent personal pronoun used in this text is the first person plural (e.g., we, our, ourselves). Pimm (1987) commented on the ambiguous use of the term *we* in mathematical discourses, noting that it can be used to denote the author(s), the authors together with the reader, or the mathematical community. Ultimately, however, this convention is characterized by the vagueness of its referent. Pimm noted that the effect on him of reading such a text was as follows:

> [C]hoices had been made, ostensibly on my behalf, without me being involved. The least that is required is my passive acquiescence in what follows. In accepting the provided goals and methods, I am persuaded to agree to the author's attempts to absorb me into the action. (p. 72-3)

Thus, while the use of this personal pronoun could be interpreted as emphasizing the human nature of mathematics, it may actually be a way to exert authority.

In this textbook, the use of *we* certainly seems to indicate some use of formality, at least when it is the only personal pronoun present. In the Finance chapter, the use of *we* was balanced by other personal pronouns, particularly *you*. This contributes a tone that feels more personal. On the other hand, in the chapters on Trigonometry and Euclidean Geometry, *we* drastically outnumbers the instances of *you*, the only other personal pronoun. When not balanced by other personal pronouns, *we* denotes a much more formal tone. Thus, *Everything Maths* has a consistently formal tone. This is not particularly consistent with the statements in the national curriculum document characterizing mathematics as a human, social endeavor.

Questions and Imperatives

Everything Maths contained many more imperatives than questions, with the imperatives sometimes labelled as questions. This gives the text a more authoritative voice (Herbel-Eisenmann, 2007), especially when combined with the exclusive use of *we* as a personal pronoun (Pimm, 1987). It also contains many more exclusive imperatives than inclusive imperatives. This means that the student/reader is positioned primarily as a *scribbler*, rather than a *thinker* (Rotman, 1988). While both roles are necessary to become a mathematician, a better balance between the two should be achieved. The Finance chapters in particular positioned the reader almost exclusively as a scribbler.

HOW KOREAN ELEMENTARY MATHEMATICS TEXTBOOKS DEVELOP INVERSE RELATIONS: CONCRETNESS FADING

Ji-Won Son
University at Buffalo-SUNY
jiwonson@buffalo.edu

Seung Jung Jo
University at Buffalo-SUNY
sjo5@buffalo.edu

Despite of the significance of inverse relations in elementary mathematics, how student might be supported to learn the relations remains largely unknown. By examining the presentation of the inverse relations in a representative Korean elementary mathematics textbook series, this study explores how the Korean textbooks may facilitate the transition from concrete to abstract representations to promote student learning of the relations. A total of 138 instances of the inverse relations were identified. Findings revealed several important aspects of the Korean textbook series. First, inverse relations were contextualized in real-world situations through the method of storytelling within introductory problems. In addition, the use of multiple visual representations in concrete representations facilitated students' sense-making of computational procedures in abstract representations, which aligns with the process of concreteness fading.

Keywords: Algebra and Algebraic Thinking, Elementary School Education

Introduction

Inverse relations among fundamental mathematical ideas have been recognized as a critical foundation for school mathematics. However, students consistently have difficulties in understanding the inverse relations for two reasons: its abstract nature, and its irrelevance to their lives. Given the key role of textbooks as the primary resource of learning, this study aims to narrow such research gap by exploring representational transition in textbooks through an examination of the inverse relation between addition and subtraction in a representative Korean textbook series. From curriculum perspectives, the purpose of study is to examine learning opportunities that are presented in Korean textbooks. Since international textbook analysis examines how curriculums in high-achieving countries provide students with opportunities to learn, investigating Korean math textbook is expected to contribute to the development of students' understanding of the relations (Son & Senk, 2010; Son, Watanabe, & Lo, 2017). The study is centered on the following questions: (1) How are introductory, guided, and practice problems interweaved to support the learning of inverse relations in Korean textbooks?; (2) How are concrete and abstract representations connected to present inverse relations?; and (3) How is the learning of inverse relations spaced over time?

Theoretical Perspectives

Inverse relations are one of the most important relationships in elementary mathematics because reasoning with inverse relations plays a key role in the development of mathematical thinking and computational effectiveness. With such importance, the Common Core State Standards for Mathematics (CCSSM) (National Governors Association Center for Best Practices & Council of Chief State School Officers [NGA & CCSSO], 2010) have emphasized that elementary students are expected to learn about relationships between the four operations. An understanding of inverse relations is necessary to comprehend the four basic arithmetic operations and to develop early algebraic thinking (Nunes, Bryant, & Watson, 2009). The knowledge of inverse relations can help to simplify students' computational difficulties. Inverse relations are useful to flexibly compute [e.g., 81–79 = ( ) can be thought of 79 + ( ) = 81 (Ding, 2016; Torbeyns, De Smedt, Stassens, Ghesquière, & Verschaffel, 2009), check computations (e.g., verifying that 27–12 = 15 by computing 15 + 12 =

27; Baroody, 1987), and solve difficult word problems such as initial unknown change problems in which a quantity may increase but the solution may involve subtraction.

Despite of its significance to all aspects of early mathematics, previous research has shown that many students tend to fail to gain a formal understanding of inverse relations (Torbeyns et al., 2009; Ding, 2016). According to prior research (e.g., De Smedt et al., 2010; Torbeyns et al, 2009), formal instruction on inverse relations is lack of the learning of abstract knowledge in concrete contexts. The previous research has been proved the concreteness fading, “the process of successively decreasing the concreteness of a simulation with the intent of eventually attaining a relatively idealized and decontextualized representation that is still clearly connected to the physical situation that it models” (as cited in Ding & Li, 2014, p. 105), to be an effective method for learning scientific principles and mathematical rules (Goldston & Son, 2005).

Methods

We chose to examine Korean textbook series published by the Ministry of Education, Science, and Technology (MEST). The MEST textbook series held the teaching of each topic in one chapter containing several interrelated lessons. In each lesson, there are three steps: introductory, guided, and practice problem. All introductory, guided, and practice problems in the textbook series were examined as an instance of inverse relations. We also consider each identified instance as either a concrete or an abstract representation based on its overall nature. Furthermore, since we consider that concreteness and abstractness are viewed as relative in this study, for each instance, we coded the levels of concreteness and abstraction. For concrete representations, we differentiated several types of problem formats including (a) word problem with visual representation, (b) visual representation and (c) word problem. From (a) to (c), there was a decreasing level of concreteness because the visual information became less involved. For abstract representations such as computation problems, we differentiated the types of numbers. We viewed one-digit computation as relatively less abstract than two- and three-digit computation because the former might be more familiar to students and multidigit computation might require regrouping, which could involve more cognitive loads. After coding, we first counted the frequency of all the problem types. Then, we counted the frequency of instances for the inverse relation between addition and subtraction under the three contexts: introductory, guided, and practice problems, respectively. We conducted the detailed analyses at three tiers: (1) only introductory problems, (2) the total problems across chapters over grades, and (3) only the problems related to inverse relation. We examined the common patterns emerged from introductory problems. We also examined the representational changes from introductory to practice problems across chapters over grades. Furthermore, we examined only the problems that formally and informally instruct the inverse relation between addition and subtraction.

Summary of Selected Findings

A closer examination of the Korean textbooks along three dimensions revealed several noticeable pedagogical techniques that seemed to facilitate the transition from concrete to abstract representations.

The Method of Storytelling

The Korean textbooks presented 462 problems across chapters from grade 1 to 2 (see Table 1). Among 462 problems, there were a total of 72 introductory, 53 guided, and 337 practice problems. Among 72 introductory problems that were situated in word problem with visual representation, there were common patterns in presenting each problem: (1) presenting a word problem with accompanying pictures; (2) involving the manipulation of concrete objects (e.g., counting by using actual stickers, drawing shapes); (3) presenting number sentences that embody the relation between addition and subtraction. All the introductory problems (n = 72) were presented in word problems with pictorial representation (see Figure 1).

Figure 1. Examples of pictures used for storytelling.

The situation in each word problem was interrelated with each other under the same theme. For example, the situations in the word problems in lesson 11, 12, and 13 of chapter 3 in grade 2 were connected to each other: playing the game of go, baking cookies, and earning reward stickers. These three situations could be traced back to the real-life situation described in lesson 1 where a second grader were writing what happened today at his school in his journal. With using a total 6-page of pictures, the method of storytelling is usually implemented. The method of storytelling can be categorized into three parts: a) discussion before storytelling; b) teacher's reading-aloud; c) making connections between the situation in the story and students' real-life situation. Through storytelling in lesson 1, the introductory problems across other lessons are intertwined and seem to be able to facilitate making connections between students' informal knowledge (and the formal knowledge of addition and subtraction. Therefore, the method of storytelling may promote the specificity of the concreteness of introductory problems.

Table 1: The Frequency of Total Problems Across Chapters from Grade 1 to 2 in KM

Grade (volume)		Introductory Problem		Guided Problem		Practice Problem		Totals per row
	Chapter	Concrete	Abstract	Concrete	Abstract	Concrete	Abstract	
1 (v. 1)	3	18	0	3	0	48	20	89
1 (v. 2)	3	14	0	8	4	28	36	90
1 (v. 2)	5	13	0	12	1	20	32	78
2 (v. 1)	3	14	0	7	5	32	72	130
2 (v. 2)	2	11	2	12	1	34	15	75
Totals per column		70	2	42	11	162	175	462

The Use of Multiple Representations

The Korean textbooks presented 459 problems including the problems directly related to inverse relation between addition and subtraction from grade 1 to 2. Among 459 problems, there were a total of 277 concrete and 182 abstract representations. Among 277 concrete representations, there were a total of 67 word problems with visual representation, 100 visual representation problems, and 23 word problems. In each grade, similar patterns were found: a) concrete representations outnumbered abstract representations; b) the proportion of the problems with visual representations was bigger than the ones without visual representations, which indicates a trend of fading concreteness within concrete representations.

The Connection Between Informal and Formal Learning of Inverse Relations

The Korean textbooks presented 138 instances of the inverse relation between addition and subtraction from grade 1 to 2. The formal instruction of the relation occurred in grade 1 (n =107). Among 138 instances, there were a total of 21 introductory problems, 14 guided problems, and 103 practice problems. Several patterns of representation uses were revealed. First, all the introductory problems were presented in concrete contexts, which were word problem with visual representation. Second, the majority of guided problems (13 out of 14) were presented in concrete contexts, which were pictorial representation. Third, practice problems involved both concrete (n = 41) and abstract (n = 62) representations.

Discussion and Implications

This study contributes to the current literature because it illustrates how formal instructional resources such as textbooks may support students' learning of inverse relations. The underlying assumption of this research is that improved curriculum quality improves student learning and teacher learning, directly and indirectly. Given Korean's students' high achievement in international assessment, the Korean approaches may suggest pedagogical supports for students' meaningful and explicit learning of the inverse relations in elementary school. We found that, inverse relations were contextualized in real-world situations through the method of storytelling. In addition, the use of multiple visual representations in concrete representations facilitated students' sense-making of computational procedures in abstract representations, which aligns with the process of concreteness fading. The findings about Korean textbooks' insights and pedagogical techniques may provide rich information for textbook designers and classroom teachers to refer back to.

NAVIGATING PROJECT-BASED LEARNING: ONE TEACHER'S DEVELOPMENT OF A PBL CURRICULUM WITH A FOCUS ON SOCIAL JUSTICE

Oyemolade Osibodu
Michigan State University
mosibodu@msu.edu

Project-based learning (PBL) is a method of instruction that can be harnessed to address issues of social (in)justice in mathematics classrooms. Using a descriptive and exploratory case study, I investigated how one teacher (re)develops the curriculum for a PBL project with a focus on social justice and the dilemma she encountered in the process. Using Remillard's (1999) framework, results indicated that PBL with a social justice lens requires careful time to plan and there are multiple dilemmas that this teacher encountered in the process.

Keywords: Curriculum, Instructional activities and practices, Equity and Diversity

Project-based learning (PBL) is a powerful pedagogical approach to use when incorporating issues of (in)equity and social justice in one's teaching. *Project-based learning* (PBL) is an innovative form of instruction that can provide students with the necessary and vital skills needed for the 21st century (Bell, 2010; Buck Institute for Education, 2003; Meyer, Turner, & Spencer, 1997). The Buck Institute for Education (BIE), an organization dedicated to helping teachers enact PBL, define PBL as "a systematic teaching method that engages students in learning knowledge and skills through an extended inquiry process structured around complex, authentic questions and carefully designed products and tasks" (BIE, 2003, p. 4). Some of the challenges noted by researchers are time to plan and design the project, alignment to standards, support for student learning, and assessment of students' learning (Krajcik, 1998; Marx, Blumenfeld, Krajcik, & Soloway, 1997; Mchugh, 2015).

Although researchers have argued for the importance of teachers planning projects that attend to important facets of PBL such as the driving question, content aligned to standards, and authenticity of the project (Markham, Larmer, & Ravitz, 2003; Marx, Blumenfeld, Krajcik, & Soloway, 1997), research has not examined in detail how teachers anticipate and achieve these goals. Research has focused on teachers' implementation of PBL (Blumenfeld et al., 1991; Krajcik, 1998), but few have focused on the planning and design stage of PBL with an emphasis on social justice and alignment to standards. A focus on the design and planning of projects in PBL is analogous to curriculum development, thus, research is needed in documenting how teachers develop curriculum for projects.

With regard to the types of projects students should tackle in PBL, the BIE, stated: "projects provide students with empowering opportunities to make a difference, by solving real problems and addressing real issues" (Buck Institute for Education, 2003). Yet, few studies of PBL have shown examples of students in PBL classrooms working on projects that address real issues of social significance (see Mchugh, 2015). Thus, as Thomas (2000) stated, "PBL practitioners are in a position of having to construct a unique instructional model almost completely on their own without guidance, texts, resource materials, or support" (p. 35). Research on *teaching mathematics for social justice* (TMfSJ) thus far has shown a need for teachers to become curriculum developers because supplementary materials are needed to address the help them achieve the goals of TMfSJ (Brantlinger, 2013; Gutstein, 2003). However, thus far, these projects have been an addendum to the classes which is different from PBL. To that end, the purpose of this study was to explore how a mathematics teacher developed the curriculum in one PBL project focused on social justice along with any dilemmas experienced in the process.

Conceptual Framework

Remillard (1999) presented a framework for examining two teachers' curriculum development. In this study, Remillard presented three stages of curriculum development which are the design arena, the construction arena, and the mapping arena. The design arena "involves selecting and designing tasks for students" (Remillard, 1999, p. 322). The construction arena involves "enacting these tasks in the classroom and responding to students' encounters with them" (Remillard, 1999, p. 322). The mapping arena "involves making choices that determine the organization and content of the curriculum" (Remillard, 1999, p. 322). According to Remillard, these arenas are not linear or isolated but are instead interrelated (see Figure 1). Although Remillard's study focused exclusively on the teachers' curriculum development with respect to a specific textbook, I found an adaptation of the framework worthwhile for this study.

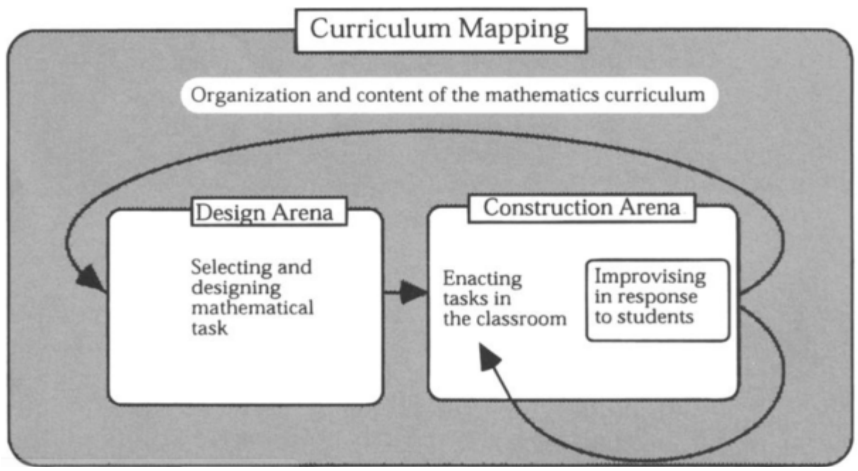

Figure 1. Remillard's (1999) Overview of the Three Arenas.

Using Remillard's (1999) three arenas (design arena, the construction arena, and the mapping arena) to frame this project, the two research questions that guided this study were:

1. Across the three arenas, how does a teacher develop the curriculum for a project in PBL while incorporating social justice and attending to the mathematics standards?
2. What dilemmas does the teacher encounter during the project development?

Data Collection and Analysis

I used a qualitative, descriptive and explanatory single case study method (Stake, 1995; Yin, 2003). Miles and Huberman (1994) define a case as "a phenomenon of some sort occurring in a bounded context" (p. 25). The bounded context in this case is this specific teacher's process across all three arenas which focuses not only on teaching mathematics using PBL, but also incorporating social justice goals and mathematics standards into her teaching. I used purposeful sampling in identifying a teacher who has taught PBL Geometry, and who has social justice goals in her teaching. A component of case study method is the use of multiple data sources to increase credibility (Yin, 2003). Therefore, I collected data from multiple sources – interviews, observations, field notes, physical artifacts – to allow triangulation in the analysis process to make the results of the study trustworthy.

Participant

Ms. Tara is a white woman in her late twenties who teaches both in Prosper High School (PHS) and Prosper New Tech High (PNTH) – "a school within a school." PHS is a visual performing arts high school located in a small urban school district in a Midwestern city. PNTH is a magnet school located inside PHS. It is a part of the national New Tech Network of schools whose focus is to "transform schools into innovative learning environments" (New Tech Network, n.d.). PNTH launched in the fall of 2014 with seventh and eighth grades and expanded to ninth and tenth grades in the 2015-2016 school year. During the study, there were about 400 students in PNTH and these students all took core classes using an integrated PBL approach. Although demographics information was not available for PNTH, I share information for PHS to provide some additional context. PHS student population was about 43% African American, 24% White, 18% Hispanic, 10% Asian, and 5% identified with races. In addition, over 60% of the students at PHS qualified for free and reduced lunch.

Ms. Tara was in her fifth year of teaching and her third year of teaching using PBL exclusively. At the time of this study, Ms. Tara taught ninth grade geometry in PHS and co-taught algebra and physics in PNTH. Given that my focus is exclusively on the mathematics, I decided to work with her on the Geometry course, as it was not co-taught with a teacher in a different discipline.

Data Collection

I worked with Ms. Tara from conception to completion of a PBL project (lasting three weeks) with an intentional social justice component. I collected data for this study in February 2017 using three types of data: interviews, physical artifacts, and field notes from classroom observations. Data collection was split into two phases: planning phase (design and mapping arena) and enactment phase (construction arena). In each of the data collection sources, I ensured that I focused on the specific project and asked Ms. Tara to zoom out to capture elements of the mapping arena.

Data Analysis

In answering the first research question aimed I organized my findings in the planning phase and the enactment phase. In the design and mapping arena, I used data from the initial interview and the planning observation and interview to inform my description and in the construction arena, my observation, field notes and trigger interviews formed the corpus of this data. I copied the transcriptions from these data sources from the InqScribe software into a word document and read every line while coding using DA (design arena), MA (design arena), and CA (construction arena) to designate the three arenas. For the second question, I sought to examine the dilemmas I observed in the planning phase and in the enactment phase of the project. I define dilemma to represent difficult choices Ms. Tara had to make given two alternatives. One way I achieved this was comparing what Ms. Tara said in the initial interview to what she stated in the trigger or final interview. I also compared what she stated in the planning interview with what I observed in the class and in my field notes. In other instances, Ms. Tara's statements indicated clear instances of dilemmas. I transcribed the data verbatim and read through the initial interview first and coded key themes that appeared salient based on my literature review and in the data. After arriving at my codes, I split the dilemmas in the planning phase and the enactment phase. Furthermore, some dilemmas were subsumed into another given their close overlap. The labeling of the dilemmas were paraphrased from Ms. Tara's own words.

Findings and Discussion

Students worked on the wheelchair ramp project that required them to determine whether the four wheelchair ramps in their school were compliant with the Americans with Disabilities Act (ADA). Ms. Tara's curriculum development for a project mostly comprised looking at the big picture. That is, she determined the project students would embark on, the mathematics content standards required, and wrote the entry letter. From my understanding at this point, I felt that the engagement between Ms. Tara and her students in the construction arena would determine the next stages of curriculum development. In the construction arena, the anticipated co-development of the project did not occur because Ms. Tara used a more teacher-centered approach resulting from dilemma she experienced.

In the planning phase, some of the dilemmas she encountered were project authenticity, project ownership, and project scaling. In the enactment phase, she faced dilemmas in the type of teaching style she employed, comparing students' ability in PNTH with those in PHS, access to technology, and not centering her social justice goal. My findings showed that the construction arena did not elicit curriculum development from the interaction between Ms. Tara and her students because her students were not given the freedom to drive their learning as is required in PBL and TMfSJ. The extensive dilemmas give rise to a need for PBL scholars to examine in more detail and perhaps over multiple projects, how teachers navigate the PBL design process especially with a focus on social justice. In conclusion, PBL is a complex endeavor that requires careful planning to enable students to engage in rich, meaningful, and complex questions. Moreover, given that authenticity is of paramount importance, teachers may not be able to develop the curriculum for projects ahead of consulting with their students. More research is needed in understanding teachers' curriculum development for PBL and to support them by assuaging the dilemmas they encounter in this process.

PARENTS' RESPONSES TO COMMUNICATION ON CURRICULUM REFORM

In Canada, parents' growing concerns about the "new math" are drawing public attention. Rather than dismiss such concerns, understanding parents' perspectives and garnering their support is essential to ongoing curriculum reform and children's success. In this paper, we present results of a phenomenographic study examining parents' conceptualization of the current mathematics curriculum. We focus specifically on parents' responses to school-to-home communication regarding mathematics curriculum reform: (a) seeking out further information, (b) accepting communication as given, and (c) resisting information disseminated. We examine parents' perceived communication through a postmodernist framework, that is to consider communication as (im)possible, inevitably political, and subjectless.

Keywords: Elementary School Education, Curriculum, Policy Matters

> The new math curriculum that my kids are learning? Honestly, I don't quite know what is all about. There has been little communication why they changed something that had worked perfectly fine into something that vague. (Parent participant)

The comment above describes the tension expressed by many parents regarding the recent mathematics curriculum change and the lack of communication throughout the reform process. In Canada, the tug-of-war between "new math" and "back to the basics" has gathered tremendous societal attention. Frustrated parents have joined coalitions (e.g., WISE Math) and launched petitions (e.g., Tran-Davies, 2013) in an effort to oppose curriculum reforms and to advocate returning to basic skills, standard algorithms, and mastery through memorization.

To identify the challenges of mathematics curriculum reform, we built on our previous work of reframing public opposition into collective concerns (McGarvey & McFeetors, 2015) to investigate parents' perceptions of curriculum change. Parent focus groups revealed that parents' opposition to curriculum reform stems from a lack of information about the curriculum and questionable student progress. This phenomenon urged us to examine communication as a condition of parents' curriculum perceptions. We previously illustrated perceived sources of mathematics curriculum-related communication described by parents (McFeetors, McGarvey, Yin, & Pinnegar, 2016). In this paper, we ask: How can we understand the range of ways parents respond to communication about mathematics curriculum reform? Our goal is to identify fruitful ways to engage in productive conversation about mathematics curriculum reform with parents.

Perspective: Related Literature & Theoretical Framework

Home-school communication is commonly viewed as a verbal or written interaction between parents and teachers through various channels or shared activities (Dyson, 2001). Researchers recognize home-school communication as a key form of parent involvement (Epstein, 1987) with benefits for students' learning and motivation (Civil & Bernier, 2006; Pattall, Cooper & Robinson, 2008). However, current practices are criticized for their "school centric" orientation (Jackson & Remillard, 2005, p. 59). Especially in the context of curriculum reform, the school-led one-way communication cannot address parents' questions about aspects of the current mathematics curriculum that are inconsistent with their own schooling experience (Bartlo & Sitomer, 2008). Even researchers tend to narrowly define the scope of communication as a planned event initiated by the school institution. For instance, Epstein (1996) specifies communicating as the process where schools are "sending home report cards" (p. 215).

We problematize this one-dimensional understanding of school-parent communication by following a postmodernist framework (Mumby, 1997) and consider communication as a fluid process where information leaks through predetermined channels. Moreover, the fluidity also reflects in the agents of communication: differentiation may not be made between sender and receiver of information. Rather, communicative processes mobilize the institutionalized subjectivity and the participants have agency to construct information and form new identities (Mumby, 1997). In other words, parents may perceive communication in ways that are not intended by schools and form their identities accordingly. The postmodernist framework requires a methodology open to the facets of parents' perspectives about communication.

Mode of Inquiry

We used phenomenography (Marton, 1986) to inquire into the range of parents' perspectives on how mathematics curriculum reform has been explained to them. Phenomenography aids in exploring "the qualitatively different ways in which people experience or think about various phenomena" (Marton, 1986, p. 31). Researchers draw phenomena into participants' awareness (Gurwitsch, 1964) to characterize and understand their perspectives. The variation in participants' perceptions aids researchers in generating categories which emerge from the data, emphasizing the meaning of participants' perspectives through related categories to provide a mapping of the field of inquiry.

Data Collection

Forty parents from urban and rural communities in a Western Canadian province participated. They were recruited through school council groups and parent networks. Using a volunteer process enabled us to listen to parents who are active in their school communities, reflective of vocal parents in the media. All participants completed a demographic questionnaire and participated in a focus group. Two-hour focus groups generated data of differing parent perspectives because participants were required to explain their perspective to others. We focused on their children's and their own experiences of learning mathematics, mathematical interactions at home, and communication received from teachers and schools about curriculum. Individual follow-up interviews were conducted with fifteen parents to elicit further specific examples and to seek clarification in understanding perspectives shared in the focus group.

Data Analysis

We used a constant comparative approach to identify parents' statements which were qualitatively different perceptions expressed about communicating mathematics curriculum reform. Phenomenographically, perception of experience can be analyzed through structural and referential aspects of participants' awareness. Two phases of analysis proceeded with individual coding, group comparison, and some re-coding. Our first sorting phase focused on structural aspects and yielded four categories of school-to-home communication forms parents received. Our second sorting phase focused on referential aspects and examined the messages parents determined within the communication forms. From these ascertained messages, we developed three categories of parents' responses to school-to-home communication which we report below.

Results: Presenting & Interpreting Categories of Description

While our previously-reported categories of communication forms (McFeetors et al., 2016) helped identify what parents counted as communication channels, our subsequent interpretation of parents' data indicated this understanding would be insufficient in developing more effective ways of communicating *with* parents about curriculum reform. In fact, the assumption that school-to-home communication (Epstein, 1996) is effective as a one-directional process has been brought into question by our participants' perspectives. Our results offer an understanding of the ways in which parents respond to the variety of communications, giving us insight into the meaning of curriculum reform parents were determining from available information.

Overall, parents' responses to communication about curriculum reform can be organized into three categories which include eight subcategories summarized in Table 1. These categories capture the broad range of parents' stances and actions resulting from the communication flowing from schools to home. Parents demonstrated through articulating their previous and current perspectives that they would freely move among subcategories depending on the context and sometimes inhabit two different subcategories simultaneously. Below we explain each category with an illuminating example from data of one subcategory. In the presentation, all subcategories will be explicated with multiple data excerpts.

Table 1: Parents' Responses to Communication about Mathematics Curriculum Reform

Seeking out further understanding	Accepting communication as given	Resisting information disseminated
• Cobbling together messages • Constructing rationales • Gathering more information • Interacting with children	• Satisfied • Concerned	• Discrediting information and sources • Dismissing information as meaningless

Seeking Out Further Understanding. Many parents wanted to support their children, and so they actively sought to develop an understanding of approaches to teaching and learning mathematics as well as mathematics content in reform-based curriculum by connecting more information. For example, Lindsey illustrates *gathering more information* when she reported, "I went to different math seminars for parents … explained some of the different things that teachers are doing in class and how to make things fun for our kids when you're doing math. And that has helped a lot for my son." She *interacted with her son* to examine new approaches and also shared these ideas with friends who in turn used her information in conjunction with formal messages from school to *cobble together messages* of how children are currently learning.

Accepting Communication as Given. A smaller proportion of parents were located in this category, perhaps because parents willing to participate in research tended toward a more active stance. However, parents who perceived *satisfaction* in amount and quality of communication attended focus groups to, in one parent's words, "make sure there's a different perspective … than the media plays things out." Maggie demonstrates confidence in her understanding of reform-based curriculum. Sarah demonstrated similar confidence, but was displeased with changes because multiple methods caused "a lot of confusion." Parents who were static in their response demonstrate an important feature of categories, that differing opinions on curriculum reform could lead to similar responses toward communication.

Resisting Information Disseminated. Parents in this category were active in their response to communication. As they received school-to-home information, they pushed back against the messages they did not see as relevant to their children's mathematics learning. Strident parents in this category *discredited information and sources*. For instance, Olga generalized without specific examples that “a lot of evidence shows...that inquiry, discovery-based learning is not the most effective way to teach” and disparaged “some educational consultants thought that this would be the best way to go.” Even though the curriculum states, “students investigate a variety of strategies” (Alberta Education, 2007/2016) the parent convinced a teacher, “the new curriculum says that you can choose one method to teach my daughter.” Communication that was assumed to be direct information was interpreted by an agentic parent in ways not intended.

Discussion

Curriculum reforms are crossroads where schools, teachers, parents, policy makers, and other education stakeholders at once face promising opportunities and unpredictable challenges in determining the future of education. A reconfiguration of home-school communication can offer parents a stance grounded in deeper understandings of curriculum reform and realize their agency to engage with their children’s school education. The research findings, therefore, can open up further possibilities of dialogue with parents and engender their support for curriculum reforms addressing the diversity of children learning mathematics.

ANALYSIS OF STUDENT WORK COMPARISON TASKS EMBEDDED IN 7TH GRADE CCSSM-ALIGNED MATHEMATICS CURRICULA

Keywords: Curriculum, Curriculum Analysis, Middle School Education

Research in mathematics education has shown the promise of teachers' examination of student work for improving teachers' understanding of students' thinking (Silver & Suh, 2014) and for assessing and improving teaching (Boston, 2014). Less research has focused on students' examination of student work as a way for students to make sense of the mathematics (Rittle-Johnson, Star, & Durkin, 2012). However, recent work (Gilbertson et al., 2016), has explored different sources of student work (student-generated, teacher-generated, and curriculum-generated) and specifically considered student work embedded in curriculum materials as a context for student learning.

Our research is guided by the question: *What types of mathematical learning opportunities are provided for students in tasks that require the reader to compare multiple instances of student work?* Based on an existing analytic framework (Gilbertson et al., 2016) for the criteria and nature of student work, this poster will present findings from a document analysis of curriculum-generated student work in CCSSM-aligned curricula with a specific focus on student work tasks that require the student reader to make comparisons among multiple examples of students' conjectures and/or strategies. Even within the same type of problem, specifically in this case, comparing student strategies, different mathematical learning opportunities are present that would require different types of engagement from the student.

In our work, we consider students' analysis of curriculum-generated student work as a "potential change in route" for research on the role of student work from the typical positioning as a professional development or professional learning tool for teachers to a learning tool for students that promotes student understanding. Our findings report on the features of the problem tasks (e.g. location in text, types of representations, whether correctness is known) and how these features relate to intended mathematical understanding (e.g. conceptual, procedural, levels of cognitive demand). This work has implications for the current learning opportunities afforded by student work in curriculum materials and possibilities for enrichment of existing tasks, informing future curriculum and assessment research and development work.

Curriculum materials are integral to the teaching and learning of mathematics and have a direct influence on what teachers actually plan for and enact in their classrooms (Brown & Edelson, 2003). Through a semi-structured think aloud interview, we study teachers' use of curriculum through the Curricular Noticing Framework (Males, Earnest, Amador, & Dietiker, 2015) which describes what teachers attend to, how they interpret what they attend to, and how they decide to respond to the curriculum materials. We discuss how each teacher moves through these three phases in an interrelated fashion and ultimately use this framework to gain deeper insight into the teacher planning process for a hypothetical lesson on slope.

The four teachers in this study were part of a cohort of Noyce Fellows (two master teachers and two novice teachers) funded by the National Science Foundation, which targets the needs of recruiting and retaining high-quality teachers to teach in high-need schools. All had experience teaching slope, but had never used the curriculum materials provided in the interview.

Findings suggest teachers engaged in all three curricular noticing phases when planning. However, each teacher shifted among phases in varying ways, as illustrated by Figure 1.

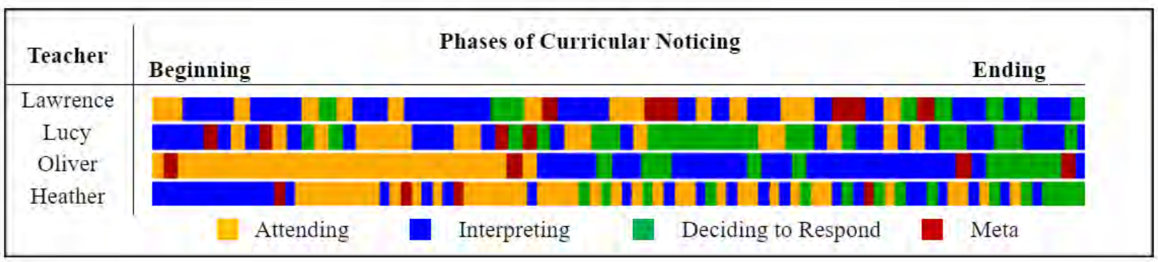

Figure 1. Phases of curricular noticing engaged in by teachers during planning session.

Even when teachers decided to respond in the same way, their interactions with the curriculum materials differed in the attending and interpreting phases. Further, we found teachers' attention to the materials was influenced by their initial interpretations, particularly when these were negative. This resulted in some teachers not engaging with a substantial portion of the materials and potentially missing opportunities afforded by the materials.

This study provides insight into how different teachers approach the same curriculum materials and produce a plan to enact in the classroom. Understanding the process of how teachers plan using curriculum materials has implications for teacher education programs, collaborative lesson planning, and curriculum development.

EQUITY IN A COLLEGE READINESS MATH MODELLING PROGRAM: LIMITATIONS AND OPPORTUNITIES

Susan Staats
University of Minnesota

Keywords: Equity and Diversity, Post-Secondary Education, Teacher Education-Inservice/Professional Development

As young adults in the United States transition from secondary to postsecondary educations, they traverse a high stakes crossroad in terms of access, preparation, and enduring financial risk. Students from non-dominant racial groups and from low income backgrounds tend to enter less-prestigious universities and they tend to take—frequently using student loans—more remedial classes that do not earn credits towards graduation compared to White and higher income students (Complete College America, 2012; Venezia & Jaeger, 2013). University algebra classes are among the most highly enrolled undergraduate courses and many students fail, withdraw or receive poor grades in these classes, requiring re-enrolment (Haver, et al, 2007). University algebra present significant barriers to students as they access and pay for a university degree.

At our university, secondary students can enroll concurrently in our university's algebraic math modeling course through a program called the Entry-Point College in the Schools (CIS) program. The program is intended to serve primarily students from groups that are under-represented at universities in terms of race, ethnicity or language status; and students with middle-range academic performance. The prospect of reducing college costs and improving academic preparation means that CIS program has grown tremendously over the last five years, from two schools serving around 30 students to over 30 schools serving 800 students.

Despite the program's popularity, its goals are only partly achieved. This poster uses several modes of reflection to report on this equity-focused CIS course in algebraic math modelling. We use Harouni's 2015 commentary on the political economy of mathematics to highlight these dilemmas in terms of the interaction of secondary and tertiary educational institutions. Harouni suggests that the content and pedagogy of mathematics education at a particular time and place are highly influenced by the purposes mathematics serves for students and by the institutional structures in which it is taught. First, we describe the legal and institutional structures that allow concurrent enrollment in secondary and tertiary courses. Then we discuss the equity objective through program enrolment data. We also offer teachers' perspectives to reveal the opportunities and tensions that they experience within the program. Tensions include whether students reduce their university course load, whether teachers are comfortable aligning their practices with university standards, and whether the program fulfils its equity goals (Pazich & Teranishi, 2014).

GENERATIVE UNIT ASSESSMENT: RE-VISIONING ASSESSMENT FOR GROWTH

P. Janelle McFeetors
University of Alberta
janelle.mcfeetors@ualberta.ca

Richelle Marynowski
University of Lethbridge
richelle.marynowski@uleth.ca

Assessment "is a process whose primary purpose is to gather data that support the teaching and learning of mathematics" (NCTM, 2014, p. 89). With a focus on assessment as process rather than product, Shepard (2000) calls for a reform in classroom assessment practices that mirrors the shifts in instructional practice and goals for education. In response, we explored the use of a performance assessment [PA] as an end-of-unit assessment which remains underutilized compared to traditional tests. The **purpose** of this project was to examine: What is the impact of designing and implementing a PA to assess students' learning at the end of a unit?

We used collaborative action research as the **mode of inquiry**. A grade 4/5 teacher and her 25 students in a suburban school participated over 4 months. The teacher collaborated in designing a geometry unit integrating two commercial games (Equilibrio and Quartex) with a blend of activity and didactic instruction, culminating in a PA where students created new puzzles for Equilibrio and identified mathematical elements. Data included: bi-weekly student work products, photographs, field notes, completed PA with screencasts, and interviews with pairs of students and the teacher. Analysis produced coding for two categories: teacher and students' perspectives on PA; and, characteristics of assessment practices that are generative.

Results indicate that using a PA was an effective unit test replacement because it was a generative unit assessment sponsoring teacher- and student-growth. The teacher noted, "I have totally changed my approach to teaching math…to focus on thinking." The students perceived higher cognitive demand as "it was bigger than just doing a unit test," yet greatly valued "a chance to show what I was thinking" and "it's better than just writing out a piece of paper your answers because you get to use your own imagination and create something." We developed four features of **generative unit assessment**, with teacher data in italics: 1) teacher's deepening awareness of students' math thinking (*lots of students shocked me at how much they knew* and *helped me understand their thinking*); 2) students' developing consolidated understanding (*they had to use the word symmetry and applying that into their tower helped them understand better* and *even in the summative assessment they were still learning*); 3) students' emerging productive disposition (*they were really excited to do math…anxiety was removed* and *they asked if I could always do it like this* and *it felt like they wanted to show their learning rather than get a [mark]*); and, 4) students' improving use of math processes (*I could see from their first tower to their second…their problem solving was something I focused on*). Student data will also be included.

In **discussion**, our interpretation of the PA experienced surpassed summative evidence leveraged to inform future teaching and learning (Harlen, 2005) to a *generative* process of growth. While an important facet of the study is a synergy between assessment and instruction, we find ourselves at a crossroads where classroom practices need to critique a means-end view of data and recognize the human endeavor of learning—where *generative assessment* occasions growth for all involved as critically important purpose of attending to students' learning.

Stereotypes of mathematical learners permeate society through storylines (or narratives) that maintain the status of whiteness (Nasir, 2016). Stereotypes typically reserved for emergent bilinguals (EBs) include an ill-preparedness for school mathematics instruction and a need of remediation and support. When these storylines manifest in the classroom they impact EBs' access to high-quality mathematics instruction, the availability of mathematical identities, and reify a marginalized status (Battey & Leyva, 2016; de Araujo, Smith, & Sakow, 2016). To understand the storylines of EBs exhibited in curriculum resources, we used positioning theory (Harré & van Langenhove, 1999) to examine the instructional supports of three high school algebra textbook teacher's guides. The decision to focus on algebra was due to its position as a "gatekeeper for [U.S.] citizenship" (Moses & Cobb, 2001, p. 14). The texts selected were from the three largest publishers and aligned with the Common Core State Standards.

Preliminary findings indicate a storyline of EBs that predominately aligns with stereotypes that reproduce racial hierarchies in white ideology. Mathematically, the storyline situates EBs in need of remediation and "below level." Specifically, the suggested accommodations center on the provision of students' engagement in repetitious, skill-based exercises. Such positionings reinforce an inferiority status, perpetuates whiteness through racial hierarchies of ability by signifying who is "good" at mathematics, and restricts the development of a mathematical identity (Battey & Leyva, 2016). Linguistically, the storylines focus on EBs' status as English learners and, in some instances, assume fluency in a first language, however the benefits of bi/multilingualism are absent. EBs are also positioned as students who lack specific mathematical vocabulary in English and benefit from learning these terms devoid of context. Such instructional approaches run counter to research, which values language-in-use to develop fluency in mathematical discourse (Moschkovich, 2002).

Although our findings may be unsurprising on the surface, they call attention to the ways teacher's guides perpetuate stereotypes of EBs on a societal scale and restrict access to high-quality mathematics instruction. In this way, such curricula can reinforce white ideology in U.S. institutions through its maintenance of the status quo (Battey & Leyva, 2016).

TEACHERS' EXPERIENCES IN INTERDISCIPLINARY UNIT DESIGN: THE ABSENCE AND PRESENCE OF MATHEMATICS

Christine Trinter
University of Notre Dame
ctrinter@nd.edu

Keywords: Curriculum, Teacher Education-Inservice/Professional Development, Middle School Education

Engaging students in authentic learning experiences is widely heralded among mathematics education communities (NCTM, 2014) but designing curriculum that centers on authentic work, is meaningful for all students, and maintains the integrity of the subject matter is not a trivial task, particularly for teachers who may have limited curriculum design expertise. Despite the role that teachers play as vehicles between curriculum and student learning, only a few studies include teachers as integral participants in curriculum design (Skilbeck, 1984). While some teachers have embraced roles as co designers of curriculum, others have refrained from making any modifications out of "respect for the expertise of the textbook authors" and perceived external curriculum developers as "experts" regarding the instructional design for their classes (Even & Olsher, 2014, p. 346). It seems that many teachers do not feel as though they have the autonomy and/or competency to develop meaningful, standards-based curriculum.

The purpose of this study was to explore the experiences of mathematics teachers as they designed authentic, interdisciplinary curriculum units and uncover teachers' conceptions of the role of standards-based mathematics curriculum within this context. The study sought to answer the following two research questions: 1. In what ways is mathematics absent and present in teachers' curriculum design work? 2. What are teachers' experiences and conceptions of designing mathematics curriculum?

In this exploratory study, the researchers worked with seven teachers at a middle school in a southeastern state, where 74.3% of students are economically disadvantaged, on designing interdisciplinary curriculum. Data was collected between September 2015 and May 2016 and includes, audio-recorded pre- and post-interviews, video-recorded bi-weekly planning meetings, teacher and student artifacts, and video-recorded classroom observations and teacher workshop days. Using Actor Network Theory (Fenwick & Edwards, 2010) as our theoretical lens together with qualitative methods, we considered the networks associated with teachers' perceptions of and choices about curriculum design. Findings indicate that teachers' initial perceptions of mathematics and its fit within an interdisciplinary unit changed during the curriculum design, implementation and reflection cycle. Preliminary mathematical ideas dissipated during the design phase and were re-imagined following unit implementation. Teachers also reported positive experiences in designing curriculum noting the investment of their time and collaborative synergy manifested in student engagement and ownership of their learning.

THE CONTINUING MARGINALIZATION OF MATHEMATICS IN PREKINDERGARTEN: A POLICY PERSPECTIVE

Amy Noelle Parks
Michigan State University
parksamy@msu.edu

Keywords: Early Childhood Education, Policy Matters

Although research has shown that mathematics is at least as important as literacy to young children's long-term academic success (Duncan et al, 2007), early mathematics continues to receive less attention than literacy in most prekindergarten programs (National Research Council, 2009). The goal of this study is to explore this lack of attention to early mathematics from a policy perspective. The research question framing the study was: How do states describe key content in literacy and mathematics for prekindergarten children and their teachers? Drawing on methods for content analysis, my research team and I examined the early learning standards for prekindergarten for all 50 states as well as any competency standards for prekindergarten teachers. These standards were organized in different ways for each state, with certification bands ranging from *Birth to Age 5* to *Prekindergarten to Grade 12*. We engaged in both quantitative and qualitative analyses of these standards, although for the sake of space, only quantitative data are reported here.

Overall, analysis showed that while a growing number of states attend to mathematics in their early learning standards for prekindergarten, most still give mathematics far less attention than literacy. For example, while only 3 states identified fewer than 20 subtopics that should be addressed with prekindergarteners in relation to literacy, 13 states specified fewer than 20 subtopics related to mathematics. While simply having more standards is not necessarily better, these data suggest that many states provided more detailed portrayals of early literacy than early mathematics. A similar relationship was found in teacher competency standards with only 4 states offering no subtopics in their literacy standards for teachers, but with 12 offering no subtopics in mathematics. Further, 13 states had no required coursework for prekindergarten teachers related to mathematics, while only 6 states had no requirements for coursework related to literacy. For both mathematics and literacy, attention to teachers' content knowledge was highly related to the structure of the certification band, with bands that ended in the elementary years generally requiring more attention to content than bands that ended with prekindergarten or kindergarten. For example, in looking at certification bands across the 50 states (n=64 because some states had multiple certification bands that include prekindergarten), 7 of the certification bands that include elementary grade levels required teachers to take courses related to mathematics, while none of the bands that stopped at prekindergarten or kindergarten required such courses. This study suggests that the documented lack of attention to mathematics in prekindergarten is not simply the result of resistance or lack of interest by teachers, but is, at least in part, systemic, resulting from a lack of attention to mathematics in state standards.

THROUGH THE EYES OF A PST: USING EYE TRACKING TO EXAMINE PLANNING WITH CURRICULUM MATERIALS

Lorraine M. Males
University of Nebraska at Lincoln
lmales2@unl.edu

Ariel Setniker
University of Nebraska at Lincoln
ariel.setniker@huskers.unl.edu

Matt Flores

Planning is one of the first out-of-classroom activities that prospective teachers (PSTs) engage in when learning to teach that is linked to improving teaching (Morris, Hiebert, & Spitzer, 2009). Furthermore, the task of planning can be difficult, particularly when using curriculum materials. Despite the complexities involved in understanding how to use curriculum materials to plan, this is an often-neglected topic in teacher education (Drake, Land, & Tyminski, 2014). We draw on the *Curricular Noticing Framework* (Males, Earnest, Dietiker, & Amador, 2015) to describe what elements PSTs attend to in CPM and PEI when planning a lesson.

Across PSTs, results indicate attention across teacher and student materials was balanced with most PSTs attending only slightly more to student materials. However, notable differences existed in the *ways* in which PSTs attended to each set of materials. Figure 1 shows a representative sample of one PSTs attention for a portion of each text. What this indicates is that this PST, like others, attended in a more sporadic manner to the PEI text than to the CPM text.

When interacting with an element of CPM, he seemed to gaze at that element and read it from start to finish. However, with PEI he moves from one element to the next, skimming the text.

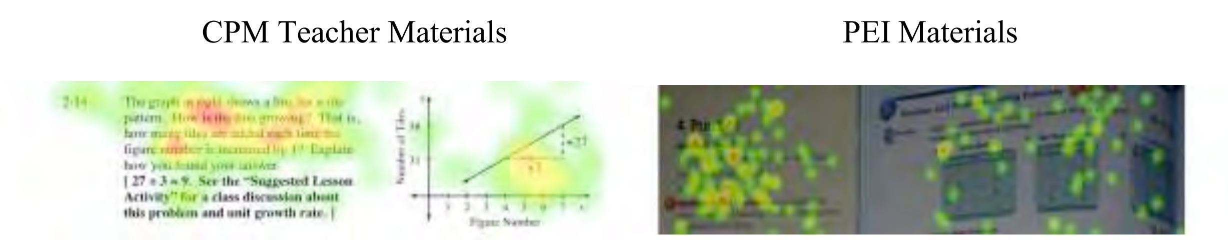

Figure 1. Attention across CPM and PEI materials.

A QUESTIONING FRAMEWORK FOR SUPPORTING FRACTION MULTIPLICATION UNDERSTANDING

Debra I. Johanning
The University of Toledo
debra.johanning@utoledo.edu

This research examined the role of the teacher in supporting students to make sense of fraction multiplication when using a problem solving approach. Using a qualitative approach, the teaching of four skillful experienced sixth-grade teachers was examined as they implemented a problem-based unit on fraction multiplication. This paper will present a questioning framework used by teachers that supported students' conceptualization in this domain and highlight resulting implications for teacher practice.

Keywords: Number Concepts and Operations; Rational Numbers; Instructional Activities and Practices; Problem Solving

This research is situated in the context of fraction operations with a specific focus on fraction multiplication. It is founded upon arguments that more attention and effort should be paid to unpacking the professional work that teachers do in classrooms (Grossman et al., 2009). The fraction operation research literature has documented that students can invent procedures for operating with fractions (Kamii & Warrington, 1999). In the domain of fraction multiplication, it has been established that students bring initial knowledge that can serve as a starting point for algorithm development (Mack, 2001). In an effort to better understand teacher practice in the area of fraction multiplication the following research questions were posed: What are key conceptual obstacles students encounter when engaged in a problem solving, rather than a procedural approach to understanding fraction × fraction multiplication? How do teachers use questioning and discursive practices to support students to make sense of what fraction × fraction multiplication is an enactment of?

How to engage students in productive mathematical discussions is challenging (Stein, Engle, Smith & Hughes, 2008). One challenge a teacher faces when working to cultivate a teaching practice where mathematics is learned through problem solving, is how to support learners without taking over or reducing the level of mathematical work students should engage in. In my work with teachers, they have commented that they do not know how to guide students when they are struggling. They find themselves explaining what to do rather than redirecting students in a way that helps them think and reason. This research was conducted to inform the creation of professional development materials to use with teachers interested in developing a practice where students are engaged in mathematical reasoning and problem solving as part of learning about fraction operations. The questioning framework for fraction multiplication that is presented here was one tool developed to support practicing teachers.

Theoretical Framework

Gravemeijer and van Galen (2003) emphasize that instead of concretizing algorithms for students, teachers can use an emergent approach where students are positioned to invent algorithms. They describe this guided reinvention process as one that starts with carefully chosen contextual problems where students model a mathematical situation. With this approach, students solve problems through modeling that leads them to reason with numbers in particular ways. Ideas for operating with numbers can emerge from work that focuses on learning to reason with numbers and exploring what is involved when numbers are manipulated in particular ways.

According to Mack (2001), students bring informal knowledge related to partitioning fractions that can support making sense of fraction multiplication. Through modeling students can develop mental images and ideas that will support their understanding of what fraction multiplication is an enactment of. Important areas to develop include fractions as operators, developing meaning for finding *parts of parts of a whole*, and developing flexibility about what is the unit. Flexibility with the unit is especially important because the unit shifts when multiplication is enacted. In additive situations the numbers (ex: 1/2 + 3/4) represent actual quantities such as 3/4 of a pound and 1/2 of a pound. In a multiplication situation one of the numbers represents a quantity. The other number is an operator. For example, when 2/3 × 1/4 is enacted the goal is to determine what 2/3 of the quantity 1/4 is. In a scenario where someone wants to plant 2/3 of 1/4 of a garden with beans there are multiple levels of partitioning taking place. Initially, a whole garden in partitioned so that 1/4 of the whole garden can be represented. Next, one must partition the 1/4 of a garden into thirds and identify 2/3 of the 1/4 in order to know what *part of the part of the whole* garden is planted with beans. Finally, in order to determine how much of the whole garden is used for planting beans, the part of the part of the whole identified for planting beans must be expressed as what fraction of the whole garden is used for beans. While it might be tempting to provide students with the shortcut that "of" means multiply, the actual enactment of multiplication with fractional numbers is much more complex.

Armstrong and Bezuk (1995) offer that in order to make sense of fraction multiplication students need partitioning experiences that lead to the analysis of relationships between partitions and the whole. From an instructional point of view it is important for students to have the opportunity to encounter and make sense of "part of a part of a whole". From a mathematical point of view, students need opportunities to explore through modeling what is happening when the operation of multiplication is enacted. This research aimed to understand the teacher's role in supporting the development of this understanding by engaging students in a problem-solving approach to fraction × fraction multiplication rather than an approach focused on demonstration of a procedure.

Methodology

The setting used for this study were the classrooms of four sixth-grade teachers and their students. Each of the teachers used the Connected Mathematics Project (CMP) II instructional unit *Bits and Pieces II: Using Fraction Operations* (Lappan, Fey, Fitzgerald, Friel, & Phillips, 2006a) as their primary curriculum. The unit uses a guided-reinvention approach to developing meaning for fraction operations. It allows algorithms to arise through student engagement with both contextual and number-based situations. In this setting assumptions can be made about the tasks used and about the fraction-related concepts that were developed prior to, and during the unit on fraction operations. In the timeline for the sixth graders who were part of this study, students came to the fraction operations unit with previous experiences that supported their understanding of fractions as quantities and their ability to model fractions. Prior to implementing the *Bits and Pieces II* unit, the *Bits and Pieces I: Understanding Fractions, Decimals and Percents* (Lappan, Fey, Fitzgerald, Friel & Phillips, 2006b) unit was also implemented.

The four teachers were skillful experienced teachers. The teachers had between 6 and 16 years of experience teaching with CMP. The researcher had prior opportunities to interact with two of the teachers in their classrooms. These interactions provided information on how the teachers organized their learning environment and engaged students to reason with mathematical ideas. The teachers had a strong understanding of the mathematics they taught and their students as learners of that mathematics. These teachers engaged their students in conversations about their mathematical work as they engaged in problem solving and reasoning. The other two teachers were identified by contacting fellow mathematics educators, researchers, and district-level personnel known by the researcher to have a history of working with teachers in CMP classrooms. They were provided the criteria described above and asked to recommend, if they could, a teacher who strongly met all of the criteria. The directions explained that a teacher must meet all criteria and to not make a nomination for the sake of nominating.

This study used a qualitative design. During the teaching of the Bits and Pieces II unit, classroom lessons were videotaped each day during the five to six weeks it took to cover the unit. In addition, teachers wore an audio recorder during each lesson. The video recorder was used to record small group discussions. When visiting the classrooms of the teachers, the researcher engaged in participant observation. This included observing, taking field notes, interacting with students during small group work time, and meeting with the teacher after the lesson to seek their perspective on the lesson and students' mathematical progress. During the part of the instructional unit that focused on fraction × fraction multiplication, the researcher visited each teacher's class during at least one day of the three to four-day lesson sequence. When the unit concluded, the researcher brought all four teachers together to examine selected student work, videos of their teaching, and discuss patterns emerging in the data.

Data analysis was guided by Erickson's (1986) interpretive methods and participant observational fieldwork. The multiple data sources allowed for triangulation. The video and audio data were transcribed and analyzed for emerging themes in relation to the research question. Questions that framed the data analysis included *"What approaches to solving problems emerged in discussions as students shared their reasoning?"*, *"How did teachers respond to students?"*, *"How did teachers direct the mathematical focus of these discussions?"*, and *"What approach did the teacher take when students struggled mathematically?"* When the researcher met with the four teachers, emerging themes along with relevant classroom video clips from lessons were reviewed. It was during this process of data reduction and collaborating with the teachers that the researcher began to identify data that answered the research questions. From this analysis a questioning framework was developed that captured interactions teachers had with students when using an emergent approach to fraction × fraction multiplication. The questioning framework is presented in Figure 1. The questioning framework was linked with issues referred to as "sticky points". The sticky points emerged and became articulated during the researcher's discussions with teachers about their interactions with students. Sticky points are common areas where students struggle mathematically to make sense of the enactment of fraction × fraction multiplication. These are also documented in the literature (ex.: Mack, 2001; Armstrong & Bezuk, 1995). The sticky points are one's that typically or expectedly emerge when instruction uses students' ideas as the starting point. The questions that form the questioning framework were apparent in the classroom teachers' dialogue with students as the teachers attempted to move students through these sticky points toward valid mathematical ideas and understandings.

Results

The CMP curriculum introduces students to fraction multiplication using the context of selling pans of brownies at a school event. A typical problem might ask the following: *What fraction of a pan of brownies will I have if I buy ¾ of a pan that is ½ full.* This context leads to development of an area model. Student were given a labsheet with squares (brownie pans) that they used to model the problem by developing a drawn visual representation of what happens when buying ¾ of ½ of a pan of brownies. Through drawing the students begin to develop a mental image of what fraction multiplication is an enactment of and reason about what each fraction represents in the process. As students draw models to enact and solve the problem there are common sticky spots that arise. The teachers anticipated and used these as opportunities to build new ideas related to understanding fraction multiplication. Figure 1 contains the questioning framework that emerged from the analysis of classroom data described in the methodology section. It is reflective of the mathematical interactions the teachers had with students while working to model and solve brownie pan problems as part of making sense of what fraction × fraction multiplication entailed.

1. What is the problem asking you to do?
2. Tell me about your picture. What does it show?
3. How much are you starting with? How can you show that?
4. What is the problem asking you to find? How can you show that?
5. How much of what you started with do you need?
6. How much of the whole pan do you need?
7. How many pieces are in a whole pan?
8. How many of those pieces do you end up needing?
9. Do you have more than you started with or less? Why does that make sense?
10. What number sentence would write to show what the problem is asking you to do mathematically?

Figure 1. Questioning framework for fraction × fraction multiplication.

As in most any class, students will need support based on where they are in their overall fraction understanding—some more than others. Rather than show students what to do, teachers posed questions to focus their attention on particular mathematical ideas while students worked to develop a picture that modeled what was happening in the brownie pan scenarios they were presented with. See figure 2 as one possible model that a student might develop. Asking students what they are starting with by posing question 3 (also see Fig. 2a), which in the ¾ of ½ scenario is the second fraction ½, and asking students why this makes sense, is used to establish which fraction is the starting quantity. In the problem context, ½ of a pan is an actual quantity. The fraction ¾, which is the operator, is focused on when asking question 4 (also see Fig. 2b). While a teacher could tell students what fraction they should draw first when making their model, the expectation of teachers observed was that students engage in reasoning and problem solving. They wanted students to figure out what they were being asked and work accordingly using what they knew about fractions and partitioning. This is why the teachers asked questions 1 through 4. These questions helped with one of the common sticky points—which fraction do I start with and which fraction am I operating with when modeling a fraction times fraction situation. Often, students want to start with the first fraction written in the problem statement. They want to begin by partitioning and shading the brownie pan to show ¾ of a pan of brownies. However, they need to begin by showing that there is half of a pan of brownies to start with. Questions 3 and 4 when used together draw out or direct reasoning toward what each of the fractions in the multiplication problem represents visually. Students need to understand what each fraction represents—one is a starting quantity and one is an operator. Questions that ask students to read (and reread) the problem context support their ability to process and reason about what the problem is describing as well as asking.

A second sticky point was what represents the unit being partitioned and named. When the problem starts, the unit is the whole brownie pan. You start with half of a whole pan of brownies. When asked to find ¾ of ½ of the pan, the unit or whole that is partitioned is half of the pan. When asked to find ¾ of ½, students may not be aware that there is a shift to a new unit and they mark or partition the full brownie pan. In other words, they find ¾ of the whole pan rather than ¾ of ½ of the pan. Also, while a student may correctly partition the half pan into fourths, they may not be able to articulate why it makes sense to do this. Together questions 3 and 4 draw and focus student reasoning on what each of the fractions represent when the problem is enacted. Question 5 (also see fig. 2b) focuses on what part of the part of the whole do you need. With ¾ of ½ of the pan, question 5 leads students to articulate that they need ¾ of ½ of the whole pan. When students can articulate this, they might then realize they need to shade ¾ of ½ of the pan. Or, perhaps a teacher might respond, “If you need ¾ of ½ of the pan, how could you show that in your picture?” At this point most student realize that they need to partition ½ of the pan into four equal parts and shade three of the parts. Question 6 then aims to get students to articulate that they need ¾ of ½ of the whole pan. In some cases this led the teacher to prompt the student to write beside or under their picture “¾ of ½ of a pan”. In other words, students were prompted to express and record that the brownie pan scenario could be captured or expressed as “¾ of ½ of a whole pan”. This will eventually support question 10 (also fig. 2d) that asks what number sentence could you write to show what the problem is asking you to do mathematically.

2a.  **Q3: How much are you starting with?** **[½ of a pan of brownies]**	**2b.**  **Q4: What is the problem asking you to find?** **Q5: How much of what you started with do you need?** **[¾ of ½ of the pan of brownies]**
2c.  **Q6: How much of a whole pan do you need?** **Q7: How many pieces are in a whole pan?** **Q8: How many of those pieces do you end up needing?** **[3/8 of the whole pan of brownies; 8; 3]**	**2d.**  **Q10: What number sentence could you write?** **¾ of ½ of a full pan is 3/8** **or** **$\frac{3}{4} \times \frac{1}{2} = 3/8$**

Figure 2. Possible model representing ¾ of ½ of a pan of brownies.

A third sticky point involved expressing the solution based on what the problem is asking. Questions 7 and 8 (also see fig. 2c) are designed to direct attention to what the problem is asking—what part of the part of a whole pan of brownies would get if you bought ¾ of ½ of a pan of brownies. Often students say the solution is ¾. While it is true that ¾ of ½ of the pan is shaded, the solution is expressed as the portion of the original unit or the part of one whole pan. This requires a second shifting of units from finding part of ½ of a pan back to finding a part of one whole pan of brownies. The solution 3/8 is the part of the whole pan of brownies that are bought. Question 7 directs students to determine how many 1/8 pieces are in the whole pan. Question 8 focuses on how many 1/8 pieces are being bought. In addition to these questions, teachers might also ask students to reread the problem and to determine what they were asked to find. In the CMP curriculum the brownie pan problems ask, "What fraction of a *whole* pan of brownies is bought?"

As students experience the shifts across units, and because they are developing a visual model to reason with, the teachers focused on what was happening in relation to a fourth sticky point. Drawing from their work with whole numbers, students often think that multiplication leads to a product that is larger than the factors being multiplied together. Question 9 prompts students to look at their brownie pan picture, (or array model when they begin to use symbolic rather context-based problems) and consider that when they multiply by a faction that the solution is less than then what they started with. This sets up an opportunity to discuss what is happening when multiplying fractions and why fraction × fraction multiplication leads a solution where you have less than what you started with.

Returning to question 10, which may not be posed until after modeling and discussion of multiple problems, students are prompted to attach symbolism to the situation and their models. In the data this question led to discussions about why, for example with ¾ of ½, that the solution is expressed in eighths, and why there would be "three" eighths. From discussion of the ideas related to their models and what fraction × fraction multiplication is an enactment of, the algorithm "multiply numerators, multiply denominators" began to emerge. While the initial problems posed used the brownie pan context, students also worked with non-contextual fraction × fraction multiplication problems. While the idea that students could think of multiplication as finding a fraction "of" a fraction was addressed, the teachers focused discussions on finding a "part of a part" and used the brownie context to give meaning to this when instructional tasks shifted from contextual to symbolic. As students responded to questions from the framework they engaged in the thought processes associated with the enactment of fraction × fraction multiplication. The concept of fraction × fraction multiplication as finding a part of a part was supported.

Discussion and Significance

NCTM (2014) argues the importance of letting students engage in productive struggle. Often teachers are concerned that by not demonstrating up front to student what to do to solve a problem it will lead to confusion among students. How to support students and not "tell" is challenging. Providing teachers with problem contexts such as the brownie pan scenario is important in supporting a change in practice. However, a good problem alone does not help teachers develop ways to help students when they are stuck or get students started solving problems without telling them how. Good problem contexts do not ensure a teacher will have a way to support student problem solving. The questioning framework in coordination with "part of a part" problem contexts like the brownie pan problems is a potential tool for helping teachers shift away from a practice based on telling. While it sits outside the scope of research reported here, this framework in conjunction with video case analysis was used with teachers in a professional development setting. These teachers were working to develop their practice to use an emergent approach to fraction operations. Preliminary data analysis suggests that the questioning framework was an important support for teachers working to engage students in fraction multiplication algorithm development based on a problem solving approach.

Just as students benefit from learning to persist, teachers also need to learn to work through students' moments of uncertainty. Making sense of student reasoning while at the same time making instructional decisions about how to reply or what to ask in discussions with students, and how to guide without taking over student thinking is complex (Stein, Engle, Smith & Hughes, 2008). Facilitating discussions with students about what is happening as they work on problems such as those presented here may be daunting to teachers who are new to or working to develop a practice where students engage in problem solving and reasoning. The questioning framework described here, especially when paired with analysis of student work and classroom video cases in a professional development setting, can offer teachers a plan for listening to and responding to their students. It provides a pathway for supporting student reasoning so that teachers do not feel they have to resort to telling.

DESIGN RESEARCH ON PERSONALIZED PROBLEM POSING IN ALGEBRA

Candace Walkington
Southern Methodist University
cwalkington@smu.edu

Algebra is an area of pressing national concern around issues of equity and access in education. Recent theories and research suggest that personalization of instruction can allow students to activate their funds of knowledge and can elicit interest in the content to be learned. This paper examines the results of a large-scale teaching experiment where 8th grade students posed, solved, and shared algebra problems related to their out of school interests in topics like sports, video games, and social networking. Results suggest that the teaching experiment improved both learning of and interest in algebra compared to "business as usual" instruction, particularly for those students who were struggling. Theoretical and practical implications are discussed.

Keywords: Middle School Education, Design Experiments, Algebra and Algebraic Thinking

Algebra is a gatekeeper to higher-level mathematics, with significant implications for both equity in education and students' economic attainment (Moses & Cobb, 2001). Failure rates in algebra continue to be high, especially among low-income students and students of color (Allensworth, Nomi, Montgomery, & Lee, 2009). Students' interest in learning math declines over adolescence generally (Frenzel, Gotez, Pekrun, & Watt, 2010), and during algebra courses specifically (McCoy, 2005). Concepts from algebra are not seen as being connected to students' worlds, including their home and community activities (Chazan, 1999). Math curricula are often not designed to be relevant to students from diverse backgrounds (Ladsen-Billings, 1995).

Exploring ways to connect math to students' lives, experiences, and funds of knowledge is critical to making algebra both accessible and captivating. All students bring to the classroom mathematical funds of knowledge (Civil, 2007; Moll & Gonzalez, 1994), ways of reasoning quantitatively from their home and community. Students draw upon rich algebraic ways of reasoning when pursuing their out-of-school interests in areas like sports and video games (Walkington, Sherman, & Howell, 2014). If these funds of knowledge can be brought into the classroom, they may allow students to better access and understand mathematical ideas (Boaler, 1994; Walkington, 2013).

This paper reports a study where 8th grade students pose their own personalized "algebra stories." Personalization refers to the instructional approach of making connections between students' interests in topics like shopping, music, and social networking, and instructional content they will be learning in school (Cordova & Lepper, 1996; Walkington, 2013).

Theoretical Framework

The theory behind personalization draws upon two major ideas – interest as a motivational variable, and mathematical funds of knowledge. Interest is the psychological state of engaging and the predisposition to re-engage with objects, events, or ideas (Hidi & Renninger, 2006). Higher levels of interest have been associated directly with improved performance and learning (Potvin & Hasni, 2014). Higher interest is also connected to important mediators of learning like attention, engagement, persistence, perceived competence, and use of learning strategies (Kim, Jiang, & Song, 2015; Linnenbrink-Garcia, Patall, & Messersmith, 2013), and with motivational variables like self-efficacy, self-regulation, and achievement goals (Harackiewicz et al., 2008). Personalizing instruction by connecting it to students' out-of-school interests may thus elicit their interest for the content to be learned, allowing for increased engagement and motivation.

Galindo, E., & Newton, J., (Eds.). (2017). *Proceedings of the 39th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* Indianapolis, IN: Hoosier Association of Mathematics Teacher Educators.

Students also bring to the classroom funds of knowledge from their home and community lives that are historically-accumulated and culturally-developed (Civil, 2007); students' out-of-school interests are one dimension of these funds of knowledge. Prior research has explored the creation of instructional school units around children's experience with money and with home-based knowledge of gardening and construction (Civil, 2007). Interviews with families have revealed that they use mathematical practices while cooking, sewing, engaging in construction, and scheduling (Gonzalez, Andrade, Civil, and Moll, 2005). Using students' funds of knowledge can increase their legitimate participation in the classroom (Barton & Tan, 2009). Thus personalizing instruction to students' out-of-school interests may allow students to draw upon their prior knowledge of using quantities and numbers in everyday life in useful ways, allowing them to better understand and access the mathematical content to be learned.

Problem-posing – the activity of having students author mathematical tasks – "improves students' problem-solving skills, attitudes, and confidence in mathematics, and contributes to a broader understanding of mathematical concepts and the development of mathematical thinking" (Singer, Ellerton, & Cai, 2013, p. 2). Learning to pose a mathematically valid story problem is a challenge for students who must come to appreciate the importance of problem features. When posing a story problem, students must first avoid making common errors like posing non-mathematical, trivial, or unsolvable questions (Silver & Cai, 1996). They next must select units of measure and include realistic quantities that relate to one another in a known fashion (Silver & Cai, 2005). Research on personalization has thus far focused on problem-solving instead of problem-posing – the present study extends this research.

Prior research on personalizing mathematics instruction to students' out-of-school interests in topic like sports or movies has found that this approach elicits interest (Hogheim & Reber, 2015), and can promote learning (Cordova & Lepper, 1996; Walkington, 2013). However, effects are small, and producing banks of personalized problems is difficult for curriculum developers. In the present study, we enlist the students as the authors of their own algebra stories. In this way, learning becomes "personalized" as the students themselves write and solve problems based on their out-of-school interests in topics like sports, social networking, and video games. We examine the effects a 4-day teaching experiment which implemented personalized problem posing, sharing, solving. The research questions are: (1) How does participation in the teaching experiment impact students' understanding of algebraic concepts? and (2) How does participation in the teaching experiment impact students' interest in and self-efficacy for algebra?

Method

Procedure and Participants

This paper describes the fourth phase in a five-phase design-based research program (Brown, 1992; Collins, Joseph, & Bielaczyc, 2004). In design research, educational researchers "engineer" learning interventions and theories, with continuous adjustment and experimentation, to allow evidence-based claims to be made. The initial phases of the design research involved interviews and a small-scale pull-out teaching experiment where students posed, solved, and shared personalized problems. We then applied a teaching experiment methodology to four intact classes of 8th grade students to further develop and refine hypotheses. We follow the definition of a teaching experiment in Steffe and Thompson (2000) where students' mathematical development is tracked over time as emerging hypotheses about the "mathematics of students" arise and are tested. We set out to tackle a widely-acknowledged issue at our site – students' struggle to solve algebra story problems - and coordinated pragmatic and theory-based concerns as we determined "in the moment" and after each session how to guide learning.

The procedure for the teaching experiment was as follows. During a pre-test, students indicated which topics they were interested in: sports, video games, social networking, shopping, food/cooking, cell phones, computers, part-time jobs, and reading/writing. For students in the experimental group, selections were used to place them into groups of 3-5 students who all shared one of these interests. During each class, groups would solve algebra problems about topics the group was interested in like sports or cell phones. The problems they solved were written by the researchers, but were almost always based on problems that students in the classes had previously written. After solving a personalized problem, groups would be asked to write their own problem with a similar type of linear function (e.g., no intercept, negative slope, system) that corresponded to their group's shared interest. They would solve their own problem, and sometimes would trade problems with another group. The class would discuss both the problems students solved and the problems they posed. Learning was personalized in that students were writing and solving problems based on their out-of-school interests.

We also employed a comparison group. The two teachers participating in the teaching experiment taught approximately half of their class sections using "business as usual" instruction, and pre- and post-assessments were distributed to both the 4 classes participating in the teaching experiment and the 3 classes receiving "business as usual" instruction. Although comparing a teaching experiment delivered by a research team to a single teacher implementing their normal instruction may not be balanced, our purpose was to simply explore what the possibilities and limits of this approach might be. The problem-posing intervention may actually be more effective when delivered primarily by the classroom teacher, as teachers have far greater familiarity with their students and the curriculum.

Participants included 171 students (94 experimental and 77 control) in 7 classes of two teachers. Two of the classes (45 students; 1 class in experimental and 1 class in control) were 8th grade Algebra I classes where more advanced students were placed. The other 5 classes (126 students; 3 classes in experimental and 2 classes in control) were regular 8th grade math classes. Students were enrolled in a middle school in a large metropolitan area. Participants were 56% female, 90% Hispanic, 4% African-American, 4% Caucasian, and 2% Other race/ethnicities, with 91% Economically Disadvantaged (ED) and 39% Limited English Proficient (LEP). Eight students (all in the experimental group) had a special classification where they were immigrants who had been in the country for less than a year and spoke only or mainly Spanish.

Measures and Analysis

All participants took a pre-test that measured their knowledge of linear functions. There were 2 forms of the pre-test, which were randomly distributed within each class. Each form contained 3 algebra story problems, and then an additional prompt where students were asked to pose their own story problem. This fourth item was included because we were wondering whether students' willingness to pose a problem at pretest would interact with the degree of benefit they received from the teaching experiment. The post-test contained identical items, with one exception – for students not in Algebra I, instead of the prompt asking them to pose a problem, they were instead asked to solve a problem that involved direct variation (i.e., a directly proportional relationship with no intercept term). Because of how the teaching experiment unfolded, far more time than anticipated was spent on direct variation, so it seemed important at post to measure students' understanding. Pre-tests and post-test items were identical across the experimental group and the control group. Items were drawn from released items on algebra assessments like the state standardized test and the Smarter Balanced assessment.

On the first page of their pre- and post-test, all students were given an 11-item questionnaire. The first 8 items were from the situational interest scale in Linnenbrink-Garcia et al. (2010) (example item: "I enjoy the subject of algebra."), and the final 3 items were self-efficacy items written based on Bandura (2006; example item: "I feel confident in my ability to do algebra."). Cronbach's alphas for each scale were between 0.88 and 0.90, suggesting good reliability.

Gains from pre- to post-test were analyzed using mixed effects logistic regression models. The outcome variable was a 0/1 indicator of whether each student got each problem on their post-test correct. Random effects were added for student ID and problem ID. This analysis method was used because it could handle that different students got different forms of the test, and it allowed for there to be a different "difficulty level modifier" (modelled as a random effect) for each individual problem. Fixed effects included a 0/1 variable for condition (control or experimental group), pre-test score (with each part of each problem on the pre-test being counted as 1 point), and which course the student was enrolled in (8^{th} grade math or Algebra I).

Because random assignment was conducted at the level of a classroom, we knew that there could be significant pre-existing differences between students in different class periods. For example, in our sample, special education students tended to be in certain periods, as did students in our subgroup of recent immigrants to the U.S. For this reason, we sought to include as many additional predictors to compensate for pre-existing differences between class periods as possible – including gender, ED, LEP, Talented and Gifted (TAG), and Special Education (SPED) status, students' score on the mid-year standardized mathematics test administered by their district that took place shortly before the teaching experiment, students' initial level of situational interest in and self-efficacy for mathematics, and whether the student was a recent immigrant. We only, however, retained fixed effects that were significantly predictive in the models. In addition, on the pre-test, the final question asked all students to try to pose an algebra problem about their interests. Scoring this problem as "correct" was problematic and therefore it was not included in the calculation of the pre-test score. Instead, we created a 0/1 indicator variable that simply showed whether the student had attempted to pose a problem. We were particularly interested in whether students' willingness to pose a problem at pre-test would moderate the effectiveness of the teaching experiment. Models were initially fit without interaction terms (Model 1) and then all two-way interactions with Condition were subsequently tested (Model 2). For the situational interest and self-efficacy measures, each student's 1-5 ratings for each scale was averaged, and used as the outcome in a linear regression model. Similar fixed effect predictors were tested for inclusion, including Condition, average rating on the pre-questionnaire, and grade level. *D*-type effect sizes were calculated using the method outlined in Chinn (2000); in Cohen (1988), effect sizes of 0.2, 0.5, and 0.8 are considered small, medium, and large, respectively.

Results

Table 1 shows how the experimental and control groups compared on pre-measures and the post-test. While they were very comparable in terms of the measures of interest and self-efficacy, the experimental group had directionally lower scores on both the pre-test and the mid-year district standardized assessment.

Table 1: Comparison of Experimental and Control Group

	Control Group Avg (SD) (*N*=77)	Experimental Group Avg (SD) (*N*=94)
Situational Interest	3.07 (0.87)	3.04 (0.85)
Self-Efficacy	3.00 (0.94)	3.06 (0.98)
Pre-test Score	22.84% (28.05)	20.46% (30.03)
Mid-Year Standardized Test	49.10% (15.40)	44.83% (17.78%)
Post Test	31.28% (29.59)	34.37% (29.31)

The latter difference neared significance in a one-tailed *t*-test ($p = .053$). As mentioned previously, these differences are not surprising given the clumsy nature of random assignment at the classroom level. For this reason, it is clear that post-test differences between groups should be interpreted using statistical methods that take into account relevant covariates, like our regression models.

Performance on Algebra Post-Test

Results for the regression analyses predicting performance on the post-test items are given in Table 2. Model 1, the main effects model, shows that being in the personalization condition significantly enhanced post-test performance, with a small-to-medium effect size calculated at d=0.35 (Odds=1.87). Other factors that enhanced post-test performance included higher scores on the pre-test and the district standardized test, being in Algebra I, not being a recent immigrant, and attempting to pose a problem on the pre-test. The latter main effect is somewhat surprising, given that it also had a small-to-medium effect size calculated at d=0.39. This variable might be indicating students' level of proficiency with the English language, which may be important when solving algebra story problems.

Model 2, the interactions model, revealed an interaction between condition and course, where personalization was most beneficial for students not in Algebra I with a medium effect size d=0.53 (Odds = 2.60). There was not a significant effect of personalization on learning for students in Algebra I (B=0.954-1.025=-0.071). The effect of personalization on post-test performance is being driven by the subgroup of students who are most in need of assistance – those placed into the lowest mathematics track. These students were considerably more likely to solve post-test problems correctly if they participated in the teaching experiment, compared to business-as-usual.

Table 2: Mixed Effects Logistic Regression Models Showing Post-Test Performance

	Main Effects Model (Model 1)				**Interactions Model (Model 2)**

Ratings on Interest and Self-Efficacy Post-Questionnaire

Results for the regression analyses predicting interest ratings on the post-questionnaire are in Table 3. For the main effects model (Model 3), the only variables that predicted interest at post were interest rating on the pre-questionnaire and score on the district standardized test. However, in Model 4 which tested for interactions with condition, there was a statistically significant interaction between condition and students' tendency to write a story problem on the pre-test of algebra skill. For students who wrote a story problem at pre-test, there was no difference in interest between the experimental and control groups on ratings of interest (B=0.307-.489=-0.182, p=0.165). However, for students who did not write a story problem at pre-test (62.6% of students), there was a significant positive difference in interest ratings at post of 0.307 points (95% CI [0.101,0.514]), p=.004), favoring the personalization group. Receiving personalized instruction does seem to be associated with an increase in interest, but this effect is limited to students who prior to the teaching experiment had potentially weaker problem-writing skills. This again suggests the personalized problem-posing activities are benefitting struggling students. Regression results for the self-efficacy items (not shown) showed no significant effects for Condition or for the interaction of Condition with any of the other predictors (ps > 0.1).

Table 3: Linear Regression Models Showing Avg. Interest Ratings on the Post Questionnaire

	Main Effects Model (Model 3)			Interactions Model (Model 4)		
Fixed Effects:	**B(SE)**	**95% CI**	**Sig.**	**B(SE)**	**95% CI**	**Sig.**

Problems Posed by Students

An analysis of what occurred during the 4 days of the teaching experiment, while important to this research as a whole, is beyond the scope of the current paper – here our research questions focus only on pre-/post- differences. However, we give some examples of problems written by students in Table 4 to provide some context for the quantitative results.

Table 4: Problems Posed by Students

Session of Teaching Experiment	Example of Problem Students Posed
Session 1	David is Instagram famous and every minute he gets 40 likes. Fill in the chart with the number of likes he will get in 4 minutes.
Session 2	Lucas is playing GTA Band every time he dies, he loses $40.00. Write a linear equation that shows the relationship between money and every time he dies.
Session 3	The Dallas Stars are destroying the Red Wings tonight. In the first period it was 11-2. If this keeps up for the next two periods, what will be the final score? Make a linear equation.
Session 4	Melanie had 60% of battery on her phone. She lost 10% every hour. Write a linear equation that shows the relationship between % of battery and hours.

Discussion and Significance

We contrasted an approach where students posed, solved, and shared problems related to their out-of-school interests to business-as-usual instruction in 8^{th} grade math classes. The control group experienced direct instruction where they solved problems on worksheets and discussed them as a class. An interesting facet of the comparison is that the control group tended to solve many more problems per class period (10-20 problems), while the experimental group focused in on posing and solving just a few. To an outside observer, the control group likely appeared to be more orderly and efficient. However, the experimental group learned more from the "messiness" involved with grappling with challenging mathematical ideas, and also in some cases saw increases in their interest in learning algebra. This is consistent with other studies on researcher-delivered (rather than student-generated) personalization (e.g., Walkington, 2013). However, compared to this prior research on personalization, here were see a slightly bigger effect size (medium instead of small), and this is also one of the first studies to test personalization with a more diverse student population. This study is also the first classroom study to put students at the center of the personalization process where they are posing their own problems based on their interests and experiences.

This study shows the potential of pedagogical approaches that make mathematics meaningful and relevant, conceptualize students as competent agents who can control their own learning, and that allow for rich mathematical discussions around challenging ideas (e.g., Moses & Cobb, 2001; Boaler, 2002). This study was carried out in an urban middle school in danger of not meeting state mathematics achievement benchmarks, with large class sizes and a diverse student population, many of whom did not speak English as their first language. Approaches that utilize and value the funds of knowledge that all students bring with them to the classroom can improve learning and interest and promote equity (e.g., Civil, 2007). Although funds of knowledge research has been critiqued for not employing multiple methods (Rios-Aguilar, Kiyama, Gravitt, & Moll, 2011) like quantitative analyses of effectiveness, this study expands the research base. An approach where students draw upon their own funds of knowledge, rather than rely solely on the teacher to make connections to their lived home and community experiences, could be significantly easier to scale and more authentic. This study also offers evidence that the activation of interest and student learning of mathematics go hand-in-hand (e.g., Hidi & Renninger, 2006; Mitchell, 1993). Challenging activities can increase the motivation of students struggling in the mathematics classroom, if proper supports (like funds of knowledge) are utilized. And finally, the results of this study inform the next iteration of our design-based research trajectory, the ultimate goal of which is to build an intervention that teachers can implement in different classroom contexts.

We review research literature concerning "number sense" from several related fields. Whereas other authors have pointed to difficulty defining "number sense" or to some degree of inconsistency in the literature, we argue instead that this is a case of polysemy: There are 3 different constructs that go by the same name. In this article, we clarify the research literature concerning "number sense" by naming and defining these 3 constructs, identifying similarities and differences between them, and contrasting themes in each body of literature by drawing upon a sample of 124 research articles that focus on "number sense."

Keywords: Number Concepts and Operations

> What's in a name? That which we call a rose, by any other name, would smell as sweet. — Juliet in Romeo & Juliet, William Shakespeare

There has been increasing interest in "number sense" from researchers in fields including experimental psychology, mathematical cognition, special education, and mathematics education. As an illustration, in a search for research articles with "number sense" in the title, we found 13 articles published in the 1990s, 40 articles published in 2000–2009, and 71 articles published in 2010–2016. Yet there seem to be a wide variety of uses of the term *number sense*. For example, consider the following two article titles: "Relationships among computational performance, pictorial representation, symbolic representation and number sense of sixth-grade students in Taiwan" (Yang & Huang, 2004) and "Wild number sense in brood parasitic Brown-headed Cowbirds" (Low, Burns, & Hauber, 2009). As this contrasting pair illustrates, we find a wide range of uses of the term *number sense* in the research literature.

More broadly, researchers in the social and behavioral sciences have become concerned with impediments to progress resulting from confusion over constructs (Brown, 2015; Gintis, 2007; Larsen, Voronovich, Cook, & Pedro, 2013; Le, Schmidt, Harter, & Lauver, 2010; Shaffer, DeGeest, & Li, 2016). Two particular issues have the potential to plague the research literature: synonymy and polysemy. *Synonymy* refers to different terms having the same meaning. *Polysemy* refers to the same term being used in different ways. Larsen et al. (2013) argue that these issues result in a proliferation of constructs and meanings, leading to "reverse progress" (p. 1532) as less is known over time about relationships between constructs, relative to the number of constructs that appear in the literature. As we will demonstrate, we regard the varied uses of the term *number sense* in the research literature as a problematic case of polysemy.

Many authors have noted difficulties defining "number sense" or disparities in the definitions and descriptions found in the literature (e.g., Andrews & Sayers, 2015; Berch, 2005; Dunphy, 2007; Howell & Kemp, 2005; 2009; 2010; Lago & DiPerna, 2010). In a seminal article published 25 years ago, McIntosh, Reys, and Reys (1992) emphasized the need to clarify the meaning of "number sense" in order for related research to progress. More recent articles have pointed to differences in definitions and assumptions about "number sense" but have assumed that these reflect different "perspectives" concerning a single construct, rather than fundamentally different constructs with the same name (Berch, 2005; Andrews & Sayers, 2015).

The above critiques of the "number sense" literature have each been situated within a particular field. Our review, which is a product of collaboration between researchers in special education and mathematics education, is concerned with the need for greater clarity in the "number sense" literature across fields. In this article, we categorize the literature focusing on "number sense" based on researchers' definitions and assumptions. Our systematic review of a sample of 124 research articles leads to a clear conclusion that is responsive to the issues identified above: Instead of disagreement over a single construct, we find three distinct "number sense" constructs at play in the literature. We argue that this is a problematic case of polysemy and a microcosm of broader issues of construct confusion in the social and behavioral sciences. It is difficult for research concerning a particular "number sense" construct to advance so long as authors continue to attempt to draw upon literature concerning different constructs that go by the same name. These different constructs involve contrasting assumptions about the nature of "number sense" and they are embedded in traditions with distinct orientations and concerns.

Method

We conducted a literature review to answer the following research question: How is the term *number sense* used in research literature in the social and behavioral sciences? In particular, how is "number sense" defined, and what assumptions do researchers make about the nature of "number sense"? We searched five databases (Academic Search Complete, Education FullText, ERIC, JSTOR, and Psyc INFO) for research articles with "number sense" in their titles. It was important to control the scope of our review in this way, because we sought to identify how "number sense" was defined and analyzed and to identify characteristics of "number sense" research. This being our purpose, including all articles that made any mention of "number sense" would have muddied our results. The numbers of journal articles that mentioned "number sense" varied from 168 to 1,587 in the databases listed above, and many of these were not research studies or were studies that did not focus on "number sense." For the purposes of our review, the relevant studies were those in which "number sense" was central to the research. We found the inclusion of "number sense" in the title of the article to be a reasonable proxy for this centrality.

We searched for all such articles that met the criteria described above and that were published on or before December 31, 2016. We focused on research articles published in peer-reviewed journals. Thus, we filtered out practitioner articles, books and book reviews, and conference abstracts and proceedings. We also filtered out publications not written in English. A final count of 124 articles qualified for inclusion in our sample. We recognize that some high-quality articles concerning "number sense" may not be included in our sample as a result of these requirements. Our purpose was not to provide comprehensive reviews of the literature belonging to each "number sense" tradition. It was to identify and describe "number sense" constructs based on a sufficient sample of the research literature associated with each construct.

In addition to the sample of articles described above, we consulted seminal works and publications of historical significance that explicitly addressed "number sense." We identified these based on their being cited frequently in our sample of research articles and/or representing a synthesis of research related to "number sense" in a particular research tradition. We included in this category the works of Dehaene (1997/2011), Geary, Berch, and Koepke (2015), Sowder and Schappelle (1989), and Sowder (1992). Consulting these sources provided us greater access and insights into the history of "number sense" research and enabled us to answer questions concerning definitions, assumptions, findings, and themes in cases in which a consensus could not be identified within our sample of articles.

We initially read a selection articles from our sample, focusing on authors' interpretations of "number sense" and the apparent origins of those interpretations (based on citations and use of key constructs), as well as the populations studied and methods used. We proceeded using open coding to define distinct "number sense" constructs. We refined our definitions through constant comparative analysis as we reviewed additional articles (Corbin & Strauss, 2008). Once we had reached a saturation point, we settled on three constructs: (a) *innate number sense*, (b) *early number sense*, and (c) *mature number sense*.

We grouped the bodies of literature related to each of the three constructs into distinct *research traditions*. We each took primary responsibility for reading and summarizing the literature belonging to one of the traditions. We developed these summaries iteratively with feedback from one another. We then compared our summaries based on key concepts, analytic approaches, findings, and themes. Questions that arose concerning similarities and differences between traditions or lack of clarity regarding any terms led us to return to our sample of articles and/or our set of seminal publications for answers. This process, too, was iterative. We refined our summaries of the aspects of each tradition in order to focus more clearly on the similarities and differences between traditions. Length constraints for this manuscript do not permit us to report on the research traditions in any detail; however, the themes that we identified helped to focus our descriptions of the "number sense" constructs and related concepts from each tradition.

Findings: Three "Number Sense" Constructs

We describe the three "number sense" constructs, along with key concepts related to each of them, based on our review of the literature. We also highlight similarities and differences in assumptions that distinguish these constructs.

Overview of the Three "Number Sense" Constructs

Innate number sense (INS) is believed to be an inborn set of neurological abilities that is common to humans and some animals. Thus, INS research involves infants, children, adults, and non-human animals (e.g., Libertus & Brannon, 2009; Halberda & Feigerson, 2008; Low et al., 2009). This construct concerns perception and discrimination of magnitudes, rather than explicit knowledge of number words or symbols. Much of the research with humans involves observing brain activity while participants perform tasks such as determining which of two sets consists of more items (e.g., Dehaene, 2001; Libertus & Brannon, 2009; Stoianov & Zorzo, 2012). Dehaene (1997/2011) believes that most people are born with an equal endowment of number sense and, therefore, INS is not predictive of success in learning mathematics. Dehaene's use of the term *the* number *sense* (with the definite article *the* and emphasis on the word *number*) is indicative of the view of INS as an innate sense, which is related to visual and auditory perception.

Early number sense (ENS), in contrast to INS, includes learned skills that involve explicit number knowledge, such as counting items using number words and comparing numbers represented symbolically as numerals. Some researchers believe that ENS builds upon the more basic INS (Andrew & Sayers, 2015; Aunio et al., 2005; Geary, et al., 2015). Levels of ENS skills vary from person to person and are influenced by education and experiences in early childhood (Cheung & McBride-Chang, 2015; Dunphy, 2006). ENS is regarded as an important predictor of success in school mathematics (Dyson, Jordan, & Glutting, 2011; Locuniak & Jordan, 2008; Jordan, Kaplan, Locuniak, & Ramineni, 2007). Accordingly, ENS skills are well aligned with school mathematics, especially in the early childhood years (preschool to Grade 2). Typically, studies of ENS involve young children or students with disabilities. ENS research does not belong to a single field. It is conducted primarily by researchers in mathematics education, special education, and cognitive psychology.

We use the term *mature number sense* (MNS) to distinguish the "number sense" construct that features prominently in the mathematics education research literature. MNS encompasses multidigit and rational number sense, and studies focus primarily on middle-grades (i.e., upper elementary and middle school) students and preservice teachers. Like ENS, the MNS construct refers to something learned, rather than innate. In contrast to ENS, MNS is typically described in terms of *components*, which refer to conceptual structures and habits of mind, rather than skills (e.g., McIntosh et al., 1992; Reys & Yang, 1998). For example, MNS is associated with flexibility in mental computation (Markovits & Sowder, 1994). Furthermore, whereas ENS is well aligned with school mathematics, MNS is often contrasted with school mathematics: Students who competently perform computations using standard algorithms may not exhibit characteristics of MNS, such as flexibility (Reys & Yang, 1998; Reys et al., 1999).

Key Concepts in "Number Sense" Research Traditions

Having provided an overview of the three constructs, we delve deeper into related concepts that appear in the three corresponding research traditions.

Key concepts in INS research. According to Dehaene (2001), "Number sense is a short-hand for our ability to quickly understand, approximate, and manipulate numerical quantities" (p.16). INS is considered part of an evolutionary process related to neurological abilities. Specifically, three neurological abilities are associated with INS: perceptual subitization, magnitude discrimination, and the use of a mental number line. *Perceptual subitization* can be defined as rapidly or immediately identifying numerosities of sets consisting of up to three or four items (Clements, 1999; Dehaene, 2001). Any numbers that are beyond four are then approximated with less precision (Clark & Grossman, 2007). *Magnitude discrimination* consists of indicating the difference in cardinality between two sets of items (presented visually or auditorily) (Dehaene, 2001). The *mental number line* is a mental approximation of magnitude based on a continuous number line believed to be present in an individual's mind (Clark & Grossman, 2007). The use of a mental number is inferred from the ability to "quickly decide that 9 is larger than 5, that 3 falls in the middle of 2 and 4, or that 12 + 15 cannot equal 96" (Dehaene, 2001, p. 16). (Although comparisons of numerals require explicit number knowledge, they are taken as evidence of a mental number line in humans who have developed such knowledge.)

Key concepts in ENS research. ENS is conceptualized and studied as a set of skills. In a prominent example, Jordan and colleagues (2006) focused on "assessed skills that have been validated by research and are relevant to the mathematics curriculum in primary school" (p. 154). Six main skills are focal in ENS research: number recognition, counting, number patterns, number comparison, number operations, and estimation. *Number recognition* requires children to associate the number symbols with the vocabulary and meaning of numbers. *Counting* includes ordinality, cardinality, and counting backward or forward starting with an arbitrary number. *Number patterns* is the ability to copy a given pattern or identify a missing number in a sequence. *Number comparison* refers to awareness of the magnitude of given numbers and the ability to make comparisons between different magnitudes. *Number operations* involves the ability to perform simple calculations of sums and differences within 10 or 20. *Estimation* refers to magnitude estimation of symbolic and non-symbolic quantities, including the use of a number line to identify the approximate location of a number (Andrews & Sayers, 2015; Berch, 2005;

Baroody et al., 2012; Ivrendi, 2011; Jordan et al., 2006; Howell & Kemp, 2010; Malofeeva, Day, Saco, Young, & Ciancio, 2004; McGuire, Kinzie, & Berch, 2012).

Key concepts in MNS research. McIntosh and colleagues (1992) provided a definition of MNS that has often been cited or paraphrased:

> Number sense refers to a person's general understanding of number and operations along with the ability and inclination to use this understanding in flexible ways to make mathematical judgments and to develop useful strategies for handling numbers and operations. It reflects an inclination and an ability to use numbers and quantitative methods as a means of communicating, processing, and interpreting information. It results in an expectation that numbers are useful and that mathematics has a certain regularity. (p. 3)

The above description seems to capture the gist of the term *number sense*, as it is commonly used in the mathematics education community. It focuses on habits of mind and ways of behaving mathematically that are considered desirable, such as flexibly manipulating numbers.

Despite this holistic definition, MNS is typically partitioned into up to six components: *understanding of the meaning and size of numbers* (e.g., to compare fractions), *understanding and use of equivalent representations of numbers* (e.g., to write rational numbers in different ways), *understanding the meaning and effect of operations* (e.g., to reason about the effect of dividing by a number between 0 and 1), *understanding and use of equivalent expressions* (e.g., to compare expressions involving different numbers and/or operations), *flexible computing and counting strategies for mental computation, written computation, and calculator use* (e.g., to select strategies and perform mental computation), *and measurement benchmarks* (e.g., to estimate the height of an object) (Reys et al., 1999; p. 62). Many studies use assessments designed to measure specified components of number sense (e.g., Yang & Lin, 2015).

Similarities and Differences

In summary, INS is regarded as innate and equally distributed among normal people at birth. It is also found in some animals. INS consists of a set of basic neurological abilities, which do not account for success in learning mathematics. ENS, by contrast, is regarded as learned. It is unequally distributed among people and is not found in animals. ENS is typically conceptualized as consisting of a set of skills, and these skills are well aligned with primary-grades mathematics. MNS is also learned and unequally distributed among people. It is typically described as consisting of a set of components, which include conceptual understandings and habits of mind. In contrast to ENS, MNS is often described as being at odds with students' typical experiences in school mathematics and the mathematical knowledge and orientation that result.

Discussion and Conclusion

Whereas other authors have observed differences in definitions or interpretations of "number sense," they have assumed that this confusion surrounds a single construct (Andrews & Sayers, 2015; Berch, 2005). For example, Berch (2005) referred to "*the* concept of number sense" (p. 333, emphasis added) and Andrews and Sayers (2015) described "number sense" as "*a* poorly-defined construct" (p. 257, emphasis added). These previous observations were made from the perspective of researchers in the ENS tradition, and their purpose was not to clarify the "number sense" literature more broadly. Whereas INS and MNS research represent two extremes, ENS research lies in between them, and particular studies may lean closer to one side or the other. Thus, it is ENS researchers who face the most potential for confusion in attempting to navigate the muddled "number sense" literature. It is no surprise, then, that ENS researchers have taken the lead in recent efforts to clarify what "number sense" means in order to facilitate progress in ENS research.

Our systematic review led to the identification of three "number sense" constructs. To the best of our knowledge, our review of the "number sense" literature is the first of its kind. It had the express purpose of analyzing the use of the term *number sense* in research literature across fields in order to disentangle the meanings and assumptions associated with the term. The contrasting features of the constructs underscore the need to clearly distinguish them.

The results presented above contribute to the literature by clarifying distinctions between three constructs that have gone by the same name. The widespread use of the term *number sense* to refer to three distinct constructs belonging to different traditions has led to some confusion and has not gone unnoticed in the literature. By systematically coding the articles in our data set according to the authors' assumptions about "number sense" and their methods of investigation, we were able to clarify the nature of the construct within each tradition.

The differences that we identified in definitions and assumptions are not a trivial observation about the literature. We noted in our review many instances of inappropriate citations across research traditions. For example, some MNS articles cite INS research to support their claims about "number sense" despite the fact that their research concerns a different construct. To be clear, authors working in one "number sense" tradition should not be citing authors working in another tradition, unless there is explicit acknowledgment of the differences between traditions and unless there is a particular reason for the citation. We suggest that researchers use terms such as INS, ENS, or MNS to distinguish the "number sense" construct that they are investigating. Although "number sense" is a catchy term that rolls off the tongue, its loose usage across related research traditions has led to confusion and impediments to progress.

In conclusion, we find in the "number sense" literature a problematic case of polysemy. As Larsen et al. (2013) state, "The task of integrating research by connecting synonymous constructs and parsing polysemous constructs is an urgent one if behavioral science is to advance" (p. 1533). We agree, and we add that the same issue applies to research in the social sciences. In particular, in order to propel progress in "number sense" research in a variety of fields, there is a need to clarify the construct under investigation within each tradition.

EXPLORING THE STRUCTURE OF EQUIVALENCE ITEMS IN AN ASSESSMENT OF ELEMENTARY GRADES

Rashmi Singh

Karl W. Kosko
Kent State University
kkosko1@kent.edu

This study is focused on the structure of equivalence problem to probe the evolution from operational to relational view of students' understanding of equals sign. We propose a modified construct map which incorporates the intermediate levels in such a transition which were previously ignored. Our findings suggest that the structure of number sentences (place value and the position of answer box) has undeniably significant role in developing students' conception of equivalence. In addition, the designed and validated example presented here could potentially serve as a tool for better assessment of understanding of equivalence.

Keywords: Number Concepts and Operations, Algebra and Algebraic Thinking, Elementary School Education, Assessment and Evaluation.

Background / Overview

There is a consistent and increasing focus by educational researchers on the development of elementary grade algebraic reasoning, specifically in regard to the use of open number sentences (e.g. 4 + ☐ = 5 + 7) (Falkner, Levi, & Carpenter, 1999; McNeil & Alibali, 2004; Molina & Ambrose, 2008; McNeil, Fyfe, Petersen, Dunwiddie & Berletic-Shipley, 2011). Such open number sentences often include expressions on both sides of the equation and are often introduced as arithmetical equations where students are tasked to find the unknown or missing number in place of a blank or empty box. This affords students the opportunity to explore the underlying structure of an arithmetical equation and improve their understanding of the meaning of symbols and operations. Various researchers (Mc Neil & Alibali, 2004; McNeil et al., 2006; Sherman & Bisanz, 2009; Powell, 2014) suggest that many elementary students are introduced to only traditional arithmetic equations (i.e., a + b = c). These studies suggest that such *operations equals answer* type equations encourage the operational view and may hinder students' development of a relational view of the equals sign.

In an operational view of the equal signs students carry the notion that the equals sign means *makes*, *produces the answer*, *find the total*, or as an indication *to do something* such as computation (Behr, Erlwanger & Nichols, 1976; Kieran, 1981; Seo & Ginsburg, 2003; Knuth, Stephens, McNeil & Alibali, 2006; McNeil et al., 2006; Jacobs et al, 2007). Students holding a relational view consider the equals sign as a mathematical symbol which represents the sameness of the expressions or quantities on either side of an equation (Kieran, 1981; Baroody & Ginsburg, 1983; Falkner et al., 1999; Alibali, Knuth, Hattikudur, McNeil, & Stephens, 2007; Blanton, Levi, Crites, & Dougherty, 2011). A vast majority of research suggests that a relational understanding of equivalence is a first step towards early algebraization (Falkner et al., 1999; Carpenter & Levi, 2000; Blanton & Kaput, 2005; Jacobs et al., 2007; Byrd, McNeil, Chesney, & Matthews, 2015). Students holding a more operational view tend not to develop the conceptual understanding of arithmetic and other more advanced mathematics such as Algebra (Kiren, 1981; Knuth et al., 2006; Jones, Inglis, Gilmore, & Dowens, 2012; Rittle-Johnson, Matthews, Taylor, & McEldoon, 2011). Thus, the traditional way of introducing equal sign ($a + b = c$) tends to focus predominately on step-by-step computation to find the answer rather. By contrast, explorations of the underlying structure or number relations between and within the expressions appears to require alternative forms of equations.

The research to date generally interprets the structure of equations as open number sentences ($a + b = c + \square$) vs traditional arithmetic equations ($a + b = \square$). However, it is unclear whether and to what degree other mathematical structure within such equations interacts with children's conceptions of equivalence. Namely, place-value is an aspect of mathematical structure that children engage concurrently with their developing conceptions of equivalence. The aim of this study is to investigate the role of number structure, specifically place-value with whole numbers, in students' conception of mathematical equivalence. To facilitate this purpose, we examined third grade students' responses to a conceptions of equivalence assessment using psychometric analysis.

Theoretical Framework

Numeric Structure in Number Sentences

Traditionally, most studies on equivalence define two basic categories of students' conceptions of the equals sign: operational and relational. More recently, Rittle-Johnson et al. (2011) elaborated on this dichotomy (operational vs relational) and expanded it into four levels ranging from rigid operational to comparative relational. Students at Level 1, the rigid operational level, are expected to successfully solve the traditional format (i.e., a + b = c). Students at Level 2, the flexible operational level, maintain an operational view of the equal sign with some flexibility to correctly solve and accept the atypical or "backwards" equations (i.e., c = a + b and a = a) as valid. At Level 3, the basic relational level, children successfully solve, evaluate, and encode equation structures with operations on both sides of the equal sign (such as a + b = c + d or a + b - c = d + e). Finally, children identified at Level 4, the comparative relational level, show a more nuanced understanding of the equals sign. These students can correctly solve and evaluate equations by comparing the expressions on both sides of equal sign. Students at this level use compensatory strategies. For example, in solving 37 + 24 = 36 + □, such students may recognize that 36 is 1 less than 37 and use this knowledge to determine that the unknown number must be one more than 24 (Carpenter et al. 2003).

More recently, Singh & Kosko (2015, 2016a) observed other possible levels in the continuum of conception of equivalence. Therefore, we argue that further modifications to the field's models for the ways students consider equivalence are needed. Specifically, students who can successfully solve $a + b = c + d$ types of equations are currently evaluated as holding a *basic relational* conception of the equals sign. However, Rittle-Johnson et al (2011) suggest that the construct is continuous, which allows for the possibility of other sub-constructs between consecutive levels.

Singh and Kosko (2015) conducted a teaching experiment with a variety of equivalence problems and found that some students demonstrated a *pseudo-relational conception* (PRC) of equivalence. Specifically, student with a PRC can solve problems of the form $a + b = c + \square$ when the numbers involved allow them to regroup 10's and 1's in an obvious manner. For example, in problems like 34 + 25 = 50 + □**,** such students first regroup 10's from 34 and 25 (30 + 20 = 50), which is visually available on right hand side. Thus, these students are then able to add the ones (4 + 5 = 9) to find the solution. At first glance, it may seem like these students hold a relational view of equivalence. However, when closely comparing their strategies in other equations of the same structure but different numeric structure, it was apparent that the place-value structure of such equations allowed students to use different strategies than working with other $a + b = c + \square$ types of equations. For example, in solving 15 + 24 = 20 + □, a student successful with the prior example failed to provide the correct solution when using their regrouping of 10's and 1's strategy. This suggests that the mathematical structure numbers in an equation, such as that of place-value, plays an important role in students' conceptions of equivalence. This was verified in another study by Singh & Kosko (2016a) in which the authors found that some students can successfully solve problems like 4 + 5 + 8 = □ + 8 by finding the answer 9 (i.e., 4 + 5), whereas the same students demonstrated a different conception in solving very similar problem like 7 + 6 + 4 = 7 + □☐. These students used an *adding all then subtracting* strategy to solve the problem 7 + 6 + 4 = 7 + □☐. Specifically, students first added 7 + 6 + 4 and then the 7 on the right-hand side to get 24. They then subtracted 7 to obtain the answer 17. Singh and Kosko (2016a) suggest that the use of this strategy may have more to do with the position of the missing value box than students' operational or relational view of the equal sign.

Conceptual Model for Conception of Equivalence

To define the way an equivalence problem is presented to students, different researchers have used different terminologies, or the same terminology with different meanings. Molina & Ambrose (2008) used the term structure in reference to the structure of mathematics operations. Later, Molina, Castro, & Castro (2009) used the term structure in the same sense as used by Kieran (1989), describing the surface structure of arithmetic and algebraic expressions. Recently. Stephens et al. (2013) used the term "equation structure" as opposed to focusing on probing their computational fluency. This study uses a broad definition of structure of number sentences which includes an emphasis on place value and the position of the missing value box(es). Thus, the definition differs significantly from the meaning of structure used in prior studies.

Using our definition of structure of number sentence, and based both on our previous findings (Singh & Kosko, 2015; Singh & Kosko, 2016a), and ongoing work with elementary students, we suggest six levels of conception of equivalence along a continuum (Figure 1). The construct map in Figure 1 includes levels from basic operational (least sophisticated) to full relational (most sophisticated). A student at the basic operational level can successfully solve traditional number sentences (a + b = c) with various positions of unknown or box such as 6 + 7 = ☐ or 5 + ☐ = 9, while students at the flexible operational level can successfully solve less typical number sentences (e.g. 19 = ☐ + 3; 24 = 10 + ☐; ☐ = 5 + 7). However, both types of conceptions include student strategies that rely on an operational view of equals.

We argue that the transition from flexible operational to basic relational is not always smooth and is accompanied by the existence of *pseudo-relational level*. Students at this level are able to solve number sentences which have operations on both sides (such as a + b = c + d), but only in cases where the number sentences can be solved by using regrouping of ones and tens addends.

Similar to the pseudo-relational level, students at the basic relational level can successfully solve number sentences which have operations on both sides (a + b = c + d) with the position of the box directly after or before the equals sign. Such students can confirm the sameness of expressions on both sides of the equals sign through computation.

Prior to a full relational conception, we suggest some students demonstrate what we describe as an advanced basic relational level. This level is characterized by students who can successfully solving number sentences with operations on both sides (a + b = c + d), but such students may use either computation or compensatory strategies. Finally, at the full relational level, students can successfully solve number sentences which have operations on both sides (such as a + b = c + d) and two unknowns either both on same side or one on each side of equal sign by relying predominately on compensatory strategies.

Direction of Increasing sophistication in "Mathematical Equivalence"

Students	Responses to Items
Full Relational	Anticipates successful use of compensatory strategies to solve item types, e.g. □ + 28 = 46 + ○;
Advance Basic Relational (□ at the end of RHS of =)	Anticipates confirmation of the sameness of expressions on both sides of equal sign either using computation or compensatory strategies in items e.g. 15 + 27 = 18 + □
Basic Relational	Anticipates confirmation of the sameness of expressions on both sides of equal sign with computation in items e.g. 13 + □ = 24 + 8; 27+ 16 = □ + 35.
Pseudo-relational (with regrouping	Anticipates to solve specific items e.g. 22 + 15 = 30 + □ by regrouping of ones and tens of addends. Students get first addend in right side of equal sign by regrouping tens of both addends of left side and find the unknown by simply regrouping ones.
Flexible-Operational	Anticipate to solve atypical number sentences such as operations on right e.g. 19 = □ + 3; 24 = 10 + □; □ = 5 + 7 or 12 = □.
Basic Operational	Only successfully solve traditional number sentences (a + b = c) with various positions of unknown or box such as 6 + 7 = □ or 5 + □ = 9.

Direction of Decreasing Sophistication in "Mathematical Equivalence"

Figure 1. Construct map for knowledge of equivalence.

The different levels of students' conception of equivalence are included in the construct map shown in figure 1. As discussed above, prior studies (Singh & Kosko, 2015,2016a) describe students' transition from operational to relational conception of equivalence is not always smooth. Rather, students' holding an operational view may do things that resemble, but do not comprise, a relational view of equivalence (i.e. *pseudo-relational*) when solving some specific types of equations. The construct map in figure 1 illustrates that as students move in a continuum they should engage in different levels of conception of equivalence.

Methods

Sample

Data were collected in Fall 2016 from 157 third grade students (49.7% male; 50.3% female) in a suburban school district in a Midwestern U.S. state. Students were enrolled in one of eight classrooms across four schools in the district. The district includes a predominately white student population (74%), with a significant portion of economically disadvantaged students (40%).

Test Development and Item Design:

Our previous work on equivalence indicates some observable gaps in Rittle-Johnson's established framework (Singh & Kosko, 2015, 2016a). In order to address these gaps, we designed a new assessment utilizing the aforementioned construct map. An initial version of the assessment was piloted with fourth and fifth grade students (n = 157) with 33 items. The overall reliability (Cronbach's alpha = 0.92) of the initial test was sufficient. However, the item discrimination for several items was not sufficient. Also, the infit mean square statistics for more than a quarter of items indicated that the initial construct map lacked unidimentionality. To improve these shortcomings in item design we revised some items for better fit. First, items with insufficient fit statistics were removed or revised. Many of these items illustrated what may be different constructs related to but not identifiable as conception of equivalence. Next, true/false items were removed since these items were found to have significant structural differences than missing-value addends, and such items also tended to have too low of difficulty to provide sufficient information for the assessment. The revised instrument included 22 items across six sub-constructs along a continuum (thus, these subconstructs are theorized to be hierarchical). Figure 1 shows the revised construct map with example items for the six subconstructs.

The revised instrument was used in the analysis of Fall 2016 data. Raw data was inputted into digital files before dichotomously coding student responses (0 = incorrect answer; 1 = correct answer). This allowed for examining raw response distributions, as well as analyzing the dichotomous data via a Rasch model. The significant feature of the Rasch model is its ability to transform ordinal data into equal-interval scales (Bond and Fox, 2015). The item difficulties in the Rasch model can be determined, by the process of item calibration, independently of the distribution of persons' abilities in the data and the measurement of person's traits (i.e. abilities) is independent of test items used to measure that trait. Another useful feature of the Rasch Model is that it facilitates the process of constructing measurement variables. In other words, the model is derived independently of data, tests are then constructed to fit the model, and then the data are used to see if they conform to the requirements of the model.

Results

The equivalence assessment was found to have sufficient internal reliability (α = 0.92). Crocker & Algina (1986) suggest that a Cronbach's alpha of 0.90 or higher is sufficient for cognitive assessments. Test statistics for the Rasch model indicate sufficient item reliability (0.92) and person reliability (0.89). To examine the unidimentionality of the assessment, infit and outfit statistics were calculated. The item difficulties range from -3.14 to + 2.12, which is considered as a good practice to have a range of difficulty among items in an assessment. In this assessment, we hypothesized that the item difficulty should increase from lower (i.e. operational) to higher (i.e. advance relational) levels and item difficulty appeared to increase as expected. The infit statistics are weighted and provide more weight to the performance of person whose ability is closer to the item difficulty level whereas outfit statistics is not weighted and as a result more sensitive to outlying scores. This is the reason that investigators give more attention to any small irregularities in infit scores than large outfit scores (Bond and Fox, 2015) The average item mean-square infit statistics is 0.90 and average mean-square outfit statistics is 0.77, which is considered sufficient. Contrasting the overall sufficient item fit statistics, item 8 (12 = □) was found to have a relatively high mean square infit statistic (1.45), which indicates more randomness than expected (figure 2). We had observed similar results for such items with our pilot of grade 4 and 5 students, and data from grade 3 students indicates that this particular item format (a =□ □) may need further study in regards to the concept of equivalence. We decided to remove this item from our final equivalence assessment, given the continued poor fit across samples. All remaining items appeared to have sufficient fit (Bond & fox 2015), with point-biserial statistics ranging between 0.65 to 0.79. To examine how items hypothesized to target specific levels along the continuum in the construct map, a Wright map was constructed (figure 2).

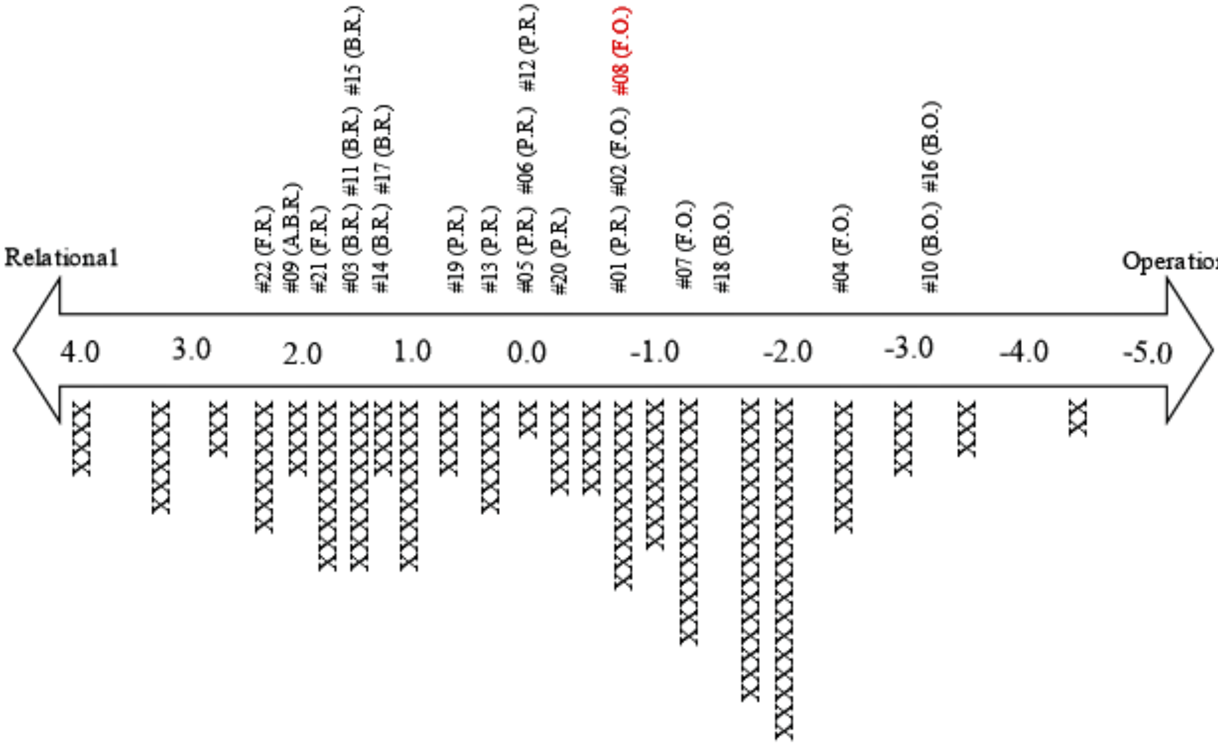

Figure 2. Wright map for equivalence assessment.

The Wright map shown in figure 2 was produced by ConstructMap 4.6.0 (Kennedy et al., 2010). Targeted levels of sophistication (see Figure 1) are abbreviated after each item number (*B.O.=Basic Operational; F.O.=Flexible Operational; P.R.=Pseudo-Relational; B.R.=Basic Relational; A.B.R.=Advanced Basic Relational; and F.R. Full Relational*). The location of items in the Wright map (Figure 2) aligns well with the hypothesized level of sophistication on the construct map (Figure 1). However, certain items (i.e., 8, 2, 18, & 21) visually appear at the same level as items at lower or higher hypothesized levels. Examination of the items' delta statistics and associated confidence intervals indicates that those items hypothesized as more relational than operational do indeed have higher delta statistics.

Item 21 (☐ + 28 = 46 + ○) had a lower delta statistic than predicted, and therefore appears lower on the Wright map than expected. After a close inspection of students' raw responses, it was observed that some students put a zero in the circular blank position "○." However, the the instructions for this item stated that students should "find a number bigger than 10 to write in the ☐…[and] any other number to write in the ○ that makes the problem true". By allowing for the possibility of students to use zero, it may have reduced the difficulty of the item. Specifically, the item was meant to engage students in composing and decomposing number in relation to equivalence. Thus, instructions for these items may need revision in future assessments.

Discussion and Conclusion

Through our findings, we establish that the structure of number sentences, particularly in regard to the role of place value, has a significant role in students' conception of equivalence. The results of our statistical analysis indicate that students may rely on more visually obvious aspects of place value in solving equations. This may appear to be relational at face value, but is not as sophisticated a conception of equivalence as other similarly formatted number sentences. Motivated by our findings from previous work (Singh & Kosko, 2015, 2016a) we incorporated new intermediate levels in Rittle-Johnson and colleagues' (2011) framework of students' conception of equivalence. Our suggested, modified construct map appropriately incorporates students' transition from basic operational to full relational understanding by considering these additional transitional stages. Furthermore, the designed and validated assessment described here can serve as a tool for researchers and practitioners interested in students' conceptions of equivalence.

Our results provide useful guidelines for instructors and curriculum designers. Specifically, our findings suggest more attention be paid to the role of place value in the teaching and learning of equivalence. Furthermore, there is a need for more careful examination of students' understanding of equivalence in regard to various mathematical concepts. Future research is needed to confirm and extend the findings presented here. For example, prior research has found relationships between students' conception of equivalence and multiplicative reasoning (Singh & Kosko, 2016b). Given the connection identified here regarding place value, a better understanding of how equivalence interrelates with children's developing number sense is highly needed. Additionally, findings presented here provide evidence that the structure of items similar to a = □ is in need of further study, given that understanding the *Reflexive Property of Equivalence* is crucial for students' success in future advanced mathematic. We expect that by conducting such research, the field may better understand why such items do not consistently align students' conceptions of equivalence.

This study found that place value appears to be inherently tied with conception of equivalence. These results are highly significant and need additional study. There appear to be other connections between various concepts and equivalence research (Singh & Kosko, 2016b), potentially indicating that students' unit coordination may relate to their coordination between expressions. Such interrelationships warrant detailed investigation.

We investigate thirty-three second and fifth-grade students' solution strategies on integer addition problems before and after analyzing contrasting cases with integer addition and participating in a lesson on integers. The students took a pretest, participated in two small group sessions and a short lesson, and took a posttest. Even though the results reveal significant gains for both grades from pretest to posttest, second graders gained significantly higher than fifth graders. In this paper, we explore students' treatment of the negative sign and describe this gain difference.

Keywords: Number Concepts and Operations; Elementary School Education; Cognition

When students encounter new concepts, they try to apply their prior knowledge in an effort to make sense of the new information. Consequently, children's negative integer knowledge builds upon their whole number understanding (Bofferding, 2014). The transition from working with whole number concepts to interpreting new number classes appropriately requires substantial time and considerable conceptual change (Vosniadou, Vamvakoussi, & Skopeliti, 2008). However, there is a noteworthy time gap between when children learn about whole number concepts and the introduction of negative numbers. While whole numbers are introduced at an early age, negative numbers and operations are currently not taught until sixth and seventh grade (National Governors Association Center for Best Practices & Council of Chief State School Officers, 2010). Introducing negative numbers in upper elementary and middle school grades could serve as a barrier to student learning. As a result of this large gap, students may interpret negative numbers in various ways given their whole number knowledge, which may influence their solution strategies in problems involving negative numbers. For instance, students may treat the negative sign as a subtraction sign (e.g., solving -4 + 7 as 7 – 4) (Bofferding, 2010). In fact, Murray (1985) found that students continued to explain that you could not take larger numbers away from smaller ones (e.g., 5 – 8) even though they could solve other negative integer problems.

Even first graders can move toward having more formal mental models of integers, integer order, and integer values by engaging in instructional activities that help them focus on the meaning of the negative sign and evaluate the numbers in relation to each other (Bofferding, 2014). Similarly, instructional activities can help students make specific connections between the results of operating with negative and positive numbers. One way to encourage these connections is via the analysis of two carefully chosen, contrasting integer problems shown as worked examples. Studies have identified contrasting cases as a powerful instructional tool that has promising results in students' developmental knowledge in the mathematics classroom (e.g., Rittle-Johnson & Star, 2007; 2009; 2011). As one of the promising ways to help students conceptualize negative number operations, this method can help students leverage their prior knowledge of whole number addition to making sense of negative number addition problem types.

However, it is not clear to what extent analyzing contrasting cases of integer addition problems could benefit younger students compared to older students. Although younger elementary students can reason productively about integers, they may need more intense experiences in order to facilitate their conceptual change. On the other hand, older students may be less willing to modify their conceptions. In this paper, we analyze the performance of younger and older elementary students before and after they compare sets of integer addition problems. Further, we explore how their interpretations of negative number addition change.

Specifically, we ask the following research questions:

1. How do second and fifth-grade students perform in solving integer addition problems before and after analyzing contrasting cases involving negative numbers?
2. How do students' interpretations of the negative sign and addition operations change before and after analyzing the contrasts?

Theoretical Framework

Interpretation of the Minus Sign

Students engaged in working with algebraic equations experience difficulty when manipulating negative numbers due to the different perceived meanings of minus signs (Vlassis, 2004). The three primary meanings of the minus sign are unary, binary, and symmetric and also play a role in students' interpretations of integer addition and subtraction problems. The binary meaning of the minus sign corresponds to the subtraction operation (Vlassis, 2004), which students with a whole number mental model will interpret to mean getting less or smaller (Vosniadou, Vamvakoussi, & Skopeliti, 2008). Students with only a binary understanding of the minus sign might ignore negatives or treat them as a subtraction sign (Bofferding, 2010). For example, -8 + 6 can be turned into a subtraction problem as 6 – 8 or 8 – 6 and might be answered incorrectly or correctly. The symmetric, or opposite, meaning of the minus sign indicates an operation of multiplying by -1. In other words, the symmetric meaning illuminates the opposite positions of negative and positive numbers (Vlassis, 2004). Students rely on the symmetric meaning when they add integers as if they were positive and make the answer negative (Bofferding, 2010). For instance, -2 + 5 might be solved as 2 + 5, with students adding the negative sign at the end, and answering -7. Finally, the unary meaning of the minus sign involves seeing the negative sign as attached to a numeral, a negative number (Vlassis, 2004). Students with a strong unary understanding will often start at a negative number and count towards or away from the negative direction (Bofferding, 2010).

Conceptual Change

In prior research, students' difficulties in interpreting minus signs were primarily reflected in situations involving successive signs in arithmetic operations. From a conceptual change lens, this is unsurprising. Until students encounter negative numbers, they would not see two successive minus signs. Their unawareness of the multiple roles of the minus sign resulted in the mistreatment of the signs and signaled partial conceptions (Vlassis, 2008). In terms of conceptual change, students were trying to make sense of new information in light of their prior knowledge. During this process, they likely formed synthetic mental models (Vosniadou & Brewer, 1992), conceptions that blend their prior understanding with new hypotheses about the meaning of the new signs. Different studies have explored students' various ways of reasoning in their arithmetic solution strategies. They framed how students' understanding of the multiple meanings of the minus sign correspond to their integer arithmetic solutions (e.g., Bofferding, 2010, Lamb et al., 2012; Murray, 1985, Vlassis, 2008). Lamb, Bishop, Philipp, Whitacre, and Schappelle (2016) claimed that no single best model exists that could be applied in students' ways of reasoning. We build on this literature by using a conceptual change lens to investigate how students' conceptions of the minus sign – and consequently their strategies – change as they explore contrasting integer addition problems.

Methods

Participants and Settings

Both second and fifth-grade students engaged in this study. We chose to work with second graders because they represent students who typically have not had formal instruction in negative numbers but have whole number understanding. We chose fifth graders because they often have heard about negative numbers and would learn about them formally in the following school year. We recruited fifth-grade students from two public elementary schools in a rural Midwestern school district where 32% of students were classified as English-language learners (ELLs) and 75% qualified for free or reduced-price lunch. Based on their pretest scores, 17 of the 32 fifth graders who returned permission slips were selected for this analysis as they had not reached the ceiling in terms of their order and value integer mental models (formal mental model) (Bofferding, 2014). It was important not to include students with formal mental models so that we could compare their growth to the second graders' growth. Because we had already worked with second graders at the schools where we recruited the fifth graders, we recruited second graders from one classroom at a different school. The public elementary school was in a small city within a Midwestern school district where 14% of students were classified as ELLs and 57% qualified for free or reduced-price lunch. Overall, 16 second-grade students from the recruited class participated.

Design and Materials

Students from both grades completed a pretest, participated in two small-group sessions, engaged in a whole-class lesson, and finally took a posttest.

Pretest and posttest. Test items were designed to evaluate students' knowledge related to integers and were identical on both pretest and posttest. Both tests took approximately 30 minutes to finish for students in both grades. Questions focused on ordering integers, integer value comparisons, integer addition, directed magnitude comparisons, and transfer problems with addition. After both tests, we interviewed some of the students to learn more about their answers and strategies and to clarify students' insights.

Small-group sessions. During the sessions, students analyzed sets of contrasting integer addition problems in groups of two to four. They analyzed worked examples of correct and incorrect solutions to integer addition problems within four different illustration contexts including (a) a gingerbread boy starting at zero and moving on a number path situated on a hill (translation model [see Wessman-Enzinger & Mooney, 2014]), (b) an ant starting at the first number in the addition problem and moving below and above ground next to a vertical number line, (c) a chip model (counterbalance model [see Wessman-Enzinger & Mooney, 2014]), and (d) a folding number line (see Tsang, Blair, Bofferding, & Schwartz, 2015). Each session took approximately 20 minutes.

In their first session, students analyzed integer addition problems with two positive numbers in comparison with adding a positive number to a negative number (e.g., $3 + 5 = 8$ versus $-3 + 5 = 2$). This contrast can help emphasize that regardless of the starting number, adding a positive number always corresponds to a movement towards the positive direction (or up). At the end of the session, students solved eight integer addition problems, four where they added two positive numbers and four where they added positive numbers to negative numbers.

In the second session, students compared addition problems with two negative numbers to addition problems with adding a negative number to a positive number (e.g., $-2 + -5 = -7$ versus $2 + -5 = -3$). This comparison can help students to realize that adding a negative number to either a positive or a negative number always results in a movement in the negative direction (or down). At the end of the session, students solved eight integer addition problems, four where they added two negative numbers and four where they added negative numbers to positive numbers. The collective

16 problems solved at the end of their both sessions composed what we call a midtest and helped us understand how they would answer the problems immediately after making comparisons with them.

Whole-class instruction. The whole-class lesson, led by one of the researchers and given separately to fifth and second graders, had two parts: interactive instruction and a game. Instruction began by helping students think about moving on an integer number path to solving integer addition problems. Therefore, adding a positive number represented moving up on the number path (going more in the positive direction), and adding a negative number indicated a downward movement on the number path (moving more in the negative direction). Students helped explain how they would move the gingerbread boy along the number path to solve example integer addition problems. As students' understanding built upon the directional movements of adding two integers, the researcher-teacher presented an additive inverse problem (e.g., -2 + 2) to introduce the "zero pair" concept. As demonstrated, zero pairs occurred when the two movements added on the number path ended at zero. Students later engaged in a game where they had to make zero pairs using positive and negative one cards.

Analysis

To address the first research question about students' performance, we ran a repeated measures ANOVA grouped by grade level on the 17 arithmetic items presented to students on the pretest and posttest. Next, in order to determine students' progress before, during, and after the study more thoroughly, we determined students' average percent correct on six common problems (-9 + 2, -8 + 8, 6 + -8, 9 + -9, -1 + -7, and -2 + -2) that were given to students on the pretest, midtest, and posttest. Students' responses to items of a similar problem type (e.g., -9 + 2 and -8 + 8) provided some insight into their interpretations of the minus signs and helped paint a picture of their conceptual change. We sought further clarification of the meanings students attributed to the minus signs through the interview data.

Results

Overview of Students' Arithmetic Gains

The results of the repeated measures ANOVA indicate a significant main effect of test, $F(1, 31) = 62.32$, $p<.001$. Students from both grades gained significantly from pretest to posttest. Table 1 shows that even though the fifth-grade students' average score on the pretest arithmetic items was higher than second graders, they scored a lower average on the posttest arithmetic items than second-grade students. In fact, based on the repeated measures ANOVA, the difference between the grade level gains is significant, with second graders making greater gains on average than the fifth graders, $F(1, 31) = 4.51$, $p<.001$.

Table 1: Students' Mean Scores (And Average Percent Correct) On Integer Addition Problems

Grade Level /Tests	Pre-test ($M \pm SD$) (average percent correct) (17 items)	Mid-test ($M \pm SD$) (average percent correct) (12 items)	Post-test ($M \pm SD$) (average percent correct) (17 items)
Second Grade (N = 16)	5.1 ± 6.2 30%	7 ± 3.8 58%	13.5 ± 2.8 79%
Fifth Grade (n = 17)	7 ± 3.9 41%	6.9 ± 2.8 58%	11.8 ± 3.8 69%

Students' Interpretation of the Minus Sign

We explored how student's interpretation of the minus sign might support the significant difference between the two grade level gains. We, therefore, investigated students' responses to six integer addition problems common to the three tests. Students' percentage correct on each problem was calculated for each group (see Table 2). On average, fifth-grade students performed better than second graders on four of the six common integer addition problems (67%) on the pretest, while second graders scored higher on all posttest common items (with one tie).

Table 2: Students' Average Percent Correct on Common Integer Addition Problems

Common integer addition		-9 + 2	-8 + 8	9 + -9	6 + -8	-1 + -7	-2 + -2
Second Grade	Pretest	38%	38%	19%	19%	31%	25%
	Mid test	44%	75%	44%	56%	81%	75%
	Post test	75%	94%	94%	69%	88%	69%
Fifth Grade	Pretest	12%	29%	41%	29%	71%	59%
	Mid test	35%	41%	47%	29%	88%	82%
	Post test	65%	82%	82%	65%	88%	47%

Note: Shaded cells indicate questions where that grade level did better than the other.

Fifth graders' pretest. Fifth graders frequently gave answers consistent with a strategy of adding a negative sign to the sum of two integers' absolute values. If students only used this strategy on the problems where it would lead to correct answers, we would expect them to use it roughly 29% of the time. Among all of the 17 integer addition problems, they had these types of answers for 46% of the problems on average. Because of this, not only did fifth graders have a higher average performance on -1 + -7 and -2 + -2 compared to second graders on the pretest, but their average scores were the highest on these compared to the other problems (9 + -9, 6 + -8, -9 + 2, and -8 + 8) where that strategy would not work. A fifth-grader, Jennifer, in describing her answer said, "They're both negative[s], so it is going to be [a] negative."

Another consistent strategy applied by fifth graders was treating the negative sign as a subtraction sign, the binary meaning of the minus sign. Across the problems fifth graders provided answers consistent with subtracting one number from the other and getting positive answers for 19% of the 17 problems on average. In six cases, students provided answers illustrating the common misconception that you always subtract a smaller number from a bigger number (e.g., solving 4 + -5 = 1). Interpreting the minus sign as a subtraction sign could help them in solving 5 + -2 = 3, which 7 fifth graders did. However, only one of them also solved 7 + -3 = 4, because they were more inclined to add the numbers. Additionally, their tendency to subtract in the treatment of the negative numbers could not help them to correctly answer problems such as -9 + 2, for which counting up or down from the negative requires unary meaning of the minus sign.

Second graders' pretest. Unlike the fifth graders, second graders did not often provide answers consistent with adding a negative sign to the sum of two integers' absolute values in the problems.

Their answers only reflected this strategy on 9% of the 17 problems on average. Also, their answers were consistent with subtracting to get a positive number only 9% of the time on average as well, which seemed more likely when the negative was first, given their better performance on -8 + 8 versus 9 + -9. When solving 6 + -8, lower number of possible answers on using subtraction operation with integers (e.g., 6 + -8 = 2 or -2 or 0) suggest they applied the binary meaning of the minus sign less often. When solving 6 + -8, Sandra who answered two demonstrated a conception of starting with the larger absolute value, "I did eight, seven, six, five, four, three, two and that is how I got it, and negative, if negative plus a positive number, you go backward to the negative." However, Edward, a second grader used the binary meaning to get a negative answer, reasoning, "Because six minus eight is negative two [be]cause it has to go below zero," also demonstrating an awareness of the unary meaning given to his answer.

Starting at the negative number and counting up or down the other number (e.g., -9 + 2 counting up -8 and -7 or counting down -10 and -11) leverages the unary meaning of the minus sign. Second-grade students' slightly higher average scores on -9 + 2 are consistent with them interpreting negative numbers as corresponding to a point on the number line, the unary meaning of the minus sign. Tara explained her solution for -9 + 2, "So I counted on my fingers negative eight, negative seven, and it is negative seven." Timmy said, "If it is a negative number plus [a] regular number, it would be less of the negatives. So, negative nine plus two equals negative seven."

Midtest. Students' gains for the six problems on the midtest show their development in interpreting multiple meanings of the minus sign. Second graders still averaged higher for -9 + 2 and -8 + 8 compared to fifth graders. Interestingly, even though fifth graders started higher in 9 + -9 and 6 + -8 on the pretest, second graders had a higher average correct for 6 + -8 on the midtest. Fifth-grade students' responses appeared to be influenced by their prior knowledge and treating the minus sign with a symmetric meaning (answering -14). In fact, fifth-grade students' consistent responses over 12 integer addition problems illustrate they applied the symmetric meaning on average for 33% of problems; whereas, second graders did so for 26% on average.

Second graders' posttest**.** Both grades' highest average was in -8 + 8 and 9 + -9, which demonstrates the significance of the zero pairs introduction in the lesson. Tara said, "I know that negative nine plus nine equals zero because negative means below zero and it is nine below zero, so it would be just zero. [Be]cause it is nine more than the negative." Timmy described a zero pair problem, "If you have a negative number plus a normal number, it would be zero. If you have normal nine plus a negative nine, it would be zero."

Surprisingly, students' average scores were lower on -2 + -2 after the midtest. Since zero was the most usual incorrect answer, one explanation could be that they identified the two same numbers and a negative sign in the problem, associated it with the zero pairs problem, and answered zero. Another second-grade student, Anthony, said, "So, I looked at it and I thought it's zero for a second. But I thought that would be negative two plus two. So, I thought negative two plus negative two would be negative four." Based on their responses, they used the symmetric meaning 15% of the time on average.

Second graders' responses to 6 + -8 did not result in -14 anymore, which reveals that they abandoned the symmetric meaning of the minus sign for this problem and treated the negative sign in a way that could provide the correct answer (unary meaning starting at -8 or binary meaning instead). Tara's unary interpretation is exemplified, "So, I know that since that is a lower number [referring to 6] than this one [referring to 8], then the answer would be still in the negatives. So, I started at negative eight and went up six." Another student, Kathryn, who interpreted the negative sign with a binary meaning said, "I did six and took away eight." The researcher asked, "So, when you ran out of six, what happened after that?" She continued, "I got into the negatives." Also, students explained their responses with zero pairs. Anthony mentioned zero pairs when solving 6 + -8, "I noticed six plus eight is 14 but six plus negative eight, when we did the zero problems [zero pairs] if it was six plus negative six, he [gingerbread man] would be going up and then go down. So, I noticed that so I did it." Further, when they answered -9 + 2 = -11, it was not necessarily because they focused on a symmetric meaning of the minus sign. Anthony started at -9 and answered -11 stating, "So, it would be nine plus whatever. It is still be going up but if you do [plus] a negative, it would have to go down." This student started to understand integer addition as involving directional movements that can be both upward or downward but was still trying to make sense of how the direction interacted with the numbers.

Fifth graders' posttest. Fifth graders scored slightly lower on -8 + 8 and 9 + -9, often answering -16 or -18 respectively, either due to overuse of the symmetric meaning or using the unary meaning and moving in the wrong direction. Further, their responses to the problem 6 + -8 involved -14, unlike second graders. Similar to second graders, they scored lower on -2 + -2, often associated with overgeneralizing the zero pairs concept. Though both grades averaged the same in -1 + -7, fifth graders did not improve from the midtest. Overall, fifth graders' responses highlighted the symmetric meaning for an average of 30% of 17 integer problems. This compared to 15% average among second graders provides initial evidence that fifth-grade students' stronger prior conception limited their ability to make use of the contrasting cases and change their thinking based on the instruction compared to the second graders.

Discussion

Our results provide insights into students' interpretations of minus signs and solution strategies for integer addition problems before and after making comparisons between them. Similar to the results of the fifth graders presented here, Murray (1985) found that adding two negatives was easy for upper elementary students compared to other integer addition problems. The results here suggest that this may be due to older students' tendency to focus on the symmetric meaning of the minus sign. Given this, one interpretation of our data is that if students naturally focus on the symmetric meaning and this interpretation persists without challenge (as could be the case with the fifth graders who relied on the symmetric interpretation heavily), they have more difficulty shifting away from it. Therefore, the second graders may have been more open to changing their conceptions about numbers, minus signs, and operations because they had not had much prior opportunity to think about them and establish strong initial conceptions. The data shows fifth graders' stronger prior conception about the negative sign influenced their future reasoning; however, second graders changed their interpretation of the minus sign throughout the study. Their willingness to apply the new information in their solution strategies helped them to improve higher.

Students experience a barrier to learning negative numbers when they have time to establish strong preconceptions without the opportunity to address them, a problem exacerbated by the location of integer standards in upper grades. In order to overcome students' difficulties in conceptualizing the negative numbers, we should provide opportunities for them to develop their integer number sense knowledge from at least second grade. Contrasting problem types (Rittle-Johnson & Star, 2009) using different conceptual models (Tsang, Blair, Bofferding, & Schwartz, 2015; Wessman-Enzinger & Mooney, 2014) helped students to improve their understanding. By capturing students' reasoning, discoveries, and interpretation through these activities, we can provide additional tasks more in-line with their needs to facilitate their learning and exploration process (Behrend & Mohs, 2005/6) throughout the following grade levels.

En este documento se describen características del objeto mental fracción de estudiantes, de 12 a 14 años de edad, de una secundaria pública, quienes tienen problemas de absentismo escolar y bajo rendimiento académico. Para ello, se diseñó un cuestionario como parte de un proyecto de investigación cuyo objetivo general es contribuir a la construcción de mejores objetos mentales fracción a través de una secuencia de enseñanza. El diseño de los ítems del cuestionario está estructurado de acuerdo con los resultados de una fenomenología didáctica de las fracciones y el contenido curricular propuesto para los últimos años de primaria. Los resultados indican que los alumnos tienen mayor éxito al responder cuestiones relacionadas con fenómenos de partición de figuras geométricas, mientras que tienen menor éxito para usar las fracciones en la recta numérica.

Palabras clave: Números Racionales, Educación Primaria, Cognición

Planteamiento del Problema y Objetivos

La enseñanza y el aprendizaje de las fracciones siguen siendo tema de interés en el campo de la investigación en matemática educativa, pese a la gran cantidad de estudios que ya se han hecho durante las últimas décadas. Algunas de las principales razones de esa preocupación se vinculan con el hecho de que las fracciones forman parte integral del curriculum matemático y porque de acuerdo con Siegler, Duncan, Davis-Kean et al. (2012) el conocimiento de esos números es uno de los predictores del desempeño en matemáticas de alumnos egresados de primaria hasta el bachillerato. Los resultados de investigaciones recientes versan sobre dificultades que los estudiantes siguen enfrentando cuando resuelven tareas o problemas que implican el uso de las fracciones (ver por ejemplo a Ni y Zhou, 2010 y Petit, Laird y Marsden, 2010) a pesar de los cambios que se han instrumentado en su enseñanza.

Por lo anterior se pretende contribuir a la construcción de un mejor objeto mental fracción de los estudiantes a partir de la educación básica. Los resultados que se exponen en este documento son de un estudio piloto hecho con el propósito de caracterizar el objeto mental fracción de los estudiantes con problemas de bajo desempeño escolar al finalizar la escuela primaria. El estudio piloto forma parte de una investigación más amplia y esos resultados se toman en consideración al estructurar un modelo de enseñanza con el cual se favorezcan procesos de construcción de mejores objetos mentales fracción de alumnos de ese tipo de comunidades.

Referente Teórico

Para el desarrollo de la investigación general se tomó como marco teórico y metodológico a los Modelos Teóricos Locales (MTLs) desarrollados por Filloy, Rojano, Puig y Rubio (1999), en donde el objeto de estudio es visto desde la interrelación de cuatro componentes que se construyen, el componente de competencia formal, el de enseñanza, el de cognición y el de comunicación.

En esta parte del proyecto se pone énfasis en los resultados de la construcción de los componentes formal y de enseñanza, ya que esas conclusiones se usaron principalmente para diseñar los ítems del cuestionario aplicado. Los resultados de la construcción del componente formal sirven como referente teórico para considerar en el diseño distintos fenómenos en los cuales aparecen las fracciones, mientras que los resultados del componente de enseñanza permiten seleccionar los contenidos de las fracciones que se evalúan en el cuestionario.

Para la construcción del componente formal del MTL se realizó una fenomenología didáctica de las fracciones, tomando como base las ideas de Freudenthal (1983), Kieren (1976; 1988; 1992) y Behr, Harel, Post, y Lesh (1992). De acuerdo con Freudenthal (1983, pp. 28-33), hacer una fenomenología es describir un concepto en su relación con los fenómenos para los cuales es el medio de organización. Una fenomenología didáctica rica ayuda a proveer a los estudiantes de una amplia variedad de ejemplos de fenómenos para construir mejores objetos mentales, entendiendo a un objeto mental como el conjunto de ideas sobre un concepto matemático (el objeto pensado) que han elaborado los alumnos y que precede a la adquisición del concepto.

Para hacer la fenomenología didáctica de las fracciones se han considerado fenómenos de las fracciones que aparecen tanto en el lenguaje cotidiano, como en la propia matemática. Las fracciones en el lenguaje cotidiano se utilizan principalmente para describir o comparar cantidades, valores de magnitud, razones o procesos cíclicos o periódicos. Los aspectos de las fracciones que se distinguen son: la fracción como fracturador, como comparador, como operador, como medidora y como número racional, ver Figura 1.

La fracción como fracturador se refiere al proceso de producir fracciones (fracturar), por medio del cual se relacionan las partes con un todo. Esto podría surgir de hacer una partición para hacer un reparto equitativo, una distribución o simplemente dividir cantidades o magnitudes con o sin resto. En el proceso de producir fracciones a partir de la relación de un todo y sus partes, el todo puede ser discreto o continuo, definido o indefinido, estructurado o carente de estructura. La parte también tiene sus variantes, mismas que se detallan en la Figura 1.

Según Freudenthal (1983) las fracciones también surgen de una comparación, la cual puede ser directa o indirecta. Cuando la comparación es directa, es decir, los objetos que se comparan se consideran o piensan como si uno fuera parte del otro, entonces esto se reduce a la fracción como fracturador. En cambio, cuando un tercer objeto media entre los objetos que se comparan, entonces la comparación es indirecta. En este último caso se establece una relación razón entre los valores de magnitud o entre los propios objetos que se comparan. En el proceso de establecer la relación razón se utiliza la fracción como medidora, ya que se puede emplear una medida no convencional o convencional para determinar valores de magnitud y así establecer la relación razón entre ambos objetos. La fracción como medidora surge también en la medición de segmentos sobre la recta numérica o como un valor que precede a una unidad de medida. Es importante mencionar que para identificar las fracciones que preceden a una unidad de medida, en el proceso fue necesario usar las fracciones en su aspecto de operador fracturante.

Se puede distinguir otro aspecto de la fracción, la fracción como operador, considerado como el inverso del operador multiplicación, es decir, el operador fracción actúa en el puro dominio del número. Se extiende esta fenomenología a un ámbito más abstracto y formal de la matemática, donde se identifica a las fracciones como elementos de clases de equivalencias del campo de cocientes que define al conjunto de los números racionales y sus propiedades.

Una explicación complementaria de los diversos aspectos de las fracciones se encuentra en Valenzuela, Figueras, Arnau y Gutiérrez-Soto (2016).

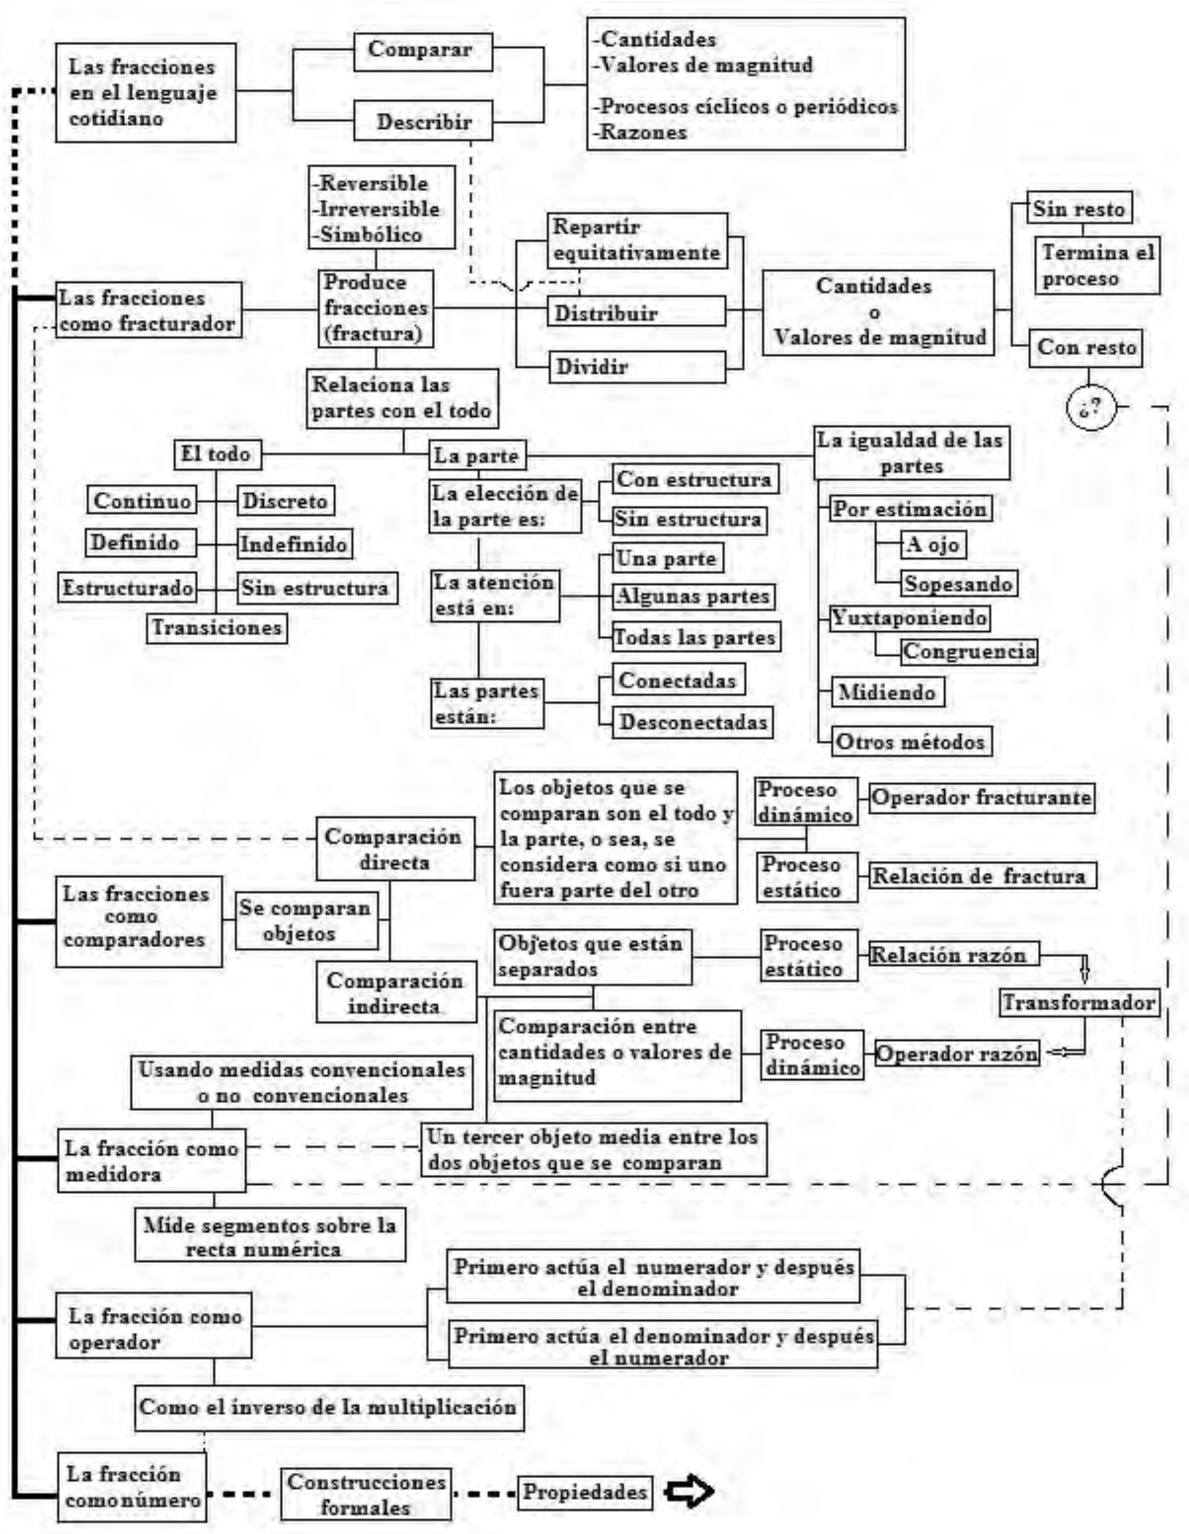

Figura 1. Usos y aspectos de las fracciones.

Diseño del Cuestionario

El cuestionario tiene seis ítems. El ítem uno está compuesto por ocho incisos, en los que se muestra en una representación de una fracción usando figuras geométricas para que el alumno escriba de forma simbólica la fracción correspondiente. En este ítem la fracción aparece como fracturador, específicamente se debe establecer una relación de fractura.

- En los incisos (a) y (c) el todo es continuo, definido y estructurado. Las partes están conectadas, su igualdad se determina por congruencia de áreas y la elección de las partes (coloreadas) es contigua. El inciso (d) cumple con estas condiciones excepto que la elección de las partes (partes coloreadas) no es contigua. Como el todo aparece partido en partes iguales se dice que se establece una relación de fractura. En el inciso (a) el todo es un rectángulo y en los incisos (c) y (d) círculos representan el todo.
- En los incisos (b), (e), (f) y (h) el todo es continuo, definido y estructurado. Las partes están conectadas, pero se definen dos unidades fraccionarias, el alumno debe completar o imaginar una partición con una unidad fraccionaria menor, por lo que la fracción podría actuar como un operador fracturante. En el inciso (h) la congruencia de las partes no es fácil de identificar. En los incisos (b) y (h) el todo está representado por cuadrados y en los incisos (e) y (f) por círculos.
- La representación del inciso (g) puede generar una transición de un todo continuo a uno discreto o viceversa, lo que puede causar una fracción propia o impropia, depende de cómo se interprete al todo.

El ítem dos tiene cuatro incisos, en cada uno se muestra una figura geométrica para que el alumno represente una fracción dada. En este caso, como los alumnos son quienes hacen la partición, la fracción aparece como un operador fracturante.

En el ítem tres se presentan dos situaciones con dos incisos cada uno, en los que aparece un todo discreto (bolas de colores), definido y estructurado de acuerdo con el color de las bolas. En el inciso (a) de cada situación se debe identificar la relación de fractura, mientras que en los incisos (b) es necesario comparar la cantidad de bolas de un color con respecto a la del otro color, por lo que la fracción aparece como una relación razón.

Sobre la recta numérica se deben representar 10 fracciones, ya sea como punto o como segmentos sobre la recta numérica; esta tarea constituye el ítem cuatro. Cinco fracciones son propias y cinco impropias; todas son menores que tres. Se han propuesto fracciones con denominadores distintos para que el alumno haga distintas particiones “a ojo”. En este ítem la fracción aparece como número en la recta numérica, pero también como medidora, se puede considerar como una unidad de medida de los segmentos sobre la recta numérica, que depende del número de partes entre las que se divide el segmento unidad, en este proceso la fracción aparece también como fracturador.

Para responder el ítem cinco los alumnos deben hacer una clasificación de fracciones propias e impropias, incisos (d) y (e) respectivamente. En los incisos (a) y (b) se piden dos ejemplos de fracciones ubicadas en un intervalo limitado por números enteros, (0,1) y (3,4) respectivamente, y en el inciso (c) el intervalo queda limitado por dos fracciones (7/8, 8/9).

El ítem seis corresponde a la resolución de un problema en el que aparecen distintos aspectos de las fracciones. En este caso la fracción se usa para describir una cantidad, como fracturador, comparador y como operador.

Población y Método

El estudio piloto se llevó a cabo con estudiantes de un instituto público de educación secundaria que se ubica en la ciudad de Valencia, España. 35 alumnos respondieron el cuestionario, 23 de ellos son de primer año y 12 de segundo, pero estos últimos asisten a un taller de regularización donde se trabajan contenidos matemáticos de primer curso. El rendimiento académico de todos los alumnos se considera bajo, de acuerdo con los criterios de evaluación que sigue el profesor de matemáticas. Además, los estudiantes tienen graves problemas de absentismo escolar.

El cuestionario se aplicó a los alumnos de primer grado de secundaria en dos sesiones de 45 minutos, los estudiantes de segundo grado lo resolvieron en una sesión. El cuestionario fue aplicado por el profesor del curso, se resolvió de manera individual y no se proporcionó ayuda.

Para realizar la caracterización de los objetos mentales de los estudiantes se han codificado las respuestas. Las correctas se han etiquetado con un 1 y las incorrectas con 0, en esta última categoría se han incluido aquellas respuestas que los estudiantes dejaron en blanco. Los resultados están organizados por cada ítem de acuerdo con las características del diseño, y también se organizan en una tabla de frecuencias en la cual se indica el porcentaje de éxito.

Resultados

Los resultados generales que se muestran en la Tabla 1 indican que los alumnos tienen mayor éxito al responder cuestiones que se relacionan con la representación simbólica de fracciones a partir de una representación gráfica, considerando modelos continuos y definidos (aspectos evaluados por medio del ítem 1). Los educandos tienen menor éxito para identificar fracciones entre dos números y clasificar fracciones como propias o impropias (aspectos evaluados mediante el ítem 5), así como para representar fracciones como puntos o segmentos en la recta numérica (aspectos evaluados a través del ítem 4). Se observa un descenso porcentual en cuanto al éxito obtenido que va del 58.21% en el ítem 1 hasta el 5.71% en el ítem 4.

Tabla 1: Resultados Globales por Ítem

Ítem 1	Ítem 2	Ítem 3	Ítem 4	Ítem 5	Ítem 6
163/280	54/140	48/140	20/350	16/175	19/140
58.21%	38.57%	34.29%	5.71%	9.14%	13.57%

Como se describió en el diseño del cuestionario, los ítems están formados por varios incisos, por esta razón varía el número de reactivos que se evalúan por ítem. Los resultados obtenidos para el ítem 1 se muestran en la Tabla 2. La información está organizada de acuerdo con las características del aspecto de la fracción como fracturador que se consideraron en el diseño del cuestionario.

Tabla 2: Resultados del Ítem Uno

<table>
<tr><td colspan="8">Representación simbólica de fracciones a partir de una representación gráfica
(Modelos continuos)</td></tr>
<tr><td colspan="7">Fracciones propias</td><td>Fracciones impropias</td></tr>
<tr><td colspan="3">Una unidad fraccionaria</td><td colspan="4">Dos unidades fraccionarias</td><td>Una unidad fraccionaria</td></tr>

<tr><td>27/35</td><td>30/35</td><td>26/35</td><td>20/35</td><td>17/35</td><td>10/35</td><td>14/35</td><td>19/35</td></tr>
<tr><td>77.14%</td><td>85.71%</td><td>74.29%</td><td>57.14%</td><td>48.57%</td><td>28.57%</td><td>40.00%</td><td>54.29%</td></tr>
</table>

Los resultados indican que los alumnos tienen mayor éxito para establecer una relación de fractura en modelos continuos donde la partición tiene solo una unidad fraccionaria (incisos a, c y d), principalmente cuando se utilizan círculos (inciso c). Esto indica que el objeto mental de los estudiantes está más relacionado con este tipo de fenómenos, pero cuando se presentan fenómenos de partición donde hay dos unidades fraccionarias (incisos b, e, f y h) el porcentaje de éxito de respuestas correctas disminuye. Un error común que cometieron los estudiantes al responder el inciso (f) que evalúa este aspecto, está relacionado con el conteo de partes sin tener en cuenta la congruencia del área de las partes. Un ejemplo se muestra en la Figura 2.

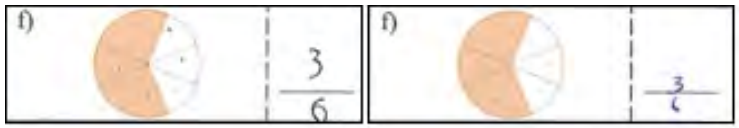

Figura 2. Respuestas de dos alumnos donde se desatiende la congruencia de las partes.

En la Figura 2 se observa el rastro de puntos que dejaron los estudiantes con el bolígrafo, lo que indica el conteo de las partes sin tomar en cuenta la congruencia. Otro error cometido al responder este inciso es el cambio de numerador por el denominador al momento de establecer la relación de fractura.

En la Tabla 1 se observa un descenso porcentual entre el ítem uno y el ítem dos de aproximadamente el 20% de éxito en las respuestas dadas por los alumnos. Esto indica que los fenómenos donde se usa la fracción como un operador fracturante requieren ser considerados en la enseñanza, particularmente cuando se tiene que representar una fracción impropia y se usan figuras geométricas menos usuales. Esto ayudaría a construir un mejor objeto mental fracción.

Los modelos discretos donde se usa la fracción como fracturador y como comparador, específicamente como una relación razón, fueron evaluados en el ítem tres y sus resultados se muestran en la Tabla 3. Con respecto a los ítems anteriores también se observa un descenso porcentual en el número de respuestas correctas. Se afirma que el objeto mental de los estudiantes está vinculado con los fenómenos donde se relaciona la parte con el todo, tanto en modelos continuos como discretos. Sin embargo, se requiere proponer para la enseñanza, más problemas donde la fracción actúe como comparador, ya que para resolver problemas relacionados con este tipo de fenómenos hay un porcentaje de éxito bajo.

Tabla 3: Resultados del Ítem Tres

Representación simbólica de fracciones a partir de una representación gráfica (modelos discretos)			
Distractor: estructurada respecto al tamaño (caja 1)		Distractor: no estructurada respecto al tamaño (caja 2)	
Fracturador	Comparador	Fracturador	Comparador
a)	b)	c)	d)
21/35	4/35	21/35	2/35
60.00%	11.43%	60.00%	5.71%

Representar fracciones en la recta numérica fue el ítem con menos éxito, ya que sólo 20 de 350 posibles respuestas fueron correctas. Las fracciones que se tenían que representar se muestran en la tercera fila de la Tabla 4.

La fracción 7/3 es la que pudieron representar correctamente más estudiantes, después 1/4 y 6/5. El hecho de que nadie haya representado correctamente la fracción 4/8 permite suponer que el objeto mental de los alumnos no les permite reconocer la equivalencia entre fracciones, porque incluso ningún alumno identificó que 2/12 y 1/6 son equivalentes.

Tabla 4: Resultados del Ítem Cuatro

Representación de fracciones en la recta numérica									
Fracciones propias					Fracciones impropias				
2/12	4/8	2/10	1/4	1/6	6/5	7/3	5/2	8/7	12/9
1/35	0/35	2/35	3/35	1/35	3/35	4/35	2/35	2/35	2/35
2.86%	0%	5.71%	8.57%	2.86%	8.57%	11.43%	5.71%	5.71%	5.71%

Uno de los errores comunes al resolver este ítem, se refiere al hecho de ubicar las fracciones en la recta numérica teniendo en cuenta solo el valor del numerador de la fracción pero sin hacer explícita una partición del segmento de recta, tal como se muestra en la Figura 3.

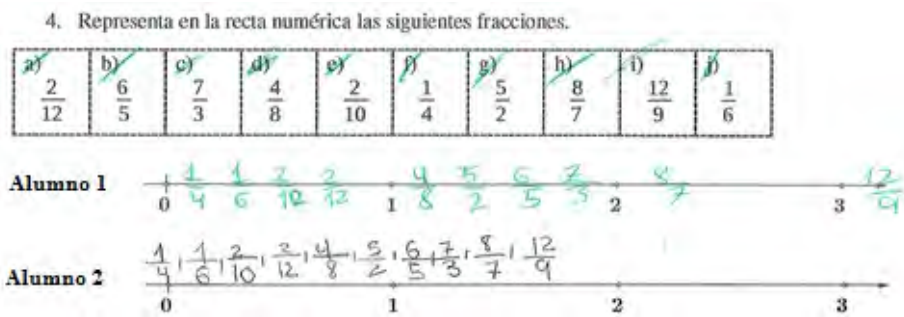

Figura 3. Representación de fracciones en la recta numérica.

Otro de los ítems de la prueba con menor porcentaje de éxito es el 5. En éste se evalúa la identificación de fracciones entre dos números enteros y entre dos fracciones, así como la clasificación de fracciones propias e impropias. Los resultados de esta evaluación permiten afirmar que los alumnos no reconocen características de las fracciones propias e impropias tomando en cuenta su relación con la unidad o la comparación entre numerador y denominador.

Los resultados de la evaluación del último ítem resultan de interés, ya que permiten confirmar que la resolución de problemas con datos numéricos en forma de fracción es otro tema en el cual los estudiantes tienen mayor dificultad.

De los resultados de los ítems propuestos en la prueba se puede afirmar que el objeto mental fracción de los estudiantes está vinculados principalmente con:

- Fenómenos de partición en donde el área de una figura geométrica, considerada como un todo continuo, definido y estructurado es dividido en partes iguales para establecer una relación de fractura, donde la igualdad de las partes se determina por congruencia de áreas. Pero cuando hay dos unidades fraccionarias los alumnos enfrentan dificultades.
- Otros fenómenos menos usuales pero que también se manifiestan se refieren a la división de un todo discreto para establecer una relación de fractura.
- Fenómenos de partición de un todo continuo y definido, donde la fracción actúa como operador fracturante, la elección de las partes es contigua y su igualdad se estima a ojo. Cuando hay variaciones en la estructura del todo los estudiantes enfrentan dificultades.

Conclusiones

Los resultados generales del test previenen que los estudiantes que participaron en la aplicación del cuestionario tienen un objeto mental fracción limitado, por lo que se requiere ofrecer una gama de actividades que promuevan la construcción de mejores objetos mentales, partiendo de fenómenos relacionados con los diferentes usos y aspectos de las fracciones que se ilustran en la Figura 1, y no limitarse a uno solo de sus aspectos durante la enseñanza de las fracciones. Ya que se hace notar que los estudiantes no transfieren de manera natural los conocimientos que tienen sobre un determinado aspecto de la fracción a otro. Por ejemplo, de fenómenos de partición donde se emplean modelos continuos como círculos o rectángulos no pueden pasar a una partición de segmentos en la recta para ubicar fracciones.

Aunado a lo anterior, se considera importante proponer actividades donde se aprovechen cada una de las particularidades que se detallan en el espécimen de fenomenología didáctica esbozado en este documento. Ya que a pesar de que los alumnos tienen objetos mentales sólidos relacionados con la fracción como fracturador, cuando se varía un poco para tomar en cuenta algunas particularidades, se observa que los estudiantes enfrentan dificultades. Respecto a los aspectos de la fracción como comparador, medidora, operador y número racional que se evaluaron en la prueba, los estudiantes mostraron un uso restringido de su conocimiento.

Los resultados también confirman que pese a que en el currículo de los últimos años de la educación primaria se propone explícitamente el estudio de las fracciones utilizando la recta numérica como recurso didáctico, así como el estudio de las características de las fracciones propias e impropias, los alumnos tienen poco éxito para resolver este tipo de tareas. Este resultado se atribuye al hecho de que estos aprendices han sido instruidos principalmente bajo el uso del modelo de áreas, ya que a pesar de que son alumnos de bajo rendimiento académico, mostraron tener conocimientos sólidos para representar fracciones propias cuando se usa dicho modelo, principalmente cuando se usan círculos o rectángulos.

In this paper characterizations of mental objects for fractions of middle school students (from 12 to 14 years old) with absenteeism problems and low academic performance, are described. A test was designed as part of a research whose general purpose is to contribute in the building up of better *mental objects for fractions through a teaching sequence. Items for the test were structured according to the results of a didactic phenomenology of fractions and the curricular content proposed for the last years of elementary school. Results indicate that students have a greater success in issues related to continuous model partitions phenomena, whereas they are less successful using fractions on the number line. Students cannot transfer their knowledge from an area model to a linear model to identify or represent fractions.*

Problem Approach and Research Objectives

Teaching and learning of fractions continue to be a subject of interest within mathematics education research. The main reasons behind this concern are that fractions are an integral part of mathematics' curriculum, and according to Siegler, Duncan, Davis-Kean et al. (2012), fractions' knowledge has been characterized as one of the predictors of students' mathematics performance from secondary to higher education. Other research findings show difficulties that students face when solving tasks or problems involving the use of fractions (e.g., Ni & Zhou, 2010; Petit, Laird & Marsden, 2010) even though changes have been made in their teaching.

With this research, we want to contribute to the building up of a better mental object for fractions of students from primary education. The results presented in this document are from a pilot study done with the purpose of characterizing the mental object for fractions of students with low performance at the end of primary school. The pilot study is part of a broader research and these results are taken into account when structuring a teaching model that favor processes to constitute better mental objects for fractions of this type of students.

Theoretical Framework

For the development of the general research, Local Theoretical Models (LTMs) developed by Filloy, Rojano, Puig & Rubio (1999) were used as a theoretical and methodological framework. From the theoretical point of view, the LTMs serve to focus on the object of study through four interrelated components: formal competence models, teaching models, models for cognitive processes, and models of communication.

In this part of the research project, the emphasis is put on the results of the construction of the formal and the teaching models components. These results were mainly used to design the items that were evaluated in the test. Results of the building up of the formal component serve as a theoretical reference in designing the test in order to evaluate tasks related to different phenomena where fractions appear. Results of the teaching component construction enable the choice of specific fractions' contents evaluated in the test.

For the construction of the formal component of the LTM a didactic phenomenology of fractions was made, based on ideas of Freudenthal (1983), Kieren (1976; 1988; 1992) and Behr, Harel, Post & Lesh (1992). According to Freudenthal (1983, pp. 28-33), to make a phenomenology is to describe a concept in its relation to the phenomena for which it is a means of organization. A rich didactic phenomenology helps to provide students with a wide variety of examples of phenomena to constitute better mental objects, understanding a mental object as the set of ideas about a mathematical concept (the thought object) that the students have elaborated and which precedes concept attainment.

To carry out the didactic phenomenology of the fractions, phenomena that appear both in everyday language and in mathematics itself were considered. Fractions in everyday language are mainly used to describe or compare quantities, magnitude, ratios, and cyclic or periodic processes. Other aspects distinguished are: fraction as a fracturer, fraction as a comparer, fraction as an operator; fraction as a measurer, and fraction as a rational number, see Figure 1.

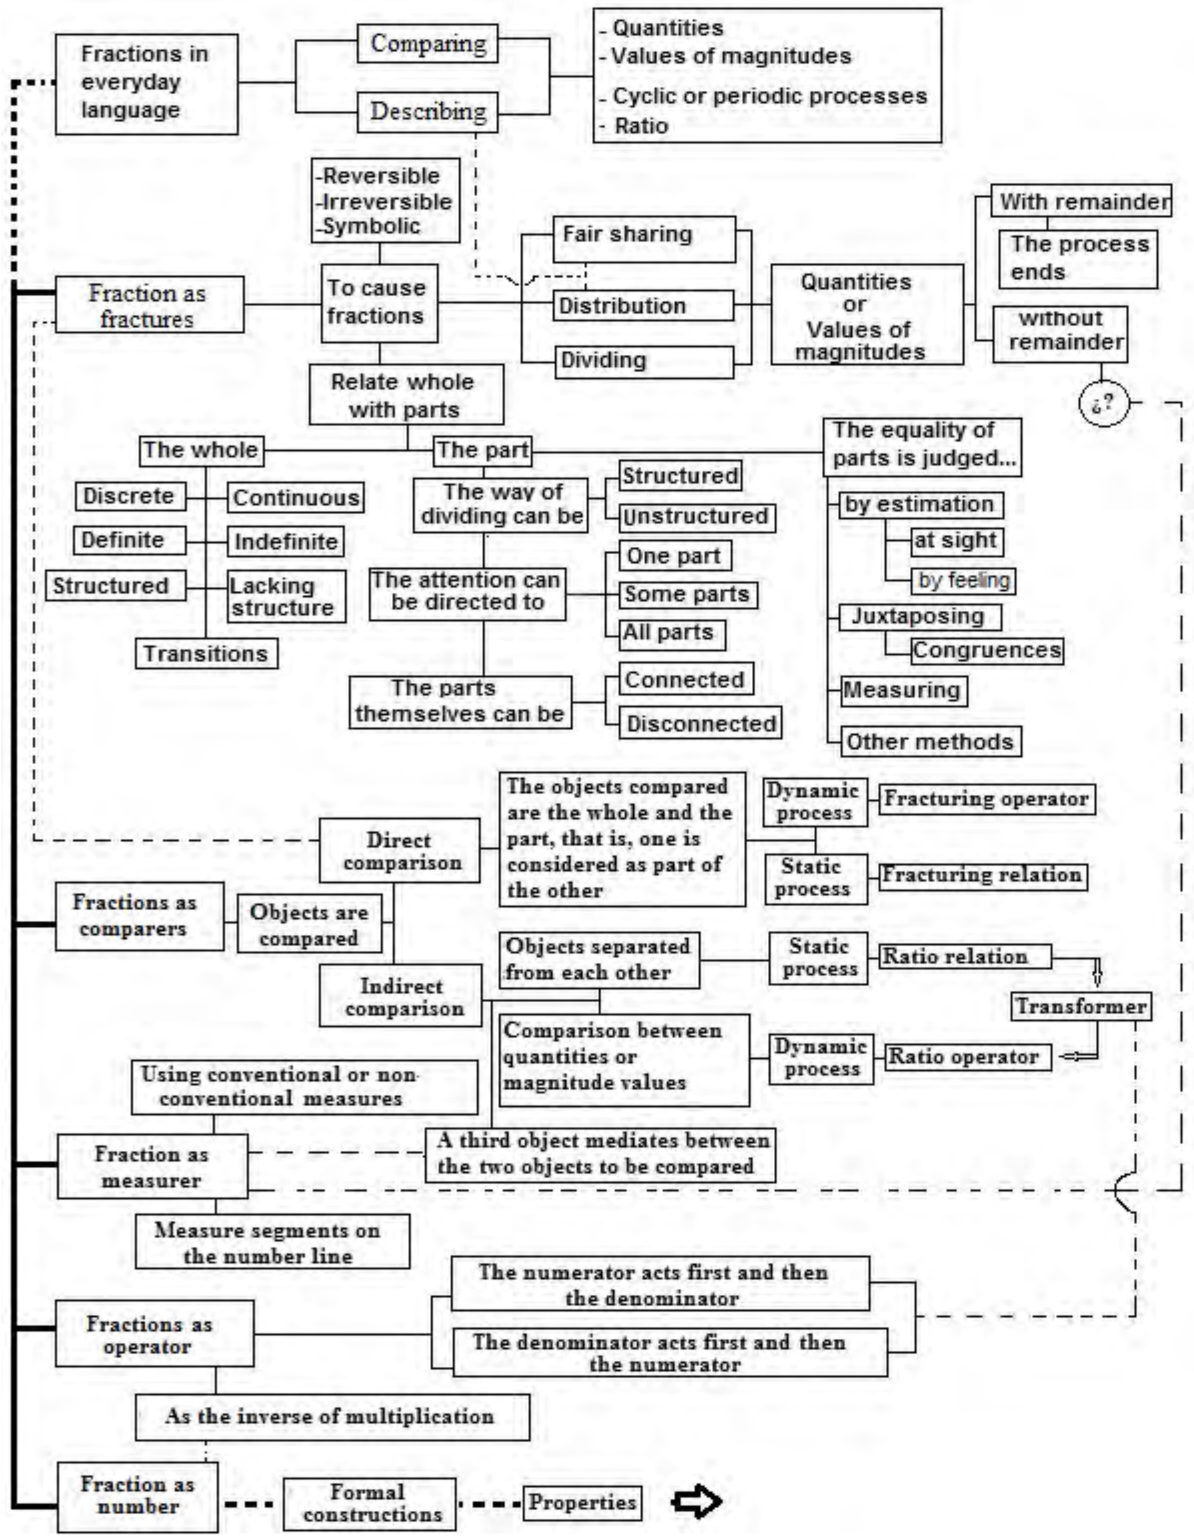

Figure 1. Uses and aspects of fractions.

Fraction as a fracturer refers to the process of producing fractions (fracturing), through which parts are related with a whole. This could arise from making a partition to make a fair sharing, a distribution or simply dividing quantities or values of magnitude with or without remainder. In the process of producing fractions in order to relate a whole with its parts, the whole can be discrete or continuous, definite or indefinite, structured or without structure. Parts also have its variants, which are detailed in Figure 1.

According to Freudenthal (1983) fractions also arise from a comparison, which may be direct or indirect. The comparison is direct when the objects being compared are considered or thought as one part of the other, in this case, the comparison is reduced to the aspect of fractions as a fracturer. In contrast, when a third object mediates between the objects being compared, an indirect comparison is carried out. In the latter case, a ratio relation between the values of magnitude or the objects that are being compared is established.

In the process of establishing the ratio relation, fractions are used as a measurer, because an unconventional or conventional measure can be used to determine magnitude values and establish the ratio relation between both objects. The fraction as measurer also arises in the measurement of segments on the number line or as a value that precedes a unit of measurement. It is important to mention that in order to identify the fractions that precede a magnitude value, in the process, it was necessary to use other aspects of fractions, for example as fracturing operator.

Another aspect of fractions can be distinguished: fraction as an operator. This aspect can be used as a fracturing operator, a ratio operator, and as a fraction operator. The last aspect is considered as the inverse of the multiplication operator, i.e, the fraction operator acts in the number's domain. This phenomenology can be extended to a more abstract and formal area of mathematics, where fractions are identified as elements of equivalence classes of the quotient field that defines the set of rational numbers and their properties.

A complementary explanation of the various aspects of fractions can be find in Valenzuela, Figueras, Arnau & Gutiérrez-Soto (2016).

Test Design

The test has six items. Item one has eight subsections. In each one a representation of a fraction is shown on a geometric figure in order that students write the corresponding fraction in a symbolic form. In this item the fraction appears as a fracturer, specifically, a fracturing relation must be established.

- In subsections (a) and (c) the whole is continuous, defined and structured. Parts are connected, their equality is determined by congruence of areas and the choice of the parts is contiguous. Subsection (d) has these characteristics except that the choice of parts (colored parts) is not contiguous. As the whole appears fractured in equal parts, a fracturing relation must be established. In subsection (a) a rectangle is use to represent the whole and in subsections (c) and (d) circles are chosen as wholes.
- Subsections (b), (e), (f) and (h) contain a continuous, defined, and structured whole. Parts are connected, but two fractional units are defined. Students must partition the whole or imagine a partition with only one fractional unit, so the fraction could act as a fracturing operator. In subsection (h) congruence of parts is not easy to identify. In subsections (b) and (h) squares represent wholes, and in subsections (e) and (f) circles are wholes.
- The graphical representation in subsection (g) can generate a transition from a continuous whole to a discrete one or vice versa, which can cause a proper or an improper fraction, depending on how the student interprets the whole.

The second item consists of four subsections. In each one, a geometric figure is shown so that students represent a given fraction. In this case, students produce a partition of the whole; for this reason, the fraction appears as a fracturing operator.

Two situations with two subsections are presented in item three, where a discrete whole (colored balls), defined, and structured according to the balls' colors is represented. In subsection (a) of each situation, the fracturing relation must be identified, while in subsection (b) it is necessary to compare the number of balls of one color with the number of balls of the other color, so that the fraction appears as comparer, specifically to identify a ratio relation.

In item four, ten fractions should be represented as a point or as segments on the number line. Five are proper fraction and the rest improper fractions. All of the fractions are less than three. Fractions with different denominators have been proposed to students to make different partitions "at sight". In this item, the fraction appears as a number on the number line, but also as a measure. It can be considered as a unit of measure of the number line segments that depends on the number of parts in which the unit segment is divided. In this process, the fraction also appears as a fracturing operator.

To answer the item five, students must make a classification of proper and improper fractions, subsection (d) and (e), respectively. In subsections (a) and (b), two examples of fractions in an interval limited by integers, (0, 1) and (3, 4) respectively, are requested, and in subsection (c) the interval is limited by two fractions (7/8, 8/9).

Item six is a problem in which different aspects of fractions appear. In this case, fractions are used to describe an amount, as a fracturer, a comparer, and as operator.

Setting and Participants

The pilot study was carried out with middle school students in Valencia, Spain. 35 students answered the test, 23 of them were studying in seventh grade, and 12 in eighth grade. The latter attended a remedial workshop where they worked on seventh grade mathematical contents. According to the evaluation criteria followed by the mathematics teacher, the academic performance of all students was considered low. The students had serious truancy problems.

The questionnaire was applied in two sessions of 45 minutes for students in seventh grade. The eighth grade students completed the test in one session. The mathematics teacher applied the test and the students solved it individually; no help was provided.

To characterize the mental objects for fractions that students had, answers were codified, using "1" for correct ones, and "0" for incorrect ones. In this last category, answers left blank were included. Results were organized by each item according to the characteristics of the design and are also in a table of frequencies that indicates the percentage of success.

Results

The general results showed in Table 1 indicate that students are more successful when answering items related to the symbolic representation of fractions, from a graphical representation, considering continuous and defined models, for example, the area model. These results show that students can establish a fracturing relation when working with this kind of representations. Students are less successful in identifying fractions between two numbers and classify fractions as proper or improper (aspects evaluated in item 5), as well as to represent fractions as points on the number line (aspects evaluated through item 4). There is a decreasing percentage of the success obtained that goes from 58.21% in item 1 to 5.71% in item 4.

Table 1: General Results by Item

Item 1	Item 2	Item 3	Item 4	Item 5	Item 6
163/280	54/140	48/140	20/350	16/175	19/140
58.21%	38.57%	34.29%	5.71%	9.14%	13.57%

As described in the design of the questionnaire, test items consist of several subsections; for this reason, the number of answers evaluated per item varies. The results obtained for item 1 are shown in Table 2. The information is organized according to the characteristics of fractions as fracturer considered in the design of the test.

Table 2: Results of Item 1

Symbolic representation of fractions from a graphical representation (Continuous models)							
Proper fractions							Improper fractions
Defined Partition			Partially defined partition				Undefined partition
Choice of contiguous parts		Choice of no contiguous parts	Choice of contiguous parts				Choice of contiguous parts
a)	c)	d)	b)	e)	f)	h)	g)
27/35	30/35	26/35	20/35	17/35	10/35	14/35	19/35
77.14%	85.71%	74.29%	57.14%	48.57%	28.57%	40.0%	54.29%

Results reveal that students are more successful in establishing a fracturing relation in continuous models where the partition is defined (subsections a, c, and d), mainly when circles are used (subsection c). This indicates that the mental object that students have is related to this type of phenomena; but, when there are partition phenomena where the fractional unit is not completely defined (sections b, e, f, and h), the success of correct answers percentage decreases especially when two different fractional units are shown. A common mistake that students made when responding to subsection (f) is related to the counting of parts and to disregard the congruence of the area of the parts. An example of this is in Figure 2.

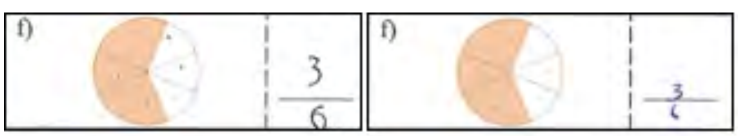

Figure 2. Answers from two students where the congruence of the parts is disregarded.

Figure 2 shows the trace of points that the students left with a pen, which indicates the counting of the parts carried out without considering the congruence of parts area. Another mistake that appears in this subsection is the change of the numerator by the denominator when establishing the fracturing relation.

There is a percentage decrease between items 1 and 2 of approximately 20% of success in the students' answers (see Table 1). The prior indicates that the tasks where the fraction is used as a fracturing operator need to be favored, in particular when an improper fraction has to be represented and when working with less common geometric figures, which would help to constitute a better mental object of the fraction.

The discrete models where the aspects of fractions as fracturer and comparator, specifically as a ratio relation, were evaluated in item 3 (see results in Table 3). In the previous items it is also observed a percentage decrease on the number of correct answers. Despite that the mental object students have is related to the phenomena where they establish a fracturing relation, in both, continuous and discrete models; however, it is necessary to propose more tasks for teaching, where the fraction acts as a comparator to solve problems related to this type of phenomena since there is a very low success rate of answers.

Table 3: Results of Item 3

Symbolic representation of fractions from a graphical representation (discrete models)			
Distractor: structured with respect to size of balls (box 1)		Distractor: non-structured with respect to size of balls (box 2)	
Fracturer	Comparator	Fracturer	Comparator
a)	b)	c)	d)
21/35	4/35	21/35	2/35
60.00%	11.43%	60.00%	5.71%

Representing fractions in the number line was the least successful item in the test since only 20 out of 350 possible answers were correct. The fractions to be represented are shown in the third row of Table 4. The fraction 7/3 was correctly represented by more students, then 1/4 and 6/5. The fact that no students had correctly represented fraction 4/8 allows supposing that the mental object students have does not allow them to recognize the fractions equivalence because no students identified that 2/12 and 1/6 are equivalent.

Table 4: Results of Item 4

Representation of fractions on the number line									
Proper fractions					Improper fractions				
2/12	4/8	2/10	1/4	1/6	6/5	7/3	5/2	8/7	12/9
1/35	0/35	2/35	3/35	1/35	3/35	4/35	2/35	2/35	2/35
2.86%	0%	5.71%	8.57%	2.86%	8.57%	11.43%	5.71%	5.71%	5.71%

One of the common errors in solving item 4, was locating the fractions in the number line taking into account only the numerator value of the fraction, but without making a partition of the line segment, as shown in Figure 3.

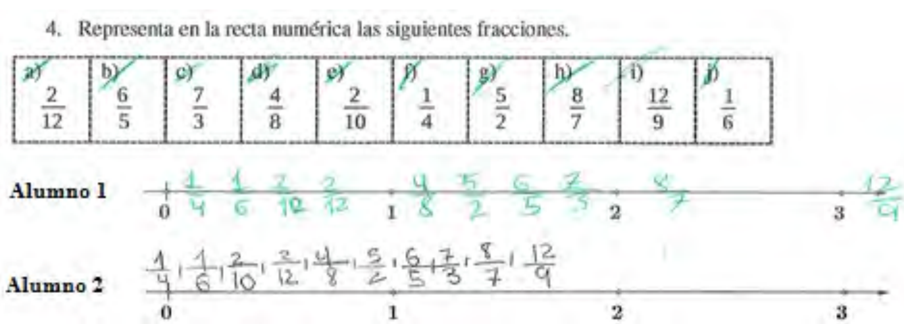

Figure 3. Representation of fractions on the number line.

Galindo, E., & Newton, J., (Eds.). (2017). *Proceedings of the 39th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* Indianapolis, IN: Hoosier Association of Mathematics Teacher Educators.

One of the other items with a lower percentage of success is item 5. The identification of fractions between two integers and two fractions, as well as the classification of proper and improper fractions, were evaluated. The results allow affirming that the students did not recognize characteristics of the proper and improper fractions taking into account their relation to the unit or the comparison between the numerator and denominator of the fraction.

The results of the last item's evaluation are interesting, those allow us confirming that the solving problem with numerical data in fraction form is another subject where students have greater difficulty since only 19 out of 140 possible answers were correct.

From the results of the items proposed in the test, it can be affirmed that the mental object fraction that students have is linked mainly to:

- Partition phenomena in which the area of a geometric figure, considered as a continuous, defined and structured whole, is divided into equal parts in order to establish a fracturing relation, and the equality of the parts is estimated by the congruence of areas. But, when the partition is not defined the students face difficulties.
- Other less usual but also manifest phenomena refer to the division of a discrete whole in order to establish a fracturing relation.
- Partition phenomena of a continuous and defined whole, where the fraction acts as a fracturing operator, the choice of the parts is contiguous and their equality is estimated "at sight". But, when there are variations in the structure or form of the whole, students face difficulties.

Conclusions

Students who participated in the test application have limited mental objects for fraction. It is necessary to offer a range of activities that will promote the construction of a better mental object; starting from phenomena related to different uses and aspects of the fractions illustrated in Figure 1, and not limited to only one of its aspects during the teaching of fractions. It is noted that students do not naturally transfer their knowledge about one particular aspect of the fraction to another one. For example, students' knowledge to solving problems related to partition phenomena where continuous models as circles or rectangles were used, do not use to make a segments partition on the number line in order to represent fractions.

In addition, it is considered important to propose activities that take advantage of each of the particularities that are detailed in the specimen of didactic phenomenology outlined in this paper. Although students showed solid mental objects related to the fraction as fracturer, it was observed that the students faced difficulties when the aspect of fracture takes account its particularities. Regarding the aspects of the fraction as comparator, measurer, operator, and rational numbers that were evaluated in the test, the students showed a very restricted use of knowledge.

The results also confirm that, although in the last years of elementary school curriculum it is explicitly proposed the study of fractions using the number line as a didactical resource, as well as the study of the characteristics of the proper and improper fractions, the students faced difficulties to solve these types of task. In fact, they did not show knowledge about it at all. This result is attributed to the fact that students have been instructed mainly under the use of the model area as a didactical resource. Although these students had low academic performance, they showed solid knowledge to represent their proper fractions when using this model, mainly when circles or rectangles were used.

In this study, we explore thirty-two second graders' performance on integer addition problems before and after analyzing contrasting cases involving integers. The students, as part of a larger study, completed a pretest, were randomly assigned to one of three intervention groups, and participated in two small-group sessions, one short whole-class lesson on integer addition, and a posttest. The group interventions differed in terms of which problems students compared in their small-group sessions. Based on students' solution strategies for integer addition problems and their treatment of negative signs, all three groups progressed in solving negative integer addition problems; however, students who initially contrasted adding two positives with adding a negative to a positive showed important differences, which we describe further.

Keywords: Number Concepts and Operations, Cognition, Elementary School Education

Providing students with early access to integer learning is important. Recent standards do not require students to learn integer concepts until sixth grade and integer operations until seventh grade (National Governors Association Center for Best Practices [NGA] & Council of Chief State School Officers [CCSSO], 2010); however, prior standards suggested that students should learn about integers as early as third grade (National Council of Teachers of Mathematics [NCTM], 2000). Moreover, current research indicates that young students can productively learn about and work with integers (e.g., Bishop, Lamb, Philipp, Schappelle, & Whitacre, 2011; Bofferding, 2014). Students who are unfamiliar with negative numbers or who over-rely on whole number concepts, will often ignore the negative signs when solving problems (e.g., $-4 + 5 = 9$) (Bofferding, 2010; Murray, 1985) or will encounter other obstacles (e.g., thinking addition always results in a larger number) (Bishop, Lamb, Philipp, Whitacre, Schappelle, & Lewis, 2014). Often, students develop incorrect and resistant conceptions, such as the belief that you cannot subtract a larger number from a smaller one (Murray, 1985). It is therefore important to help students notice early on, not only the differences between positive and negative numbers, but how they affect operations.

Contrasting cases can be a powerful instructional tool for helping students focus on important structural features in problems and give students access to new problems or solution methods. In a study on learning algebra equations, students who compared alternative solution methods gained more in procedural knowledge and flexibility than those studying multiple methods sequentially (Rittle-Johnson & Star, 2007). In a subsequent study, students with limited prior knowledge in algebra benefited more from comparing problem types than solution methods (Rittle-Johnson, Star, & Durkin, 2009). In one study, first graders noticed and made use of negative signs more if they were in an instructional condition where they compared problems with and without negative signs (Bofferding, 2014). A feature of the contrasting cases used in Rittle-Johnson and Star's (2007) work is that they involved worked examples, powerful tools for helping students learn new information (Atkinson, Derry, Renkl, & Wortham, 2000).

Some textbooks introduce negative integer addition by first presenting the case of adding two negative numbers (Hake, 2007; Pearson Education, 2014) and then contrasting it with adding two positive numbers through worked examples. Providing students with the opportunity to compare the addition of two positive numbers with that of adding two negative numbers may encourage them to notice that the numeral increases in magnitude just like with positive number addition but with a

Galindo, E., & Newton, J., (Eds.). (2017). *Proceedings of the 39th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* Indianapolis, IN: Hoosier Association of Mathematics Teacher Educators.

negative sign before the answer. This problem type tends to be one of the easiest for those recently exposed to negatives (Murray, 1985). However, if adding two negatives makes intuitive sense to students, having them see a different problem type first might provide a more productive contrast. Therefore, we investigated the following question: When learning integer addition, what role does the sequence of problem contrasts play in second graders' (a) integer addition performance and (b) the development of solution strategies?

Conceptual Change Framework

Students' initial mental models for number are based on whole number understanding. As students learn about new numbers, they make sense of them in light of their prior understanding (Vosniadou, Vamvakoussi, & Skopeliti, 2008). With negatives, this can lead to a series of transition and synthetic mental models based on how students interpret the order and value of negatives (Bofferding, 2014).

Interpretations of the Minus Sign

Successful integer contrasting cases should help students interpret and make use of the meanings of the minus sign in productive ways. There are three meanings that students might ascribe to the minus signs in arithmetic problems (binary, symmetric, or unary), which play "a major role in the development of understanding and using negative numbers" (Vlassis, 2004, p. 471). The binary interpretation of the minus sign corresponds to the subtraction operation (Vlassis, 2004). Students with only a binary understanding of minus signs might ignore negatives or treat them as subtraction signs (e.g., solving 6 + -8 as 6 – 8 = 0 or 8 – 6 = 2) (Bofferding, 2010). The symmetric or opposite meaning indicates an operation of multiplying by -1 (switching from positive to negative or negative to positive) (Vlassis, 2004). Students rely on the symmetric meaning when they add integers as positive and make the answer negative (e.g., solving -2 + 5 as 2 + 5 and answering -7) (Bofferding, 2010). The unary meaning of the minus sign is that of the negative sign, designating negative numbers. Students with a strong unary understanding will often start at a negative number and count, either solving -2 + 3 by counting incorrectly, "negative three, negative four, negative five," or correctly, "negative one, zero, one" (Bofferding, 2010), depending on their conceptions of addition and integer values. Those with a strong binary and weaker unary understanding may still solve 6 + -8 as 6 – 8 but actually get -2.

Interpretations of Addition

When students add with positive numbers, they learn that counting up corresponds to an increase in a number's magnitude (Vosniadou, Vamvakoussi, & Skopeliti, 2008). However with negative numbers, students need to learn that adding a positive number corresponds to moving right on the number line (or up); whereas, adding a negative number corresponds to moving left on the number line (or down) (Bofferding, 2014). Stranger still, they need to understand that adding a positive or negative could result in either an increase or decrease in magnitude from the initial number (e.g., with -3 + 1, the final answer -2 has a smaller magnitude than -3 but for 3 + 1, the final answer 4 has a larger magnitude than 3). In this paper, we discuss how students' pattern of responses on negative addition problems changed following opportunities to analyze different sets of contrasting problems.

Methods

Participants and Design

Participants included 32 second graders (from a larger study with 109 second graders) from two rural, elementary schools in the Midwest (where 32.2% of students were English-language learners and 75.2% qualified for free or reduced-lunch). These students were chosen because when solving the integer addition problems on the pretest, they consistently answered by adding the absolute values of the numbers, ignoring the negative signs (e.g., -4 + 6 = 10 or -1 + -7 = 8) and sometimes answering random positive numbers. After completing a pretest, students were randomly assigned to one of three intervention groups. Students in each group analyzed different sets of contrasting integer addition problems over two sessions, engaged in one integer addition lesson, and finished by taking a posttest.

Data Sources

Pretest and posttest. Although students answered a range of integer problems (e.g., ordering, comparing values, missing addend problems), we focus the present analysis on 14 integer addition problems that students solved on both the pretest and posttest (see Table 1). These were presented to students on one page in their regular classes, and students were asked to solve them as best as they could. Within a few days after students took the pretest, we interviewed 20% of the original sample to learn more about how they solved the problems.

Table 1: Arithmetic Problems Given on the Pretest, Posttest, and Midtest

Negative + Negative	Positive + Negative			Negative + Positive		
-6 + -4	5 + -2	4 + -5	9 + -9*	-5 + 5	-2 + 0	-4 + 6
-1 + -7*	6 + -8	7 + -3	0 + -9	-9 + 2*	-3 + 1	-1 + 8
-4 + -3**, -2 + -2**	4 + -6**	8 + -3**		-1 + 3**	-8 + 8**	

**Indicates a problem also given on the midtest; **Indicates a problem only given on the midtest*

Small-group sessions. As mentioned, students were divided into three intervention groups (sequential, intuitive, and conflicted). Of the 32 students who ignored all negative signs on the pretest, 11 students were from the sequential group, 12 were from the intuitive group, and 9 were from the conflicted group. When studying the contrasts, students worked in small groups of 2-3 students from their same intervention groups. Students in the *sequential group* analyzed each type of addition problem separately and in contrast to similar problems. Students in the *intuitive group* first compared adding two positive numbers versus adding two negative numbers, an intuitive contrast. Students in the *conflicted group* compared adding two positives with adding a negative to a positive in session one (we called this group conflicted because addition usually makes a larger number). During the second sessions, students analyzed the two other types of problems they did not see in their first session (see Table 2).

Each group saw their contrasts within four different illustrated contexts: an inclined number path situated on a hill, a vertical number line showing ants moving below and above ground, positive and negative chips, and a folding number line (see Tsang, Blair, Bofferding, & Schwartz, 2015). Students discussed and wrote about the similarities and differences between the problems and pictures; analyzed incorrect answers based on research of students' common misconceptions (e.g., ignoring the negative sign); and determined how to use the illustrations to correctly solve the problems. At the end of each session, students solved 6 integer addition problems related to the problem types they explore during that session for a total of 12 problems (9 with negatives) across the two session. We refer these collective problems as the midtest in the analysis and results (see Table 1).

Table 2: Problem Types that each Group Solved During their Two Small-Group Sessions

	Sequential Group	Intuitive Group	Conflicted Group
Session 1	P + P vs. P + P, then N + N vs. N + N	P + P vs. N + N	P + P vs. P + N
Example:	3 + 5 vs. 4 + 4, then -3 + -5 vs. -4 + -4	3 + 5 vs. -3 + -5	3 + 5 vs. 3 + -5
Session 2	N + P vs. N + P, then P + N vs. P + N	N + P vs. P + N	N + N vs. N + P
Example:	-7 + 2 vs. -6 + 1, then 7 + -2 vs. 6 + -1	-7 + 2 vs. 7+-2	-7 + -2 vs. -7 + 2

Note: N = negative integer, P = positive integer

Whole-class instruction. Students participated in a 30-minute lesson focused on solving addition problems using a number path. Adding a negative number corresponded to going down or getting more negative and adding a positive number corresponded to going up the number path or getting more positive, leading to the introduction of additive inverses or "zero pairs" (e.g., -2 + 2). Students then played a card game using one stack of "1" cards, one stack of "-1" cards, and a die, where the goal was to collect cards in order to make zero pairs.

Analysis

To analyze students' integer addition performance, we marked each addition problem as either correct or incorrect and conducted a median test (a nonparametric test used for small sample sizes) on the pretest-posttest gain scores across groups. We did not include midtest results in the median test because the midtest did not have completely identical items.

In order to look for qualitative changes in students' solution strategies, we classified students' solutions to the integer addition problems on the tests according to their treatment of the negative signs and strategies, relying primarily on their response patterns for each negative integer problem type (positive plus positive, positive plus negative, and negative plus positive) and supplemented by interview data. First, we identified students who correctly answered all problems and designated them as *all correct, unary meaning*. If they had one incorrect within a problem type, we identified the type based on the codes and included it with the *all correct* code. For example, all of the students discussed here provided answers on the pretest consistent with ignoring the negative signs and adding the two numerals (e.g., -6 + -4 = 10; 6 + -8 = 14). Given the stability of their response pattern, we considered these students to be using this strategy even if we did not interview them; in some cases we did have interview data to confirm it. On the midtest and posttest, students sometimes provided responses that could have been coded in more than one way (*adds negative sign* vs. *directional* or *subtraction (negative)* vs. *directional)*. In these cases, we used their other responses within the problem type to infer which strategy they used and checked them with the transcripts when available. For example, students could get -6+-4 correct by either knowing that adding a negative means moving to the left on the number line or by adding 6 + 4 and making it negative. If students used the *adds negative sign* strategy on their other problems consistently, we assigned the same code to -6 + -4 = -10 (see Table 3).

Table 3: Strategies Second Graders Used on the Integer Addition Problem Types.

Strategies	Explanation (coded within each problem type)	Example: -4 + 1
Adds Negative Sign[3]	Student answers problems by adding the absolute value of the numbers and then making the answer negative.	4 + 1 = 5, so -5
Subtraction[2] (positive)	Student uses the negative sign as a subtraction sign and gets positive answers.	4 – 1 = 3 or 1 – 4 = 0
Subtraction[2, 3] (negative)	Student uses the negative sign as a subtraction sign and gets negative answers (or makes answers negative).	1 – 4 = -3 or 4 – 1 = 3, so -3
Ignores Negatives	Student ignores the negative signs.	4 + 1 = 5
Negative as Zero[1/2]	Student treats negatives as equivalent to zero.	0 + 1 = 1 or 4 – 4 + 1 = 1
Positive	Student answers with random positive numbers.	-4 + 1 = 10
Negative	Student answers with random negative numbers.	-4 + 1 = -8
Directional[1]	Students' answers are consistent with starting at the negative number and counting up or down the absolute value of the other number but not in a reliable direction.	-4 + 1 = -5 but -9 + 2 = -7
(Deviation)	Deviations to one of the above codes were noted when students' answers to a certain problem did not follow the pattern of the rest of the problems. This occurred particularly with the additive inverse problems (*zero pair*) that were part of instruction, problems where they had to *add zero*, or if a student *skipped* a problem.	

Meaning of minus sign: 1 = unary, 2 = binary, 3 = symmetric

Results

Performance on Integer Addition Problems

Overall, students in the conflicted and intuitive groups spent about 20 minutes in each of their sessions. Students in the sequential group spent about 40 minutes in each of their sessions because each problem type was explored in sequence instead of in comparison to a different problem type. Because the students discussed here ignored negatives on the pretest, they all started with scores of zero. Students in the conflicting contrast group had the highest median gain score from pretest to posttest (11.0) compared to those in the sequential group (8.0) and the intuitive group (4.5), X^2=5.869, p=.053. The conflicted contrasting group had significantly higher median scores than the intuitive contrast group. There was no significant difference between the conflicted and sequential groups; however, the conflicted group made higher gains with an intervention that was half as long as the sequential group. Table 4 presents additional information about the groups' performance on the pretest and posttest, as well as on the midtest. Not only did the conflicted group have the greatest median increase from pretest to posttest, but they also had the greatest increase in mean percent correct from pretest to midtest, from midtest to posttest, and from pretest to posttest.

Table 4: Groups' Performance on the Pretest, Midtest, and Posttest Addition Problems

Group	**Pretest (14 items) Mean (SD); %**	**Midtest (9 items) Mean (SD); %**	**Posttest (14 items) Mean (SD); %**
Sequential (n=11)	0 (0); 0%	1.7 (1.8); 19%	7.0 (4.9); 50%
Intuitive (n=12)	0 (0); 0%	1.8 (1.9); 20%	5.6 (4.0); 40%
Conflicted (n=9)	0 (0); 0%	2.3 (2.1); 26%	9.4 (3.6); 67%

Table 5 shows an additional breakdown of the problems by problem type on the midtest and posttest. Recall that the sequential and intuitive groups solved the N+N problem type (N=negative integer) at the end of their first session while students in the conflicted group solved the P+N problem type (P=positive integer). Across the three problem types, 5 out of 11 (45%) sequential group students, 6 out of 12 intuitive group students (50%), and 7 out of 9 conflicted group students (78%) correctly solved at least one problem on the midtest. On average, the groups did the best on problems related to the contrasts they saw in their first session.

Table 5: Students' Percent Correct for Each Problem Type on the Midtest and Posttest

Midtest	**N + N (3 items)** Average correct (% correct); Median	**N + P (3 items)** Average correct (% correct); Median	**P + N (3 items)** Average correct (% correct); Median
Sequential (n=11)	.82 (27%); 0.0	.36 (12%); 0.0	.55 (18%); 0.0
Intuitive (n=12)	**.92 (31%)**; 0.0	.42 (14%); 0.0	.42 (14%); 0.0
Conflicted (n=9)	.78 (26%); 0.0	**.56 (19%)**; 0.0	**1.0 (33%); 1.0**
Posttest	**N + N (2 items)**	**N + P (6 items)**	**P + N (6 items)**
Sequential (n=11)	1.0 (50%); 1.0	3.1 (52%); 4.0	2.9 (48%); 2.0
Intuitive (n=12)	1.1 (54%); 1.5	2.2 (36%); 1.0	2.3 (39%); 1.5
Conflicted (n=9)	**1.2 (61%)**; 1.0	**4.2 (70%); 5.0**	**4.0 (67%); 5.0**

Interpretations of the Negative Sign and Addition

Analysis of students' use of the negative sign and strategies for solving the integer addition problems provides additional insight into differences between the groups. Across the nine negative integer problems on the midtest, the sequential group had 5 out of 11 people (45%) continue to ignore the negatives when solving all of the problems. The intuitive group had 4 out of 12 people (33%) and the conflicted group had only 1 out of 9 people (11%) ignore all of the negatives. On the other hand, students in the conflicted group, who added negatives to positives in their first session, had more people interpret negative signs as subtraction signs (binary meaning) and subtract the numbers. The students in the other groups were more likely to make the answers negative if they did subtract (combination of symmetric and binary meanings) or add a negative sign after adding the absolute values (symmetric meaning). Finally, 75% of the students in the intuitive group, 55% of students in the sequential group, and only 22% of students in the conflicted group used a consistent strategy across all of the midtest problems.

On their first session recording sheets, many students in the sequential group ignored negatives. For example, one student ignored the negative signs when copying down two of the problems; another student wrote that the correct answer to -6 + -4 = 10, even though this was identified as wrong on the page. Students in the intuitive group paid much more attention to the negative signs, noticing when problems did or did not have them. Similarly, students in the conflicted group also noticed the negative signs, and, during follow-up interviews, one student indicated that it meant to “go back.”

On the posttest, on the problems where students had to add both a positive and negative number, 2 out of 11 students (18%) in the sequential group, 4 out of 12 students (33%) in the intuitive group, and 2 out of 9 students (22%) in the conflicted group had responses consistent with adding the absolute values and making the sum negative (symmetric meaning) for at least one problem type. On the other hand 2 out of 11 students (18%) in the sequential group, 2 out of 12 students (17%) in the intuitive group, and 5 out of 9 students (56%) in the conflicted group correctly answered all questions for each problem type (allowing for one mistake per type), such as N + P. These students got negative answers on problems when they couldn’t just add a negative sign, suggesting they had some unary understanding of the minus sign, accepting negatives as numbers in their own right.

Discussion

The results presented here provide insight into how students’ strategies and ways of thinking about the negative sign can be influenced when given access to integer problems through contrasting presentations. Although students with limited prior knowledge did well comparing problem types and when presented sequentially as in prior research (Rittle-Johnson, Star, & Durkin, 2009), their intervention took twice as long and the conflicted group still made higher gains. This data suggests students who initially do not acknowledge the negative sign might benefit most from analyzing contrasts where the initial focus is on the result of the operation (Positive + Positive vs. Positive + Negative) as opposed to the change in sign (Positive + Positive vs. Negative + Negative).

Based on the collective students’ gains by the midtest, exposure to the contrasting cases helped them change their thinking about the meaning of negatives and their use in addition problems. Further, their differences in strategy use suggest that depending on their contrasts, analyzing the problems gave them differential benefits in interpreting the problems. Students’ further gains from the midtest to the posttest suggest that the instruction made additional impact but that the conflicted group benefitted most, especially in terms of changes in their strategies.

Students in the sequential and intuitive groups were more likely to ignore the negative signs, suggesting that they had not developed a usable meaning for the negative signs after analyzing problems that included two negative numbers. Others in these groups were likely to add the absolute values of the numbers and then add the negative sign to the answer, suggesting they interpreted the negative signs as having a symmetric meaning (Vlassis, 2004). However, it is not clear that they understood a negative number as being an opposite of a positive number. A more accurate description may be that they saw the negative sign as a descriptor. By comparison, students in the conflicted group were more likely to interpret the negative sign as indicating a binary operation. Although they initially gave mostly positive answers, a focus on the negative sign as a subtraction sign reflects a shortcut often taught to students (i.e., adding a negative number is the same as subtracting a positive number). Interestingly, by the posttest, the conflicted group did better than the other groups overall, suggesting an improvement in identifying when the minus sign designates a negative number for beginning their count or when it designates an operation.

This research explores the interplay between students' understandings of proportional and functional relationships. Approximately 90 students participated in an early algebra intervention in Grades 3–5. Before the intervention and after each year of the intervention, we evaluated their understandings of proportional and functional relationships. Data revealed that among Grades 4 and 5 students who identified a correct function rule, a higher percentage were unsuccessful solving a proportional reasoning problem than those who were not able to identify a correct function rule. Namely, the data suggest that students' development of functional thinking may interfere with their development of understanding proportional relationships.

Keywords: Algebra and Algebraic Thinking, Elementary School Education

Decades of reform initiatives in teaching and learning algebra (e.g., National Council of Teachers of Mathematics, 2000, 2006) have brought about the "algebrafication" of elementary grades mathematics in which a number of core algebraic concepts are introduced into classroom curriculum and instruction (Kaput & Blanton, 2001). While research has documented the development of students' understanding of these concepts, what is less well understood is the interplay between concepts that, at face value, seem to be developmentally complementary to one another (e.g., functional thinking and proportional thinking). In what ways does learning particular algebraic concepts support or hinder the learning of other algebraic concepts? This question lies at the core of our study in which we examine the ways in which children's understandings of two concepts appear to interact and potentially constrain the development of their algebraic thinking. Specifically, we investigate the interplay between students' understanding of proportional relationships and students' understanding of relationships between quantities that co-vary in a non-proportional way (e.g., the functional relationship $y = 2x + 2$).

We chose to study these concepts because recent findings have shown that elementary students can reason about and describe relationships between co-varying and corresponding quantities (e.g., Blanton & Kaput, 2004; Schliemann et al., 2003) and, in fact, that even students in kindergarten and first grade can engage in this kind of thinking about co-varying and corresponding quantities (e.g., Blanton, Brizuela, Gardiner, Sawrey, & Newman-Owens, 2015; Brizuela, Blanton, Sawrey, Newman-Owens, & Gardiner, 2015).

Our Early Algebra Intervention

This research is part of a three-year longitudinal study (viz., Blanton et al., 2017) whose overarching goal is to design, implement, and evaluate a Grades 3 – 5 early algebra intervention. We based the intervention on a synthesis of Kaput's (2008) analysis of algebra in terms of content strands and thinking practices (see Blanton, Stephens, et al., 2015 for an elaboration of the intervention). In particular, using Kaput's content analysis of algebra we frame the content of our

Galindo, E., & Newton, J., (Eds.). (2017). *Proceedings of the 39th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* Indianapolis, IN: Hoosier Association of Mathematics Teacher Educators.

intervention in terms of four fundamental thinking practices that characterize algebraic thinking: (1) *generalizing*, (2) *representing*, (3) *justifying,* and (4) *reasoning with* mathematical structure and relationships. We also identified several "big ideas" of algebra, that is, principles in a domain that are essential to developing an integrated understanding in that domain (Shin, Stevens, Short, & Krajcik, 2009) and that reflect content spaces in which the core practices of algebraic thinking (e.g., generalizing) can occur. The big ideas of algebra that comprised the early algebra intervention are as follows: (a) equivalence, expressions, equations, and inequalities; (b) generalized arithmetic; (c) functional thinking; and (d) variable.

One of the areas that becomes increasingly important as students transition into middle grades is proportional reasoning (NGA & CCSSO, 2010). Because of the connections between proportional reasoning and functional thinking, particularly as it relates to issues of rate of change and slope, we were interested in the interplay between students' functional thinking, developed as part of our Grades 3 – 5 early algebra intervention, and their early notions of proportional reasoning addressed in the regular curriculum. At face value, these two conceptual areas seem developmentally complementary to one another. Proportional reasoning involves generalizing two related quantities in which "the ratio of one quantity to the other is invariant" (Blanton, Stephens, et al., 2015, p. 43). Functional thinking involves "generalizing relationships between (two) covarying quantities and representing" those generalizations "using natural language, algebraic notation, tables, and graphs" (Blanton, Stephens, et al., 2015, p. 43). We view proportional reasoning as a subset of functional thinking because all proportional relationships can be described as functions, but not all functional relationships are proportional relationships. The purpose of this study is to investigate the interplay between students' functional thinking, developed as part of our Grades 3 – 5 early algebra intervention, and their early notions of proportional reasoning addressed in the regular curriculum.

Methods

We share data collected from a three-year longitudinal study in which we implemented and evaluated our early algebra intervention. To evaluate our early algebra intervention we assessed the algebraic thinking of students who participated in our intervention at several time points using a pretest and posttests.

Participants

At the pretest, participants included 103 Grade 3 students from a school in southeastern Massachusetts. The school's district is 8% non-white, 5% ELL students, and 20% low SES students. Due to attrition, 90 students participated in the entire early algebra intervention (i.e., participated in Grades 3 – 5).

Intervention

The Grades 3 – 5 intervention consisted of approximately 18 lessons per year and engaged students in the aforementioned algebraic thinking practices of generalizing, representing, justifying, and reasoning and the targeted big algebraic ideas. One member of our project team served as the classroom instructor for the intervention, beginning with the Grade 3 cohort and continuing with this cohort through the completion of Grade 5. The intervention was taught as part of students' regular mathematics instruction. The sequence of 18 lessons in each of Grades 3 – 5 included 6 lessons focusd on functional thinking. Functional thinking lessons were designed to get students to generate data, use function tables to organize data, identify functional relationships and represent in words and variables, and use these relationships to make inferences about function behavior. Lessons also included developing graphs to represent functions and interpreting functional behavior in graphs through quantitative and qualitative means. Functional thinking tasks focused primarily on linear functions, but also included quadratic and exponential functions. Proportional reasoning concepts were not explicitly taught in the intervention.

The instructional sequence was organized into Grades 3, 4, and 5. For each year of our intervention, we listed learning goals and organized them according to the associated big idea. The lessons were designed to address these learning goals. Each lesson began with a small-group discussion regarding a previously addressed learning goal, so that learning goals were revisited throughout the lessons. Then, a new learning goal was addressed through small-group problem solving and a whole-class discussion. Associated assessments were designed to test the effectiveness of the intervention by evaluating students' understandings of the big ideas and administered at the beginning of the intervention (Grade 3 pretest) and after each year of the intervention (Grade 3 posttest, Grade 4, and Grade 5).

Data Collection

Students who participated in the intervention were assessed at the beginning of Grade 3, and then again at the end of each year in Grades 3 – 5 using grade-level assessments designed by the project team. The same Grade 3 assessment was used as a pre/post measure in Grade 3, while the Grades 4 and 5 assessments included some identical items and some new items. Each assessment consisted of about 12 items (10 were multi-part open response, 2 were multiple choice). Here we focus on students' responses to two items that appeared on the assessments at each grade level.

The first item (see Figure 1), the *Caterpillar* task (adapted from NAEP, 2003), is designed to evaluate students' ability to reason proportionally. The second item, the *Brady* task (see Figure 2), was designed to evaluate students' understandings of functional relationships. Here, we focus in particular on part c2, which was designed to assess students' ability to generalize and represent a functional relationship using variables. Both of these items appeared on all four assessments given across Grades 3 – 5.

Data Analysis

Responses were scored using a coding scheme developed by the project team to capture both correctness of student responses as well as the types of strategies students used (Blanton, Stephens, et al., 2015). For the response to the *Caterpillar* task to be coded as correct, students must have provided a response of 30. If students also provided an explanation that demonstrated proportional reasoning, coders further identified the way that the student reasoned proportionally (i.e., as using calculations, tables, pictures, a unit rate or repeated addition). If students provided an incorrect answer, coders labeled the response with one of the incorrect strategies or "other." If no explanation or indication of strategy was provided, coders labeled the response "answer only." Here we focus on a specific incorrect strategy, incorrect linear relationship. Students who demonstrated this strategy wrote a response of "25" and typically explained that they used the linear relationship "$2x + 1$" to find their solution. Students found this solution because the relationship "$2x + 1$" results in the example provided, 5 caterpillars and 2 leaves.

A fourth-grade class needs 5 leaves each day to feed its 2 caterpillars. How many leaves would they need each day for 12 caterpillars? Explain how you got your answer.

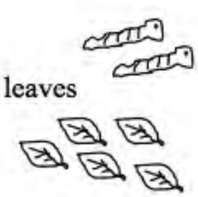

Figure 1. Proportional reasoning item (*Caterpillar* task).

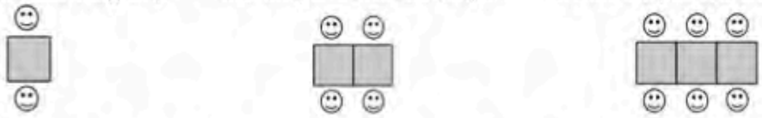
Galindo, E., & Newton, J., (Eds.). (2017). *Proceedings of the 39th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* Indianapolis, IN: Hoosier Association of Mathematics Teacher Educators.

Brady is celebrating his birthday at school. He wants to make sure he has a seat for everyone. He has square desks.

He can seat 2 people at one desk in the following way: If he joins another desk to the first one, he can seat 4 people: If he joins another desk to the second one, he can seat 6 people:



a) Fill in the table below to show how many people Brady can seat at different numbers of desks.

Number of desks	Number of people
1	2
2	4
3	
4	
5	
6	
7	

b) Do you see any patterns in the table from part a? If so, describe them.

c) Think about the relationship between the number of desks and the number of people.
   1. Use words to write the rule that describes this relationship.
   2. Use variables (letters) to write the rule that describes this relationship.

Figure 2. Functional thinking item (*Brady* task).

When refining the coding scheme, we conducted iterative analyses of students' responses to these items. First, we identified strategies already documented in the research literature on children's algebraic thinking. For example, research shows that children may begin generalizing functional relationships by focusing on particular instances, demonstrating a recursive strategy (Blanton, Brizuela, et al., 2015). These external strategies served as a starting point for developing our coding scheme. If a response did not fit an external strategy, it was grouped with similar responses. We then identified patterns in these responses and developed new codes to capture these responses.

For the response to part c2 of the *Brady* task to be coded as correct, students must have written a function using variables to represent the relationship at hand (e.g., $y = 2x$). If students provided an incomplete (e.g., $2x$) or incorrect answer, coders labeled the response with the appropriate incorrect strategy. If a student's response could not be categorized using our coding scheme, coders labeled the response as "other."

Inter-rater reliability scores were computed for 20% of the items and at least 80% agreement was achieved between the coders. When coders disagreed, they discussed codes until agreement was obtained.

Results

In this section, we share results from the two written assessment items and focus on relationships we observed between students' understandings of functional and proportional relationships. For the *Caterpillar* task, we focus on one strategy in particular, the incorrect linear relationship strategy because we found an unexpected relationship between this strategy and another strategy. Students who used the incorrect linear relationship strategy incorrectly generalized a linear relationship between the number of caterpillars and the number of leaves (e.g., $2x + 1 = y$) were coded as using this strategy. For the *Brady* task, we also focus on one strategy, the correct function rule. Students who demonstrated this strategy correctly identified a function rule and represented it using variables in an equation.

We observed a trend in the ways that students who generalized functional relationships on part c2 of the *Brady* task reason about the *Caterpillar* task. In particular, the data revealed that among the students in Grades 4 and 5 who identified a correct function rule using variables to describe a generalized relationship between the two covarying quantities, a higher percentage of those students demonstrated the incorrect linear relationship strategy on the *Caterpillar* task than did the overall population of students. That is, the data suggest that in the context of the intervention, students' development of functional thinking and the development of their understandings of proportional relationships may be related. Although we are not certain of the nature of this relationship, these data suggest that some students' development of functional thinking may impede the development of their understandings of proportional relationships in the context of the intervention.

Table 1 shows the percentage (and number) of students who identified the correct function rule in response to the *Brady* task in Grades 3, 4, and 5. The number of students who identified the correct function rule is listed in parentheses. The data reveal that as students progressed through the intervention, they were better able to write the correct function rule using variables.

Table 1: Overall Student Performance on *Brady* Task

	Gr 3 Pre	Gr 3 Post	Gr 4	Gr 5
Correct Function Rule	0.00% (0)	35% (36)	64% (61)	67% (60)

The percentages in Tables 2 – 4 were calculated using the number of students who used the correct function rule for each grade (as shown in Table 1). In other words, the denominator for each percentage in Tables 2 – 4 is the number of students (in parentheses) for the respective grade in Table 1. Table 2 shows how the subgroup of students—the 36 students—who identified the correct function rule at the Grade 3 posttest performed on the *Caterpillar* task at each time point. Table 3 shows how the subgroup of students—the 61 students—who identified the correct function rule at the Grade 4 test performed on the *Caterpillar* task at each time point. Table 4 shows how the subgroup of students—the 60 students—who identified the correct function rule at the Grade 5 test performed on the *Caterpillar* task at each time point.

Table 2: Percentage of Gr 3 Post Students who Provided a Correct Function Rule (*Brady* Task) and Used the Incorrect Linear Relationship Strategy (*Caterpillar* Task)

	Gr 3 Pre	Gr 3 Post	Gr 4	Gr 5
Incorrect Linear Relationship	0%	3%	7%	12%

Table 3: Percentage of Gr 4 Students who Provided a Correct Function Rule (*Brady* Task) and Used the Incorrect Linear Relationship Strategy (*Caterpillar* Task)

	Gr 3 Pre	Gr 3 Post	Gr 4	Gr 5
Incorrect Linear Relationship	0%	7%	13%	30%

Table 4: Percentage of Gr 5 Students who Provided a Correct Function Rule (*Brady* Task) and Used the Incorrect Linear Relationship Strategy (*Caterpillar* Task)

	Gr 3 Pre	Gr 3 Post	Gr 4	Gr 5
Incorrect Linear Relationship	0%	12%	30%	30%

Table 5 shows the percentage of all students who demonstrated the incorrect linear relationship strategy in Grades 3, 4, and 5. By comparing the performance of the subgroups on the *Caterpillar* task (Tables 2 – 4) to the overall performance of students on the *Caterpillar* task we noticed that students who identified the correct function rule were more likely to also demonstrate the incorrect linear relationship strategy in Grades 4 and 5 than was the general population of students.

The percentage of students identifying the correct function rule in response to the *Brady* task who demonstrated the incorrect linear relationship strategy in response to the *Caterpillar* task is less than the total percentage of students who demonstrated the incorrect linear relationship strategy in response to the *Caterpillar* task in Grade 3. We do not believe we can draw many conclusions from this due to the low overall performance on the *Brady* task in this grade. However, as success on the *Brady* task increases into Grades 4 and 5, we feel that more can be said about the interaction between students' strategy use on these items.

Table 5: Percent of Students who Used the Incorrect Linear Relationship Strategy (*Caterpillar* Task)

	Gr 3 Pre	Gr 3 Post	Gr 4	Gr 5
Incorrect Linear Relationship	2%	5%	9%	20%

Of the subgroup of students who identified the correct function rule in response to the *Brady* task in Grades 4 and 5, the percentage that also demonstrated the incorrect linear relationship strategy in response to the *Caterpillar* task is greater than the overall percentage of students who demonstrated the incorrect linear relationship strategy. Interestingly, the reverse relationship holds true for Grades 4 and 5 as well. That is, of the subgroup of students who demonstrated the incorrect linear relationship strategy in Grades 4 and 5, the percentage who also identified the correct function rule is greater than the overall percentage of students who identified the correct function rule.

Table 6: A Representative Student's Responses in Grades 4 and 5

	Incorrect Linear Relationship Resonse to *Caterpillar* Task	Correct Function Rule Response to *Brady* Task
Grade 4	X Y L c 5 2 25 12 the rule Well I saw it was 2×Y+1=X So I did 12×2+1=25	D×2=P D=Desks P=People
Grade 5	Cater. X | leaves Y 2 | 5 12 | 25 Rule: X·2+1=Y	X·2=Y

Table 6 shows one student's responses to both tasks at the Grades 4 and 5 assessments. This student was selected because his strategy gives an example of the combination we focus on in this paper. We chose to show the students' responses in both Grades 4 and 5 because we observed that several students demonstrated both strategies in both Grades 4 and 5. Specifically, 8 students demonstrated both these strategies in Grade 4. Of those 8 students, 6 of them also demonstrated both strategies in Grade 5. An additional 11 students demonstrated both strategies in Grade 5, totaling to 17 students.

Discussion

The results presented here highlight the complexity of the interrelated concepts involved in studying corresponding relationships in the elementary grades. It leads us to question the role of proportional reasoning in the regular curriculum and how that of functional thinking in our intervention (or even the regular curriculum, to the extent that functions are addressed in elementary grades) coincide.

Moreover, the findings reveal that the characteristics of corresponding relationships that are salient to students are not what we anticipated when designing the intervention. That is, the findings highlight that educators need to be cautious when drawing conclusions about what children know and how it is they come to know it. The findings show that while children may have knowledge of a particular concept, functional thinking in this case, they might misappropriate the concepts and tools in other situations. We can infer from the student's responses shown in Table 6 that this student, and based on the percentages shown in Tables 2 – 4 likely many students, chose to use one of the tools they were taught (e.g., a function table) to use when interpreting functions to represent the *Caterpillar* task. Students are taught function tables as a tool for interpreting functional relationships. Therefore, the fact that this student correctly responded to the *Brady* task and used a function table to interpret the *Caterpillar* task makes sense in the context of our intervention. The reason we did not observe students incorrectly responding to the *Brady* task and using the incorrect linear relationship strategy is because they did not have the tools (e.g., a function table) for interpreting functional relationships.

Lastly, we believe the data displayed in Table 6 highlight that when children come to know a concept in a certain way, they struggle to change the way they know that concept, especially in different contexts. This observation may indicate that students' thinking is entrenched from year to year because the context is relatively consistent. McNeil and Alibali (2004) noted that students resist adapting their understandings of the equal sign in different contexts and we view this finding as relevant to our interpretation of our findings. Similarly, our prior research (e.g., Strachota et al., 2016) on students' understanding of the equal sign and functional thinking have led us to consider how different contexts and co-developing big ideas might impede or support the development of children's algebraic reasoning. We believe these studies are a small slice of an increasingly important area of research in early algebra. In order to move forward in supporting students in developing understandings of algebraic concepts, we must better understand the interplay between concepts.

Due to the nature of our data (i.e., written assessments) we do not know with certainty what students might have been thinking when they demonstrated the incorrect linear relationship strategy. However, we can infer that students who demonstrated this strategy associated some aspect of the proportional relationship with the process of writing a function rule using variables. Moving forward, we hope to investigate what aspects of the task are salient to the students who use the incorrect linear relationship strategy and use these data to refine our instruction.

We acknowledge the limitations of this study specifically the small sample size of the subgroups and the fact that only two tasks are considered, but hope the findings will serve as the premise for future research that takes the same line of inquiry. Researchers have long advocated that algebra be developed as a longitudinal curricular strand. We agree with this perspective, and believe that our findings reveal the importance of continuously supporting students in developing understanding of core algebraic concepts associated with functional thinking and proportional reasoning. Further, we view the conceptual areas of proportional reasoning and functional thinking as interrelated, and recommend that early algebra curricula be designed to synthesize these core concepts of algebra, as well as all core concepts of algebra.

THE PROCESSES AND PRODUCTS OF STUDENTS' GENERALIZING ACTIVITY

agatza@umail.iu.edu

Generalization has been a major focus of curriculum standards and research efforts in mathematics education. While researchers have documented many productive contexts for generalizing and the generalizations students make, less attention has been given to the processes of generalizing. Moreover, there has been less work done with high school students in advanced mathematical contexts. To address these issues we use a model of learning that enables us to make explicit the processes of generalizing. We exemplify this model of learning in the context of an interview study with high school students working on cubic relationships.

Keywords: Cognition, Learning Theory

Generalization has been a major focus of the Common Core State Standards as both a process and content standard. One reason for this focus in curriculum standards is that mathematics educators have identified that generalizing activity is a central means through which students construct new knowledge and as such should be a primary focus of school instruction (Davydov, 1972/1990). To date a majority of the research on generalization has taken place with elementary and early middle school students (grades K-7) in part because it is seen as a basis for and route to algebraic reasoning (e.g., Carraher, Martinez, & Schliemann, 2008). Furthermore, many of these studies have focused on patterns or functions that involve linear relationships, however, researchers have argued that there is a need for investigation of studying generalizing in situations that can involve non-linear relationships as well as studies that include older students (Amit & Neria, 2008). Dorfler (2008) has also identified that researchers studying generalization have focused their attention on developing contexts for generalization and characterizing the kinds and qualities of generalizations students make within these contexts. However, he identifies that there has been significantly less attention paid to the processes involved in generalizing (see Ellis, 2007 for an exception). To address these issues, we report on an interview study conducted with eight 10^{th}-12^{th} grade students who worked on establishing cubic relationships. We situate our work within a framework for studying learning where a central reason for this is so that we can specify particular processes involved in generalizing.

Theoretical Framework

Ellis (2007) differentiates between generalizing actions and reflection generalizations; a generalizing action is an action that precedes and may support a formal statement of generalization (i.e., is a process involved in generalizing) and a reflection generalization is a formal statement of generalization that a student expresses verbally or symbolically (i.e., a product of generalizing actions). We find this distinction useful in outlining our framework for learning which is based in scheme theory. A scheme is a repeatable way of operating that consists of three parts: an assimilatory mechanism, an activity, and a result (Piaget, 1970; Von Glasersfeld, 1995). The assimilatory mechanism involves a student in making an interpretation of a problem situation. The activity of a scheme involves the use of mental operations on imagined or perceptually present material, which transform the assimilated situation into a result. When a person re-processes the result of a scheme so that she can anticipate it prior to carrying out the activity, we call this an act of interiorization, and we consider the person to have constructed a concept. Concepts, then, are the results of schemes that are available to a person prior to operating and are what a person uses to assimilate situations.

For a scheme to be repeatable in different experiential situations means that its formation entailed generalizing actions (Ellis, 2007): A person uses the same scheme in two or more different experiential situations, which implies that the person has abstracted some similarity among the experiential situations because they trigger, vis-à-vis assimilation, the same scheme. We make the distinction between assimilation and *generalizing* assimilation to mark when a generalizing action happens in a particular experiential situation (Piaget, 1970); assimilation entails the re-activation of a scheme, but the abstraction of similarity among current and past situations is not a primary feature of this re-activation. Assimilation is *generalizing* when a primary feature of the re-activation of a scheme is the abstraction of similarity among the current and prior situations. We consider this abstraction of similarity to be a generalizing action that entails an act of learning because a person modifies the assimilatory mechanism of a scheme.

One marker that distinguishes situations involving assimilation and those involving generalizing assimilation is that in the latter case a person may experience a perturbation, a sense of cognitive dissonance. This perturbation may be expressed as uncertainty about what to do to solve a situation even though from the perspective of an observer a student has a scheme that could be used to solve the situation. The resolution of this kind of perturbation can occur through an abstraction of similarity between the current and prior situations in which a student has used his or her scheme. We provide one empirical example of this kind of learning later in the paper.

We consider a second type of learning to be within the realm of generalizing actions as well. We call this type of learning a functional accommodation; a functional accommodation differs from a generalizing assimilation in that a student makes a modification to the *activity* of her scheme in the context of its use (Steffe, 1991). We specifically consider a functional accommodation to entail a generalizing action when it enables a student to solve a broader range of situations. We provide three empirical examples of this kind of learning later in the paper.

The claim that a student has engaged in a generalizing assimilation or a functional accommodation means a researcher is inferring that some modification that was novel occurred in the context of a student using his or her scheme. We highlight that such processes are in the province of reflective abstraction where a reflective abstraction involves a projection of a novel way of operating from a lower to higher level along with the reorganization of the novel way of operating at the higher level (Piaget, 1970). Here we consider the "lower" and "higher level" to be defined by the fact that the scheme itself becomes more general in nature either because the assimilatory structure is broadened to include new experiential situations or because the change in activity of a scheme allows a student to solve a broader range of problems.

None of the acts of learning described to this point necessarily involve a student in being consciously aware of having made a modification to his or her scheme. This is a key reason that we consider them to be in the realm of what Ellis (2007) calls generalizing actions—actions that precede a formal statement of generalization. Further, we note that generalizing actions can occur in the absence of an actual formal statement of generalization yet they are an important part of documenting the *processes* involved in generalizing. We consider formal statements of generalization, what Ellis calls reflection generalizations, to be in the province of a reflected abstraction (Piaget, 1970)—a retroactive thematization of a way of operating that brings this way of operating to conscious awareness. We consider reflection generalization to be in the province of a reflected abstraction because to make a formal statement of generalization entails becoming to some extent consciously aware of how one is operating. Moreover, as Ellis's definition suggests, a reflection generalizations involve symbolizing—formal statements of generalization are made either with natural language or mathematical notation (both symbol systems).

Following Von Glassersfeld (1995), we view symbols as involving bi-directional relationships among a sound/graphic image, a person's re-presentations, and a concept (p. 131). The most important point of Von Glassersfeld's model for this paper is that when a person has constructed a symbol, any one of the three (a sound/graphic image, a person's re-presentations, and a concept) can call up any of the others. This observation means that a sound/graphic image (e.g., a verbal statement or the letter "*x*") can be used to call forth a concept where a concept is the operations of a scheme that no longer need to be implemented either mentally or materially in order for a person to consider them to be part of an experiential situation. We provide one empirical example of a reflection generalization that involves the processes of symbolizing.

Methods and Methodology

We provide empirical examples of generalizing actions and reflection generalizations from an interview study conducted with eight 10^{th}-12^{th} grade students. We conducted two hour long video recorded interviews that focused on problems like the *Card Problem.*

> *Card Problem.* You have the 2, 3, and King of Diamonds, a friend has the 2, 3, and King of Hearts, and another friend has the 2, 3, and King of Clubs. A three-card hand consists of one card from each person's hand (order does not matter). How many different three card hands are possible to make? How many three-card hands have no face cards, exactly one face card, exactly two face cards, and exactly three face cards?

The aim of this problem was for students to develop the equivalence that $3^3 = (2 + 1)^3 = 2^3 + 3 \bullet (2^2 \bullet 1) + 3 \bullet (2 \bullet 1^2) + 1^3$. We conjectured that this equivalence could grow out of reasoning that there were a total of 3^3 possible three-card hands, that this total could be quantified as $(2 + 1)^3$ because each person had 2 non-face card and 1 face card, and also that this total could be quantified as $2^3 + 3 \bullet (2^2 \bullet 1) + 3 \bullet (2 \bullet 1^2) + 1^3$ because: the number of three card hands with no face cards was 2^3; there were 3 ways to have one face card with each way having $(2^2 \bullet 1)$ three card hands, etc. During the interviews, students were encouraged to represent this reasoning using a 3-D array that represented all possible three card hands (Figure 1a), and to identify different regions of this array that represented three card hands that had no face cards (Figure lb, green region), one face card (Figure 1b, three blue regions, only two visible), two face cards (Figure 1b, three yellow regions), and three face cards (Figure 1b, red region). Students then worked toward a statement of generalization that $(x + 1)^3 = x^3 + 3 \bullet (x^2 \bullet 1) + 3 \bullet (x \bullet 1^2) + 1^3$. We regard the examples as "learning in process" because it was not possible to determine from two interviews the extent to which the modifications that students made were lasting.

Empirical Examples: Learning, Generalizing Actions, and Reflection Generalizations

Example one assimilation versus generalizing assimilation. We use Shante's solution of the Subway and Card Problem to illustrate generalizing assimilation. Shante solved the Subway Problem with relative ease she concluded that there should be 24 possible sandwiches.

Subway Problem: Subway has two kinds of bread, three kinds of cheese, and four kinds of meat. A sandwich is one bread, one cheese, and one meat. How many possible sandwiches can subway make?

The interviewer then asked her to determine the total number of possible three card hands in the Card Problem, which included making a number of sample three card hands with actual cards. When she was asked how many possible three card hands she could make, Shante responded quickly that there would be 27 three card hands because the answer would be “three times three times three.” However, when asked to explain the multiplication problem and to represent her solution, Shante expressed uncertainty.

I: Why is it that (three times three times three)?
S: Three cards, three hands and three kings? Wait. Okay. Can you say the question again? [The interviewer asks the question again, but Shante is still confused. The interviewer asks Shante to make a tree diagram]
….
S [responding to a question about making a tree diagram for the problem]: Okay. Wait a minute. Okay, now wait. What's going on here? Okay, so this would be a K and a three, and then the rest would branch out from that, right? [writes “K-3-2” on her paper.]
….
S [she has stated that the two in the “K-3-2” is the two of spades, and is responding to the interviewer’s question about what the other cards represent]: It will be … a K heart and a three heart … I think that's one hand.

Shante’s solution indicated that a critical difference for her in solving the Card Problem was determining what a valid three card hand was—in the Subway Problem it was clear to her that a sandwich could not consist of one bread and two cheeses. However, in the Card Problem it was unclear to her that a three card hand should not consist of one spade and two hearts, despite the fact that she had made three card hands with actual cards and these three card hands contained only one spade, one heart, and one diamond. The primary difference in these two situations seemed to be that each person had the same kind of object, cards, that were differentiated by suit whereas in the Subway Problem the objects were not of the same kind. This led to a perturbation for Shante, “this problem got me all the way messed up”, that she eventually resolved by relating the suits of the cards to the Subway Problem, “Could the spades be like the meats?....The diamonds could be like the cheeses?....Oh, the hearts would be like the bread!” Because Shante’s abstraction of similarity between the two situations was a primary feature of her solution of the problem, we considered her solution to involve a generalizing assimilation, which was an act of learning that entailed an adjustment to the assimilatory mechanism of her scheme.

Example two recursion of a scheme. Our second example is drawn from a 10th grade student in the interview study and allows us to examine a functional accommodation that involved recursion. Trevon was initially presented with a modification of the Subway Problem that involved four breads and six meats. Trevon said, “In my head I’m attributing one bread to each meat. … and if you do that, it would just be 4 times 6. [He subsequently made the beginning of a tree diagram].” Trevon was able to quickly complete the task and provide a justification for his way of operating, which we take as indication that he assimilated the situation using an extant scheme. The activity of his scheme involved multiple operations, but we highlight that it included a systematic use of his *pairing operation*, an operation that involves a student in creating the sandwich as a unit that contains two units (i.e, a bread and a meat), a pair. This operation can be the basis for establishing the identity that one times one is one, and we focus on it because it is a key feature of students’ solutions of combinatorics problems that differentiates them from other multiplicative situations.

Later in the interviews, Trevon was presented with the Card Problem where each person had three cards. He responded that the number of possible three card hands would be, “eighteen”, explaining, “there’s six combos [indicating hearts and diamonds combined] for each card and there’s three cards total [indicating the three spades]. So, that’s six times three.” Our interpretation of Trevon’s response was that he assimilated the Card Problem using the scheme he used to solve the Subway Problem. There were three spades that could be paired with each of six cards. The interviewer asked him to show the eighteen three card hands with the actual cards. To do so, he initially fixed a spade and simultaneously moved two cards, one heart and one diamond, to be paired with the spade. By doing so he essentially treated the heart and diamond cards as if they were like the meats in the Subway Problem, meaning he did not pair the heart with the diamond first to establish a heart-diamond pair. He experienced a perturbation, however, because he was trying to monitor which three card hands he had created and was not able to do so. His monitoring led him to introduce a novel way of operating: he paired each heart with each diamond, and took the result of this scheme, the nine heart-diamond pairs, as material to operate on with his scheme, pairing each heart-diamond pair with a spade.

We interpret this as a functional accommodation that entailed taking the result of his scheme as input for using his scheme again. For this reason, we consider the functional accommodation to have involved recursion; the recursive process did not involve his use of any novel operations. However, it involved more than just repeated use of the scheme—the result of the first instantiation of the scheme was embedded in the result of the second instantiation of the scheme. We consider this embedding process to be key to recursion. Moreover, we consider this to be a generalizing action because it broadened the class of problems Trevon could solve.

Example three embedding novel operations into the activity of a scheme. As our description of Shante’s activity in Example One suggested she had constructed a scheme for solving problems like the Subway Problem with breads, meats, and cheeses, and vis-à-vis a generalizing assimilation used her scheme to solve the Card Problem. She solved each problem representing the set of outcomes as either a list or as a tree diagram, and the operations she used to solve the problems were comparable to those outlined for Trevon in Example Two. The interviewer had the goal of having students represent the solution of these problems using multiple 2-D arrays, and then a single 3-D array. For the Subway Problem, Shante easily created two 2-D arrays (Figure 2a) to represent the problem. The interviewer asked her what was changing as she “moved horizontally along the x-axis” and she said, “the cheeses”, and responded similarly to a question about, “the meats”.

The interviewer then said that the goal was to think about how Shante could use her two-dimensional arrays to make a three-dimensional array, specifically asking, “what direction could you move for the breads to change?” Shante responded that she thought her listing of the breads in Figure 2a would “just be a title” for each array, and indicated that she was uncertain about what direction she might move in order for the breads to change. To further investigate this issue, the interviewer had Shante make two 2-D arrays using snap cubes (Figure 2b). After significant questioning, Shante figured out that she could stack one array on top of the other, and the interviewer had her make an array for a third bread (Figure 2c). At this point she still had “no idea” in which direction you’d move for the breads to change so the interviewer asked her to imagine where all the sandwiches with bread four, five, six, and seven would be, and for each she responded, “right above” all the sandwiches for the prior bread. The interviewer then asked her “if you had to draw a line to show where the breads would be represented (like the lines she had drawn for the meats and cheese), how would she draw it?” Shante responded, “It would be going up!”, and to show she put a pencil at the vertex of the bread and cheese axis in Figure 2c. From the perspective of mental operations, we consider Shante to have envisioned translating her 2-D array up one unit six times, and from this translation to have abstracted an axis on which the breads could be located that were similar to the axes for meats and cheeses.

Figure 2a (left), 2b (center), 2c (right).

To determine what other operations Shante might be using in her production of a 3-D array, the interviewer asked her to locate in Figure 2c where the sandwich with the second bread, second cheese, and third meat would be. Shante initially pointed to the top of the 3-D array where the sandwich with bread three, cheese two, meat three was located, and said, "It's like in this [pointing downward with her pencil], and then pointed to where the sandwich containing bread two, cheese one, and meat three was located, and said, "It's like right next to this one [pointing inward with her pencil towards where the cube was located]." She then clarified that by "in this" she meant "underneath" the cube that she had pointed to on top of the array.

Her identification that the cube for bread two, cheese two, meat three was "underneath" the cube that represented bread three, cheese two, and meat three, indicated that as part of translating the layers of her array upward she had also translated the referential system upward (i.e., the meat-cheese axes), and could use that to locate points in her 3-D array. The fact that she also identified the cube for bread two, cheese two, meat three as "next to" the cube for bread two, cheese one, and meat three, indicated that she could envision switching frames of reference; she used the meat-bread axes to locate the correct cube in the "cheese 1" plane, and then envisioned that the correct cube would be translated one unit inward on the 3-D array. We consider her switching frames of reference to be indication that she could mentally rotate the "meat-cheese axes" to become the "bread-meat axes".

We consider the operations of translation and rotation to have been *embedded* in the activity of her scheme for producing the set of outcomes. Because these operations were not part of her initial solution to the problem, we consider this to have been a functional accommodation to her scheme. We consider this functional accommodation to be a generalizing action because it allowed her to create a spatial structuring for a broader class of objects where her spatial structuring for 2-D arrays was embedded in her spatial structuring for 3-D arrays vis-à-vis the operations of translation and rotation.

Example four operating on the result of a scheme with operations external to the scheme. DeShay entered the interview study with a scheme for solving combinatorics problems like the Outfits and Subway Problem, and with relative ease could represent the set of outcomes using a 3-D array. We took this as indication that her scheme for solving such problems included the operations described in example two and three. Moreover, these operations seemed well established for DeShay, and so we considered that the result of these operations (the set of outcomes represented as a spatially structured 3-D array) was material that she could operate on with operations that were external to her scheme for producing them. To illustrate this issue, we provide data where DeShay was finding the regions of her 3-D array that corresponded to a three card hands that had a certain number of face cards, specifically the three card hands that contained one king where the king was the king of spades.

> D: Okay, so we have…Want to start with the king of spades, so it'd be these-by-these [points to the region in the 3-D array that represents the twenty-five three-card hands that contain the king of spades, Figure 3a], but it wouldn't be any in this row because that's the king of hearts (Figure 3b). So, it's just these four by these four. But it wouldn't be any -- or, these four by these five (Figure 3c). But it wouldn't be any of the very bottom because that's the king of diamonds (Figure 3d). So, it's this four by that four (Figure 3e).

To solve this problem DeShay took the *intersection* of the set of three card hands that contained the king of spades with the set of three card hands (Figure 3a) that contained the king of diamonds (Figure 3b), and *eliminated* this from the original set because those three card hands would contain both the king of spades and king of diamonds (Figure 3c). She then used these operations recursively: she took the *intersection* of this new set ("these four by these five") with the set of three card hands that contained the king of diamonds (Figure 3d), and *eliminated* these three card hands because they contained the king of spades and king of diamonds (Figure 3e).

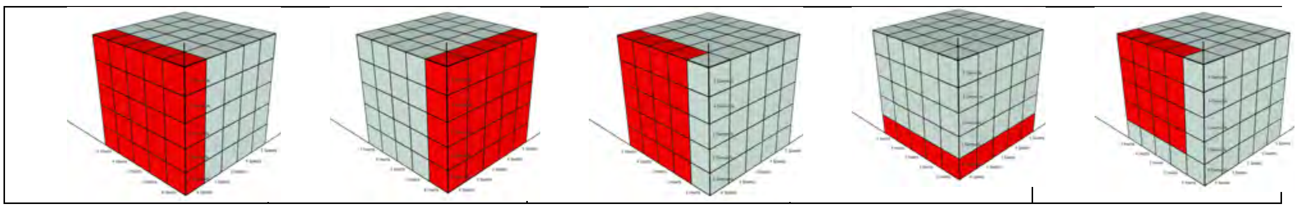

Figure 3a (left), 3b (second from left), 3c (middle), 3d (second from right), 3e (right).

We consider this functional accommodation to entail DeShay using operations external to the ones that produced the set of three card hands represented as a 3-D array. We consider it to be a generalizing action because DeShay's implementation of these operations led to the abstraction of a spatial structuring like the one shown in Figure 1b where she no longer had to implement the operations in order to impose the spatial structuring on future cases of the problem, represented as other cubes (e.g., a seven by seven by seven cube or a one hundred by one hundred by one hundred cube). She could simply assimilate future situations with the result of her operating, a cube that contained eight regions.

Example five reflection generalization involving reflected abstraction. After solving versions of the Card Problem that involved three, four, and five cards, the interviewer asked DeShay to imagine and describe what the cube would look like for the case of six cards, and then asked her if she could write a formula for if there were an unknown number of non-face cards. DeShay first wrote, "$y=1+x$" where y was the total number of cards and x the total number of non-face cards, and then wrote "$(1 + x)^3 = x^3 + (1 \bullet x^2 \bullet 3) + (1^2 \bullet x \bullet 3) + 1^3$." We considered these to be symbols that DeShay could use to call forth the operations outlined in examples two through four without actually having to implement these operations in full. We make this inference based on explanations like the following of how she got "$(1 \cdot x^2 \cdot 3)$":

> D: There would be one option times …Oh. Can't exactly put the multiplication sign. Times x options, also times it by x options again, because with one suit you'd only have one king [points to where the king of spades is represented in the 3-D array] and the other ones you would have
>
> ….

> x different cards to pick from, so x times x. And then you'd also multiply it by three for the three suits. Then you get one times x squared times three.

Her explanation clearly referred back to the Card Problem. Throughout these explanations, she gestured to the five by five by five cube, showing imagined locations of where particular regions would be in the general case. We took this as indication that the mathematical symbols she could use to stand in for operations that could be implemented, but no longer needed to be, and which were closely tied to re-presentations of her activity in prior cases of the problem.

We considered this to be a reflection generalization based on reflected abstraction because it was a final formal statement of generalization that grew from a retroactive thematization of her reasoning. DeShay stated as much when talking about Figure 5b, saying "So, this will be the formula to solve because this is pretty much similar to all these other ones [points to the cases of three, four, five, and six cards in her chart], except we had numbers to plug into them."

Discussion

One central contribution of this work is that our study of generalizing is situated within a framework for learning, which allows for the identification of different processes involved in generalizing. We do not consider our examples to be comprehensive, but rather illustrative. The first example illustrated how a student broadened the assimilatory mechanism of her scheme; the second example illustrated a student that recursively used his scheme, taking the result of a scheme and operating on it with operations that were internal to the scheme; the third example illustrated a student who embedded novel operations into an already extant scheme; and the fourth example illustrated a student who took the result of a prior scheme (a 3-D array) and operated on it with operations that were external to the scheme. Beyond just characterizing these different processes, situating the study in a framework for learning allows for a clear distinction between statements and actions that a student makes that are general, but involve no novel ways of operating (i.e., are based on extant schemes), from those that do involve novel ways of operating (i.e., that involve learning). The final example then shows the connection between the operational structures that students developed during the interview study and their expression in symbolic form. As such the paper provides an exemplar of how symbols function in a way that is compatible with Von Glasersfeld's (1995) model of this process.

Endnotes

[i] Students created an array with snap cubes that were all the *same* color like Figure 1a. We used snap cubes because we could find no good way to physically or virtually represent a 3-D discrete array.

A PROSPECTIVE SECONDARY MATHEMATICS TEACHER'S DEVELOPMENT OF THE MEANING OF COMPLEX NUMBERS THROUGH QUANTITATIVE REASONING

This study investigated a prospective secondary mathematics teacher's development of the meaning of the Cartesian form of complex numbers during a teaching experiment. We illustrate that through shrinking/stretching of the distance(s) between the roots and the x-coordinate of the vertex of any quadratic function one might conceptualize complex numbers as a single entity, element of a well-defined set, rather than a prescription of certain operations. Such awareness also yield to answering why quadratic functions have to have conjugate roots once they have a complex root.

Keywords: Teacher Education-Preservice, Algebra and Algebraic Thinking

Introduction

Developing new sets of numbers, such as complex numbers is needed on the part of teachers (Karakok, Soto-Johnson, & Anderson Dyben, 2014) and their students (Nordlander & Nordlander, 2012). However, research has shown that neither (prospective) teachers nor students do have a robust conception of complex numbers such that they have difficulty in thinking of both algebraic and geometric representations of complex numbers representing the same number (Karakok et al. 2014; Panaoura, Elia, Gagatsis & Giatilis, 2006). The primary goal of this research was to investigate how someone might develop the algebraic and geometric representations of the Cartesian form of complex numbers as an extension of real numbers through quantitative reasoning (Thompson, 1994). Quantitative reasoning occurs through quantitative operations. Thompson (1994) defined quantitative operation as "a mental operation by which one conceives a new quantity in relation to one or more already conceived quantities." (p. 184). Dwelling on quantitative reasoning both for the design of the teaching sessions and the analysis, this study particularly investigated the following research questions: How does a prospective secondary mathematics teacher develop the meaning of the Cartesian form of complex numbers? What meanings of the Cartesian form of complex numbers does a prospective secondary mathematics teacher develop during an instructional sequence involving quantitative reasoning?

Method

Participants

The participant of the study was one prospective secondary mathematics teacher, Esra, who was in the fourth year of her five-year undergraduate program. For the selection of the participant, first, a written pre-assessment was given to 21 prospective secondary mathematics teachers in a public university in Turkey where the medium of instruction is English. The participation was voluntary. Then, based on the preliminary analysis of their answers, seven of them were chosen to conduct a 45-minute long clinical interview. Analyzing the transcribed pre-interviews and the written pre-assessment, as opposed to choosing the most mathematically capable ones, we looked for participants who had a range of learned concepts and limited understandings. Esra suited such criteria (See results from the written pre-assessment and the pre-interview).

Data Collection and Analysis of the Study

The teaching experiment methodology was employed in this study. Data collection included three phases: I) a pre-interview after a written pre-assessment (the selection of the participants), II) the teaching sessions, and III) a post-interview after a written post-assessment. Phase I was already explained above. For Phase II, the teaching sessions, we first developed a hypothetical learning-sequence for the participant. The second author implemented the teaching experiments consisting of three 75- to 120-minute sessions and the first author operated a digital video camera and an audio recorder. Then, two weeks after the last teaching session, one-hour long structured, task-based post-interview was conducted with the participant. For the analysis of the pre-and-post interview data, we read the transcripts line-by-line. We focused on Esra's justifications and reasoning behind her answers and also what procedures, representations, and formulas she used. For ongoing analysis for teaching experiments, we reflected on the sessions and interpreted Esra's evolving understandings and constructs of the targeted concepts and also focused on potential understandings to be developed by her. Also, we focused on her weaknesses/difficulties and possible explanations for such weaknesses/difficulties. For the retrospective analysis, we identified interaction sequences in which Esra's actions and utterances provided information about her thinking.

Results

Results from the Pre-Interview and the Written Pre-Assessment

Esra was able to define quadratic functions algebraically and represent them geometrically as a parabola. Also, given the algebraic expressions for the roots she was able to explain the meaning of $-\frac{b}{2a}$ algebraically as the half of the sum of the roots of a quadratic equation. She also stated that it referred to the "abscissa of the vertex" and the midpoint of the roots on the real number line, geometrically. She also was able to explain the meaning of $\frac{\sqrt{\Delta}}{2a}$ as the distance of the roots to $-\frac{b}{2a}$. However, she was not able to reason about what $\Delta = 0$ and $\Delta < 0$ meant geometrically. Also, during the written pre-assessment, Esra had defined complex numbers as ".. the numbers in the form of $a + bi$ where $a, b \in R$ and $i = \sqrt{-1}$". She could refer to the three cases of delta and the roots of the quadratic equations being real and complex numbers and had stated that complex numbers included real numbers. Though, when asked, she stated "I have no idea why real numbers are the subset of complex... That is how I learned". Similarly, Esra had written that x and y algebraically referred to real numbers in the form of $x + iy$. Then, during the interview when asked again, she stated "I still think that both can be real". Also, for the questions why they were real numbers and what they referred to geometrically she said "I don't know".

Results from the Teaching Sessions: Esra's developing the definition of Complex Numbers

To take Esra's attention to the dynamic nature of the distance between the roots and the x-coordinate of the vertex, we asked how many parabolas having the same x-coordinate of the vertex one could draw. She stated that one could draw infinitely many parabolas having the same x-coordinate of vertex as in the figure she drew (See Figure 1). We then asked her "what was changing and what did remain invariant in the parabolas she drew given the algebraic form of $f(x) = ax^2 + bx + c$?".

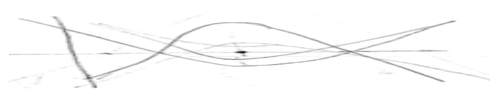

Figure 1. Esra's drawing many parabolas with the same x-coordinate of the vertex.

She stated that the values of a, b, c and also x and y were all changing. She also stated that since these values were changing the roots' distances to the x-coordinate of the vertex was also changing; but, the ratio of $-\frac{b}{2a}$ did not change. Then we asked her to come up with specific examples. She wrote; $y = 2x^2 - 8x + 6$, $y = 4x^2 - 16x + 7$, y= $6x^2 - 24x + 1$. Then we gave her the following examples on GeoGebra such as $x^2 + 2x - 8$, $x^2 + 2x - 4$, $x^2 + 2x - 1$, $x^2 + 2x$, $x^2 + 2x + 1$ to think about: The reason was to allow her to imagine the movability of the distances of the roots to the x-coordinate of the vertex so that she could reason through the geometric meaning of $\Delta = 0$ and

$\Delta < 0$ since she was not able to do so during the pre-assessment. She was able to comment that the x-coordinate of the vertex was the same for all of them albeit the roots' distances to it has changed. She also claimed that the roots' equi-distances from the vertex was invariant in each specific example. Then we asked her to put all the information on the Real number line. She drew (See Figure 2) and explained:

Figure 2. Esra's showing the roots on the real number line she drew.

Esra: Delta is here $[x^2 + 2x + 1]$ with its roots ($x''_{1,2}$,0). None, it is 0. $\frac{\sqrt{\Delta}}{2a}$ is none…It means the overlap of this point with the roots and with the abscissa of the vertex. Eee delta is 0.

R: What was it in the others, here, when there were two roots in here [on the x axis]

E: When $\frac{\sqrt{\Delta}}{2a}$ exists...

The excerpt indicated that acknowledging that the distances of the roots from the x-coordinate of the vertex decreased further and got to a point until there was no distance between the roots and the x-coordinate of the vertex algebraically meant that $\frac{\sqrt{\Delta}}{2a} = 0$. It also meant that there were no distances between the roots for such kind of a quadratic equation geometrically. At that point she stated,

E: ... I can generate parabola from all real numbers... I can add and divide by two. I can draw infinitely many parabolas having the same abscissa of the vertex, and because of that all the roots can be the numbers on the real number line.

The excerpt is important because Esra reversed her thinking in a way that she started from real numbers and given two real numbers she could find the midpoint that would have indicated the x-coordinate of the vertex from which she would have drawn infinitely many parabolas. At that point, we asked what would happen to $-\frac{b}{2a}$ and $\frac{\sqrt{\Delta}}{2a}$ after that point. She stated that the x-coordinate of the vertex would stay on the real number line but she would not be able to put the roots' distances on the real number line anymore because "It $[b^2 - 4ac]$ is smaller than zero". Then we asked her if she could re-write the expression $[b^2 - 4ac]$ in terms of a positive expression. She was able to write: $b^2 - 4ac = -(b^2 - 4ac).(-1)$ and $b^2 - 4ac$=$(4ac - b^2).(-1)$. Then we asked if she could place this expression into the general algebraic expression of the roots: She wrote: (See the first two lines in Figure 3). When we asked if she could write it separately she stated "Normally I cannot take it out". But then she stated that she was not working with real numbers anymore, she said "I run out of them [real numbers]". Then, when we asked if she could state the expression using symbols she wrote (See the last two line in Figure 3) and stated: "Let's say there are infinitely many [quadratic] functions, and the x-coordinate of the vertex of any quadratic function is t...and m is the distance from one of the roots to the x-coordinate of its vertex."

What is interesting is that Esra was able to make sense of the values of "t" and "m" not only algebraically but also geometrically: She knew that "t" stood for $-\frac{b}{2a}$ and "m" stood for $\frac{\sqrt{-\Delta}}{2a}$. She also could relate those values to the quadratic functions such that those values referred to the x-coordinate of the vertex of any quadratic function and the roots' distances to it. Though, it is important to state that Esra's geometrically making sense of "m" was limited because not the value "m" on its own but "$m.\sqrt{-1}$" referred to the roots' distances to the x-coordinate of the vertex. When asked what kind of numbers t and m were, she stated"..ee they are real." and her explanation was "because we have taken a and b as real numbers, $-\frac{b}{2a}$ becomes real and here this number inside $[-\Delta]$ is a real number

Galindo, E., & Newton, J., (Eds.). (2017). *Proceedings of the 39th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* Indianapolis, IN: Hoosier Association of Mathematics Teacher Educators.

and it becomes real number outside the root. And when we divide it by $2a$, which is real, it $[m]$ is real number again". Then to define complex numbers, she stated "Ee I obtain them from the real roots of quadratic functions. If they are eee.., okay correct, I obtain them from their real roots. Okay, I obtain [complex numbers] from unreal ones [the unreal roots] as well. The numbers obtained from the roots of all quadratic functions are complex numbers. Exactly. They give complex numbers."

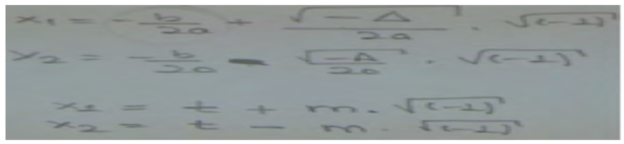

Figure 3. Esra's re-writing the roots of the quadratic equations.

Conclusion

Research on complex numbers has shown that students consider "…the geometric and algebraic representation as two different autonomous mathematical objects and not as two means of representing the same concept" (Panaoura et al., 2006). In this research, through quantitative reasoning focusing on both the algebraic and the geometric meanings of the components of the roots of quadratic equations, i.e. $-\frac{b}{2a}$ and $\frac{\sqrt{\Delta}}{2a}$, Esra was able to develop the meanings of the Cartesian form of complex numbers, $x + iy$, both algebraically and geometrically. In particular, we argue that starting with the examination of any quadratic function and its graph focusing on the quantities (e.g., the roots and the x-coordinate of the vertex), and answering the question of how many parabola(s) someone can construct with the same x-coordinate of the vertex might have the following affordances on reasoning on complex numbers on the part of students: First, thinking of the existence of infinitely many parabolas enabled Esra to focus on (imagine) the 'movability' of the distances of the roots to the x-coordinate of the vertex. That is, as a quantity, $\frac{\sqrt{\Delta}}{2a}$ could *shrink* and/or *stretch* (dilate) and this was imagined by thinking parabolas as shown in Figure 1. Thinking of the movability of the roots' distances to the x-coordinate of the vertex also allowed Esra to think of the placements of them on the real number line too. Once Esra reached such a point in her cognition; that is, once she imagined and thought about the movability of the roots' distances to the x-coordinate of the vertex shrunk to zero it triggered the necessity that real numbers were not sufficient enough to consider the roots of all quadratic functions with real coefficients. Such realization also afforded understanding why complex numbers involved real numbers too. This was important because research has shown that students had difficulty in recognizing that any number is a complex number (Nordlander & Nordlander, 2012). Esra's re-writing the roots as $x_{1,2} = -\frac{b}{2a} \pm \sqrt{-1}\frac{\sqrt{(4ac-b^2)}}{2a}$ allowed her to realize what the components of the complex numbers $z = x \pm iy$ meant algebraically and geometrically. Esra was also able to define complex numbers as the elements of the roots of any quadratic equation with real coefficients (i.e., as members of a well-defined set).

ACTIVATING A FOURTH LEVEL OF UNITS COORDINATION

Recent research has highlighted the developmental importance of units coordination for students' continued mathematical learning. In this study, we introduce a task that ostensibly involves four levels of units. We examine student responses to this task and how they relate to student responses from tasks that assess students' coordination of three levels of units. This investigation helps to (1) characterize students' coordination of four levels of units in activity and, (2) explore the potential to use such activity as a valid indicator of students' interiorized coordination of three levels of units. Results of the study provide preliminary evidence for the validity of the task because it positively relates to another measure of units coordination and positively predicts students' construction of an iterative fraction scheme.

Keywords: Number Concepts and Operations, Rational Numbers, Assessment and Evaluation

Purpose

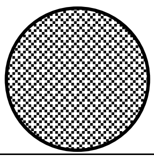
Recent research has highlighted the developmental importance of the ability to interiorize three levels of units coordination for middle grades mathematics concepts (e.g., Hackenberg & Tillema, 2009; Norton & Wilkins, 2012; Ulrich, 2016; Tillema, 2014). In this study, we introduce a task that, from the researchers' perspective, involves the coordination of four levels of units. We examine student responses to this task and how they relate to two other tasks: one measuring students' coordination of three levels of units and one measuring the construction of the iterative fraction scheme (IFS), for which coordinating three levels of units is a prerequisite (Hackenberg, 2007; Norton & Wilkins, 2012). This investigation helps to (1) characterize students' coordination of four levels of units *in activity*, and, (2) examine the potential of such activity as a valid indicator of students' interiorized coordination of three levels of units.

In order for a task to successfully measure the existence of a conceptual construct, such as units coordination, it is important that the task be novel and not be susceptible to solution strategies that could circumvent the need to use the concept in question. For example, Task 3 (see Figure 1), which has been used as an indicator of three levels of units coordination in studies with younger children (e.g., Norton & Wilkins, 2012), might be solved by older children by way of a memorized procedure to find equivalent fractions, thus by-passing the need to mentally coordinate three levels of units (cf. Lovin et al., in press).

In theory, students who can manipulate two levels of units in activity have interiorized the construction of (one level of) units; similarly, if a student can coordinate three levels of units in activity they have interiorized the coordination of two levels of units (Hackenberg & Tillema, 2009; Norton & Boyce, 2015). By extension, if a student were able to coordinate four levels of units in activity, this might suggest that they have interiorized the coordination of three levels of units. The purpose of this exploratory study is to use solutions to Task 1 (see Figure 1) to investigate the potential use of a task that involves four levels of units as an indicator of the interiorization of the coordination of three levels of units, particularly with older students.

(1) Consider the following situation involving chips inside of cups, inside of boxes, inside of crates. There are 3 chips in each cup, 4 cups in each box, and 2 boxes in each crate. If you have 9 chips, how many more cups do you need to make a crate?

(2) Suppose that below is $\frac{6}{5}$ of Sam's pie. Draw Sam's amount of pie.



(3) The pizza shown below is 2/3 of a whole pizza. If each person wants 1/9 of a whole pizza, how many people can share the amount shown below?

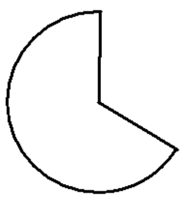


Figure 1. Tasks designed to elicit coordination of units and the iterative fraction scheme.

Theoretical Framework

Units coordination (Steffe, 1992) refers to the ways that students can quantitatively relate different units, and the term is often used to specifically refer to the ability to mentally distribute one composite unit (integer greater than 1) across the elements of another composite unit, yielding what is, to the observer, a multiplication. For example, a student could imagine 4 people who each get 6 brownies, and distribute the 6 across the 4 units of 1 (people) to get the total number of brownies, 24. In this situation, if the student is aware of the 24 as being made up of groups of 6's, then the student can think of 24 as being made up of units of 1 or units of 6. Therefore, the student is working with at least two levels of units in activity.

By reflecting on the activity and results of this kind of units coordination (cf., Simon & Tzur, 2004), students might interiorize the coordination of two levels of units, allowing them to use them when assimilating situations (Norton & Boyce, 2015). For example, such a student may be able to add 24 three times, while keeping track of the number of 6's in the final sum. At that point, 24 itself has become a unit of counting that is coordinated with 6's and 1's, so the student is coordinating three levels of units in activity. Students who have interiorized three levels of units could take the entire structure (3×24 as being made up of 4×3 6's and (4×3)×6 ones) for granted and use it in further operating. This could involve further multiplicative or additive coordinations (Ulrich, 2016), such as realizing that 6 is made up of 5 and 1, so that we can also think of 3×24 as made up of twelve 5's and twelve 1's.

Currently, we hypothesize that students do not need to coordinate more than three levels of units at a time because they can recursively apply their units coordinating schemes to the results of those schemes without mentally keeping track of all the quantities along the way. One might wonder if this implies that only two levels need be coordinated simultaneously with further coordination carried out recursively. However, interiorizing three levels of units seems to be a prerequisite for many mathematical concepts. In particular, Hackenberg (2007) found that understanding fractions as "numbers in their own right" (p. 27) (rather than ratios of two numbers, or a comparison of parts in the fraction to parts in the whole) relies on the interiorization of three levels of units (the fraction itself, the unit fraction, and the whole). The scheme for understanding fractions in this way is called the iterative fraction scheme (Steffe & Olive, 2010).

Method

The study involved 34 pre-service elementary teachers. These teachers were enrolled in two sections of a graduate level elementary mathematics methods course in the fall of 2016 and 2017. Participants completed three tasks as part of their final exam for the methods course (see Figure 1). We designed Task 1 to elicit the coordination of four levels of units *in activity*. The strength of this task is that it does not initially offer known strategies that would allow participants to solve the problem without coordinating units. However, it is possible for participants to solve the task by coordinating two two-level structures simultaneously, and in essence not activate a fourth level of coordination. Task 1 was coded for correctness (0 = incorrect; 1 = correct).

Task 3 has been used in other studies to elicit the coordination of three levels of units (see Norton & Wilkins, 2012) and is used in this study to provide comparative data to evaluate the convergent validity of Task 1. We designed Task 2 to elicit participants' iterative fraction scheme (IFS). Responses to this task are used to evaluate the predictive validity of Task 1. Tasks 2 and 3 were coded for indication of operating with an IFS and three levels of units coordination, respectively (0 = no indication; 1 = indication).

In order to examine the relationships between the tasks we created three contingency tables for pairs of tasks (see Table 1). In order to evaluate the predictive validity of Task 1, we measured the association between responses to Task 1 and Task 2 using the gamma statistic (G) and tested for directionality using the Exact Binomial test. In order to evaluate the convergent validity of Task 1, we examined the relationship between Task 1 and Task 3 based on a comparison of the proportion of correct and incorrect responses to the tasks.

Results

We present the contingency table for Task 1 and Task 2 in Table 1a. Based on these data we documented a relatively strong relationship between responses to Task 1 and Task 2 ($G = .75$, p [one-tailed] $< .05$). By examining the eight off-diagonal entries, we can further ascertain evidence of developmental order, that is, whether three levels of units coordination precedes the construction of an IFS. In this case, we see that of the eight participants who answered one or the other task correctly (but not both), seven answered Task 1 correctly, which is statistically significant, exact binomial $p = .035$. Together, these results provide evidence for the predictive validity of Task 1. That is, three levels of units coordination (measured by Task 1) is associated with and precedes the construction of an iterative fraction scheme (measured by Task 2).

We present the contingency table for responses to Task 1 and Task 3 in Table 1c. Based on these data, 29 out of 34 participants (85%) answered both items correctly providing evidence that success on either item is indicative of success on the other. Furthermore, for the five students that only answered one of the tasks correctly, the prevalence of correctness or incorrectness was not found to be concentrated with either task, exact binomial $p = .813$. Together, these results provide evidence for the convergent validity of Task 1. That is, both tasks tend to be measuring the same construct; in this case, correctness of Task 1 provides evidence for the coordination of three levels of units. However, because no participants answered both items incorrectly, the claim about the association between the tasks may be weakened. Further study involving a sample of students of more varied ability would help to verify this claim.

Conclusions

In this study, we introduced a task that ostensibly involves four levels of units. Our goal was to examine the potential of such tasks as indicators of the interiorization of three levels of units coordination. The task was designed to provide a novel situation for which most students do not have a readily available solution strategy, and so, responses are likely to be a true indicator of units coordination. Results of the study provide preliminary evidence for the convergent and predictive validity of the task as it positively relates to an established measure of units coordination and positively predicts students' construction of an iterative fraction scheme. Future research on similar tasks would benefit from a qualitative analysis of participant responses and a wider range of participants, but initial findings show the potential for assessing three levels of units coordination by using tasks that activate a fourth level of units coordination.

ANALYSIS OF THE RELATIVE DIFFICULTY OF DIFFERENT INTEGER PROBLEM TYPES

Aran W. Glancy
Purdue University
aglancy@purdue.edu

Christy Pettis
University of Minnesota
cpettis@umn.edu

This paper describes an analysis of students' relative abilities to solve different types of integer addition and subtraction problems. Logistic regression and hierarchical methods revealed that, even before instruction, certain problem types proved fairly easy for students while other were extremely difficult. Specifically, certain problems involving subtracting a negative were particularly challenging. These differences have important implications for instructional strategies used to teach integer operations.

Keywords: Number Concepts and Operations

On the surface, addition and subtraction with integers, i.e. positive and negative numbers, are straightforward operations, but middle school teachers consistently find these concepts difficult to teach. When students encounter these types of problems, typically in sixth or seventh grade, they struggle to understand why subtracting a negative actually increases the result. To help their students, teachers often employ a variety of models (e.g., number lines or chips), contexts (e.g. temperature, or money), and/or procedural rules (e.g. "keep-change-change") (Tillema, 2012, Whitacre et al., 2011). These approaches are often most helpful for certain types of integer problems and exhibit weaknesses when applied to other problem types. For example, a student might solve $5 + (-3)$ by thinking of having $5 and owing someone else $3, leaving $2. This approach is much more difficult, however, for a problem like $5-(-3)$, where the idea of removing an owed amount is not as easily understood. Typically, these differences between the effectiveness of models, contexts, or rules for different problem types are not addressed in the literature, and classroom teachers tend to focus on common models and contexts that, while effective for some problems, are not helpful for the most difficult integer subtraction problems. The tacit assumption being that providing students productive ways to think about certain problem will help them to be more successful on all problems. The goal of this analysis is to examine student performance on different integer addition and subtraction problems to highlight the significant differences in difficulty between the problems. Once the most difficult problems are identified, we can examine the weaknesses of common instructional approaches in supporting student thinking around those problems and hopefully move forward in designing better, more effective instructional strategies.

Theoretical Framework

The majority of research on the teaching and learning of integer operations focuses on two areas: how students conceptualize positive and negative numbers, and the models and contexts that teachers use to teach these concepts. Bofferding (2014), Bishop et al. (2016), and Whitacre et al. (2011) for example, examined the ways that young children reasoned through symbolic integer problems, demonstrating that even in early grades students are capable of applying a variety of approaches to integer problems. These authors also found that students often try to apply or extend whole number reasoning strategies to signed number problems with varying degrees of success. While the ways students conceptualize integers and the strategies they use to solve problems are well documented, the effectiveness of those conceptions or strategies for different types of problems is less well understood.

The other major strain of research revolves around different instructional strategies used to teach students to add and subtract integers. Battista (1983) outlined the use of collections of charged particles for modeling integer addition and subtraction, and Hayes and Stacey (1998) described a similar strategy involving integer tiles (yellow and red *chips* representing positive and negative numbers respectively). Stephan and Akyuz (2012) documented the use of *debts* and *credits* (a more intentional application of the context of *money*) in conjunction with a number line model. Tillema (2012) described using contextual stories that embody models such as colored chips or number lines, and Whitacre et al. (2011) pointed out several other models and contexts such as temperature, and directed distance/motion on the number line that appear frequently in textbooks. In most of these cases, the articles discuss in general the merits and disadvantages of each of these approaches; however, these discussions rarely examine the ways these approaches interact with specific types of problems. Very little research has yet attempted to look at the structural properties of different integer problems and connect those properties to students' difficulties or successes with the problems.

Methodology

This study uses both logistic regression and hierarchical linear methods to examine the relative performance of students on different types of integer addition and subtraction problems. The data for this analysis came from a pilot study of 6th grade students at a suburban, midwestern public school.

Research Question

The question addressed with this analysis is "How are structural characteristics of integer addition and subtraction problems related to students' abilities to successfully solve those problems?" Although there are a variety of ways to categorize the structural properties of integer addition and subtraction problems, for this analysis, problems were categorized by the sign of the addends (for addition) or of the minuend and subtrahend (for subtraction), by the sign of the answer, and by the primary operation. Based on this classification, there are 12 types of integer addition and subtraction problems. The problem types and their (arbitrary) identifiers, along with an example for each type, are summarized in Table 1.

Participants and Instruments

The participants in this study were all of the students (n = 159) in the sixth grade class of a suburban, midwestern middle school. The students were spread across three teachers and seven classes, and represent all ability and demographic groups present at the school. In recent years, the school has typically scored slightly below average on state standardized tests, and approximately 40% of students are on free or reduced lunch.

The data in this analysis come from a 15-question free response test involving single digit integer operation problems of different types (see Table 1). "Whole number" problems, i.e. problems that did not require students to engage with negative numbers such as 2 + 3 = 5, were omitted as they were deemed not necessary. The frequency with which each type was tested is also shown in Table 1. Each problem was scored correct (1) or incorrect (0). This test was given prior to instruction as we were interested in students baseline abilities on these problems.

Analysis and Results

The analysis proceeded in two phases. In the first phase, a simple logistic regression was performed to model the probability of success on a specific problem given the problem type and controlling for the student's overall ability as measured by his or her total score on the test. *Figure 1* shows a plot of 95% confidence intervals for the predicted probabilities of success for each problem type after controlling for a students' overall score. Notably, students are fairly successful on the addition problems (Types 2-5) and two of the subtraction problems (Types 11 and 15) even prior to instruction, while Types 12, 13, and 14 showed extremely low success rates.

Table 1: The Twelve Integer Problem Types and Examples

	Identifier	Problem Types	Example	Number of Test Items
Addition	Type0	(+) + (+) = (+)	2 + 3 = 5	0
	Type1	(+) + (-) = (+)	3 + (-2) = 1	0
	Type2	(+) + (-) = (-)	3 + (-5) = -2	1
	Type3	(-) + (+) = (+)	(-2) + 3 = 1	1
	Type4	(-) + (+) = (-)	(-3) + 2 = -1	1
	Type5	(-) + (-) = (-)	(-3) + (-2) = -5	1
Subtraction	Type10	(+) - (+) = (+)	5 – 3 = 2	0
	Type11	(+) - (+) = (-)	5 – 7 = -2	1
	Type12	(+) - (-) = (+)	5 – (-2) = 7	3
	Type13	(-) - (+) = (-)	(-5) – 3 = -8	2
	Type14	(-) - (-) = (+)	(-3) – (-5) = 2	3
	Type15	(-) - (-) = (-)	(-5) – (-2) = -3	2

The logistic regression makes it clear that certain problems are more difficult than others, but it is not able to account for the potential for individual students to respond differently to the more challenging problems. For this reason, a secondary analysis was carried out using a hierarchical repeated measures approach (Raudenbush & Bryk, 2002). In this analysis, the test items were treated as nested within students, and the students' scores on individual problems were aggregated over problem type (as a percent) and were treated as repeated measures of the students' general ability to solve integer problems. Based on the results of the logistic regression analysis, a difficulty score was assigned to each problem type (the log-odds for that problem) and this difficulty score was used as the predictor for the repeated measures. If there were truly no difference between problem types, we would expect the slopes for each student relative to the problem difficulty to be zero. In this case, a two-level model was fitted (problem type scores nested within students), where problem difficulty was used as a level 1 predictor and overall score (grand mean centered) was used as a level 2 predictor. Intercepts and slopes were allowed to vary randomly. This analysis revealed that the slopes were not zero (*difficulty slope* = 0.135, p <0.001), instead implying that between the easiest and hardest problems (a difference in log-odds of about 2.2) we would expect a difference in score of about 30%. Additionally, the slope corresponding to the interaction between problem difficulty and overall score, 0.34, ($p < 0.001$) indicates that higher overall scores actually increase the impact of problem difficulty making the gap between the hard problem and the easier problems even larger.

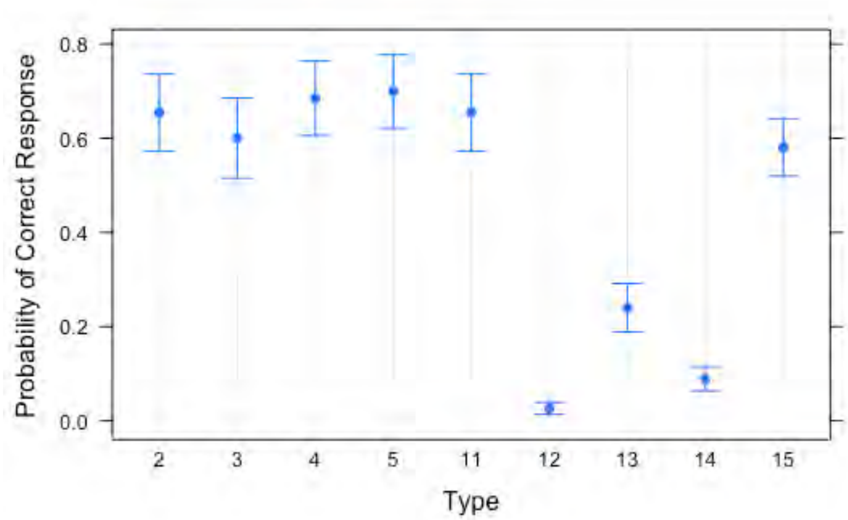

Figure 1. 95% Confidence Intervals for the probability of success for an average student on each problem type after controlling for overall pre-test score.

Conclusions

Based on this analysis, all integer addition and subtraction problems are not alike. Specifically, problem types 12, 13, and 14, appear dramatically different from the rest. Furthermore, the significance of the interaction between the problem difficulty and the students' overall score implies that these problems are, relatively speaking, even more difficult for the stronger students. This indicates that careful thought should be given as to how to help students think about and solve specific problem types, namely those involving subtracting a negative, not just integer operations problems in general. Additionally, because not all models and metaphors work equally well for all types, these results suggest that students would benefit from instruction targeted at those models and metaphors which are most helpful for the most challenging problem types.

COLLEGE STUDENTS' KNOWLEDGE OF THE EQUAL SIGN AND ITS RELATION TO SOLVING EQUATIONS

Decades of research have documented young students' misunderstanding of the equal sign. Further, these misunderstandings matter, as young students' knowledge of the equal sign relates to their performance on key algebra problems. However, much less is known about whether knowledge of the equal sign matters beyond elementary and middle school – after students have completed Algebra and have experience with the equal sign in a variety of contexts. In the current study, we assessed 189 college students' knowledge of the equal sign and examined how it related to their performance on formal algebra problems. College students varied in their definitions of the equal sign. Further, students who only provided operational definitions of the equal sign were less likely to solve and interpret key algebra problems correctly. Results suggest that knowledge of the equal sign matters well beyond elementary and middle school.

Keywords: Algebra and Algebraic Thinking, Problem Solving, Standards

Introduction

A large body of research has focused on students' understanding of the equal sign – a concept fundamental to algebra (e.g., Baroody & Ginsburg, 1983; Behr et al., 1980; Matthews et al., 2012; McNeil & Alibali, 2005). The equal sign is ubiquitous at all levels of mathematics, and relational knowledge of the equal sign is included in the Common Core State Standards as early as first grade (National Governors Association Center for Best Practices, 2010).

Unfortunately, decades of research have established elementary and middle school students' difficulties with the equal sign indicating that they often view it operationally, as a signal to do something. Indeed, many students define the equal sign as "the answer" or "the total" (e.g., Alibali et al., 2007; Behr et al., 1980; McNeil & Alibali, 2005), and these definitions matter. For example, in Knuth et al. (2006), approximately one third of middle school students provided a relational definition of the equal sign (e.g., "the same"), and those students were almost twice as likely to solve algebra equations correctly (e.g., $4m + 10 = 70$) as students who did not.

Much less is known about older students' knowledge of the equal sign and whether it matters for their success on algebra problems. Younger students' difficulties with the equal sign are often thought to stem from their overly narrow experience with problems presented in a standard "operations-equals-answer" format (McNeil & Alibali, 2005). College students, however, have already passed Algebra and have experience with the equal sign in a variety of contexts. That said, some limited research suggests that an operational view of equations persists among college students. For example, undergraduates sometimes solve standard equality problems (e.g., $6 + 8 + 4 = 7 + \_\_$) using operational "find the total" strategies, particularly under speeded conditions (e.g., Chesney et al., 2013; McNeil & Alibali, 2005). But no research to date has documented college students' explicit knowledge of the equal sign and whether it relates to their equation-solving success. Moreover, few studies with students of any age have examined the relation between students' knowledge of the equal sign and their conceptual interpretations of variable expressions (e.g., $3a$, $a + 3$). Variable expressions are fundamental in Algebra, yet do not contain the equal sign. We contend that if knowledge of the equal sign is truly foundational for algebraic thinking, it should predict performance on a variety of algebraic tasks – including tasks with expressions that do not include the equal sign (Kieran, 1981).

Galindo, E., & Newton, J., (Eds.). (2017). *Proceedings of the 39th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* Indianapolis, IN: Hoosier Association of Mathematics Teacher Educators.

Method

Participants

Participants were 189 college students attending a large public university in the western region of the U.S. The student body at the university is 53% female, has an average age of 26, and 92% are in-state residents. Participants (~58% female) were recruited from their college-level developmental math courses and they received course credit for their participation.

Measures

Equal sign definition. Students provided written responses to two questions: "What does this symbol (=) mean?" and "Can it mean anything else?" Responses to each question were coded as relational, operational, or other (see Knuth et al., 2006). A response was coded as *relational* if it expressed the idea that the equal sign means the "same as" or the "same amount" and as *operational* if it expressed the idea that it means "add the numbers" or "the answer." Responses coded as *other* included definitions such as "equal to." Some students provided more than one interpretation, so we also assigned an overall code indicating their "best" interpretation (e.g., if they provided a relational and an operational definition, their best code was relational).

Algebraic equation-solving. Students also solved a set of three basic equations. Approximately half of the students (n = 92) completed Version 1 and the other half of the students (n = 97) completed Version 2. See Table 1 for the items. Responses were coded as correct if the student provided the numerical answer that satisfied the equation.

Table 1: Equation-Solving Items on Each Version of the Assessment

Version 1	Percent Correct	Version 2	Percent Correct
$13 = n + 5$	97%	$10 = z + 6$	98%
$c + c + 4 = 16$	83%	$c + c + 4 = 16$	65%
$z + z + z = z + 8$	78%	$m + m + m = m + 12$	64%

Algebraic expression-interpretation. Students also provided written responses to the following: "Cakes cost c dollars each and brownies cost b dollars each. Suppose I buy 4 cakes and 3 brownies. What does $4c + 3b$ stand for?" On Version 1 of the assessment, the symbols used were mnemonic in that the price of a cake was represented by c and the price of a brownie was represented by b. On Version 2, the symbols used were traditional in that the c and b were replaced by the letters x and y. This contrast has been of interest because use of mnemonic symbols may strengthen students' naïve conceptions that variables in algebraic expressions stand for labels instead of quantities (Küchemann, 1978; McNeil et al, 2010). Responses were coded as correct if it indicated that the letters stood for the cost or price of the cakes and brownies.

Results

Students varied in their definitions of the equal sign. Only 66% of sampled college students provided a relational definition of the equal sign. Nearly half (47%) provided an operational definition, and nearly a quarter (23%) provided a vague, "equal" definition. In terms of students' "best" definitions, 65% were relational, 18% were other/equal, and 17% were operational.

We examined the relation between students' equal sign understanding and their performance solving algebraic equations. We created a total equation-solving score by summing their scores on each of the three equation-solving items. Figure 1 shows their performance.

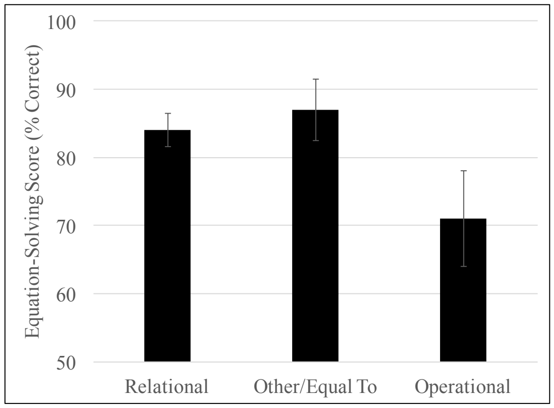

Figure 1. Percent correct on equation solving as a function of equal sign definition.

Providing only an operational definition was predictive of college students' equation-solving scores. Students who only provided an operational definition had lower equation-solving scores (M = 71%, SD = 33%) relative to other students (M = 85%, SD = 24%), $t = 2.30$, $p = .02$. This was primarily driven by performance on the more difficult algebraic equations. For example, students who only provided an operational definition were significantly less likely to solve $z + z + z = z + 8$ correctly relative to students who provided relational or other/equal to definitions (56% vs. 83%), χ^2 (1, N = 92) = 5.35, $p = .02$, and less likely to solve $m + m + m = m + 12$ correctly relative to other students (30% vs. 69%), χ^2 (1, N = 97) = 5.81, $p = .01$.

We also examined the relation between students' equal sign interpretation and their conceptual interpretation of an algebraic expression – a key mathematical object in algebra that does not include the equal sign. Overall, 65% of college students interpreted the expression correctly by indicating that the variables stood for the costs of the cakes and brownies. Of all the incorrect responses, 48% were the common "labels" error (e.g., interpreting the variables as labels for the objects; "four cakes and three brownies"). However, performance varied somewhat by the letter used. Students given the x-and-y version were somewhat more likely to interpret the expression correctly than students given the c-and-b version (72% vs. 60%), χ^2 (1, N = 189) = 2.79, $p = .09$. Further, students given the x-and-y version were significantly less likely to make the common labels error than students given the c-and-b version (9% vs. 24%), χ^2 (1, N = 189) = 7.06, $p = .01$. This suggests that, even among college students, the use of mnemonic letters can interfere with the ability to conceptually interpret the algebraic expression. Importantly, students' equal sign definitions were related to performance. Students who only provided an operational definition were significantly less likely to interpret the expression correctly relative to other students (47% vs. 71%), χ^2 (1, N = 189) = 6.48, $p = .01$, and somewhat more likely to make the labels error (27% vs. 14%), χ^2 (1, N = 189) = 2.97, $p = .09$. These relations were similar for both expressions, but somewhat stronger for the expression containing the mnemonic c-and-b letters.

Conclusion

We examined college students' knowledge of the equal sign and its relation to their performance on key algebraic problems. We found that college students varied in their definitions of the equal sign. Although many students endorsed a relational understanding, many also endorsed an operational understanding, and a small minority *only* provided an operational definition. Importantly, knowledge of the equal sign mattered. Students who only provided an operational definition were less likely than their peers to solve key algebraic equations correctly and to interpret an algebraic expression in a conceptually correct way. These results extend previous research on the importance of the equal sign with elementary- and middle-school students (e.g., Knuth et al., 2006; Matthews et al., 2012), and suggest that knowledge of the equal sign is important beyond these early grades, even after students have completed Algebra.

These findings provide support for the theoretical relation between understanding of equality and formal, algebraic reasoning (e.g., Linchevski & Herscovics, 1996). As in prior work with younger students (e.g., Alibali et al., 2007; Knuth et al., 2006), we found that knowledge of the equal sign was related to equation-solving success among college students. However, we also found that knowledge of the equal sign was related to students' conceptual interpretation of an expression with variables – a key algebraic problem that does *not* include the equal sign. Thus, this research establishes a more general connection between knowledge of equality and algebra – students who view the equal sign operationally also tend to view equations and expressions in terms of processes and operations rather than as objects or structures that can be manipulated (Kieran, 1981; Linchevski & Herscovics, 1996). In general, this research highlights a need to focus on the importance of the equal sign beyond middle school.

DEVELOPING FUNCTION UNDERSTANDING THROUGH DEPENDENCY RELATIONS OF CHANGE

Amy Ellis

mfatihdogan@adiyaman.edu.tr

Understanding function is a critical aspect of algebraic reasoning, and building up functional relationships is an activity increasingly encouraged at the elementary and middle school levels. This study identifies how one group of middle-school students leveraged their rate of change thinking to inform the development and understanding of correspondence rules. Drawing on an analysis of a 15-day teaching experiment with 6 eighth-grade students, we introduce three dependency relations of change concepts – recognition, identification, and translation – and discuss how these concepts support students' transitions to more formal algebraic expressions.

Keywords: Algebra and Algebraic Thinking, Middle School Education

Research Issues and Purpose

Recommendations for fostering students' algebraic understanding include introducing functional relationships in upper elementary and middle school (e.g., Blanton & Kaput, 2011), with researchers arguing that functions can unite a wide range of otherwise isolated topics, encourage student inquiry, and provide a rich context for generalization and justification. However, students' difficulty in developing function understanding is well documented (Stephens et al., in press), highlighting the need to better support an emerging function concept that is flexible and mathematically productive. Approaches to function often distinguish between correspondence views (e.g., Smith, 2003) and covariation views (e.g., Confrey & Smith, 1994; Thompson & Carlson, in press). Separately these approaches emphasize either a direct mapping relationship between x and y, or attention to a coordinated change in one quantity with associated change in the other. These two ways of thinking about function are often presented as separate approaches, with researchers advocating for flexibility across these modes of reasoning in order to inform a more robust understanding of function (Stephens et al., in press). It remains an open question, however, how one can leverage a covariation perspective to inform the correspondence view and vice versa. In this paper, we address the following research question: How might students capitalize on their understanding of function from one mode of reasoning in order to inform their thinking in the other? In particular, we characterize the transition made by middle-school students who leveraged their coordinated change thinking to inform the development of correspondence rules in the context of instruction about quadratic functions. We identify three student concepts, which we term *dependency relations of change* concepts, that address how students recognized and developed links between these modes of reasoning.

Theoretical Framework and Background

Two perspectives typically drive a function-based approach to algebraic reasoning: the correspondence perspective and the coordination/covariation perspective. The correspondence view emphasizes a function as a relationship between members of two sets, in which $y = f(x)$ represents a mapping, with each value of x is associated with a unique value of y (Smith, 2003). This view underlies traditional instruction on functions (Yerushalmy, 2000), and offers the affordance of emphasizing the development of closed-form rules that can be used to analyze and predict function behaviors. In contrast, Thompson and colleagues (e.g., Thompson & Carlson, in press) and Confrey and Smith (e.g., Confrey & Smith, 1994) offer a covariation model, although they address ideas of covariation differently. Confrey and Smith describe an approach relying on coordinated changes of x- and y-values, in which one can coordinate a shift from y_m to y_{m+1} with a corresponding shift from x_m to x_{m+1}. Such an emphasis on the coordination of sequences is a natural fit for tasks relying on images or tables that present successive states of variation.

Thompson and Colleagues (e.g., Saldanha & Thompson, 1998) also discuss ideas of covariation, but from the perspective of identifying students' reasoning about quantities that vary, together, either simultaneously or interdependently. This form of reasoning involves mentally coordinating two varying quantities while attending to how they change in relation to one another, and thus represents a dynamic perspective of covariation. This work also leverages the notion of quantity as a conceptual entity composed of a person's conception of an object, a quality of the object, such as length or height, an appropriate unit for measurement, and a process of assigning a value to the quality (Thompson & Carlson, in press). For the purposes of this paper we use the term *covariation* to refer to students' dynamic coordinated images of change, and *coordination* to refer to students' static coordinated images of change. In both cases, students can begin to develop an understanding of classes of functions in terms of their characteristic actions (e.g., recognizing that linear functions represent a constant rate of change while quadratic functions represent a rate of change that is constantly changing).

Methods

The data presented are from a 15-day videotaped teaching experiment conducted with 6 8th-grade students. The participants included 3 students in general 8th-grade mathematics, 2 students in pre-algebra, and 1 student in 8th-grade algebra. None of the participants had been introduced to quadratic function in their mathematics courses at the time of the study. Each session lasted 1 hour, and all sessions were transcribed. Our aim was to build students' understanding of quadratic function from a rate-of-change perspective, in which quadratic growth is conceived as a constantly changing rate of change. We therefore grounded students' exploration in one context, that of a rectangle that grew while maintaining its length/height ratio. Students worked with computer simulations of different growing rectangles and made area predictions, created algebraic rules for height and area, and made graphs representing those relationships.

Data sources included video and transcripts from the teaching sessions and copies of the students' written work. Following the constant comparative method (Glaser & Strauss, 1967), we developed emergent categories of student concepts about quadratic growth and function based on evidence from students' written work, descriptions of their ideas, drawings, and gestures. Each co-author independently analyzed each of the 15 sessions before coming together to discuss and reconcile code decisions. This led to a series of iterative revisions to the coding scheme on a day-by-day basis until no new codes emerged.

Results: Identification of Dependency Relations of Change

We present three concepts within a family of related ideas we call *dependency relations of change*. These concepts address how students can leverage coordination thinking into the development of correspondence relations by attending to how the magnitude of change in one quantity determines the magnitude of change in an associated quantity. Students evidenced three stages of thinking as they began to shift from coordinated changes to relating those changes to direct correspondence rules: *recognition*, *identification*, and *translation* (Table 1).

Below we provide excerpts characterizing students' thinking across the three concepts. The students invented a number of terms to capture the change in quantities. They described the change in height and length values as "DiH" and "DiL", respectively, referring to the difference in successive height or length values when organized in a table or a series of figures. The students used the term

"RoG" to refer to the rate of growth of the rectangle's area for successive increases in height/length, and they used the term "DiRoG" to refer to the difference in the rate of growth of the area, $\Delta(\Delta A)$.

Table 1: Recognition, Identification, and Translation

Concept Definition	Data Example
Recognition: Understanding that the magnitude of the change in one quantity determines the amount of change in another quantity. Student understands that there is a dependency relation without determining what that relation is.	*Jim*: So, couldn't your rate of growth be, like, really high instead of just…if you're going, like, every other one, or you can go like every 5 or whatever (referring to increases in height values). So your rate of growth (for the area) can change no matter what.
Identification: Quantifying the relation between changes in associated quantities. Student can identify a quantity (or its change) as dependent on and determined by the change in the associated quantity and can characterize this dependency relation.	*Tai*: (Referring to a table of values coordinating successive height (H), length (L), and area (A) values for a growing rectangle) DiRoG divided by DiL equals…and, divided by DiH equals 2. [Here he verbally expressed the relationship $\left[\frac{\frac{\Delta\Delta A}{\Delta L}}{\Delta H}\right] = 2$.]
Translation: Expressing the relation between changes in two quantities in an algebraic rule, such as $y = ax^2$. Student understands the rule in terms of a relation of change.	*Daeshim*: [Wrote the equation $A = \frac{5}{3}h^2 + 4$] *Bianca*: Where did you get that? (Referring to 5/3). *Daeshim*: DiL over DiH. [Here $a = \frac{\Delta L}{\Delta H}$]

As shown in Table 1 with Jim's comment, the students first understood that the change in height, for instance, would determine the rate of growth of the area and $\Delta(\Delta A)$, but they could not yet determine how that change would affect the other changes. Tasks providing different tables of values for the same rectangle induced the students to begin to account for how multiple quantities changed together. For instance, consider a task that presented four tables of height/area pairs for the same growing rectangle. Each table grew by uniform increments in height, which were 1 cm, 2cm, 5 cm, and 10 cm respectively. Prior to this task the students had characterized the DiRoG as the rate at which a rectangle added units as it grew in height and length, so they knew that it would be greater for larger increments (*recognition*), but they did not know how much larger. For the Four Tables task, however, Tai found a way to relate the DiRoG to the changes in both the height and the length (*identification*): "Take the DiRoG of the area, and you divide by the difference in the length…and also divided by, the difference in height…and, always equals 2." Tai identified a dependency relation between ΔH, ΔL, and $\Delta(\Delta A)$, but he did not connect that relation to a correspondence rule. Similarly, Bianca noticed that $\Delta(\Delta A)$ could be expressed solely in terms of the change in height values: "So it's basically like 3 DiH squared times 2", which Tai then expressed as "$3 \times [\text{DiH}]^2 \times 2$ = DiRoG of Area". The students correctly wrote the rule $A = 3h^2$ to express the area in terms of height, but they struggled to understand how the parameter 3 related to the quantities length, height, or area.

The *translation* concept emerges when students leverage their coordination thinking to create and make sense of correspondence rules. For instance, two days later the students worked with a rectangle with the following height and area values: (2, 1), (5, 6.25), (7, 12.25), (8, 16), and (10, 25). Bianca realized that the length was ¼ of the corresponding height for each pair and wrote "$h(.25h)$" to express the area. Tai then reacted to Bianca's rule by exclaiming, "The DiL divided by DiH equals that number (0.25)." Tai had divided the *change* in length by the *change* in height for each successive pair of values, and found the ratio to be 0.25. Subsequently, Tai and the other students began to determine ratios of change in order to develop correspondence rules (*translation*). For instance, given a new task with three pictures of a growing rectangle with an unchanging "tail" of 4 square cm, the students determined that for each 3-cm increase in height, there was a 5-cm increase in length. They were then able to form the rule A = $5/3h^2 + 4$. Daeshim explained the parameter 5/3 as the ratio of ΔL to ΔH, and Bianca noted that one could also think of this as the ratio of sides for any given rectangle. Ultimately the students also related the parameter "a" to Δ(ΔA), but learned that they had to account for Δ*h*, expressing this relationship as "a = DiRoG/2" when Δ*h* was 1.

Discussion

The teaching experiment students began attending to functional relationships through coordinated changes, an approach common with middle-school students (Stephens et al., in press). Ultimately they were able to leverage coordinated changes in the associated quantities height, length, and area in order to make sense of the correspondence rules they wrote. The students understood those correspondence rules – particularly the parameter "a" – in a number of ways, with the more powerful meanings being those that emerged from their activities of coordinating growth in the relevant quantities. These findings suggest that coordination and correspondence views do not have to arise separately or in parallel, with robust understanding being limited to translating across forms of reasoning. Rather, correspondence rules can emerge from a coordination view and can also represent a formalization of the activities of coordination and covariation. This suggests an avenue for future research in investigating the ways in which covariation and coordination can support function understanding across the function families.

This study explores the conditions that support students in forming verbal generalizations in one Grade 4 classroom's discussions. By analyzing the student-teacher discourse in ten teaching segments, we coded for purpose of statement, as well as technique for fulfilling the purpose. We identified sixteen statements of generalization. The data reveal that students' generalizations are linked to discursive moves associated with the purpose of extending and the techniques of requesting for justification and justifying. We argue the findings have implications for instruction that fosters generalizing.

Keywords: Algebra and Algebraic Thinking, Elementary School Education

Generalizing is "intrinsic to mathematical activity and thinking" (Kaput, 1999, p. 137), yet students struggle to generalize, often make weak generalizations, and rarely justify their generalizations (Breiteig & Grevholm, 2006). Supporting generalizing in the mathematics classroom requires a better understanding of the conditions that encourage students' generalizing. This issue is central to our research, which seeks to understand the nature of the discourse that supports students' generalizing. In particular, the study reported here explores the conditions that support students in constructing generalizations in Grade 4 classroom discussions. Working from the premise that discourse represents the interrelationships between thought and speech (Truxaw & DeFranco, 2008), we examine teacher-student discourse to gain insight into students' generalizing.

Generalization and Discourse

We define generalization as the situated activity of "lifting" and communicating reasoning to a level where the focus is no longer on a particular instance, but rather on patterns and relationships of those particular instances (Kaput, 1999, p. 137). To explore how discourse supports generalizing we use the concepts of linguistic moves. Moves are utterances that can be categorized based on the speaker's purpose. For example, initiating moves occur when the teacher introduces an idea, knowing that it will likely prompt centering or extending moves (Lobato, Clarke, & Ellis, 2005). Re-centering moves are responses to the conversation changing track or needing redirection (Love & Suherdi, 1996) and provide conceptual anchoring. Extending moves are used to obtain or offer additional information through elaborating or enhancing ideas (Gonzalez & DeJarnette, 2012). And centering moves continue the conversation without changing the track. Recentering, centering, and extending moves are responsive in nature, meaning they are usually a part of an exchange (Truxaw & DeFranco, 2008). Each move may also be assigned to a technique. The technique is the way in which the speaker fulfills their purpose. For example, if the purpose of a teacher's move is to extend, she might use the discursive technique of requesting justification.

Methods

Participants (n=21) were from one Grade 4 classroom participating in an early algebra intervention that was taught by a member of our research team. All lessons in the intervention were video recorded and transcribed. Each video recording was segmented into clips of classroom discussion, of which the first ten were selected for analysis.

This research is a part of a larger project (viz., Blanton et al., 2015), aimed at designing and evaluating the effectiveness of a longitudinal early algebra intervention in Grades 3-5. Clips were selected by the larger research team based on their representation of exemplary teaching to be used in professional development supporting the implementation of an early algebra intervention. Analyzing these clips allowed us to focus on the discourse-rich moments of the lesson. Clips were de-identified using gender appropriate pseudonyms and numbered randomly.

We conducted a multi-level analysis of the classroom discourse. That is, the transcribed videos were organized by each speaker's (students or teacher) statement. Then, based on the inferred goal of the speaker, each move (or utterance) was coded for purpose and technique for fulfilling that purpose (Gonzalez & DeJarnette, 2012). Additionally, we recorded generalizations (Ellis, 2011), and situated these generalizations in the discourse in order to describe the discursive moves and techniques that contributed to and resulted from the generalizations. We identified statements within discussions that could be characterized as generalizations according to Kaput's (1999) definition. Namely, we coded statements made by students that indicated their reasoning was no longer on a particular instance, but rather on general patterns and relationships of those particular instances (Kaput, 1999). At least two members of our research team coded each transcript. Codes were discussed until agreement was reached.

Findings

In the ten clips that were analyzed, we identified 14 techniques. Here we report on two interrelated techniques. The first technique, requesting justification, occurred when the speaker, usually the teacher, responded to an idea by encouraging the original speaker to support their idea by providing an explanation. The second technique, justifying, occurred when the speaker (formally or informally) described why they believed his or her idea is true.

We found 16 student utterances that were characteristic of Kaput's definition of generalization. Clips were ranked based on the frequency of generalizations with respect to the length (in number of turns and time). Clips 3, 5, and 6 were the most generalization-dense based on the total number of generalizations and the total turns in each segment. Whereas clips 2, 7, and 8 were the most generalization-sparse. Important differences between these clips in terms of purpose, techniques of the teacher, and techniques of the students are captured in Table 1. The percentages refer to the frequency of a particular purpose or technique within the discussion.

Of the 16 utterances coded as generalizations, 11 were coded as Student Response as Justifying Technique. This finding supports prior findings (e.g., Ellis, 2011) regarding the relationship between generalizing and justifying; specifically that generalization and justification are interrelated, inseparable mental activities.

We identified a variety of techniques, but here we focus on two techniques—Teacher Request for Justification Technique (rejust) and Student Response as Justifying (just)—because we noticed a relationship between these techniques and generalizations. In particular, we observed that in comparison to the generalization-sparse clips the generalization-dense clips had a higher percentage of the techniques, teacher requests for justification and student responses as justifying. Conversely, in the generalization-sparse clips, we found an overwhelming percentage of student responses that do not map to a technique. This finding indicates that students frequently reply with an answer only (no explanation) in the generalization-sparse clips.

Table 1: Generalization-Dense Clips Vs. Generalization-Sparse Clips

	Generalization-dense Clips			Generalization-sparse Clips			Overall
	Clip 3	Clip 5	Clip 6	Clip 2	Clip 7	Clip 8	
Extending Purpose Moves	26.3%	13.7%	12.5%	6.4%	2.6%	8.3%	11%
Teacher Request for Justification Technique	6.7%	15.4%	0%	0%	3.5%	0%	8.4%
Student Response as Justifying Technique	50%	27.3%	50%	0%	10%	0%	12.3%
Student Response with No Technique	25%	48.5%	0%	74%	80%	83%	15.6%

Furthermore, we observed that the generalization-dense clips have a higher percentage of moves with the purpose of extending. For instance, extending occurred when a teacher used domain-specific vocabulary to rephrase a student's idea, or when a question is posed to encourage a student to provide additional explanation.

Drawing from the data presented in Table 1, we conclude that generalizations occur in an environment where: (1) The teacher pushes for more extending purpose moves; (2) The teacher requests justification from student answers; and (3) The students provide justification for previous answers that do not contain reasoning. Because moves and techniques occur on different levels, finding (2) and (3) are subsets of finding (1). Additionally, finding (2) and (3) often occur sequentially because one prompts the other.

Discussion

In the generalization-dense clips, we observed a higher percentage of extending purpose moves. Whereas, we noticed the generalization-sparse clips lack a high frequency of extending moves. Instead, the teacher spends a majority of class time recentering or centering the class discussion, which implies that more time is needed to help students understand the basis of the problem being addressed. Such situations minimize actions that push students into deeper problem solving. We claim teaching segments that utilize extending moves are more likely to result in student generalizations because those instances push the students to provide more information within their responses.

In the generalization dense clips, we observed a higher percentage of teacher requests for justification. These requests for justification often take the form of a follow-up question to a student response. For example, the teacher may ask, "How do you know?" or "Why?," encouraging students to explain their reasoning. This was the most common catalyst for student justification as well as generalization. Since the teacher's requests for justification were linked to students' generalizations, we saw a higher percentage of student justifying techniques in generalization-dense clips. Justification techniques occurred when students explained why their answer was correct. For instance, we observed one student (Steven) respond to the question "$m = 1 \times$ ___" as "m." Following the teacher's request for justification ("How do you know?"), Steven justified his answer as shown in Table 2. Due to our multi-level analysis of purpose, technique, and generalizations, this example represents a statement that could be characterized as both a generalization and a Student Response as Justifying (just) technique. The teacher's response technique is confirming (cf). It is also important to note that students often begin justifying statements by using the word "because."

Table 2: Excerpt from Clip 5 on Student Generalizing

Speaker	Move/Utterance	Purpose	Technique
Teacher	How do you know?	Extend	rejust
Steven	Because *m* can equal any number and 1 times anything would equal that number.	Recentering	just
Teacher	Very, very, good. Excellent	Centering	cf

We argue that the results of this study have a high-impact potential to inform instruction, because educators are able to incorporate the techniques that encourage generalization into curriculum. We suggest these findings be viewed as a starting point for research on supporting mathematically productive generalizing in the elementary classroom. Moving forward, we aim to build on and refine our claims by analyzing a broader sample of classroom discussion segments, so they have direct implications for educators. We also recognize that there are many ways to support generalizing, and that this is only one approach. We hope that future research explores this avenue and aims to uncover other ways to support generalizing, because research in this area is critical to advancements in mathematics education.

GRADE 5 CHILDREN'S NUMBER LINE DRAWINGS FOR INTEGERS

Nicole M. Wessman-Enzinger
George Fox University
nicole.enzinger@georgefox.edu

Three Grade 5 children participated in twelve weeks of a teaching experiment on integer addition and subtraction, and participated in four individual interviews across the 12-weeks of the teaching experiments. Drawing on the theoretical perspective of learner-generated drawings, the types of number line drawings produced by the children are qualitatively described. The children often unconventionally drew different types of number lines drawings (Number Sequence, Empty Number Line, Number Line). The results point to the importance of making sense of children's constructions before imposing integer instructional models.

Keywords: Number Concepts and Operations, Elementary School Education, Cognition

We know that children often use strategies that incorporate drawings for solving addition and subtraction problems with positive integers (Carpenter, Fennema, Franke, Levi, & Empson, 2015). Children often use drawings paired with direct modeling or counting strategies as they invent strategies for solving whole number addition and subtractions problems. Although there is significant research into the different instructional models for the teaching and learning of integers (e.g., Javier, 1985), we know little about the drawings that children employ as they transition from using positive integers to negative integers. Bofferding (2010) demonstrated that children often use a number path, or a sequence of numbers written in boxes, when solving integer problems. Other researchers have shown that children will use a variety of ways to reason about the integers which include order-based reasoning (e.g., Bishop et al., 2014; Bishop, Lamb, Philipp, Whitacre, & Schappelle, 2014). Order-based reasoning is when a child draws upon the order of integers to make decisions about integer addition and subtraction (e.g., -2 + 3 may be determined by counting up 3 from -2). Despite the vast amount of research on the ways that student think about integers (e.g., Bofferding, 2014; Bishop et al., 2014), we need to know more about the ways that children reason about integers in relationship to the types of drawing they produce, such as number lines. Understanding children's invented drawings has potential to provide insight into ways we design instruction for negative number.

Theoretical Framework

This study draws on learner-generated drawings (Van Meter & Garner, 2005). Learn-generated drawings provide insight into the cognitive processes. Learner-generated drawings are: (a) "intentionally constructed to meet a learning goal"; (b) "meant to depict represent objects accurately"; and (c) "for which the learner is primarily responsible for construction" (p. 290). This research brief addresses these learner-generated drawings by looking at: What types of number line drawings did the Grade 5 children construct as they solved integer addition and subtraction open number sentences?

Methods

Three Grade 5 students from a rural Midwest school participated in a 12-week teaching experiment (Steffe & Thompson, 2000) centered on integer addition and subtraction, using both contextual problems and open number sentences. I used several structured task-based interviews (Goldin, 2000) to evaluate the children's' understandings of solving open number sentences in four individual sessions across the teaching experiment. During these sessions the open number sentences were provided on paper, with no manipulatives and only a box of markers available. The students were asked to explain their reasoning for solving the open number sentences. In these four sessions, the students solved 20, 23, 25, and 25 integer addition and subtraction open number sentences, respectively.

Each drawing produced by the children constituted the unit of data— there were 93 units for each child and 279 total units of data for this investigation. A constant comparative method (Merriam, 1998) was utilized for each of these units of data, beginning with an expectation that children may draw objects as they do for whole numbers (Carpenter et al., 2015), number lines (Saxe et al., 2013), empty number lines (Verschaffel, Greer, & De Corte, 2007), or number paths (Bofferding, 2010).

Types of Number Line Drawings Produced

The different types of Number Line visual mediators that emerged are highlighted and defined in Table 1. I present the frequency in which each mediator was used in Table 2. Then, I describe examples of Number Sequence, Empty Number Line, and Number Lines produced by the children.

Table 1: Different Number Line Visual Mediators Produced by Grade 5 Students

Type of Visual Mediator	Example of Visual Mediator
Number Sequence: Numbers are used in an ordered manner or list. Lists of numbers include negative or positive integers in a sequence.	Empty Number Line: There is a segment of a number line that does not use equipartitioning, but numbers are listed on the number line. The distances on the empty number line may be highlighted. Negatives may be on the right or left on a horizontal line. Negative may be on the top or bottom of a vertical line.	Number Line: There is a segment of a number line that attempts equipartitioning. Negatives may be on the right or left on a horizontal line. Negative may be on the top or bottom of a vertical line.	
Number Sequence

Alice produced Number Sequences paired with objects to help her describe and solve the number sentence -2 – 8 = □ (see Figure 1). For example, Alice first produced objects, using tallies, determined a solution of 6 for the number sentence -2 – 8 = □ and then she connected her Number Sequence to her objects. In contrast, when Jace solved □ – -2 = 1 (see, e.g., Figure 1) he created a Number Sequence by drawing numbers vertically and ordered (1, 0, -1). He used this ordered list of integers to count 2 backwards from -1 to 1, determining a solution of -1.

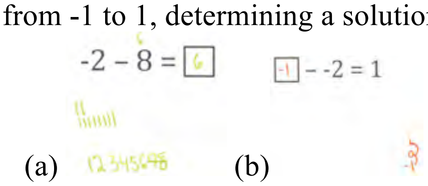

Figure 1. Number sequences produced by Alice (a) and Jace (b).

Empty Number Line

When Jace produced Empty Numbers lines he demonstrated flexibility with the positioning of the Empty Number Line—whether horizontal or vertical. He, for instance, also placed the negative integers flexibly on the right or left the Empty Number Line (see, Figure 2).

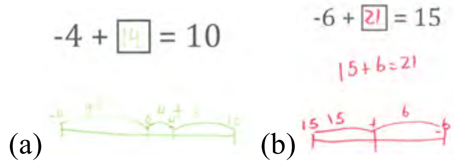

Figure 2. Empty number lines produced by Jace with negatives on left (a) and right (b).

As illustrated in Figure 2, Jace also used the Empty Number Line for determining the distance in between two integers as he solved addition or subtraction problems. In contrast, Kim focused more on moving from one point to another, using the Empty Number Lines.

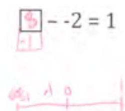

Figure 3. Empty number line produced by Kim, using distance as a directed movement.

For example, As Kim solved □ – -2 = 1 she first thought the answer was 3 and then decided to change her solution and drew a number line.

> The answer was one and here was a negative two (points at -2). So I sort of knew the only way I could get to a positive, which was the one (points at 1), which was to like have a smaller negative number (points at -2) besides 0 and then negative two. And, the only number was negative one (points at box with -1)

She started at -1 and moved to the right to 0, "losing -1," and then moved right to losing another -1 to 1.

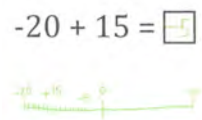
> When you subtract the two off of it, it would go, but when it hit zero it's lost one (marks number line). So, it has zero. It has one remaining over, so you could just add onto and go into the positive area. And it, when you got done using your remainders it'd be one...

Number Line

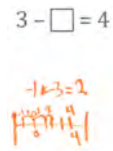
Jace and Kim drew Number Lines. Jace, for example, created a line segment from -20 to 20 when he first solved -20 + 15 = □ (see Figure 4). This was the first problem he solved in the first session and he began with equipartitioned units from -20 to -5 by starting with -20 and moving to the right 15 units drawing a tick mark each time. Similarly, Kim drew a line segment and partitioned her segment, from -2 to 5, as she attempted to solve 3 – □ = 4 (see Figure 4). Kim also used this Number Line drawing as she addressed a problem in the second session, which she was not able to solve.

The different types of drawings created are a significant component to understanding children's thinking because they illustrate the students' constructed meanings. As this study was conducted with these children prior to formal school instruction with negatives and they were not provided manipulatives or explicit instructional models, their drawings highlight the sophisticated nature of their mathematical inventions of the number line. Although we have insight into the types of drawings that children may produce for whole numbers (e.g., Carpenter et al., 2015), these descriptions of number line drawings illustrate what this may look like for children that work with integers.

(a)



(b)



l4. Number lines produced by Jace (a) and Kim (b).

Discussion

Top-down approaches where students are required to utilize a particular instructional model (e.g., number line models that specify particular movements to solve integer subtraction) may not be the best way to begin integer instruction. Rather, children should be allowed to produce and create their own drawings, which could then serve as the instructional models.

INVESTIGATING ELEMENTARY PRE-SERVICE TEACHERS' DISTRIBUTIVE REASONING AND PROPORTIONAL REASONING

Fetiye Aydeniz
Indiana University
faydeniz@indiana.edu

To investigate the relationship between PSTs' quantitative understandings of distributive reasoning and proportional reasoning, two 12-episode teaching experiment were conducted with two pairs of PSTs. During the experiments, PSTs were asked to work on particular mathematical tasks tailoring their ways of thinking regarding to proportional reasoning. Preliminary findings indicate that one of the participants was mostly illustrating the results of her way of thinking as opposed to engaging in distributive reasoning. She also had some powerful ways of thinking and did not need to show a distributive partitioning operation (DPO). On the other hand, another participant showed evidence of distributive partitioning schemes and operations throughout the experiment, which enabled her to find unit ratios and create equivalent ratios.

Keywords: Teacher Education-Preservice, Cognition, Algebra and Algebraic Thinking

Distributive reasoning plays an important role in the development of ratio reasoning (Steffe, Liss II, & Lee, 2014). An illustration of this statement would be that one way of thinking about ratios is measuring one quantity in terms of the other. If there are three tbsp. of powder and five oz. of water, the three tbsp. must be distributed across those five oz. to determine the quantity of powder that goes with one ounce. Alternately, the five oz. must be distributed across those three tbsp. to know how much water goes with one tbsp. of powder. Establishing a unit ratio, say 3/5 tbsp. of powder for each ounce of water, involves distributive reasoning. Making these unit ratios and being able to distribute them is a powerful way of establishing equivalent ratios. So, construing the distribution as measuring one quantity in terms of another quantity demonstrates that distributive reasoning is involved in proportional reasoning and reasoning with ratios.

The main purposes of this research, which is part of my dissertation project, are to understand how pre-service teachers (PSTs) reason distributively and proportionally, and to examine relationships between PST's distributive reasoning and proportional reasoning. Specifically, the research questions for this study are: (1) How do PSTs solve problems that involve proportional relationships? (2) How do PSTs reason distributively? (3) What schemes, operations, and concepts are involved in PSTs' construction of proportional reasoning? (4) What are relationships between PSTs' distributive and proportional reasoning?

Conceptual Framework

A Quantitative Approach

Thompson (2010) defines a quantity as a scheme consisting of an object, a quality of the object, an attribute of this object that has a unit of measure, and a process that the attribute's measure entails a proportional relationship with its unit. Throughout this paper, following Thompson, I interpret quantitative operations as mental operations and regard these operations as essential aspects of quantitative schemes because this approach allows me to account for PSTs' schemes and operations when they reasoned quantitatively with ratios.

Operations and Schemes

The concept of schemes, or goal-directed ways of operating that involve an assimilatory mechanism, activity, and result, is a substantial part of Piaget's theory of knowledge (von

Glasersfeld, 1995). My study is based on the mathematical thinking in PSTs' operations, which are components of schemes. Based on Steffe and Olive (2010), I define a distributive partitioning operation (DPO) as partitioning n items among m shares by partitioning each of the n items into m parts and distributing one part from each of the n items to the m shares. For example, when asked to equally share three candy bars with five people, a student with a DPO would partition each of the three candy bars into five equal parts and take one part from each bar to determine a share. Steffe and colleagues (2014) also originated the ideas of a distributive partitioning scheme (DPS) and a reversible distributive partitioning scheme (RPDS). A child who has constructed a DPS could interpret one share as n/m of one unit by taking 1/m of each n item, while a child with an RDPS could interpret one share as 1/m of all the units and see that n/m of one unit is equal to 1/m of all the units, and could also justify that iterating n/m m times does indeed produce n items (Liss, 2014).

Methods

To launch each of the two small scale intensive 12-episode teaching experiments, I conducted 60-minute task-based selection interviews with 8 PSTs to assess their multiplicative reasoning, distributive operations, and initial ways of reasoning with ratios. Then, I invited four PSTs to participate in my dissertation project. Based upon the similarities in their reasoning, I matched them in two pairs. In this paper, I will present some data from one of the pairs: Maggie and Rose. The teaching experiment consisted of 12 45-minute sessions (two episodes in each week for each group) for a total of 6 weeks. They worked in pairs on particular mathematical tasks related to distributive and proportional reasoning. All teaching experiment sessions were video-recorded and all written work were collected. During episodes, PSTs often used a software program called JavaBars (Biddlecomb & Olive, 2000). After each teaching session, I processed data, kept a digital research journal, watched video, took notes, and discussed conjectures with my advisor to organize my plans and develop the tasks for the next episode. Following teaching experiments, each PST participated in a 60-minute follow up interview to elicit their reasoning and experiences after the teaching experiment.

The data were analyzed retrospectively (Steffe & Thompson, 2000). Through retrospective analysis, I formulated a second-order model of PSTs' reasoning with ratios. A second order model is a researcher's constellation of constructs to describe and account for another person's ways and means of operating (Steffe, von Glasersfeld, Richards, & Cobb, 1983). For this purpose, I repeatedly viewed the relevant video files, transcribed major portions, and took detailed analytic notes. I also wrote memos and conjectures about changes and persistent constraints in PSTs' ways of thinking and operating, and about interactions that may have supported these changes and constraints. Finally, I wrote a document comparing these models and synthesizing the interactions that contributed to changes.

Preliminary Analysis

So far, I found qualitative differences in how PSTs represented and thought about proportional reasoning. I support this claim by demonstrating how they worked on the Lemonade Mixture Problem in the teaching experiment. Because I am still analyzing my data, I will present a very small but important portion of what I have right now.

Near the end of episode 7, I had already created a sketch showing 1 tbsp. and 1 ounce bars in JavaBars (Figure 1, upper left). The main question was "How much tbsp. of lemonade powder would go with 1 ounce of water if 3 tbsp. of lemonade powder with 16 ounces of water are the ingredients of the "best" lemonade?" To solve that problem, Rose worked on JavaBars and Maggie worked on paper. Rose first created her 3 tbsp. and 16 oz. bars (Figure 1, upper right). She then copied the 3 tbsp. bar, divided each part into 16 mini-parts, and filled them in blue, peach and red, respectively

(Figure 2, bottom right). She pulled out one mini-part from each tbsp. bar and joined these 3 mini-parts under 1 ounce of water bar (Figure 2, bottom left). Looking at 3 mini-parts she pulled out, Rose stated that 3/48 tbsp. of powder, which can be simplified to 1/16, would go with 1 ounce of water. Rose has demonstrated a DPO when pulling out one mini-part from each bar to get 3 mini-parts for 1 ounce of water after dividing each of the tbsp. bars into 16 mini-parts. However, her answer was 1/16 tbsp. not 3/16 tbsp. since she did not relate her answer to the unit bar, 1 tbsp.

In Episode 8, after probing with me, Rose realized that since 3 mini-parts together are 1/16 of 3 tbsp., if she repeats 3 mini-parts 16 times it would give her 3 tbsp. bar. So she corrected her answer as 3/16 tbsp. of powder. Then she repeated 3 mini-parts 16 times in her JavaBars picture. I infer that repeating 3 mini-parts 16 times might have helped her see her reasoning with the picture. During that justification, she has also constructed an RDPS when she repeated 3 mini-parts 16 times to see that would give her whole 3 tbsp. bar.

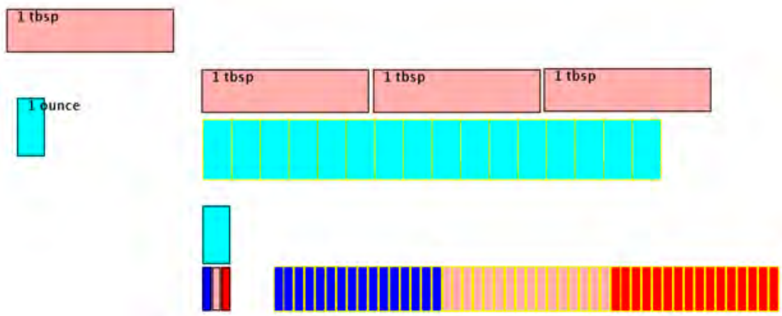

Figure 1. Rose's work on the Lemonade Mixture Problem.

Maggie first drew out 3 tbsp. of powder and 16 oz. of water. She said she wanted to start with how many tbsp. of powder goes with how much ounces of water. After figuring out 5 1/3 oz. goes with 1T of powder, she drew 5 1/3 oz. of water in three groups and she wanted to find out how much tbsp. of powder goes with 1 ounce by highlighting the first 3 mini-parts of her first 5 1/3 drawing (Figure 2). She stated that she needed to be her pieces even that is why she divided every 1 ounce in 3 mini-parts to find the proper fraction. Then she realized every three mini-parts would give her how many tbsp. of powder in 1 ounce and said she needed to look at the whole picture—including other two 5 1/3 drawings, which has totally 48 mini-parts. She said the answer is not 3/16 because she needed to think all three 5 1/3 oz. groups. So she said the answer is 3/48 (she counted all mini-parts) and she simplified it to 1/16. Maggie has not demonstrated a DPO in solving this problem. Her way of thinking is pretty similar to what she did before with other lemonade mixture problems. Representing the powder and water together in the same bar might have masked showing the distribution idea and focusing on the unit bar (1 tbsp.) as well.

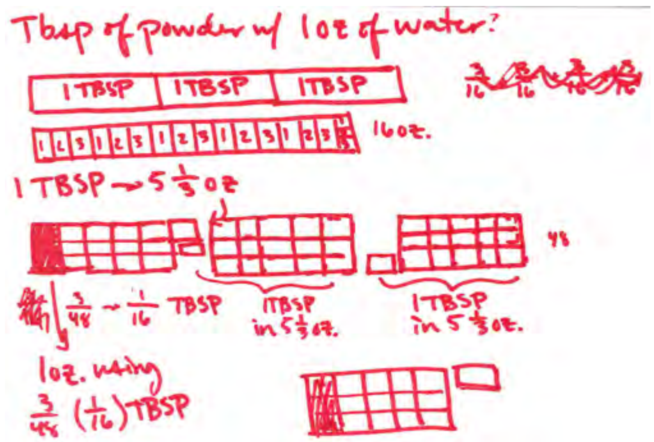

Figure 2: Maggie’s work on the Lemonade Mixture Problem.

In Episode 8, although Maggie might have interpreted Rose’s idea/justification, she did not make it her own. When I asked about her justification, she realized that she needs to focus on the 1T bar not all 3T bars saying "But then I guess it is 3/16 [she meant 3/16 tbsp. of powder would go with 1 ounce of water] because I counted up all of the 48s. But if you are counting up for 1T it is just three-sixteenths [pointing out her first drawing]. Cause I counted up all 48. Well, I know that it is 1/16 of 3T then I was just trying to think in my head how you can like mathematically prove it."

Discussion

The teaching experiment data presented above provides several important results. First, Rose mostly showed evidence of demonstrating a DPO and even an RDPS when she was reasoning with ratios. This helped her create unit ratios and use these unit ratios to find any other equivalent ratios. Second, Maggie had powerful ways of thinking and a desire to understand other people’s reasoning. She did not spontaneously produce these ideas when she was working on problems even though she could understand and justify them in interactions with me and Rose. She did not necessarily do so, perhaps because she did not see them as more powerful than her own. Therefore, having her own powerful ways and not adopting others’ ideas as her own could also help us understand why Maggie did not need to show use of a DPO in reasoning with ratios.

Through a theoretical framework emphasizing the importance of fidelity of implementation (FOI), this paper explores how 3rd grade teachers implemented an early algebra intervention, and the extent to which the FOI related to student learning. The data for this report are taken from the first year of an experimental research project. Videotaped classroom observations, our primary measure of FOI, were coded by adding to and adapting the Mathematical Quality of Instruction (MQI) instrument, and student performance was measured by overall score (correctness) on an algebra assessment. Results revealed a significant positive relationship between teachers' implementation and their students' performance.

Keywords: Algebra and Algebraic Thinking, Elementary School Education, Assessment and Evaluation

This paper reports on the fidelity of implementation (FOI) of 3rd grade teachers as they implemented an early algebra intervention, and the relationship between FOI and student learning. The data from this study are taken from the first year of an experimental research project (Project LEAP: Learning through an Early Algebra Progression) that tests the hypothesis that children who receive comprehensive, longitudinal early algebra instruction during the elementary grades are better prepared for algebra in middle school than children who have only arithmetic-based experiences during elementary grades.

Theoretical Framework

The treatment of algebra in school mathematics has changed dramatically over the past two decades. The *Common Core State Standards for Mathematics* (National Governors Association Center for Best Practices and Council of Chief State School Officers [NGA Center & CCSSO], 2010) calls for algebraic reasoning to start in Grade K and span across the grades. In response to this challenge, we initiated a study to examine the effectiveness of an early algebra intervention in Grades 3-5. The intervention consisted of 18 lessons and teachers also attended ongoing professional development to support their implementation of the intervention.

The focus in this paper is on the relationship between student performance outcomes and teachers' FOI of the early algebra intervention. Our goal was to measure the fidelity with which teachers in diverse demographic settings implemented the intervention and how this intervention affected student learning outcomes. Measuring FOI revealed differential patterns of implementation and their relationship to the intervention (Mowbray et al., 2003), a critical factor in evaluating an intervention's effectiveness (NRC, 2004; Summerfelt & Meltzer, 1998) and promoting external validity (O'Donnell, 2008).

Methodology

Three school districts (including approximately 240 classrooms and 3,400 children) participated in the cluster randomized trial, with entire schools being assigned to either the experimental or control condition. During the first year of implementation, we focused on third grade classrooms, and subsequently followed these children into fourth grade.

Data sources for the study reported here are classroom observations and student assessment data. Classroom observations (videotaped LEAP lessons) were conducted with a subsample of experimental teachers (n=50). All teachers were observed twice except for one, for a total of 99 observations.

Student participants were given a one-hour, written algebra assessment as a pre/post measure. The assessment was designed by the project team (Blanton et al, 2015) and measured students' understanding of early algebra. We have assessment data from approximately 800 students in the observed classrooms. For the purposes of the analyses reported here, student assessment data were coded according to item correctness.

We coded classroom observation data with a specific focus on the degree to which teachers implemented the early algebra materials with fidelity as well as the quality of mathematics instruction. Teachers were rated on 5-point Likert scales on each of the three cognitive demand variables created by the project team: *justify an answer*, *generalize a mathematical relationship*, and *represent with variables*. Separate codes were given for whole class work and individual/group work. Observations were also coded for six items adapted from the Mathematical Quality of Instruction (MQI) instrument (Hill et al, 2008): efficient use of class time, clear presentation of mathematics, student engagement, teacher attention to student difficulty, teacher use of student ideas, and precise use of mathematical language and notation.

Approximately 15% of videos were double coded in order to assess inter-rater reliability. Factor analysis was then employed in order to create composite variables that could be used as teacher-level predictors of student outcomes (i.e., student performance on the early algebra assessments) in a multilevel analysis.

Results

As a first step, we looked at the implementation of the intervention. Lessons in this early algebra intervention consist of two parts – the Jumpstart (a review and warm up activity related to the objectives of the lesson) and the main early algebra activity. The jumpstart activity was completed in 95% of observed classes. Of those that did, 100% of the observed classes included whole class discussion led by the teacher, 67% included individual student work, 32% included group work, and 35% included student-led presentations. Jumpstarts activities lasted, on average, 15 minutes and 32 seconds (*SD* = 07:54).

Once the Jumpstart was completed, lessons moved on to the early algebra task. Overall, in 90% of observed classrooms teachers read the problem aloud or had a student read the problem. In 52% of classrooms, teachers ensured students understood any terms or concepts that might be unfamiliar to them. Teachers demonstrated methods of presenting numerical information that might be unfamiliar to students in 42% of classrooms.

After the lesson was introduced, in 71% of the observed classrooms students worked on their own (either independently or in groups) on the bulk of the remainder of the activity. During individual/group work, teachers were rated on whether they were active or passive. An active teacher would actively visit individuals/groups to help students with questions, but also to challenge their thinking. A passive teacher would go around to groups only when asked, and would be largely reactive to students' needs rather than being proactive and challenging mathematical thinking. In 69% of observed classrooms, the teacher was coded as "active."

LEAP Cognitive Demand Variables: Justify, Generalize, Represent

A rating of 1 indicates that a teacher did not ask students to justify, generalize, or represent at all, while a rate of 5 indicates that the teacher asked students to justify, generalize, or represent in a way that went beyond the lesson expectations (see Table 1).

Table 1: Mean (SD) Justify, Generalize, and Represent Ratings

Whole Class			Individual Group		
Justify	Generalize	Represent	Justify	Generalize	Represent
3.75 (1.02)	3.51 (1.08)	3.00 (1.25)	2.91 (1.39)	2.55 (1.33)	2.10 (1.34)

Adapted MQI Codes

With the exception of *imprecision*, which was coded on a 4-point scale, all MQI items were coded using a 5-point Likert scale. For all items, 1 is the most "negative" rating, indicating inefficient use of class time, severely distorted mathematics, total lack of student engagement with the lesson, student difficulty without any teacher remediation, no substantive use of student ideas, or imprecision that obscured the mathematics of the lesson (see Table 2).

Table 2: Mean (SD) Adapted MQI Ratings

Efficiency	Math is Clear	Engaged	Attends to Student Difficulty	Uses Student Ideas	Precision in Language
3.33 (1.11)	4.24 (0.96)	3.80 (1.00)	3.56 (0.99)	3.85 (0.93)	3.31 (0.83)

Inter-rater reliability was assessed for the cognitive demand and MQI data using weighted Cohen's kappa. The analysis suggested that raters had acceptable levels of agreement (κ_w>.60) for all MQI variables, for the three individual/group cognitive demand variables, and for the whole class represent variable. However, there was only moderate agreement for two of the whole class cognitive demand variables: whole class generalize (κ_w =.54) and whole class justify (κ_w =.53). For this reason, subsequent analyses do not include the whole class variables.

Relationship Between FOI and Student Performance

We hypothesized that several of our observed variables would be correlated due to their association to latent (unobserved) variables. In order to identify these underlying latent variables, factor analysis using principal components analysis was utilized.

The six MQI variables and the three individual/group cognitive demand variables were entered. A two-factor solution, which explained 71% of the variance, emerged. The three individual/group cognitive demand codes (justify, generalize, represent) were added together to create a composite variable, "cognitive demand," M = 7.55, SD = 2.82, and the six MQI variables were added together to create a composite variable, "MQI," M = 22.25, SD = 3.79.

Using these composite variables as level 2 (teacher-level) predictors, we conducted a multilevel regression analysis to explore the relationship between the teacher-level FOI variables and student performance. The baseline measure of performance, grade 3 pre-test, was included as a student-level (level 1) predictor, and a measure of SES (percentage of students with free or reduced lunch) was included at the school-level (level 3).

After controlling for baseline performance and school-level SES, the cognitive demand composite variable was found to be a significant predictor of students' score on the LEAP post-assessment, $\gamma = .015$, $t(30) = 3.093$, $p < .001$. A one-unit increase in cognitive demand score was associated with a 1.5% increase (.015 points) in post-test score. The MQI composite variable was not a significant predictor of student performance.

Discussion

Understanding the ways in which teachers implemented the early algebra intervention and how it impacted student learning have important implications for this particular study and, more broadly, how we as a community understand the complexity of finding ways for educational research to influence actual instruction and have an impact on the mathematics learning of large numbers of students. This is critical if we are to take educational innovations to scale.

Aspects of teachers' implementation were significantly positively related to their students' performance on the early algebra assessments. Given the range of the cognitive demand composite variable (3 to 14), students in classrooms where the teacher received the highest rating outperformed their peers in the classroom of the lowest rated teachers by an average of 16.5%. Therefore, students of teachers who implemented the intervention with higher fidelity had higher mean scores on the early algebra assessment, suggesting that these students are better prepared for algebra in middle school than their peers whose teachers implement with lower fidelity.

REASONING WITH CHANGE AS IT RELATES TO PARTITIONING ACTIVITY

Biyao Liang

University of Georgia
kvcmoore@uga.edu

This paper discusses a pre-service secondary teacher's mental actions in the context of her partitioning activity and reasoning about amounts of change (i.e., coordinating the amounts of change of one quantity for changes of another) to structure dynamic situations. We illustrate ways of thinking that necessitated that she carried out partitioning activity, and thus had difficulty re-presenting actions when reasoning with changes on graphs and situations.

Keywords: Cognition, Advanced Mathematical Thinking, Algebra and Algebraic Thinking

Background

Researchers have shown that quantitative reasoning—the mental actions involved in conceptualizing a situation in terms of a structure of measurable attributes (Thompson, 2011)—and covariational reasoning—the mental actions involved in coordinating quantities changing in tandem (Carlson et al., 2002)—are critical for students' rate of change understandings (Johnson, 2015; Thompson, 1994). Highlighting the complexities in the ways students conceive of relationship between covarying quantities, these researchers have called for a closer look into students' reasoning about *amounts of change* in order to explain nuances in students' rate of change understandings. Inspired by the aforementioned research, this study aims to gain a better understanding of students' reasoning with amounts of change in relation to their partitioning activity. We draw on both Carlson et al. (2002) and Saldanha and Thompson's (1998) theories of covariational reasoning, with particular attention to Level 3 (i.e., students' coordination of amounts of change of one variable with respect to changes in another) of Carlson et al.'s (2002) covariation framework. For example, given a graph or a situation, a student can partition one quantity into equal increments and visualize the amounts of change of the other quantity corresponding to the endpoint of each increment. We refer to this particular kind of activity including the mental operations involved when we use *partitioning activity* throughout the paper.

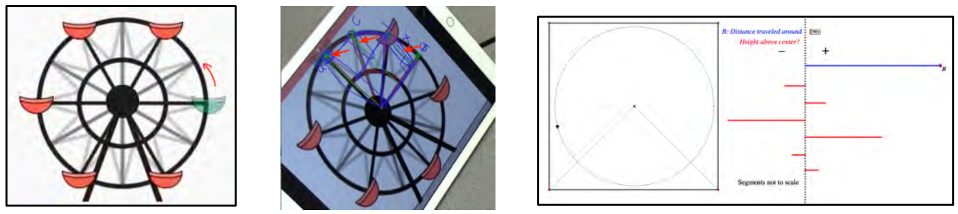
Methods

This paper reports results of a semester-long teaching experiment (Steffe & Thompson, 2000) with Lydia, who was in her first semester of a four-semester secondary math education program. We conducted 12 teaching sessions with her and videotaped and digitized them for analysis. In both ongoing and retrospective analyses efforts, we conducted a conceptual analysis (Thompson, 2008) in combination with open and axial techniques (Corbin & Strauss, 2008) in order to develop models of her mathematical thinking. Specifically, our iterative analyses efforts involved constructing hypothetical mental actions that viably explained Lydia's observable and audible behaviors. We also continually searched for instances that the models could not account for, and modified our models or attempted to explain developmental shifts in her meanings.

Results

The Taking a Ride and Which One Task

In our first teaching sessions, we designed the Taking a Ride task (Figure 1a) to support students in reasoning about the relationship between the height of the green rider above the horizontal diameter of the wheel and the arc length the rider has traveled. Lydia initially claimed, "the arc length has increased to this [*drawing an arc on the first quarter of the circumference of the wheel*] while the distance from the center has increased to that [*drawing a vertical segment from the top position to the center of the wheel*].” Eventually, Lydia constructed successive amounts of change of height (see the blue segments in Figure 1b) for successive, equal changes in arc length. Noticing that these blue segments decreased in magnitude, Lydia concluded that as the arc length is increasing by equal amounts, the amount of increase in height is decreasing.



(a) (b) (c)

Figure 1: (a) Animation for the Taking a Ride task; (b) Lydia identified the amounts of change of height on the animation; (c) The Which One task.

Immediately following this task, we presented the Which One task (Figure 1c), where we presented a simplified version of the Ferris Wheel with the position of a rider indicated by a dynamic point on a circle. We informed Lydia that the topmost blue segment represents the arc length the rider has traveled counterclockwise from the initial three o’clock position. We then asked Lydia to determine which of the six red segments, if any, accurately represents the rider’s height above the horizontal diameter as the rider’s arc length traveled varies. Lydia chose a red segment (which represented a normatively correct solution), oriented it vertically, and put it inside the circle (Figure 2a). She then confirmed that the length of the segment matched the height of the dynamic point for different states (Figure 2b). We then asked if the segment entailed the amounts of change relationship constructed in Figure 1b, to which she responded:

Lydia: Not really. […] Um, don’t know. [*laughs]* Because that was just like something that I had seen for the first time, so I don’t know if that will like show in every other case […] for a theory to hold true, it like – it needs to be true in other occasions, um, unless defined to one occasion. […] I saw what I saw, and I saw that difference in the Ferris wheel, but I don’t see it here, and so –

I: And by you don’t see it here, you mean you don’t see it in that red segment?

Lydia: Yes.

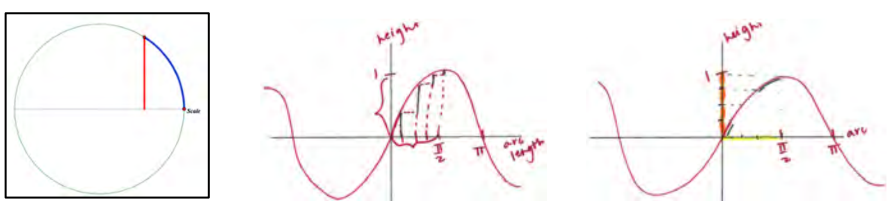
(a) (b) (c)

Figure 2: (a) Lydia was working on the Which One task; (b) Lydia was checking the red segment point-wisely; (c) We were assisting Lydia to identify amounts of change of height.

We draw attention to Lydia referencing height increasing by decreasing amounts as a “theory” that needed to be tested despite her having already identified that the red segments worked point-wisely with respect to traversed arc length; her knowing that the red segment worked for each state did not imply by necessity that the red and blue segments existed in a covariational relationship consistent with the relationship between height and arc she identified in the Taking a Ride task. Furthermore, after we assisted her in denoting amounts of change of the red segment (i.e., height) for successive cases (Figure 2c), she responded in surprise that her "theory" held true in the current situation. Collectively, her activity was a contraindication that she had constructed a re-presentable quantitative relationship between co-varying quantities; rather, her understandings were rooted in carrying out particular activity of partitioning in order to make amounts of change perceptually available for comparison on the specific representation (Figure 1b). That is, when moved away from the original representation to a novel context with magnitudes changing continuously, she did not envision the same quantitative relationship of those magnitudes because from her perspective, she was carrying out a different activity (i.e., point-wise checking of the red segment) than the one in the previous situation.

The Circle Task

In the ninth teaching session, we asked Lydia to recall her graph related to the Circle Task in the previous session. The Circle Task included an animation of a circle with a point moving along the circle, with the red segment representing the height above the horizontal diameter and the blue segment representing the arc length traced out as the point traveled along the circumference of the circle (Figure 3a). Lydia drew from memory the graph shown in Figure 3b, created equal partitions along the horizontal axis, and denoted corresponding height magnitudes and amounts of change of height (Figure 3b). She claimed, "arc length is increasing at a constant rate, and height is increasing at a decreasing rate." We note that Lydia was only talking about *one* quantity (either height or arc length) when she used the word "rate" as opposed to using "rate" to describe the multiplicative comparison between *two* co-varying quantities. In response to Lydia discussing each quantity separately with respect to "rate," the teacher-researcher drew a copy of the graph with equal partitions along the vertical axis (Figure 3c). She described, "you're increasing in height at a constant rate, and then our arc length is increasing at an increasing rate."



(a) (b) (c)

Figure 3: (a) The Circle Task; (b) Lydia's graph; (c) The teacher-researcher's graph.

Noticing that Lydia described height as both "increasing at a decreasing rate" and "increasing at a constant rate," the teacher-researcher questioned her in ways that would draw her attention to comparing the two claims. She explained:

> *Lydia:* […] Because [height] increases at a decreasing rate [*pointing to Figure 3b*], and I'm assuming, I am assuming that the pattern would probably hold [on Figure 3c] if we did this [*pointing to the partitions in Figure 3b*], um, kind of test […] so I'm kind of seeing that maybe that pattern would hold. I haven't tested it, so I can't say that –

This demonstrated Lydia's difficulty with imagining or anticipating the partitions of Figure 3b on Figure 3c, and her continued work on the task indicated uncertainty with conceiving "height is increasing at a decreasing rate" on Figure 3c due to the perceptually available equal partitions of height. She was constrained by the partitions she perceived on the graph to the extent that without physically carrying out subsequent partitioning activity, she could not take those partitions represented on Figure 3b as relevant to Figure 3c.

Discussions

Through our analysis, we found that although the partitioning activity assisted Lydia's reasoning with amounts of change, it did not necessarily support her abstracting an operative covariational relationship between quantities. That is, when confronted with a series of similar situations, and without carrying out particular sensorimotor actions (e.g., drawing lines to partition one quantity and highlights the amounts of change of another) to produce perceptually available results, she had difficulty *re-presenting* the actions and its results mentally. By "re-presenting" an activity, we employ Piaget's notion of *re-presentation* to refer to a student's ability to mentally run through an activity and coordinate the results of the activity when the perceptual situation that originally led to the coordination is not actually present (von Glasersfeld, 1995). Lydia's difficulty with mentally re-presenting partitioning activity particularly constrained her thinking in situations that differed in segment orientation and placement (e.g., the Which One task) or situations where perceptual features of previous results were absent (e.g., Figure 3c). We highlight that when carrying out an activity dominates a student's thinking of graphs and situations, that student might have difficulty with reasoning with novel representations because of not having the coordination of such activity (e.g., the underlying quantitative relationships and operations) mentally available in those representations. Moving forward, we call for continued explorations into how students reflect upon their partitioning activity and abstract quantitative relationships and structures (e.g., rate of change).

STUDENTS' APPROPRIATION OF MATHEMATICAL DISCOURSE IN A DISCOURSE-DRIVEN CLASSROOM

Salvador Huitzilopochtli
University of California- Santa Cruz
shuitzil@ucsc.edu

Judit Moschkovich
University of California- Santa Cruz
jmoschko@ucsc.edu

This study explored how students appropriated mathematical and discursive practices in a class whose teacher took a discursive approach to instruction while supported by professional development and a curriculum designed with equity and discourse in mind. The study deployed a theoretical framework that used Academic Literacy in Mathematics (Moschkovich, 2015) as a framework for analysis of visual representations and Talk Moves (Anderson, Chapin, & O'Connor, 2011). The study examined a 4th-grade classroom in the San Francisco Bay Area where roughly three out of five students were English Language Learners and 19 out of 20 were low-income. Results showed that students appropriated the Talk Move, "Do you have any ideas?" for multiple purposes.

Keywords: Classroom Discourse, Elementary School Education

The National Council of Teachers of Mathematics (NCTM) and California Common Core State Standards (CCCSS) call for students to participate in mathematical discussions (CDE, 2014). However, few students enter classrooms already knowing how to participate in these kinds of discussions. The purpose of this qualitative study was to examine how students appropriated mathematical and discursive. The study is part of a larger research project, led by the Early Mathematics Education Research Group (EMERGe) at Stanford University. The following questions, in part, guided the exploration of mathematical communication:

1. In a setting where a teacher attempts to provide mathematics instruction that supports a discursive approach, do students appropriate discourse practices provided and/or promoted by the teacher or curriculum?
    a. If so, which ones?
2. How do students make use of multiple representations when engaged in mathematical discussions during group work?

Theoretical Framework

Academic literacy in mathematics has three integrated components: mathematical proficiency, mathematical practices, and mathematical discourse. Mathematical proficiency refers to the "expertise, competence, knowledge, and facility" that is required to successfully learn mathematics and is a "cognitive account" of mathematical activity vis-à-vis the five strands of proficiency (NRC, 2001); Conceptual Understanding, Procedural Fluency, Strategic Competence, Adaptive Reasoning, and a Productive Disposition. Defining characteristics of mathematical practices come from the NCTM standards and the Common Core State Standards include problem solving, sense-making, reasoning, modeling, and looking for patterns, structure or regularity (California Department of Education, 2014). Finally, Moschkovich describes mathematical discourse as the "communicative competence (Hymes, 1972) necessary and sufficient for competent participation in mathematical practices" (Moschkovich, 2015b, p.47)

A sociocultural perspective on mathematics learning views mathematics learning as a "discursive activity that involves participating in a community of practice" and mathematical activity is framed by mathematical knowledge, practices, and discourse (Moschkovich 2002, 2015b). Within a

Galindo, E., & Newton, J., (Eds.). (2017). *Proceedings of the 39th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* Indianapolis, IN: Hoosier Association of Mathematics Teacher Educators.

sociocultural approach, the assumed mechanism for learning is appropriation. Appropriation refers to the process by which learners come to use "cultural tools" for themselves and transform them for their own purposes (Moschkovich, 2004 and Rogoff, 1990).

Setting and Curriculum

The professional development and curriculum supported the teacher's efforts to facilitate mathematical discussions through the promotion of Talk Moves (TMs). TMs are described as the tools that enable productive classroom discussions in mathematics through four steps:

Step 1. Helping individual students clarify and share their own thoughts,

Step 2. Helping students orient to the thinking of other students,

Step 3. Helping students deepen their reasoning,

Step 4. Helping students to engage with the reasoning of others (Anderson, Chapin, & O'Connor, 2011, p. 13).

The unit of instruction, *The T-shirt Factory (2007),* was designed to provide students with a rigorous curriculum and invite their active participation. It is written as a simulation where groups of students establish a T-Shirt factory and keep their warehouse organized while focusing on unitizing, place value, and equivalence (Fosnot, 2007).

Methods

Field observations, student work, and video recordings (of group work and whole-class discussions) were collected during the instructional unit (17 instructional days, total). Field observations were taken primarily as an observer. Interactions with students were minimized. Researchers gathered samples of student work on two occasions (Days 3 and 6 of the instructional unit). Video data for this study were selected from a subsample of six lessons (two each from the beginning, middle, and end of the unit) to see if there were any changes in student discussions. Each lesson typically included time for Small Groups, during which students worked on assigned tasks in groups of 1 – 4. For each of the six lessons, 1 – 2 small group work sessions (which were student-centered activities) were transcribed and coded. The analysis started by locating episodes in the video recordings of small groups where students were engaged in the focal mathematical practice, Model with mathematics. Within these episodes, I looked for evidence of mathematical proficiency (either Conceptual Understanding or Procedural Fluency) and cataloged which discursive practices students appeared to appropriate. Then, I looked for evidence of student coordination of multiple representations, including utterances, when engaging in mathematical discussions. In the interactions I looked for situated meanings of words and phrases.

Results

The teacher often used the "Do you have an idea?" TM as an invitation to explore students' prior knowledge and followed up with a "Say More" TM for elaboration or clarification. There was one student that demonstrated the variety of situated meanings that a single TM could engender. During Day 2 of the instructional unit (see Figure 1 for a copy of the problem on which students are working), Jefferson used the "Do you have an idea?" TM five times (pseudonyms are used for all participants in the study). However, two distinct purposes emerged: 1) use of the TM as a request for answers, and 2) use of the TM as a deflection. In all cases, Jefferson initiated the conversational exchange using the TM and meaning was determined by the characterization of the outcome initiated by the TM when Chloe responded.

Number of Rolls	Number of Loose T-Shirts
	13 33

Figure 1. Student Problem. Jefferson and Chloe's instructions: *Bundle the shirts. How many ways can you find?*

For example, in the excerpt below, Chloe answered Jefferson's question in a manner that suggests she interpreted the question as a request for an answer; not an idea or a solution process.

1 *Jefferson:* Ok. Do you have any idea?
2 *Chloe:* Yeah. Yeah. Yeah. Yeah. What's the number?
3 *Jefferson:* It is 13.
4 *Chloe:* We could make one pile… One row of ten and three left over.
5 *Jefferson:* Oh yeah! So, one pile of ten. Three loose ones. ((writes down response and raises hands victoriously)) So, ok, we need another two.

When Chloe responded with an answer, "One row of ten and three left over" (Turn 4), Jefferson didn't hesitate to acknowledge the response with hands in the air and stated the need for 'another two'. When the students attempt the second problem (see Figure 1 for the problem and the excerpt below), the students similarly construct the purpose of the TM as a request for answers.

60 *Jefferson* …Now we're on to thirty-three. Do you have any ideas?
61 *Chloe* Ok. We could make.. three rows of ten and another three rows of tens.

Chloe's suggestion is incorrect; however, these instances suggest that Chloe interpreted the question as a request for answers. Other uses of the TM seem to have been used for the purpose of deflection. In Turn 36, below, Chloe indicated that she "already gave [him] two ideas" and, in Turns 38 and 40, asserted that she has no more 'ideas'. Jefferson's persistence and the pair's ultimate abandonment of the task suggest that he was using the TM to deflect having to contribute a novel solution or process (see excerpt, below).

35 *Jefferson*: Ok. Let's get to work. I said do you have any ideas?
36 *Chloe:* I already give you two ideas.
37 *Jefferso*n: I know you have more.
38 *Chloe:* No, I don't.
39 *Jefferson:* Why are you laughing, huh? Dude, I know that you have ideas.
40 *Chloe:* No, I don't.
41 *Jefferson:* I think we're already done with this. So,…
42 *Chloe:* Go get a new one.

In the excerpt below, Jefferson appears to use the TM to deflect responding, again.

76 *Chloe* Write three T-shirts and three left-overs.
77 *Jefferson* **I was gonna do that. Your turn to do ideas.**
78 *Chloe* I already told you one.
79 *Jefferson* No! Those were me. I did do it.
80 *Chloe* No. You just do that one.
81 *Jefferson* We need to hurry up. … I don't think we need these [unifix] cubes.
[Turns 82 – 83 omitted]

84 *Chloe* Ten. Twenty. Thirty. Thirty-one. Thirty-two. [modeling with Base-10 blocks while speaking] You could make three piles of ten…
85 *Jefferson* Ok.

Chloe, reluctant to give additional answers, stated, "I already told you one" (Turn 78). Jefferson claimed credit saying, "Those were me" (Turn 79) and pressuring Chloe by saying "We need to hurry up" (Turn 81). Chloe conceded and offers another possible answer, "You could make three piles of ten…" (Turn 84). Jefferson successfully deflected his obligation. There was scant evidence of the appropriation of TMs by the students at large. The interactions above illustrate how the TM "Do you have any ideas?" was appropriated and transformed by a student to suit his own purposes.

Discussion/ Conclusion

In this study, students appeared to appropriate a TM when engaged in mathematical activity. The purposes seemed to reflect a request for answers to a problem or a deflection of responsibility to answer. This study reflects how students can appropriate and transform practices in unpredictable ways. Further research is warranted to determine how 'purpose' can be addressed and incorporated into mathematical discussions so that students can reap their full benefit.

STUDENTS' MEANINGS FOR EXTENSIVE QUANTITATIVE UNKNOWNS

A series of three design experiments was conducted with middle school students to investigate relationships between students' rational number knowledge and algebraic reasoning. After the first experiment a change was made in the investigation of students' construction of extensive quantitative unknowns. Students were asked to represent in pictures and equations the values for an unknown height measured in two different, multiplicatively-related measurement units. The work of 13 students operating at two levels of multiplicative reasoning was analyzed to identify differences and similarities. Students operating at the lower level of reasoning required substantial support to construct unknowns with implicit quantitative relationships, while students operating at the higher level of reasoning constructed unknowns with explicitly embedded units.

Keywords: Algebra and Algebraic Thinking, Middle School Education

It is well known that secondary students develop concepts for unknowns and variables that are often quite different from what teachers and curriculum developers intend. Common and persistent issues include that students see letters as standing for labels of objects rather than quantities and for known rather than indeterminate values (e.g., Knuth, Alibali, McNeil, Weinberg, & Stephens, 2005; Küchemann, 1981). In addition, an increasing number of secondary students take algebra courses (Stein, Kaufman, Sherman, & Hillen, 2011), and so algebra teachers are tasked with working with a greater diversity of students. This phenomenon has been managed in several ways, from tracking lower-skilled students into double periods of algebra (Nomi & Allensworth, 2013) to teaching all students in heterogeneous groups with supports such as a 2-year algebra course (Boaler & Staples, 2008). In whatever ways diversity is managed, more needs to be known about the algebraic thinking and learning of a wide range of secondary students in order to inform the kind of supports that both students and teachers need.

To address these issues, we conducted three iterative design experiments with small groups of cognitively diverse middle school students in which we studied relationships between their rational number knowledge and algebraic reasoning. Analysis of the first experiment led us to revise our approach to developing concepts of unknowns. The purpose of this paper is to describe and account for how the students in the second and third experiments conceived of what we call *extensive quantitative unknowns* (EQUs). For example, consider the relationship between two values of the unknown height of a school measured in feet and inches: The number of inches that can fit into the height is 12 times the number of feet that can fit into the height because each foot in the height is equivalent to 12 inches. We call these problems Single Unknown Problems, and we posed them with non-standard measurement units to promote rethinking of relationships that students might take for granted when working with standard ones. Our research questions are: (1) How did the students conceive of EQUs? (2) How can we account for their conceptions?

Approach to Algebraic Reasoning and an Analytical Tool

A Quantitative Approach

In our experiments we took a quantitative approach to algebraic reasoning, in which a *quantity* is a property of one's concept of an object or phenomenon "that can be subjected to comparison" (Steffe & Olive, 2010, p. 49). Quantities can be extensive or intensive (Schwartz, 1988): Extensive quantities can be directly counted or measured (e.g., a distance), while intensive quantities are often created out of multiplicative comparisons of extensive quantities (e.g., amount of distance covered per unit of time). In our experiments we focused first on extensive quantities because, generally speaking, they are more basic than intensive quantities.

To conceive of an extensive quantity requires conceiving of a measurement unit, of the property as subdivided into these units, and of a way to enumerate these units to find a value (Thompson, 2011). However, extensive quantities can be thought about absent values, which makes them useful algebraically (Smith & Thompson, 2008). We conceptualized an EQU as an extensive quantity for which a value is not known, but for which a value could be determined. In our experiment we focused primarily on distances. So, an EQU could be thought of as a distance for which we have a measurement unit; we can imagine subdividing the distance into those units; but we don't know how many of those units will be needed to span the distance.

Students' Multiplicative Concepts

In our work we use students' multiplicative concepts as a key analytical tool. We conceive of students' multiplicative concepts as the interiorized results of students' units-coordinating schemes (Steffe, 1994). *Interiorization* refers to re-processing the result of a scheme so that students can anticipate it prior to activity. A *units coordination* involves two composite units (units of units), and it means to distribute the units of one composite unit across the units of another composite unit. For example, a units coordination of 5 and 7 involves distributing 7 units of 1 across each of the units of the 5 to get a unit of 35 that students structure in various ways.

Students who have interiorized two levels of units (MC2 students) can treat a length as a unit of units, or composite unit, prior to activity (Hackenberg & Tillema, 2009; Steffe & Olive, 2010). For example, MC2 students can imagine taking a 1-meter length and partitioning it into 5 equal parts without having to actually make the partitions. In other words, they can treat a length that represents 1 meter as a unit containing 5 units, a two-levels-of-units structure.

Furthermore, MC2 students can make three levels of units in activity: They can insert units into each unit in solving a problem. For example, they can insert 7 parts into each of the 5 parts in the 5/5-meter and determine that they have made 35 parts in all. However, in further activity the 35/35-meter becomes only a unit of 35 units; these students do not continue to view the 35/35-meter as a unit of 5 units each containing 7 units. So, MC2 students can consistently take two levels of units as given and create three-levels-of-units structures, but they don't maintain these structures in further operating. In contrast, students who have interiorized three levels of units (MC3 students) can maintain three-levels-of-units structures in further operating.

MC2 and MC3 students are the focus of this paper, so we don't discuss students who have interiorized only one level of units (MC1 students) here. We note that operating with a multiplicative concept is relatively stable: Progressing from one concept to another requires a significant reorganization of schemes that can take two years (Steffe & Cobb, 1988). Current estimates are that about one-third of incoming sixth-grade students are MC1 students, with MC2 and MC3 students making up the rest of the population (Norton, Boyce, Phillips, Anwyll, Ulrich, & Wilkins, 2015).

Method and Data Analysis

To launch each of the three 18-episode design experiments, we implemented a selection process with 21-24 7th- and 8th-grade students: a 30-minute interview and a 12-item worksheet. The interview questions and worksheet were designed to assess students' multiplicative concepts and fractions knowledge. Our aim was to use this process to invite three MC1, three MC2, and three MC3 students to participate in each experiment; however, MC1 students declined to participate. So, we invited six MC2 and three MC3 students to participate in each experiment. In the second and third experiments there was some attrition, resulting in 7 students in the second experiment (4 MC2, 3 MC3) and 6 students in the third experiment (3 MC2, 3 MC3).

In each experiment the 18 1-hour episodes ran twice per week and were video-recorded with one stationary and two roaming cameras. During episodes students often worked in groups of two or three using a software program called JavaBars (Biddlecomb & Olive, 2000), and student work was recorded with Screenflow (Telestream LLC, 2013). Sometimes students worked in groups that were cognitively more homogeneous (e.g., all MC2 students) and sometimes more heterogeneous (e.g., both MC2 and MC3 students).

One researcher (the first author) served as the teacher. Other team members operated roaming cameras, took notes, and interacted with students. Between episodes the team processed data, kept an Episode Index, watched video, took notes, and discussed conjectures to prepare for the next episode. Following each experiment each student participated in a 45-minute interview to assess the student's understanding of topics from the experiment and experience of the class.

For this paper we engaged in two phases of analysis. First we formulated a second-order model (Steffe, von Glasersfeld, Richards, & Cobb, 1983) of each of the 13 students' rational number and algebraic reasoning as it was addressed in the experiments, including students' concepts of unknowns. Second-order models are generated out of researchers' theoretical constructs, models from prior research, and a commitment to use constructs in an orienting but not deterministic way (Clement, 2000). To accomplish this analysis, we repeatedly viewed video files, transcribed major portions of video, and took detailed notes (Cobb & Gravemeijer, 2008). We also wrote and discussed memos (Corbin & Strauss, 2008): interpretations of and conjectures about students' ways of operating and about interactions in which those ways of operating occurred. Then, in the second phase we looked across the students to articulate differences in how students operated with unknowns and to account for these differences based on our models.

Analysis

We found qualitative differences in how MC2 and MC3 students represented and thought about EQUs: MC2 students constructed *implicit* quantitative unknowns, while the MC3 students constructed unknowns with explicitly embedded units. We support these claims by demonstrating how students worked on Single Unknown Problems. Often MC2 students did not represent the two values for the unknown height accurately (from our perspective) in pictures or equations; those who did represent the two values accurately in pictures and equations still demonstrated conflations that to us indicate their equations did not reflect embedded measurement units. Sometimes MC3 students also developed incorrect equations (from our perspective) but revised their work upon questioning; furthermore, their comments about their revised equations demonstrated that the equations did reflect embedded units. So, while both kinds of thinkers showed evidence of the construction of EQUs, their concepts of them differed significantly.

Due to space limitations, we cannot demonstrate student work here; we will do so in the presentation of this paper and in a manuscript that we will develop out of this work.

Discussion and Conclusions

This study suggests that MC2 students require substantial teacher support to create equations representing quantitative unknowns, and they may develop only an implicit understanding of the quantitative structure that we see. In contrast, the construction of EQUs, complete with an awareness of embedded units, is in the province of MC3 students. However, in our study, both MC2 and MC3 students benefitted from explicit discussion about the meanings they attributed to letters. We see developing both common and different supports for algebraic learners like these students to be at the heart of what is needed for access to algebra.

VIDEOS OF PRESCHOOL MATHEMATICAL THINKING FOR TEACHER LEARNING

Paul N. Reimer
Michigan State University
reimerp1@msu.edu

Recent reports on the state of mathematics education call for a deeper understanding of mathematics developmental progressions and recommend improved teacher training for early childhood educators. However, few studies have explored the nature of preschool teachers' existing knowledge, beliefs, and orientations toward children's mathematical thinking. This report describes the initial phase of a project aimed at deepening teacher knowledge of how young children construct mathematical understanding. The video interviews described in this report illustrate the counting stages through which preschool children progress and show potential for use in professional learning settings as teachers reflect on their existing knowledge and work to develop more sophisticated interpretations of children's mathematical thinking.

Keywords: Early Childhood Education, Learning Trajectories, Teacher Knowledge

Introduction and Purpose

Early childhood mathematics education has been a topic of increased interest and numerous recommendations (NAEYC and NCTM, 2010; Duncan et al., 2007). Early mathematics teaching requires a particular knowledge base that includes an understanding of children's developmental and learning processes (Sarama, Clements, Wolfe, & Spitler, 2016). While enhanced knowledge and skills have been shown to produce positive influence on change in teaching practices (Garet et al., 2001), less is known about the specific knowledge base needed for early childhood mathematics teaching (Parks & Wager, 2015).

We are engaged in a research and development project to explore ways to provide early childhood educators with increased opportunities to identify children's existing mathematical knowledge and maximize learning opportunities in mathematical play. In the initial phase of this project–the focus of this research report–we collected video examples of children's mathematical thinking in one-on-one play-oriented interviews with preschoolers and explored what might be noticed about children's knowledge and ways of thinking. In a future phase, we will use these videos with early childhood mathematics educators as potential routes for developing teacher knowledge, addressing beliefs, and strengthening child-oriented pedagogical practices. In this study, we addressed the following research question: What aspects of children's counting schemes are evidenced through interactions with play-oriented tasks in video-recorded interviews?

Theoretical Framework

This project's goals and activities are situated within a constructivist epistemic framework. Consistent with the theories of Piaget, we assume that children construct understanding and develop knowledge as a function of their natural ability to think (Kamii & DeClark, 1985). This epistemology points to the role a child's existing knowledge plays in the construction of new knowledge. We draw on work by Steffe, Richards, and Cobb to support the identification of the stages through which children progress as they develop a counting scheme (1983). Of particular interest to us is the "child's progress in counting…marked by decreasing dependence on perceptual material. The first step in that direction is the ability to count figural representations of perceptual items (i.e., visualized images), which, though presented in the context of the task, are not perceptually available at the moment" (Steffe, Richards, & Cobb, 1983, p. 36-37).

Galindo, E., & Newton, J., (Eds.). (2017). *Proceedings of the 39th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* Indianapolis, IN: Hoosier Association of Mathematics Teacher Educators.

For teachers, we acknowledge that enhanced pedagogical skills are needed to recognize and make use of children's knowledge during play (Wager & Parks, 2016). To structure our future work with early childhood educators, we will rely on the construct of teacher noticing (Jacobs, Lamb, & Philipp, 2010) and the use of videos of children's thinking in a professional learning setting to explore potential pedagogical strategies with teachers. Studies by Sherin and Van Es suggest that video use can support teacher noticing and may influence the focus of teachers' attention (2005). In fact, video from teachers' own classrooms has been shown to be a useful tool in helping teachers consider their current practices and explore new strategies (Borko, Jacobs, Eiteljorg, & Pittman, 2008). We also consider the role of teachers' beliefs as they develop and enact new teaching practices (Borko & Putnam, 1996). Consistent with findings that written vignettes of classroom activity have the potential to elicit preschool teachers' beliefs (Lee & Ginsburg, 2007), we suggest that the use of these videos will show similar potential.

Method

The data for this phase of the project were collected through video-recorded interviews with preschool children from two Head Start preschools in the Western United States. Research associates interviewed all preschool children whose parents provided consent. Twenty children were selected for ongoing interviews based on the goal of obtaining a sample of children representative of gender, initially observed counting level, and primary language. These 20 children were interviewed biweekly over the course of 12 weeks.

Interviews were conducted consistent with the constructivist teaching experiment goals of "formulating and testing hypotheses about various aspects of the child's goal-directed mathematical activity in order to learn what the child's mathematical knowledge might be like" (Steffe, 2002, p. 177). Within each 10-15 minute interview, children were presented with several short play-oriented tasks in which they were asked to count items, say a number word sequence, produce collections of a given number, tell the number of items in small sets without counting, sort plastic animals into groups by color and count them, count claps or marbles dropped into a cup, count hidden items, or build block towers and count the number of blocks used. Following each week of interviews, video episodes were analyzed for evidence of children's mathematical thinking and anecdotal notes were taken. During this analysis interviewers discussed observations and planned tasks and questions they would consider in the following interview.

Preliminary Findings

All interviews were video-recorded and analyzed by the team of research associates. Initial findings revealed that children brought a range of counting concepts and skills to the tasks, evidenced in the ways they counted items and responded to questions. Table 1 presents a sampling of our observations consistent with established research drawn from the analysis of the video interviews. We then offer one vignette from video collected to illustrate a specific example noted in the table.

In one interview [noted in bold in the table], the interviewer asked Mario (pseudonym) to count the number of marbles that were dropped into a cup. The marbles remained hidden from Mario's view while being dropped and while in the cup. The following portion of the interview took place after Mario had correctly produced counts of three and two marbles.

Mario: (Summarizes his previous two counts). I got three and two. (Shows finger pattern of three on left hand with thumb, forefinger, and middle finger. Shows finger pattern of two on right hand with forefinger and middle finger.)

Interviewer: Good job, you made them with your fingers. OK, let's do it again. (Slowly drops four marbles into the cup while Mario listens.)

Mario: Four. (Quickly shows finger pattern of three on his right hand with thumb, forefinger, and middle finger).
Interviewer: (Shows Mario the cup).
Mario: (Touches each marble inside the cup as he counts.) One, two, three, four. I got four!

Table 1: Observations Based on Counting Types (Steffe et al., 1983; Wright et al., 2006)

Emergent	Perceptual	Figurative
may use number word sequence, but may not coordinate words with items	counts to find out how many items are present	counts items in a screened collection or may count items in more than one screened collection
may count items of a collection multiple times and arrive at different number words	**counts perceptual unit items, coordinates correct number word sequence with items**	counts substitutes for perceptual items (visualized spatial patterns, sequentially raised fingers or other movements, verbal items)
may use number word sequence from "one" in response to "How many are there?"	may count two addends and not count joined collection when asked how many	
may make finger patterns for numbers one to five	may reorganize items to facilitate counting	

Mario recognized the sound of the marbles hitting the bottom of the cup as something to be counted, and progressively produced more accurate counts of the marbles. While Mario has some finger patterns for numbers to five, he may lack a consistent pattern for four. In further interactions with Mario, asking him about the finger patterns he shows for his counts may help him to reconcile this inconsistency.

Discussion

The videos collected during this phase of the project provide specific examples of preschool children's thinking in counting activities and demonstrate the range of counting types that may exist in a preschool classroom. Furthermore, our analyses suggest that early learning environments are comprised of children who are operating at varied levels of understanding. Our goal in the subsequent phase of this project is to use these videos as models of early mathematical thinking to encourage discussion and reflection among teachers in professional learning settings. Using the construct of noticing, we plan to support teachers in learning to identify ways in which children may be operating and encourage the implementation of child-oriented pedagogical practices that acknowledge these existing understandings. We believe these video artifacts have the potential to surface the implicit theories teachers hold about how young children come to know and understand mathematics and could prove to be helpful tools in developing early educators' knowledge, beliefs, and practices.

Acknowledgements

This project is being conducted through the AIMS Center for Math and Science Education. I would like to thank my research associates Wilma Hashimoto, Aileen Rizo, Jason Chamberlain, and Elizabeth Gamino for their collaborative effort throughout this project.

WHOLE NUMBER AND INTEGER ANALOGIES

Nicole M. Wessman-Enzinger
George Fox University
nicole.enzinger@georgefox.edu

This research brief highlights analogy use of a Grade 5 student, Kim. Kim participated in four individual interviews across 12-weeks, embedded within a teaching experiment. Drawing on the theoretical perspective of in-between and within-domain analogies, I analyzed how Kim drew upon analogies as she solved the integer open number sentences during the individual interviews. These analogies are distinguished between whole number and integer analogy use. I connect existing research with descriptions of whole number and integer analogy.

Keywords: Number Concepts and Operations, Elementary School Education, Cognition, Middle School Education

Children are capable of reasoning about negative integers in productive and sophisticated ways prior to school instruction (e.g., Bofferding, 2014; Bishop et al., 2014; Featherstone, 2000). Although there are different ways to describe children's thinking about integers—mental models (Bofferding, 2014), ways of reasoning (Bishop et al., 2014), and conceptual models (Wessman-Enzinger, 2015)—there is much agreement that children frequently utilize analogies as they make sense of integer addition and subtraction (Bishop, Lamb, Philipp, Whitacre, & Schappelle, 2016; Bofferding, 2011; Bofferding, 2014; Wessman-Enzinger, 2015). In fact, analogical reasoning is likely a component of all learning (Vosniadou, 1989).

Bofferding (2011) described the different types of analogies that children make, ranging from comparisons that involve surface features to deep structural comparisons, and comparisons that involve both. A surface feature comparison, for example, includes comparisons like $-5 - 9 = \square$ to $9 - 5 = \square$, because both number sentences involve the same digits. A deep structure comparison includes recognizing that $3 - 7 = \square$ is different from $7 - 3 = \square$. Bishop et al. (2016) described different comparisons, or analogies, that are logical necessities: variations in signs, variations in operation, and variations in addends. A variation in sign when number sentences like $3 - 7 = \square$ and $3 - -7 = \square$ are compared. Variation in operations includes comparisons like $-5 + 2 = \square$ and $-5 - 2 = \square$. Variations in addends includes comparing $-1 + 4 = \square$ and $4 + -1 = \square$.

Although differentiating these types of comparisons is important, researchers do it differently (Bishop et al., 2016; Bofferding, 2011; Wessman-Enzinger, 2015). This work seeks to understand the structural similarities of these different types of analogies and potentially connect this work by drawing on Vosniadou's (1989) definition of analogical reasoning.

Theoretical Perspective

Vosniadou (1989) characterized the mechanism behind analogical reasoning as the following: (a) "retrieving a source system (Y), which is similar to X in some way"; (b) "mapping a relational structure from Y to X"; (c) "evaluating the applicability of this relationship structure for X" (p. 422). She also highlighted two different types of analogies: between-domain and within-domain analogies. *Between-domain analogies* are when two comparisons are made (i.e., comparing Y to X), but these comparisons have similarity in structure, but are in two different systems (i.e., $X \ni \{A\}$, $Y \ni \{B\}$). *Within-domain analogies* are comparisons that belong to the same, or very close, conceptual domains. For example, if I compared wavelengths of air to wavelengths of water this would be a between-domain analogy since water and air are different structures. But, if I compared amplitude and frequency of sounds waves these would be within-domain analogies since amplitude and frequencies of sounds waves belong to the same conceptual structure. Vosniadou stated, “The distinction between within-domain and between-domain analogical reasoning is not a dichotomous one. Rather, it represents a continuum from comparisons involving items that are clear examples of the same concept to items that belong to different and remote domains” (p. 415). Specific to this brief report, I address the distinction between whole number and integer analogy (between-domain and within-domain analogies), and use one student, Kim, to illustrate this difference.

Method

Context of Study

Three 10-year old Grade 5 children from a rural Midwest school in the United States participated in a 12-week teaching experiment (Steffe & Thompson, 2000). These Grade 5 children made ideal participants because they did not have prior instructional experiences with operations with negative integers. As part of this study, the children engaged in four individual, structured task-based interviews (Goldin, 2000). These structured task-based interviews provided space to evaluate the children’s understandings of open number sentences individually, while they solved the same integer number sentences types (Murray, 1985) across the 12-weeks. Group sessions of the teaching experiment were about solving integer problem in contexts, not intended to support analogy use, and are described elsewhere (Wessman-Enzinger, 2015). The data generated for this study comes from when the children solved open number sentences during the individual sessions.

Individual Interviews

Across the individual sessions, the student solved open number sentences of the same type. For instance, -20 + 15 = ☐ is considered the same problem type as -16 + 4 = ☐, aligning with the problem type -a + b = ☐, a > b (Murray, 1985). The transcript for solving each of these open number sentences constituted the unit of data— there were 93 units for each child and 279 total units of data for this investigation. For this report, Kim is selected as case study because she had the most units of data coded with analogical reasoning.

Data Analysis

A second researcher and I examined the data utilizing a constant comparative method (Merriam, 1998), looking for the use of analogy as defined by Vosniadou (1989). We compared and negotiated all differences on this first coding of analogy. During the secondary pass of data, I developed the definition of analogy further with the distinction between whole number analogies and integer analogies, relating to Vosniadou’s within-domain and between-domain analogies.

Descriptions of Analogical Reasoning with Integer Addition and Subtraction

Children utilized *analogy* when they compared integers in a way that connects an integer addition and subtraction number sentence to different addition and subtraction number sentences. The two subcategories of analogy, whole number analogy and integer analogy, constitute types of analogy use. *Whole number analogies* are comparisons of integer addition or subtraction open number sentences to other addition or subtraction problems with only whole numbers, or positive integers. For example, Kim compared -15 – -4 = ☐ to 15 – 4 = 11 (correctly determining the solutions to -15 – -4 = ☐ as -11). Her comparison, 15 – 4 = 11 is a number sentence with only whole numbers. *Integers analogies* are comparisons of integer addition or subtraction problems to different, and not necessarily equivalent, integer addition or subtraction problems. Integer analogies include the comparison of an integer addition and subtraction problem to a number sentence with at least one negative integer. For example, Kim compared ☐ – -3 = 2 to 1 – -3 = 4 (correctly determining the solution to ☐ – -3 = 2 as -1). Her comparison, 1 – -3 = 4, involved negative integers in the number sentence this time. For both of these examples, the comparisons are not mathematically equivalent: $-15 - -4 \neq 15 - 4$ and $-1 - -3 \neq 1 - -3$. This aligns to Vosniadou's (1989) definition of analogy that two comparisons are related, but not necessarily structurally equivalent. What distinguishes analogical reasoning is the relation is not the equivalence, but the comparison of addition and subtraction problems to other addition and subtraction problems. Thus, both whole number analogies and integer analogies are examples of analogical reasoning (Vosniadou, 1989). This distinction between whole number and integer analogy is described in more depth next.

Whole Number Analogy

Kim utilized whole number analogy when she solved $-12 + -5 = \square$ in the following excerpt:

> (Writes -17 in the box.) Both of the numbers have the negative sign in front of them. That means that they are both negatives. And, that's pretty much the same thing as twelve plus five when you add a negative twelve plus five. It's just negatives this time. So you just (shrugs) ... the twelve plus five and got seventeen. And I just added the negative onto it. … It comes out as the exact same answer, but the only difference is that they add a negative sign to it.

In this excerpt, Kim stated that $-12 + -5 = \square$ is "pretty much the same" as $12 + 5 = \square$. Kim's direct comparison of $-12 + -5 = \square$ to $12 + 5 = \square$, only includes whole numbers is a typical example of whole number analogy.

In the excerpt above Kim drew upon whole number analogy and determined a correct solution. However, sometimes as Kim drew upon whole number analogy she obtained incorrect solutions. For example, she compared $-5 - 4 = \square$ to $5 - 4 = 1$. As Kim solved $-5 - 4 = = \square$, she concluded the answer was -1, "Five minus four equals one. Pretty much the same thing. You don't really need the negatives."

Integer Analogy

Kim constructed integer analogies included when she made comparisons to number sentences with negative integers. For instance, Kim compared $-4 + \square = -19$ to $-4 + 15 = 11$ (correctly determining the solution of $-4 + \square = -19$ as -15). She made her comparison, $-4 + 15 = 11$, to help her determine that the solution to $-4 + \square = -19$ needed to be negative. She, then made a second comparison, a whole number analogy, comparing $-4 + \square = -19$ to $4 + 15 = 19$. In contrast to whole number analogy, comparing $-4 + \square = -19$ to $-4 + 15 = 11$ constitutes an integer analogy because it involves negative integers.

Kim also constructed integer analogies that did not lead to a correct answer or made comparisons to number sentences that are not true. For example, Kim drew upon integer analogy as she compared $3 - \square = 4$ to $3 - -1 = 2$. But, $3 - -1$ does not equal 2. Consequently, Kim's use of integer analogy could not help her produce a correct solution since $3 - -1 \neq 2$.

Discussion & Final Remarks

The distinction between whole number and integer analogies reported here relates to Vosniadou's (1989) within-domain and between-domain types of analogies. Whole number analogy related to between-domain analogy in the sense that these types of analogies connect the whole numbers to integers. Integer analogy is a type of between-domain analogy in that, although the two integer number sentences are not necessarily mathematically equivalent, the children relate these two different types of integer number sentences in their own unique ways.

Crossroads are a place where a road crosses a main road or connects two main roads, one of the conference themes this year. This theme resonates in this research. First, this research represents a crossroad as it connects well-traversed work in analogy (Vosniadou, 1989) and current research with integers (e.g., Bishop et al., 2016). In alignment with prior work on children's thinking about integers that illustrates that different types of comparison are made (Bishop et al., 2016; Bofferding, 2011), Kim used whole number and integer analogy differently, developing use of integer analogy and using analogies to obtain correct solutions. These results extend this work of Bofferding (2011) and Bishop et al. (2016), but also complement and connect this work by illustrating that these types of comparisons (e.g., surface features, deep structure, variation in operations, varying order of addends) are capable of being grouped as whole number analogy and integer analogy. A surface feature comparison (Bofferding, 2011) or variations in operations (Bishop et al., 2016), for example, could be a whole number or integer analogy. Analogy use represents a crossroad where integer research is connected.

Acknowledgments

Data collected was supported by the Illinois State University Dissertation Completion Grant. Dr. Edward Mooney, from Illinois State University, coded the data as the second researcher.

Introduction

This analysis is situated within the Improving Formative Assessment to Support Teaching Algebra (iFAST Algebra) Project, an NSF-DRK12 grant focused on enhancing middle-school mathematics teachers' formative assessment practices in algebraic function. The project involves design and study of a professional development program that aims to develop teachers' understanding of the hypothetical learning trajectories (HLTs) embedded in their classroom curriculum. The integration of HLTs into teaching requires framing them in ways that are interpretable and useful for teachers. One such framing establishes a set of dimensions for linear-function tasks to highlight key conceptual obstacles and landmarks along an HLT. We document how dimensions and representations play out in a sequence of tasks across a middle-grades curriculum (CMP3). We show how key task features signal conceptual concerns along HLTs in algebra.

Analysis of Dimensions and Representations of Linear-Function Tasks

Our framing of *task dimensions* draws from an approach to algebraic task analysis (Leinhardt, Zaslavsky, & Stein, 1990) in which functions-related graphing tasks were investigated using four constructs: action called for, contextualizing situation, type of variables, and location of mathematical attention. In addition, the importance of translating among *representations* of algebraic functions— tables, graphs, equations, pictures, and verbal situations—is well documented (see Brenner, et al., 1999). We first analyzed several pilot tasks to further specify dimensions and levels for each, and refine representation codes (Figure 1). We then applied the refined tools to all tasks.

Results

Preliminary analysis identified key dimensions levels with a hypothesized direction of increasing complexity. When analyzed against these dimensions, the sample of tasks in CMP3 reflected a robust distribution of task features, particularly with respect to translations among representations, mathematical actions, and explicitness of parameters in the function representation. Analysis also identified key conceptual transitions in the curriculum (e.g., introduction of non-proportional linear functions, non-positive slopes, tables with non-unitary input increments).

DIMENSION	LEVELS		
Situation	Contextual Abstract		
Data fit	Exact Approximate		
Proportionality	Proportional	Non-proportional	
Slope value	Positive only	Negative, zero, or undefined	
Inputs/outputs	Whole-number values only	Include negative values and/or rational values	
Explicitness	m and b explicit	m and b partially explicit	m and b implicit
Actions	Interpretation Value calculation Construction		

Hypothesized direction of increasing complexity

The give-me-*n* task (e.g., asking a child for 3 or 5 chips from a pile of 10 chips) is used widely in developmental research as the operational definition of a child's understanding of small numbers (*n*-knower level) and the cardinality principle (CP) with larger *n*s (CP-knower level). The CP entails recognizing that the last number word used in the counting process represents the total. However, the give-me-*n* task, which entails mapping a number word to a collection, may be cognitively more challenging than the how-many task, which involves mapping a collection to a number word and, thus, provides a direct measure of these constructs. Two studies were undertaken to evaluate whether the two tasks produce equivalent results for subitizing small numbers (n-knower level) and an understanding of the CP (CP-knower level).

Study 1 entailed comparing 60 3-year-olds' (M = 43.2 months, SD = 3.1 months) performance on the give-me-*n* and the how-many tasks with sets of 1 to 3 at three time points 3 weeks apart. A 2 (Task: how many v. give-me-*n*) x 3 (Size of $n = 1, 2$, or 3) x 3 (Time: T1, T2, or T3) repeated-measure ANOVA was conducted. This analysis yielded main effects for Task ($F[1, 59] = 17.078$, $p < .001$) and Size ($F[2, 118] = 39.069$, $p < .001$) but not Time ($F[2, 118] = .448$, $p = .64$). In addition, a Task x Size interaction was significant. Specifically, when n=3, children performed significantly better on the how-many task (mean for all three sessions = 1.494) than on the give-me-*n* task (M = 1.022), $F(1, 59) = 34.061$, $p < .001$, Cohen's $d = 0.635$.

Study 2 was undertaken to directly compare 3- and 4-year-olds' (M = 49.4 months, SD = 3.95 months) performance on the how-many and give-me-*n* tasks with larger numbers (6 & 8). In addition to a how-many task with linear arrays, a more difficult how-many task was also administered. Unlike the linear version and similar to the give-me-*n* task, the challenging how-many task entailed counting non-linear arrays and, thus, entailed more than minimal effort to keep track of which items have been counted and which need to be counted. As children may merely memorize a state-the-last-*n* rule for responding to how-many questions and may not truly understand the CP, two "how-many application tasks" (identity conservation and cardinality equivalence tasks) were also administered. These tasks involved determining a cardinal value of a collection *and* then applying this information in a meaningful manner.

Performance on the give-me-*n* task was significantly and substantially (as measured by effect size) lower than that on the how many—easy version ($p = .016$, Cohen's $d = 0.434$) and the how many—hard version ($p = .001$, Cohen's $d = 0.609$). The difference was marginally significant but still substantial for the identity conservation task ($p = .052$, Cohen's $d = 0.356$) and cardinality equivalence task, ($p = .083$, Cohen's $d = 0.352$).

The results of the present research confirm that the give-me-*n* task is but an indirect or proximate measure of the 3-knower level and the CP-knower level. Importantly, using the give-me-*n* task as the sole measure of these key aspects of early numeracy may seriously underestimate children's early number development. Performance on the give-me-*n* task more accurately reflects "*n-producer* levels": verbal subitizing-based set production and counting-based set production, which requires a cardinality concept more advanced than the CP.

ASSESSING SYMBOL SENSE BY IDENTIFYING STRATEGIC SOLUTIONS

Keywords: Algebra and Algebraic Thinking, Assessment and Evaluation, Problem Solving

When solving math problems, we can often reach the correct answer using different approaches. Some approaches are more efficient than others—for instance, you might notice a shortcut, or use a trick to quickly simplify a complex equation. The ability to identify clever solutions is part of what's known as 'symbol sense.' Researchers suggest that people who are stronger at math should be better able to recognize strategic solutions and avoid less-strategic approaches (Bokhove & Drijvers, 2010), but this notion has not been tested systematically.

The current study explored whether people can differentiate between incorrect solutions, correct but less strategic solutions, and correct solutions that are also highly strategic. In order to do this, we showed each participant a series of algebra problems. For each problem, they also saw the first step of four different approaches to solving it: an *invalid* manipulation; a valid but ultimately *useless* manipulation; a valid, helpful, but *less strategic* manipulation; and a valid manipulation that would lead to a *clever*, strategic solution (Table 1). On the basis of these four first-steps, participants rated each approach to solving the problem, using a scale from 0 (a good student should never use this strategy) to 100 (a good student should always use this strategy).

We found that participants exhibited two distinct patterns of results. Many participants gave higher ratings to clever answers, thus distinguishing these strategic approaches from formally correct manipulations that were ultimately useless or inefficient. Others did not distinguish between formally valid approaches, giving equally good scores to any approach that did not include an error (i.e., clever, less strategic, and useless approaches). Critically, the ability to distinguish strategic, clever approaches from less strategic or useless approaches was related to both algebraic skill (as measured by accuracy) and mathematical experience (as measured by the number of math courses completed). These findings suggest that the ability to recognize clever or strategic approaches—'symbol sense'—is a critical component of complex mathematical skill.

CONCEPTUAL MODEL-BASED PROBLEM SOLVING: A RESPONSE-TO-INTERVENTION PROGRAM FOR STUDENTS WITH LEARNING DIFFICULTIES IN MATHEMATICS

Yan Ping Xin, Ph.D.
Purdue University
yxin@purdue.edu

Signe, Kastberg, Ph.D.
Purdue University

victorchen@purdue.edu

About 5-10% of school age children are identified as having learning disabilities in mathematics (LDM), many of whom become at significant risk of failing the secondary mathematics curriculum. Given the increases in sophisticated and affordable technology for in and out of school, parents and teachers often turn to the many games, ‘apps,’ and web-based teaching/learning programs for help. However, there is a lack of Resources/Materials/Tools (RMTs) that focus on building *conceptual understanding* of fundamental mathematical ideas--concepts that are essential to enabling these students to understand and solve word problems and catch up with their peers. Without such RMTs, students with LDM are left further behind and virtually denied access to mathematics learning opportunities both inside and outside the elementary classroom. The purpose of this National Science Foundation funded project (Xin, Kastberg, & Chen, 2015) is to create a web-based intervention program to address the skill deficit and immediate needs of second- and third-grade students with LDM in meeting the Common Core State Standards for Mathematics. The objectives of this project include:

1. Create the curriculum content, screen design, and teacher manual for four modules of this computer-assisted tutoring program in the area of additive word problem solving;
2. Design and develop the cross-platform computer application that can be ported as web-based, iPad, Android, or windows app, which can run on different kind of computers and be accessible to students with various social economics status in a range of environment;
3. Conduct a small-scale single subject design study as well as a randomized controlled trial (RCT) study to evaluate the potential of this program in enhancing elementary students’ word problem-solving performance.

Multiple innovative features of this computer assisted tutoring program include: (a) an instructional program designed to emphasize mathematical model-based approach to promote students’ generalized problem-solving skills, (b) an emphasis on computer science technology to facilitate instruction that is computer-generated and specifically tailored to each individual student’s learning profile in real time, and (c) an emphasis on making the reasoning behind mathematics explicit to students through preparing fundamental mathematical ideas (e.g., a number as an abstract *composite unit*). This computer-assisted tutoring program represents a shift from traditional problem-solving instruction, which focuses on the *choice of operation* for solution, to a *mathematical model-based problem-solving* approach that emphasizes an understanding and representation of mathematical relations in algebraic equations and therefore promotes generalized problem-solving skills. This project is expected to make a broader impact due to its *cross-platform* (web-based, iPad, Android, or windows app) tool’s flexibility –with group or one-on-one instruction within the regular classroom settings or in pull-out settings during or after the school day, and with individuals at home.

The Problem

Development of conceptual understanding of the algorithm for adding fractions is built “using visual models, estimation, unit-fractions understanding, equivalence, and properties of operations” (Petit et al., 2016, p. 1420). These relevant concepts are investigated across grades 3-5 progressively, and by the end of grade 5, students should develop procedural fluency using the algorithm building on conceptual understanding (CCSSI, 2010). Research has suggested that addition of fractions should be developed through solving contextual problems using area models (Carmer, Wyberg, & Leavitt, 2008) and/or linear models (Izsak, Tillema, & Tunc-Pekkam, 2008). However, putting these research ideas into daily classrooms has been a challenging task. We report on a research-based lesson that promotes students’ understanding and fluency through Chinese lesson study (LS).

Method and Results

The LS occurred in a school system in a mid-size city in the southeastern USA. Three K-5 teachers implemented two cycles of a research-based lesson of addition of fractions in 5th grade classrooms. The LS was facilitated by three professors in math education from a large, public university in the city, and one math specialist from the school system. Data included lesson plans, videotaped research lessons, and post-lesson debriefings and reflection reports. Data analysis focused on capturing major changes between the two lessons and major features of lesson two. Reflection essays were analyzed through constant comparison to identify what teachers learned by the LS.

The lesson improved significantly toward developing the algorithm both conceptually and fluently. This improvement was facilitated by the development and inclusion in the second lesson of a graphic organizer involving three strip diagrams, bringing an area model and a number line together. Students represented the two fractions to be added in two of the strips of the diagram, and subdivided these into equal-sized pieces, which modeled finding fractions equivalent to the original addends only with a common denominator. This organizer aided teachers and students in more deliberately connecting the symbolic steps of the algorithm with the models. In lesson one, the students used area models to add fractions and then performed the algorithm, but the connection between the two was weak. The teachers appreciated the process of the LS and were proud of the product. They perceived their growth in knowledge about content, pedagogy and student learning, the specifics of which will be specified in the poster.

INTERSECTIONS OF QUALITATIVE AND QUANTITATIVE RESEACH: RELATIVE SIZE OF NUMBERS

Shelly Sheats Harkness
University of Cincinnati
shelly.harkness@uc.edu

Amy Brass
University of Northern Iowa
amber.g.brass@gmail.com

Keywords: Number Concepts and Operations, Teacher Education Pre-Service, Research Methods

Research studies about both children's and adults' conceptions of the relative size of large numbers have employed number line tasks and quantitative measures of analysis. While these studies have revealed important findings, missing from these analyses are the participants' reasons for their placements of large numbers on a number line. Because pre-service teachers (PSTs) are tasked with planning and implementing learning experiences, their conceptions are important for mathematics teacher educators to understand. Brass and Harkness (2017) used a socio-cultural qualitative research design and asked the question: How do PSTs think about large numbers and the relationships between large numbers? Pre-service elementary, middle, and secondary teachers' (n=128) were asked to place one billion on a number line segment with endpoints at zero and one trillion and write explanations for their placements. Nine distinct explanations for these placements were identified (Brass & Harkness, 2017).

For this poster session we will show examples of these nine different explanations (Brass and Harkness, 2017) and highlight the intersections between them and the findings of quantitative studies involving the relative size of numbers. Quantitative studies have largely been cognitive or psychological in nature and have focused on: logarithmic-to-linear shifts (Moeller, Pixner, Kaufmann, & Nuerk, 2009; Slusser, Santiago, & Barth, 2013); proportionality (Barth & Paladino, 2011; Landy, Silbert, & Gilbert, 2013; Siegler & Opfer, 2003); familiar numbers (Rips, 2013); number nomenclature (Landy et al., 2013); and, place value (Moeller et al., 2009). Most studies have treated these topics as parallel to each other; however, our aim is to show how they overlap within mathematics education. For example, concepts of place value are contingent upon both understanding of proportionality and familiarity with number names.

Our aim is to provide a deeper understanding of PSTs' conceptions of the relative size of numbers. This work will inform mathematics teacher educators so that they plan activities that help PSTs move toward proportional, spatial, and place value number sense related to the relative size of large numbers.

OPEN NUMBER SENTENCES: A BETTER WAY TO ASSESS PRECISELY THE CONCEPTION OF EQUIVALENCE

Rashmi Singh
Kent State University
rsingh9@kent.edu

Karl W. Kosko
Kent State University
kkosko1@kent.edu

Key Words: Elementary School Education, Number Concepts and Operations

It is generally accepted that a relational conception of equivalence (sameness or interchangeability of expressions), is critical for elementary students' success in latter mathematics (Blanton & Kaput, 2005). By contrast, an operational view of the equals sign (i.e. producing the answer) hinders their success. Researchers often use different types of items to assess students' conception of equivalence (Stephens et al., 2013). These items mainly fall into two categories: true/false items with closed number sentences (i.e. $a + b = c + d$) and open number sentences (i.e. $a + b = c + \square$). However, research tends not to focus on the specific advantages each type of item has in assessing conceptions of equivalence. The purpose of this study is to examine how each open number sentences and true/false closed number sentences elicit evidence of students' relational conception of equivalence.

The data used in this study includes observations of two second-grade students' in two sessions from a year-long teaching experiment. We found that both students' responses on true/false closed number sentences indicate that they have relational conception of equals sign (see figure 1). In true/false closed number sentences both students compute the answer for each side (i.e. expression) and then compares to see if both sides equal to the same answer. However, in the very next session when they got open number sentence ($8 + 5 = \square + 10$) both students represented operational conception of equal sign and put 13 in the box.

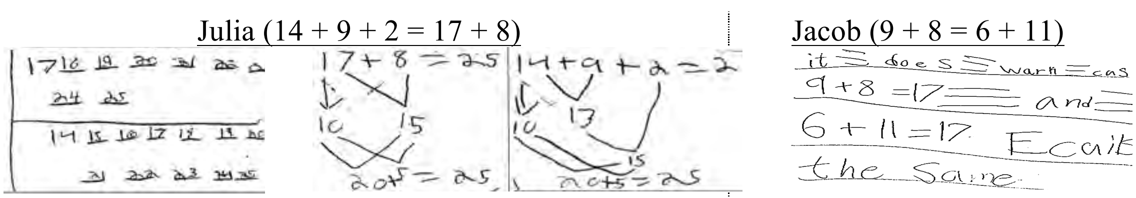

Figure 1. Participants' responses in session 13 for true/false closed number sentences.

The possible reason behind students' success in closed number sentences is that the structure of such problems allows students to treat each expression separately without seeing the equation as a math object on its own. On the other hand, in open number sentences counting and comparing scheme does not work due to the presence of unknown. Thus, open number sentences make it more obvious if students are not seeing the whole equation as an entity. It is therefore, argued that open number sentences provide better assessment items for understanding of equivalence as compared to closed number sentences.

USING MAGIC ACTIVITES TO ENGAGE STUDENTS INTELLECTUALLY

Alejandro A. Galvan
University of Texas at El Paso, USA
agalvan4@utep.edu

Kien H. Lim
University of Texas at El Paso, USA
kienlim@utep.edu

Keywords: Algebra and Algebraic Thinking

Most students are generally uninterested in mathematics because of its abstractness. Magic can captivate students because of their innate capacity to be intrigued and their proclivity to resolve curiosity. Educators have advocated the use of math magic to teach algebra (Benjamin & Brown, 2014; Matthews, 2008). In her study involving 23 ninth graders, Koirala (2005) found that math magic motivated students to learn basic algebraic concepts, and resulted in a pre-to-post improvement in solving basic algebraic problems. Recognizing the power of magic in reinforcing foundational concepts like variables, expressions, equations, and inverse functions, we implemented two magic activities in a capstone course for preservice 4-8 math teachers. In the *5-4-3-2-1-½ Magic*, students think of a secret number and perform arithmetic operations (add 5, times 4, minus 3, divide 2, add 1, add ½). Upon hearing a student's final number, the teacher-magician can spontaneously say out the corresponding secret number. In the *I-Know-Your-Final-Answer Magic*, the magician made every participants end up with the same final number.

The research questions are: (a) How do students respond to the magic activities? (b) Which type of magic activities do students enjoy more? (c) In what ways do students feel that the activities have increased their understanding and/or appreciation of algebra? Students' written work on their thoughts about how each magic worked were collected and analyzed. The other two research questions were answered using students' responses in an online survey and a focus group. There were 25 participants in this study; a few students being absent on certain days.

For the 5-4-3-2-1-½ magic, 13 out of 22 students figured out the trick using strategies like arithmetic approaches, reasoning with number patterns, and working backwards. Only two students thought of using algebra but could not figure out the trick algebraically. For the second magic, 39% successfully used algebra to show how the magic worked, 43% had errors in their use of algebra, and 18% did not even attempt to use algebra. Based on the survey and the focus group data, students overwhelmingly liked the magic activities especially the 5-4-3-2-1-½ magic, found them to be engaging and fun, and enjoyed the challenge to figure things out on their own. They appreciated its connections to algebra concepts and thereby gained a better understanding of the usefulness of algebra (a variable to represent the secret number, an expression to represent the steps, and solving for x to find the inverse function that corresponds to the trick). They found that the magic activities had reinforced what they had learned, but forgotten, about algebra. They also expressed their intent to use the magic activities in their own classroom.

Keywords: Number Concepts and Operations, Rational Numbers, Measurement, Curriculum

The Common Core State Standards for Mathematics (Common Core State Standards Initiative, 2011) highlight the importance of using "visual fraction models" for teaching and learning fractions to help students explore the underlying ideas of fraction multiplication and deepen their understanding of multiplying fractions. However, there are various misrepresentations and misinterpretations of fraction multiplication models made by teachers and students (Webel, Krupa, & McManus, 2016). Although teachers and students may assume the typical area model for the multiplication of fractions is a conceptual extension of the area model for whole number multiplication, the area model — prevalently used in current U.S. curricula for fraction multiplication — seems not a direct conceptual extension of the area model for whole number multiplication (Son, 2012). Predinger (2008) also shows (dis)continuity of the mental models of multiplication when students having transitions from whole number multiplication to fraction multiplication. It thus requires a careful investigation of the effective use of area models to help students deepen their understanding of multiplying fractions.

The purpose of this study is to consider how various area models in mathematics curricula support student understanding of fraction multiplication. Three U.S. textbooks and one Korean textbook are examined for how they offer opportunities with fraction representations, corresponding area models, and related word problems to foster understanding of fraction multiplication.

The results point out that many models are just reflecting the appearance or different characters of models themselves, not carefully reflecting students' action, thinking, and thought process in relation to models and the nature of multiplication. They also indicate that two different types of area models are used in various contexts of fraction multiplication: *the area-to-area model* and *the lengths-to-area model*. Each model reflects different aspects of a fraction and different thinking processes involved with fraction multiplication. Korean textbook uses both two models in teaching fraction multiplication, whereas U.S. curricula rarely introduce the lengths-to-area model for fraction multiplication.

These findings suggest that without a careful conceptualization of the two area models, teachers and students may overlook the conceptual ideas of fraction multiplication and connection to the models for whole number multiplication. We thus address the two types of area models representing the fraction multiplication processes in detail and discuss how to carefully introduce those models to help students attain a better understanding of the multiplication of fractions.

RESPONSE TIME CRITERION FOR DEFINING FLUENCY

Neet Priya Bajwa
Illinois State University
nbajwa@ilstu.edu

Keywords: Number Concepts and Operations

Introduction and Method

Being *fluent* with basic combinations is crucial for achieving mathematical proficiency and entails the ability to find the sums and differences of basic number combinations *efficiently* (generate the answer accurately and quickly), appropriately and adaptively (Baroody,1985; NMAP, 2008). Researchers agree that children typically progress through three overlapping phases to deduce answers to unknown facts— a) counting, b) deliberate reasoning with known facts and, c) automatic retrieval—*before* achieving fluency with basic facts or family of facts (Geary, Hoard, Byrd-Craven, & Desoto, 2004). Although words such as *quick* and *fast* are often used to define basic fact fluency, what exactly counts as *fast* is often unclear. The current study evaluated the response time criterion for defining first graders' fluency (retrieval) with basic addition and subtraction combinations. Part of a larger experimental study with a diverse group of first graders from the Midwestern U.S., the data considered for this study was drawn from 75 students who completed the larger study. The data consisted of students' answers to basic addition and subtraction problems, response-time to generate each answer and, a description on how each answer was generated.

Findings and Conclusion

All correct responses were coded for strategy type and use: *overt* (deliberate or apparent use of the strategy) and *covert* (reporting a counting/reasoning strategy when asked during follow up questioning). The proportion of overt reasoning and counting responses for addition and subtraction problems were calculated with various response time (RT) cut-offs —from 2 to 5 seconds. The 3-second response time criterion successfully differentiated between fluent and non-fluent counting, with zero responses created under 3 seconds for all problems. However, this was not the case for responses generated under 3 seconds using a reasoning strategy, with approximately 3.5% of the addition and 29% of the subtraction responses attributed to reasoning. These findings indicate that different RT cut-offs may be appropriate to define fluency in addition and subtraction problems as opposed to using one RT cut-off as a proxy for defining retrieval (or fluency).

Keywords: Algebraic Thinking, Teacher Knowledge

Pattern generalization is acknowledged in its importance as an introduction to algebra as well as in the development of algebraic reasoning (e.g., Jurdak & El Mouhayar, 2014). Figural patterns, in particular, provide opportunities to reason about diagrammatic and algebraic structure (Rivera & Becker, 2008). This study investigated the ways in which a group of prospective teachers (PSTs) attempted to provide generalizations for figural patterns. More specifically, we analyzed PSTs' approaches toward expressing generality and the relation of such approaches to PSTs' algebraic understanding of figural patterns. The research question was: how do PSTs' approaches to algebraic generalization relate to their understanding of figural patterns?

Eight PSTs at a Midwestern university in the United States participated in our study. They were in their third year of a secondary mathematics teacher preparation program. During the study, the PSTs were asked to provide generalizations for four different figural patterns. The data sources included both video-recorded clinical interviews with the PSTs and their written work on the tasks. Based on the research goal, we coded the data qualitatively and categorized the ways in which the PSTs produced their generalizations. The findings show that the PSTs employed two approaches to generalization: *rule for patterns* (attempting through trial-and-error to fit a symbolic rule onto the numeric pattern that was extracted from the figural pattern) and *rule from patterns* (drawing on numeric patterns in conjunction with the diagrammatic structure of figures to generate a symbolic rule). One PST, Amy, employed a *rule-for-patterns* approach on all of the tasks. In solving them, she attempted to fit exponential expressions onto both linear and quadratic number patterns without considering how such expressions related to the diagrammatic structure of the figures. Another PST, Jim, employed a *rule-from-patterns* approach. Across each of the tasks, Jim consistently noticed and utilized the relationship between the figure number and the figural structure to produce generalizations. A third PST, Zoe, employed both approaches. She attempted a *rule-for-patterns* approach in the first task, but later shifted her approach to rule from patterns upon recognizing an algebraic relation within the figural structures of the pattern. Our results suggest that only the *rule-from-patterns* approach is associated with drawing connections between algebraic expressions and the figures.

The algebraic understanding of students in K–12 schools has often lacked depth due to the traditional focus on symbol manipulation without meaningful connections (Lannin et al., 2006). If we wish to support students (and PSTs) in making connections and deepening their algebraic thinking as it relates to generalization and functional relationships, then there may be benefits in emphasizing the importance of sense-making in the generalization process.

Keywords: Algebra and Algebraic Thinking

The view of algebra as a purely secondary school course has been challenged in recent decades, with algebra now being seen as an important strand of study for earlier grades (NCTM, 2006). Our work addresses the premise that a comprehensive early algebra education will better prepare students for a more formal treatment of algebra in secondary schools than an arithmetic-focused curriculum (Blanton et al., 2015). We share preliminary results from a randomized study (with 46 schools) in which we compare the performance of students who experience a teacher-led early algebra intervention in Grades 3-5 to the performance of students who experience a "business as usual" arithmetic focused curriculum. Intervention students significantly outperformed the control students in Grade 3, increasing their overall assessment scores 13% more than control students. Intervention students also demonstrated more sophisticated algebraic strategies in comparison to control.

While previous research has produced "pockets" of success developing students' algebraic reasoning, often with researcher-intensive involvement and a narrower algebraic content focus, our work applies a comprehensive and sustained model for early algebra by engaging students in a greater scale and breadth of early algebra concepts under the direction of regular classroom teachers. Preliminary results suggest that early algebra can make a difference and motivate future research in early algebra instruction.

THE LOW-ACHIEVING LABEL: WHAT DOES IT TELL US ABOUT STUDENTS' CONCEPTUAL UNDERSTANDING OF VARIABLES?

William W. DeLeeuw
Arizona State University
William.DeLeeuw@asu.edu

Keywords: Algebra and Algebraic Thinking, Equity and Diversity

Algebra is often identified as requisite for the success of individuals by providing them with more college and career options. Kaput and Blanton (2000) refer to aspects of teaching practices and curricula that are focused on procedural skills instead of conceptual understanding as problematic. Students' understanding and use of variable may also be problematic as a significant aspect of algebra. Research has shown mathematics difficulties (MD) may differ from their typically-achieving peers in mathematics-specific characteristics (e.g., Geary et al., 2012). Lewis (2014) warned a limited focus of research on MD students has resulted in low procedural fluency as a de facto defining characteristic of students with MDs. This neglects the more complex and conceptually-based aspects of mathematics. This study investigated the differences between conception and use of variable of low- and typically-achieving students.

Theoretical Framework and Methodology

The framework is based on Blanton, et. al's (2015) description of a learning trajectory (LT) that characterized increasingly sophisticated levels in students' thinking about variable. Students' responses to items on a conceptual algebra progress monitoring measure (created by Foegen & Dougherty, 2010) were coded with respect to TL levels and then compared across the MD and Typical Mathematics Achievement (TMA) groups with descriptive and inferential statistics.

Results and Implications

This investigation revealed that the differences between MD and TMA students are limited and related to item complexity. More than these differences, the similarities that were illuminated by this study impact how we perceive what successful and struggling students look like. The overall low proportion of students who have a sophisticated conception of variable suggests that all students need access to better conceptual instruction and experiences in algebra. Students identified as MD may be disproportionally disadvantaged by traditional instructional practices and data-based decision making based on procedurally focused assessments and instruction. The limitations of the current ways in which students are labeled provide an opportunity to reexamine how students are identified as "successful".

USING NUMERICAL EXPRESSIONS TO SUPPORT STUDENTS TO DEVELOP A QUANTITATIVE UNDERSTANDING OF ALGEBRAIC NOTATION

Casey Hawthorne
Furman University
casey.hawthorne@furman.edu

The abstract nature of algebraic notation serves as a barrier to higher mathematics for many students, particularly those from historically marginalized populations (Kaput, 1999). Without access to a meaningful understanding of algebraic symbols, students become disenfranchised with mathematics, a situation exasperated by the predominant focus on symbol manipulation in. In response to this challenge, many scholars have advocated for the ability for students to not only manipulate symbols, but interpret the contextual quantities that expressions represent. The Common Core State Standards (2010) emphasizes this understanding as a core component of algebraic thinking, including it as one of the eight practice standards (SMP 2: Reason abstractly and quantitatively) as well as a high school algebra content standard (HSA.SSE.A.1). In addition, many researchers have characterized this understanding and documented difficulties that result when students reason and manipulate symbols void of a coherent system of referents (e.g. Harel, 2007; Kaput, Blanton, & Moreno-Armella, 2008). While the field has underscored the need for students to develop a contextual understanding of symbolic representations, limited work has explored ways to develop this type of thinking in practice.

As part of a study in which I examined the instructional practices of four experienced algebra teachers in high needs schools, a concrete method for instilling this type of thinking emerged in one particular classroom, a finding that makes a valuable connection between research and practice. Engaging students in a series of inquiry based lessons involving figural pattern generalization, one of the teachers repeatedly asked students to express their understanding of the pattern using a numerical expression. Each time he followed up by asking the class to articulate the exact quantity each symbol represented. Results indicate that this instructional move served as a *pedagogical content tool* (Rasmussen & Marrongelle, 2006). Rather than telling students or asking them to produce a new way of thinking on their own, this instructional move gently pushed them to flexibly build on their own informal thinking and approach the problem differently. Specifically, it encouraged students to make the quantities within the pattern decomposition as well as their relationships more explicit. It initiated a shift for many students from recursive thinking to an explicit view of the pattern and finally embedded their understanding of the pattern into an abstract representation. In the end, students began to automatically use numerical expressions to describe their thinking about the pattern, indicating that this act had transformed the number sentence from a calculational tool to a descriptive representation that captured the quantitative structure of the figure.

DYNAMIC MEASUREMENT: THE CROSSROAD OF AREA AND MULTIPLICATION

Nicole Panorkou
Montclair State University
panorkoun@montclair.edu

In this exploratory study, our goal was to engage students in dynamic experiences of area as a continuous quantity that can be measured by multiplicatively composing two linear measures (lengths), an approach we refer to as 'dynamic measurement,' or DYME. In this paper, we present the learning trajectory constructed from two cycles of teaching experiments with sixteen third-grade students. We discuss the types of tasks used for developing students' DYME reasoning as well as the forms of DYME reasoning students developed as a result of their engagement with these tasks.

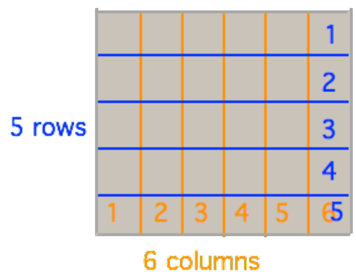
Keywords: Measurement, Technology, Learning Trajectories

Background and Aims

Measurement is defined as assigning a number to a continuous quantity (Clements & Stephan, 2004). In terms of area, several studies focused on using square units to cover surfaces and quantify that covering based on the number of square units needed to cover the surface (e.g. Barrett & Clements, 2003; Battista, Clements, Arnoff, Battista & Borrow, 1998; Clements & Sarama, 2009; Izsak, 2005; Kamii & Kysh, 2006). In these studies, structuring area first involves students counting the individual square units used to cover the surface, then counting unit composites of a row and using repeated addition to find all units, and lastly recognizing that they can count composite units in a row and a column and multiply *rows x columns*. A key structure of this approach is the construction of the grid/array that results when a rectangle is covered with square units (Figure 1a), a difficulty that students face even after extensive covering and tiling activities (Outhred & Mitchelmore, 2000). Ultimately, children must "switch" from the generalization *rows* x *columns* to the area formula of *length* x *width* (Outhred & Mitchelmore, 2000) but this "switch" is not always intuitive and results in students connecting multiplication to area by reciting, not by understanding the formula (Izsak, 2005; Simon & Blume, 1994).

Indeed, to understand how area is generated by multiplying lengths is a very different notion conceptually from the construction of a matrix like shown in Figure 1a. As Piaget argues, "the difference between the two operational mechanisms is the difference between a matrix which is made up of a limited number of elements and one which is thought of as a continuous structure with an infinite number of elements" (p. 350). Thus, "switching" from the notion of counting discrete (discontinuous) squares in rows and columns to the multiplicative relationship of combining two linear continuous measures (lengths) in an area formula can be extremely difficult for students (Baturo & Nason, 1996; Kamii & Kysh, 2006). Piaget et al. (1960) suggested that these difficulties arise because "the child thinks of the area as a space bounded by a line, that is why he cannot understand how lines produce areas" (p. 350). Area measurement involves the coordination of two dimensions (length and width) and is a multiplicative process while covering a surface with unit squares is a one-dimensional process and additive in nature (e.g. Outhred & Mitchelmore, 2000; Reynolds & Wheatley, 1996; Simon & Blume, 1994).

Consequently, our plan was to test the conjecture that that it was possible for children to experience the two-dimensional multiplicative relationship of area without relying on the switch from the rows by columns structuring; in effect, to provide evidence that students can visualize area as a dynamic continuous structure that can be measured by coordinating two linear measures (lengths). We drew on research on visualizing area as 'sweeping' through the power of motion (Confrey et al. 2012; Lehrer, Slovin, Dougherty, & Zbiek, 2014; Thompson, 2000) for designing experiences for students to visualize area as a continuous structure dynamically. For instance, as suggested by Confrey et al. (2012), we considered engaging students in dynamic experiences of generating surfaces and visualizing a meaning for area as a ‘sweep’ of a line segment of length *a* over a distance of *b* to produce a rectangle of area *ab* (Figures 1b & c).



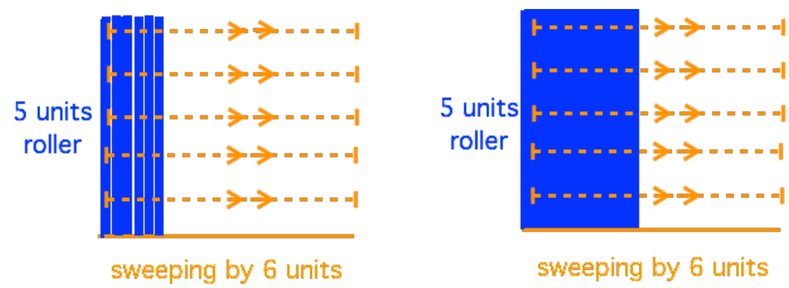


Figure 1a. Area as a discrete structure. **Figures 1b & 1c.** Area as continuous structure.

We distinguish this dynamic continuous approach from other approaches to measurement (e.g. *rows* x *columns* structuring) by referring to it as *Dynamic Measurement* (DYME) (Panorkou & Vishnubhotla, 2017). By looking at the example in Figures 1b & 1c, students visualize area as a continuous dynamic quantity which depends on both the length of the roller and the length of the swipe. This dynamic approach emphasizes the relationship between the boundaries of a shape and the amount of surface that it encloses, so that as the boundaries converge the area approaches zero (Baturo & Nason, 1996).

Although prior work (e.g. Confrey et al., 2012; Lehrer et al., 2014) identified the significance of teaching this dynamic approach, little information exists about how students’ DYME reasoning can be developed. Therefore, our goal was to examine: (1) What kinds of reasoning do students exhibit as they encounter DYME tasks? (2) What are critical aspects of students’ DYME reasoning that constitute increasingly sophisticated ways of understanding area measurement? (3) What kinds of measurement tasks, questioning, and scaffolding help students generalize concepts related to the spatial structuring of DYME?

Methods

Aiming to explore how students’ DYME thinking might be developed and progressed, our attention was drawn to research on learning trajectories (LTs), which have been widely used as an organizing framework for student conceptual growth (e.g. Clements & Sarama, 2009; Barrett et al., 2012; Simon, 1995). The design of the DYME LT followed Simon’s (1995) three components of an LT: a learning goal, a set of learning activities, and a hypothetical learning process. These components were constructed simultaneously during our LT design process; in other words, we defined our learning goals by having some instructional tasks in mind for promoting these goals and also postulated how students’ thinking of DYME may develop when they engage with our specific tasks and goals.

When formulating our initial conjectures about students’ reasoning of DYME, we synthesized existing LTs on length and area measurement (e.g. Clements & Sarama, 2009; Barrett et al., 2012; Confrey et al. 2012), and for each measurement construct we began by asking ourselves, “How can this construct be interpreted/modified/used in terms of DYME?” In contrast to other measurement LTs, the spatial structuring of DYME focuses on visualizing composites of 1-inch paint rollers iteratively dragged over a specific distance to cover a surface. In other words, a surface is described in terms of the number of 1-inch swipes (length) and the distance of each swipe (width). For example, to cover a surface of length 4 cm and width 7 cm, we need 4 swipes of 7 cm. Our design promotes students' thinking about commutativity (e.g. 4 swipes of 7 cm is the same as 7 swipes of 4 cm) and also reversibility (e.g. constructing surfaces by iteratively dragging rollers and deconstructing surfaces of length *a* and width *b* by equally splitting the surface into *a* sections of length 1 and width *b* to find area.) The target understanding of DYME involves a dimensional deconstruction (Duval, 2005), in other words analytically breaking down a 2D shape (its area) into its constituent 1D elements (length and width measures) based on relationships. Thus, two quantities (length and width) are coordinated simultaneously when making judgements about size.

In terms of task design, we used dynamic motion and paint rollers to enable students to both visualize area as a continuous quantity and coordinate the two linear measures. Our conjecture was that the paint rollers would act as bridge between the shape, and the number used to describe the size of the shape (Hiebert, 1981). To illustrate this dynamic motion, we used dynamic geometry environments (DGEs) to design our tasks. In addition to the dragging tool, most DGEs have a trace tool, which gives a trace of all the points on line segment (paint roller) following a locus as they move on the screen (see Figures 1b & c). Our conjecture was that the user would associate this discrete trace with the continuous surface formed.

We used a design-based research methodology (Barab & Squire, 2004; Brown, 1992) to develop and refine the LT and the tasks and tools focusing on two cycles of design, enactment, analysis, and redesign. The goal of Cycle 1 was to test our initial conjectures by experiencing students' first hand mathematical learning and how they construct DYME reasoning. We conducted a series of design experiments (DEs) (Cobb et al., 2003) with six pairs of third grade students. For the design of the tasks we used Geometer's Sketchpad (Jackiw, 1995). We had 6-10 sessions of 45-90 minutes with each pair of students. The outcome of Cycle 1 was a significant revision of the LT based on how students interacted with our tasks and tools.

The aim of Cycle 2 was to further demonstrate the feasibility of learning the DYME concepts and evaluate the effectiveness of the revised LT and also to test our tasks and tools with a group of students (Cycle 1 DEs were in pairs). We conducted a DE with a group of four students who participated in a STEM summer camp. Similar to Cycle 1, we had 9 sessions of 45-90 minutes each. For the design of the tasks we switched to the online version of Geogebra because of limitations of Chromebooks for downloading software.

Two stages of analysis occurred with the DE data, on-going analysis following each episode of the experiment (Cobb & Gravemeijer, 2008) and retrospective analysis at the conclusion of all DEs (Cobb et al., 2003). During the ongoing analysis, our initial conjectures evolved and we modified the tasks in light of iterative examinations of changes in students' thinking about area when interacting with the DYME tasks. During the retrospective analysis, we viewed the session videos and other data to create chronological accounts that tracked the forms of reasoning that emerged in the DE, the ways in which they emerged as reorganizations of prior ways of reasoning, and the aspects of tasks and tools that seemed to mediate those changes in reasoning. We drew on these analyses to refine the LT which included both our inferences about students' reasoning and the relationship between students' reasoning and DYME tasks.

A Learning Trajectory for DYME Reasoning

In this paper, we describe the most recent version of the DYME LT which resulted after conducting two cycles of DEs. We present each level of the LT by referring to Simon's three components: learning goals, sample tasks and examples from the student generalizations.

1. Exploring Dimensions and Area as Continuous Quantities

The goal of the first level is for students to build the idea of 2D space by using two linear dimensions (Clements & Stephan, 2004); in other words, visualizing area as a continuous structure that can change dynamically. The tasks engage students in coloring surfaces by dragging a given roller in multiple distances (Figure 2) and also matching different-sized rollers with shapes to color them and reason about the paint distance as well as the length of the roller. Students' generalizations include recognizing that the dimensions, length of the roller and the distance dragged, define how big or small a shape is, such as *"the further we drag the roller, the bigger the shape we create"* and *"the bigger the roller, the bigger the shape we create.* "At the same time, they begin to form relationships between the dynamic action of painting and the dimensions of the shape being painted by recognizing that *"the length of the roller needs to be the same as the height of the rectangle"* and *"the distance of paint is same as the base of the rectangle."*

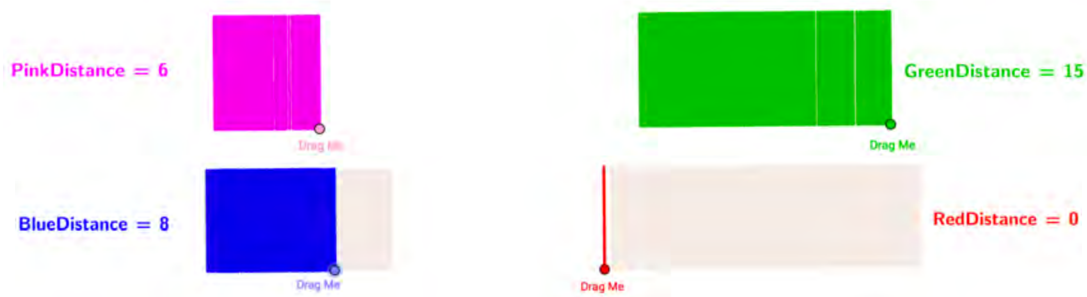

Figure 2. How far did you drag the paint roller to paint each shape?

2. Coordinating Two Dimensions to Compare Area

While in Level 1 students explored each dimension (length and width) independently, the goal of Level 2 is for the students to recognize that the measurement of a surface requires the coordination of two dimensions (Outhred & Mitchelmore, 2000; Reynolds & Wheatley, 1996; Simon & Blume, 1994). The tasks involve asking the students to fit a card into an envelope by modifying the dimensions of the envelope (Figure 3). Students are asked "What do we need to change? What stays the same?" They are asked to first write their predictions and then try it on the screen by modifying the envelope using the dragging tool. The card was movable so students could actually check if it fits in the envelope they created. Their generalizations include recognizing that to compare two shapes, they need to compare both dimensions. They also recognize that if one dimension is same they just have to compare the other dimension, e.g. *"it's bigger because it has the same base but it doesn't have the same height."*

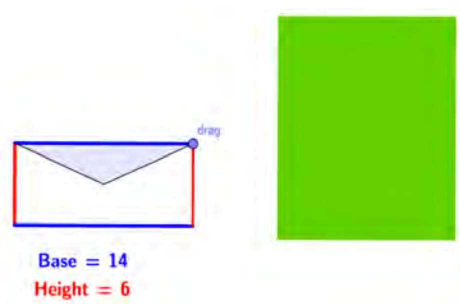

Figure 3. Modify the envelope to fit the size of the card! How big is the envelope you created?

3. Multiplicative Relationship of Length, Width and Area

The goal of this level is for the students to recognize the multiplicative relationship between the two dimensions of a rectangle and its area (Izsak, 2005; Simon & Blume, 1994). To help students identify this relationship, the tasks first involve the use of a 1-inch roller to paint shapes of different lengths and widths and constructing a repeating pattern for covering the shape (Outhred &

Mitchelmore, 2000; Reynolds & Wheatley, 1996), by considering the distance covered in one swipe with the number of swipes (Figure 4). This experience is critical for generating the use of the multiplicative 'times' language to find the space covered, such as *"this is 30 because the base is 10 and we are going to swipe three times."*

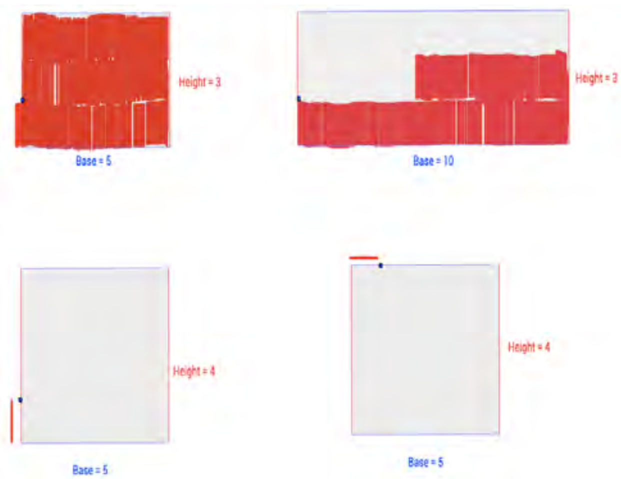

Figure 4. How far did you drag the roller? How many swipes did you need to cover the wall? How much space did you cover?

Central to the construction of area is understanding that the length measure indicates the number of unit lengths that fit along that length (Clements & Stephan, 2004). Consequently, our next goal is for the students to recognize that a roller of size *l* covers the same area as *n* rollers of size *l/n* dragged for the same distance. Our tasks include asking the students to paint the same rectangle first using 1-inch rollers and second by using rollers that are of different sizes and reason about the space covered in both occasions. At this stage, students begin splitting rollers to find the space covered, such as: "*This is a 3-inch roller. But if we cut it into 3 parts and you go across one time it is 4 and then if you go across another time it will be 8 and if you go one more time it will equal 12.*" Gradually, they begin to recognize that the space covered can be found by the length of the roller *times* the base of the rectangle or the distance of swipe. As students recognize that the length of the roller is the same as the height, they also begin using "length of roller" and "height" interchangeably, and this intuitively leads to *height times base*.

4. Multiplicative Coordination of Length and Area

The goal of this level is for students to recognize the effects on the dimensions when the area of a shape is scaled. To explore these effects, our tasks engage students in doubling and tripling areas (Figure 5) and identifying that they can double/triple areas by multiplying only one of the dimensions by the same factor, generalizing that *"to change area we need to change the base or height" or "to double the area we double just the length or just the width."* As a reverse process, we also designed tasks which engage students in doubling, tripling and halving lengths and widths of rectangles and reasoning about how area changes, such as *"since the length is going two times bigger, then the area should go two times bigger."*

As students' multiplicative thinking of area develops further, our next goal is for students to recognize that in order to split area (fractional thinking), they need to split the length or the width. The tasks engage students in creating shapes that have a fraction of an area of another shape. For example, students create a cafeteria which is 1/4 of an 8 by 5 inches garden and argue "*If we split this into four parts, then one of the parts will be the cafeteria. It would be 2 inches [the height of the* *cafeteria] because the if we use only 1-inch roller it would go 8 times across but if you use 2-inch roller then it would go 1,2,3, and that would go 4 parts."*

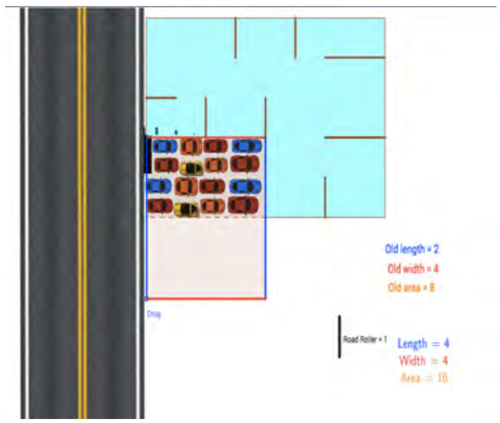

Figure 5. How can you make the parking place twice as big as it is now?

5. Identifying Area as a Multiple of its Dimensions

The goal of this level is for students to recognize area as a multiple of its dimensions and identify factors that give the same area. Our tasks involve asking students to create different rectangles of the same area (e.g. 12 sq. units) (Figure 6). This connects area measurement to geometry and the concept of congruence by recognizing congruent shapes in different orientations (e.g. 2 x 6 or 6 x 2) and describing congruence by using geometric motions such as rotation (Huang & Witz, 2011). It also directly relates to the properties of multiplication (e.g. commutative property) as well as factors and multiples. Students' generalizations include, "*length 4 and width 3 is doing 4 swipes of 3. This is same as two swipes of 6, so length 2 and width 6."* After students create all the rectangles, we ask them which rectangle has more space:

Researcher: Which one has more space?
Student 1: Everything is equal. Everything.
Student 2: The space is the same. The lengths and widths are different.

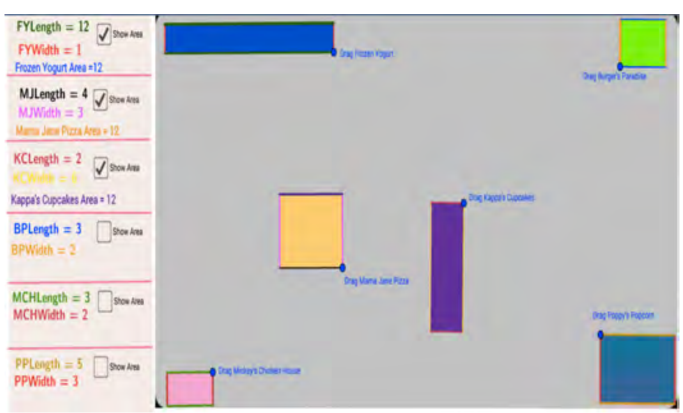

Figure 6. Each store should have an area of 12 sq. meters and different length and width from the other stores.

6. Coordination of Relative Areas

The goal of the final level is for students to coordinate relative areas. The task engages students in creating a robot with a fixed area (e.g. no bigger than 190 cm^2) by composing and decomposing shapes of fixed lengths and widths (Figure 7). As part of the task, students need to find the area of each leg (right triangle), by recognizing that if the leg is half the rectangle, then its area is half of the area of the rectangle. For instance, for calculating the area of each blue leg, students argued:

Student 1: You have to do a half of 7 and 2. We do 7 times 2 and a half of that.
Student 2: Both of them are 7 and both of them together are 14.

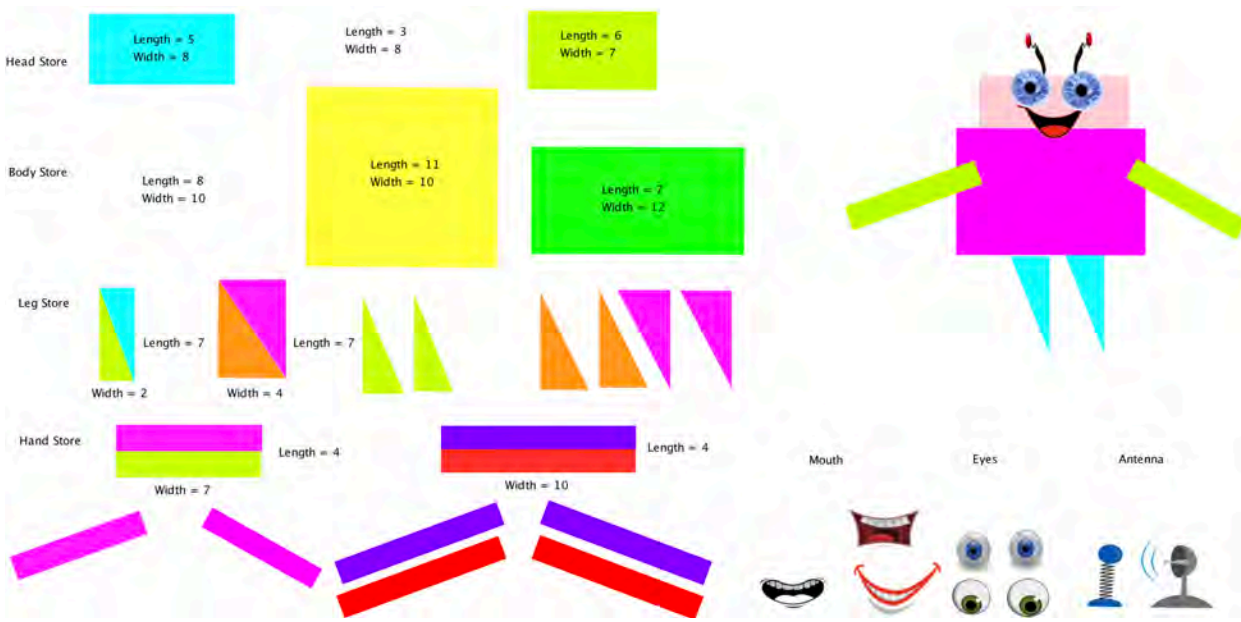

Figure 7. Make the robot as fancy as you like but its area should be no more than 190 sq. inches.

Concluding Remarks

This is an exploratory study examining a dynamic way of learning and teaching measurement. The DE findings show DYME's potential as a route to area measurement that would make the multiplicative relationship of the area formula more intuitive and accessible. The DEs helped in the design of the DYME LT, which is a conjecture of how students' DYME reasoning may evolve in the context of the specific learning activities. The LT shows that DYME lies at the crossroad of multiple mathematical ideas such as multiplication, division, fractions, (shape and unit) transformations, and covariation. Among our future goals is to explore these connections further as well as to examine how the DYME approach could complement the existing *rows* x *columns* structuring approach that is emphasized in research and schools.

Additionally, we are currently preparing a DE for a whole class to evaluate the effectiveness of learning the DYME concepts in a real classroom environment, and designing pre- and post-assessment items to evaluate students' thinking of area (as it develops) and validate the LT. We consider our findings to be very important for initiating a discussion around dynamic measurement and how it can be used for developing a conceptual understanding of area.

ELEMENTARY STUDENTS' REASONING ABOUT ANGLE CONSTRUCTIONS

Amanda L. Cullen	Craig J. Cullen	Wendy A. O'Hanlon
Illinois State University	Illinois State University	Illinois Central College
almille@ilstu.edu	cjculle@ilstu.edu	wendy.ohanlon@icc.edu

In this report, we discuss the findings from 2 pilot studies investigating the effects of interventions designed to provide students in Grades 3–5 with opportunities to work with dynamic and static models of angles in a dynamic geometry environment. We discuss the effects of the interventions on the children's development of quantitative reasoning about angle measure.

Keywords: Elementary School Education, Geometry and Geometrical and Spatial Thinking, Measurement, Technology

Geometric measurement is a branch of mathematics that integrates number and space and includes length, area, volume, and angle measurement. Based on Barrett and Smith's review of the literature in the measurement chapter of the research compendium, Smith (2016) asserted that they found markedly less research on angle measurement in comparison to the other three forms of geometric measurement (length, area, and volume). The present research on angle measurement focuses on student difficulties with several measurement concepts, including identifying and attending to the correct attribute of angle as well as angle unit, unit iteration, and origin. Specifically, students struggle to identify what is being measured when referring to size of angles and what is one degree (Keiser, 2004). Often elementary and middle school students attend to ray lengths (e.g., Clements, 2003; Keiser, 2004), and elementary, middle, and high school students are distracted by angle orientation (Mitchelmore, 1998; Noss, 1987; Fyhn, 2008). Mitchelmore (1998) argued that students need opportunities to work with both dynamic (the motion of an angle opening) and static (the resultant figure after the opening) angle models to confront their misconceptions.

Previous research has incorporated both models. Several previous studies utilized the LOGO environment (e.g., Clements & Burns, 2000; Noss, 1987; Simmons & Cope, 1993) or used a sequence of static models to indicate motion to varying degrees of success.[i] In one study, Clements, Battista, Sarama, and Swaminathan (1996) explored third grade students' understanding of angle measurement in a modified LOGO environment. These researchers found that immediate feedback helped students reflect on their turn commands and thus angle measurement (cf. Simmons & Cope, 1993) and that using benchmarks helped students assign numbers to turns. However, because there was no record of the turn during the turn in Clements et al.'s modified LOGO environment, turn commands were less salient to their students than forward or backward commands, which could be because the forward and backward commands leave a line segment as a trace, whereas there is not a similar record with turns.

Mathematics education has yet to fully determine how to address the misconceptions present in the literature since the 1980s. The authors of the Common Core State Standards in Mathematics (CCSSM, National Governor's Association for Best Practices [NGA] & Council of Chief State School Officers [CCSSO], 2010) have renewed mathematics educators' interest in elementary students' conceptions of angle and angle measurement through their definition of angle and mandate for how angle should be understood by fourth grade:

> An angle is measured with reference to a circle with its center at the common endpoint of the rays, by considering the fraction of the circular arc between the points where the two rays intersect the circle. An angle that turns through 1/360 of a circle is called a "one-degree angle," and can be used to measure angles. (p. 31)

To promote this interpretation of angle and extend the literature on angle, we designed interventions. Both were enacted in a dynamic geometry environment utilizing the computer software, Geometer's Sketchpad, to provide children with opportunities to work with movable angle situations as well as reflect on dynamic (the motion of an angle sweeping open) and static (the resulting image of an angle after sweeping open) angle models. In this report, we discuss the results from our testing of these interventions. We posed the research question: *In what ways does interacting with dynamic and static angle models affect students' reasoning about angle constructions in Grades 3, 4, and 5?*

Theoretical Perspective

We approached this study from a quantitative reasoning approach. According to Thompson (1990), "a quantity is a quality of something that one has conceived as admitting some measurement process. Part of conceiving a quality as a quantity is to explicitly or implicitly conceive of an appropriate unit" (p. 5). In the case of angle measure, quantifying involves reasoning about the unit (e.g., a degree) in terms of a quantitative relationship (i.e., a multiplicative relationship) between a fraction of the circular arc of a circle and the circle's circumference, which is consistent with the CCSSM authors' (NGA & CCSSO, 2010) recommendations for how fourth grade students should understand angle measure.

There are three types of quantity—gross, extensive, and intensive (Piaget, 1965). Gross quantity depends on perception—one object is bigger, smaller, more, less, or the same as another in terms of some attribute. Extensive quantity is additive (Piaget, 1965) and the result of unitizing activity (Steffe, 1991), whereas intensive quantity is not additive (Piaget, 1965). Instead, it requires proportional reasoning. For example, if Person A is traveling 20 mph and Person B is traveling 40 mph, we are not traveling 60 mph. We used a quantitative reasoning approach in our design of the interventions as well as in our interpretation of the findings.

Method

To investigate dynamic and static angle models affected students' reasoning about angle constructions, we wanted to observe and document changes. Thus, we utilized the microgenetic method (Siegler & Svetina, 2006). The microgenetic method has three main tenets:

> (1) observations span the whole period of rapidly changing competence; (2) the density of observation within this period is high, relative to the rate of change; and (3) observations of changing performance are analyzed intensively to indicate the processes that give rise to them. (Siegler & Svetina, 2006, p. 1000)

The data presented in this report were collected during the 2014–2015 school year at a suburban public school in the Midwestern region of the United States. In the first pilot study, we interviewed 18 students in Grades 3–5 (ages 8–12), six students per grade. For the second pilot study, we interviewed 19 students in Grade 3 (ages 8–9). Each student participated in three 4 to 18 minute individual interviews with one of the three authors of this report during the normal school day. We used a structured interview protocol and recorded the interviews using screen-capturing software, Screencast-o-matic, which also records audio. Consistent with the microgenetic method, observations were dense. The three interviews occurred on three separate days, and the mean elapsed time between first and third session was 2.9 school days (max of 5 school days). Prior to the first interview and after the third, children took a written survey. On this survey, children were asked to give a definition of angle, estimate the measure of a given angle, and construct an angle. On six items, children were asked to select one out of three angles that (a) had a specified measure, (b) had the largest measure, or (c) had the smallest measure.

Pilot 1

During the first interview, we guided each student through a tutorial on how to use four sliders in a dynamic geometry environment (i.e., Geometer's Sketchpad). Each of the sliders had a different effect. One slider opened and closed the angle, one translated the image left and right, one rotated the image of the angle, and one lengthened and shorted the rays.

During the second interview, the student went through eight trials, which we define to be a task-intervention pair (Siegler & Crowley, 1991). Specifically, the student was asked to construct an angle of a specified measure and to let the interviewer know when he or she was ready to check. During the check, the researcher clicked a check button and a ray swept from the initial ray to the angle of the terminal ray of the desired angle. In addition, benchmark rays appeared at each 30-degree interval until the ray stopped at the terminal side of the angle (see Figure 1). Note that the ray left a fading trace as it swept across the screen to provide a record of the turn (cf. Clements et al., 1996). The measure of the angle the students constructed was also briefly displayed, providing them with feedback. This feedback allowed them to compare the size of two angles (the created and desired) to their associated measure as well as to compare the difference in the created and desired angle. For example, in the sequence below a student would have had the opportunity to see a 120-degree angle, a 128-degree angle, and to see that small difference between the two was about eight degrees. During the third interview, the student went through nine trials with the same design principles.

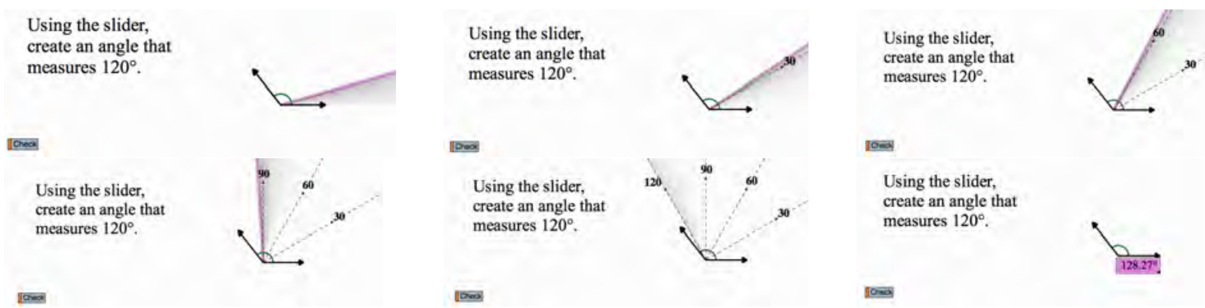

Figure 1. A sequence of screen shots displaying the labeled benchmark rays (e.g., 30, 60, 90) appearing as the student checked her attempt at a 120-degree angle.

Pilot 2

During the first interview, we asked the student to use one slider to create an angle of a specified measure on eight trials. This process was repeated for nine trials during the second interview and nine trials during the third interview. For the construction of all 26 angles, the student started with one initial horizontal ray and one slider that opened and closed the angle. For each angle, the interviewer told the student to use the slider to create an angle of a specified measure.

The 19 participants were divided between the two intervention groups: 10 were in Intervention Group 1 (IG1) and nine were in Intervention Group 2 (IG2). For children in IG1, during alternating trials in Interviews 1 and 2, unlabeled benchmark rays of 30 degrees would appear as the child used the slider to open the angle (see Figure 2). During the trials in Interview 3, the benchmark rays did not appear during any of the trials. When the child indicated that he or she was ready to check, the check button was clicked, and a ray swept from the initial ray of the angle to the terminal ray of the angle the child had been instructed to create. The main components of Pilot 2 IG1 were a subset of those in Pilot 1: Benchmark rays appeared at each 30-degree interval until the ray stopped at the terminal side of the desired angle. The measure of the angle the child constructed was briefly displayed for the interviewer to record (see Figure 1). In contrast, for children in IG2, benchmark rays appeared neither during construction nor during the check. Instead, when the check button was clicked, only the measure of the angle the child constructed was displayed. Figure 3 summaries the key components of the two pilot studies.

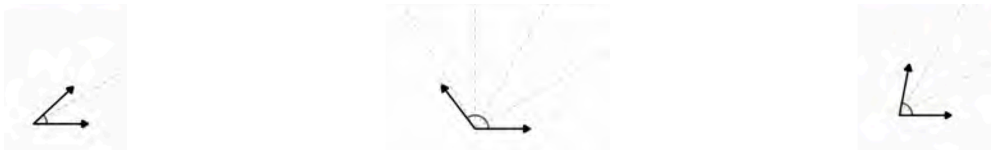

Figure 2. A sequence of screen shots displaying the 30-degree benchmark rays appearing for students in Pilot 1 and Pilot 2 IG1 as the terminal ray of the angle swept open.

Figure 3. Comparison of the key components of the two pilot studies.

In the design of both pilots (including Pilot 2 IG2), we privileged approximations of 10 degrees. During Interview 2 (Trials 9–16), we sequenced trials to pair benchmark angles with near benchmark angles (i.e., angles measuring 10 degrees more or less than one of the bench mark angles). There were four sets of paired trials (see Figure 4) to provide children with experiences that would support their development of a sense of 10 degrees. (It was our conjecture that developing a sense of 1 degree would be more difficult than developing a sense of 10 degrees.)

Trial 9, 90 degrees	Trial 10, 80 degrees
Trial 11, 30 degrees	Trial 12, 40 degrees
Trial 13, 60 degrees	Trial 14, 70 degrees
Trial 15, 120 degrees	Trial 16, 110 degrees

Figure 4. Four sets of paired trials.

We also privileged the integration of number and space. At the end of each trial, we displayed the measure of the constructed angle, providing students with the opportunity to pair the image of the constructed angle with its measure. For students in Pilot 1 and Pilot 2 IG1, this was taken further because of how the terminal ray of the angle swept open, providing students with the opportunity to pair the image of the intended angle with its measure.

In the design of Pilot 1 and Pilot 2 IG1, we privileged 30-degree benchmarks by displaying unlabeled benchmark rays at 30-degree intervals during construction on alternating trials. Additionally, the check on every trial displayed 30-degree benchmark rays with labels (e.g., 30, 60, 90). Our purpose for including these supports was to encourage students to reason about, use, and operate on specific benchmark angles as well as to encourage the integration of number and space.

In the design of Pilot 2 IG2, we privileged only feedback. Upon clicking the check button, the measure of the angle the child constructed on a given trial was displayed. This provided the children with the opportunity to reflect upon how the measure of the angle they constructed compared to the desired angle measure (cf. Jaehnig & Miller, 2007).

Discussion of Findings

Our findings indicate that the interventions had an effect on students' angle constructions. In this section we provide a representative sample of quotes to illustrate each of our three main findings.

First, we found that interacting with dynamic and static angle models increased third and fourth grade students' recognition and use of 30-degree benchmarks. Most of the third and fourth grade students did not mention the 30-degree benchmarks during the first eight trials, but by Trial 9, many of these young students in Pilot 1 and Pilot 2 IG1 were referring to them when they described what they were thinking about during or after angle construction.

- Trial 10, 80: "[While creating] 30, 60, that's about 80. [After check] I noticed that I was right, because since the 90 degree angle is um, is up I kind of noticed that if its 80 you might need to make it a little more slanted." (Bob, Grade 4, Pilot 1)
- Trial 10, 80: "I was, um, pretty close. [What were you thinking about when you made that?] Uh, well, it showed us the lines. So I knew it- one was 30, one was 60, and I knew it wouldn't be all the way– all the way to 90 but it's be a little less than 90 but a little more than 60." (Erin, Grade 3, Pilot 2 IG1)
- Trial 15, 120: "I was counting by 30s by like 30, 60, 90." (Charlie, Grade 3, Pilot 2 IG1)

Second, we found that by asking students what they noticed after the check button was clicked as part of our interview protocol, we prompted students to compare the desired and constructed angles numerically and spatially. Although this occurred for students in Pilot 2 IG2, it was more pronounced for students in Pilot 1 and Pilot 2 IG1. To illustrate, we provide four quotes below. We found the first two (from students in Pilot 1 and Pilot 2 IG1) to be qualitatively different from the last two (from student in Pilot 2 IG2).

- Trial 10, 80: "Well, I remember how last time, um, if I- I moved a lot but it was only just this much to get ta- just um like a tiny bit to get to like 74 from 70, [Mmm so 70] like 71 or something, so I didn't want to go too far from 60 because I know that's about 20 away." (Genny, Grade 3, Pilot 2 IG1)
- Trial 14, 70: "I had to make it just a little bit smaller in order to make it 70 degrees and like down here where I tried to make a 40 degree angle and I gave it too much space." (Frank, Grade 5, Pilot 1)
- Trial 11, 30: "28 degrees. [What do you think?] Good."(Pam, Grade 3, Pilot 2 IG2)
- Trial 12, 40: "35. 5 off. That's good still." (Billy, Grade 3, Pilot 2 IG2)

Third, we found that most students appeared to benefit from paired trials. Some students reasoned about a unit of 10 degrees and fractional parts of the benchmark created wedge. These students' quantitative reasoning was a bit more advanced than the students who could only reason about a little more or a little less than the benchmark rays, as illustrated by their quotes below in which they utilized specific numeric relationships (e.g., difference between the measure of the benchmark angle and the measure of the desired angle).

- Trial 14, 70: "So like 90, so that like is 60,…okay. Um, 'cuz 70 is, well obviously, uh 10 degrees larger than 60." (Amber, Grade 5, Pilot 1, created 71.97 degree angle)
- Trial 17, 150: "That, um, like the, um, the arrow, it went a little bit past it because, um, 120 is only 30 away and it seems like 30's long but it's not." (Eric, Grade 3, Pilot 1, created 139.01 degree angle)

One benefit of the microgenetic method is to have dense observations during a change to document that change. Hence, after we documented some shifts, we dug deeper to explore how one student's explanations and actions changed from trial to trial. Oscar, a fourth grade student in Pilot 1, exhibited improvement in his approximations for 10 degrees across the four sets of paired trials and clearly articulated how he learned from the previous trials. After constructing an angle that measured 86.36 degrees (for a desired angle measure of 80 degrees), Oscar explained, "I needed to go a little further back. I put, I was trying to measure about a little before the 90-degree angle." On this trial (Trial 10), Oscar correctly reasoned quantitatively about the benchmark angle measure and the desired angle measure (i.e., that 80 degrees is less than 90 degrees); however, he did not identify how much less (i.e., difference between the measure of the benchmark angle and the measure of the desired angle). On the next off-benchmark trial (Trial 12), Oscar constructed an angle that measured 47.84 degrees (for a desired angle measure of 40 degrees). When asked what he was thinking about when constructed his angle, he said, "It goes just a few shades away from the 30 degree angle, mmm, not that much." Although Oscar's constructed angle and explanation indicate he knew that a 40-degree angle was larger than a 30-degree angle, his reference to "not that much" supports an inference that he realized his attempt to create an angle that was 10 degrees more than the benchmark angle was too large. We take his explanation as evidence that Oscar had identified a 10-degree angle as a mental unit, and we predicted that his next attempt to create an angle 10 degrees more than the benchmark angle would be improved.

Based on these prior experiences, Oscar made an adjustment to his mental unit of 10-degrees on the next two off-benchmark trials (Trials 14 and 16). On Trial 14, Oscar constructed a 69.85-degree angle for a desired angle measure of 70 degrees. After checking the measure of his constructed angle, he said,

> It's like the other question...When it was asking the 40-degree, um, I went a little far; I was right there so then I kinda realized on a few more problems it was about like 80 and stuff like that—that I didn't need to go as far as I was going.

We take this as evidence that Oscar is reflecting on relating number to space—that is, his image of what a 10-degree angle looks like was too large in previous trials (Trials 10 and 12), so he had to make it smaller on this trial.

On the last off-benchmark trial (Trial 16), Oscar constructed a 110.91-degree angle for a desired angle of 110 degrees. When asked to explain his thinking before getting feedback, he said,

> I think this one is going to be right 'cuz…90 degrees. Because um, kinda of like the 60 degree and stuff, I knew that I had to go a little short, shorter because it was only 10 degrees higher than, I mean the 40 degrees… I only need it to go about right there. So then on the 90 degrees it was 20 degrees um higher than the 90 degrees so I went probably about another half of the way, right there [points to location on the screen with the cursor].

Oscar's explanation indicates that he was again reflecting on what a 10-degree angle looks like. However, how he used that 10-degree angle as a unit can be interpreted in two different ways. One interpretation is that he thought about a 20-degree angle as composed of two 10-degree angles—10 more than 90 degrees and then 10 more than that. Another interpretation is that he thought about a 30-degree angle as 10-degrees and 20-degrees and then a 10-degree angle as half of a 20-degree angle—10 more than 90 degrees (100 degrees) and then half way between 120 and 100 is 110 (i.e., "about another half of the way"). Although we expected to see Oscar use the benchmark angle of 120 degrees and think about 10 degrees less than the 120-degree angle, Oscar showed flexibility in his thinking by starting with the benchmark angle of 90 degrees to approximate a 110-degree angle. Regardless, Oscar exhibited improvement in his approximations for 10 degrees and his reasoning about angles.

Educational Importance of the Research

The experimental interventions enacted in Geometer's Sketchpad were designed to provide opportunities for students to engage with dynamic and static angle models. The results from the two pilot studies extend the previous literature on children's reasoning about angles and angle measurement. Specifically, our results suggest providing children with opportunities to reason about angles as multiples of 30 (e.g., a 120-degrees angle as four 30-degree angles) and as partitionings of 30s (e.g., a 40-degree angle as a 30-degree angle plus one-third of another 30-degree angle) has the potential to support children's recognition and use of 30-degree benchmarks. Our study also indicates that asking students what they noticed after receiving feedback on their angle constructions (after the check button was clicked) prompted students to compare the desired and constructed angles numerically and spatially.

Although we do not have evidence that the participants in this study were able to reason about angle measure by comparing the fraction of the circular arc and the circle's circumference, we do have evidence that the students were constructing their own knowledge and adapting their thinking. As illustrated by Oscar's explanations discussed in the results section, Oscar and others were adapting their thinking based on their experiences with the interventions. Specifically, Oscar's repeated attempts to approximate 10 degrees when constructing angles that were designed to be 10 more or 10 less than a benchmark angle helped him adapt this thinking and connect his numerical reasoning (i.e., 10 more degrees) to his spatial reasoning (i.e., what 10 more degrees looks like). Hence, his perception and interpretation of his experiences on these trials allowed him to describe an angle as something that can be quantified. The paired trials appeared to be an important component of the interventions in that it gave students opportunities to receive feedback on their quantitative reasoning. Thus we recommend future studies include more paired trials of 10 more or 10 less than a benchmark angle, interviewing more students from each grade level, including more trials, and parsing out the differences between groups of students with the benchmark rays and without the benchmark rays.

Endnotes

[i] Although other researchers have considered the sequencing of static images to be dynamic angle situations (e.g., Clements, Battista, Sarama, & Swaminathan, 1996; Devichi & Munier, 2013), we argue that to be truly dynamic, the sequencing of these static images needs to be more continuous.

HOW SPATIAL REASONING AND NUMERICAL REASONING ARE RELATED IN GEOMETRIC MEASUREMENT

The positive correlation between spatial ability and mathematical ability has been well-documented, but not well-understood. Examining student work in spatial situations that require numerical operations provides us with insight into this elusive connection. Drawing on student work with angle, length, volume, and area, we examine the ways in which students associate numerical operations with their spatial structurings of objects. We find that for students to correctly coordinate their spatial structurings and numerical operations, their solution methods must satisfy basic properties of measurement functions. We illustrate this claim by providing examples in which students successfully and unsuccessfully employ spatial-numerical linked structurings.

Keywords: Cognition, Geometry and Geometrical and Spatial Thinking, Technology

Numerous studies have found that spatial ability and mathematical ability are positively correlated (Mix et al., 2016). But specifying the exact nature of the connection between these abilities has been elusive, with much research in this area focused on understanding correlations between specific spatial skills (e.g., as measured by visualization and form perception tests) and mathematical performance (Mix et al., 2016). In this paper, we seek to precisely specify the spatial-mathematical connections in geometric measurement—a content area for which numerical and spatial reasoning must be properly coordinated. Indeed, de Hevia and Spelke claim that the human mind is "predisposed to treat number and space as related" (2010, p. 659). And researchers in mathematics education argue that understanding relationships between numerical and spatial reasoning is fundamental to developing a full understanding of geometric and measurement reasoning (Clements & Battista, 1992). However, although a great deal of research has investigated how students represent numbers on number lines (Gunderson, et al., 2012), in geometric measurement, numerous situations arise that are more complex than envisioning numbers on number lines. We have investigated numerous instances of these more complex situations, and in this paper, we analyze these situations to more fully understand the nature and properties of the connection between numerical and spatial reasoning in geometric measurement.

Theoretical Framework

Measurement Properties

For spatial reasoning and numerical reasoning to be properly connected in geometric measurement, certain basic properties of measurement functions must be followed, as described by Krantz: “When measuring some attribute of a class of objects or events, we associate numbers … with objects in such a way that properties of the attribute are faithfully represented as numerical properties” (1971, p. 1). That is, if *M* is the function that assigns measurement values to objects—*M(a)* is the measure of object *a*—then, consistent with Krantz et al. and basic axioms for geometric measurement (Moise, 1963), *M* satisfies the following properties:

1. If object *a* and object *b* are congruent, then $M(a) = M(b)$.
2. Object *a* is spatially larger than object *b* if and only if $M(a) > M(b)$.
3. If we join-without-intersection object *a* and object *b*, then $M(a \;\; join \;\; b) = M(a) + M(b)$.

Galindo, E., & Newton, J., (Eds.). (2017). *Proceedings of the 39th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* Indianapolis, IN: Hoosier Association of Mathematics Teacher Educators.

4. Given n copies of congruent and non-overlapping unit-measure objects a_1 ... a_n:

$$If \bigcup_{i=1}^{n} a_i \cong b, then\ nM(a_1) = M(b).$$

These properties justify the measurement iteration process in which we determine measure by iterating a unit measure to "cover" the object being measured with no gaps or overlaps. If, however, there are gaps in a unit-measure covering so that it is a proper subset of the object being measured, then Property 2 implies that the measure of the covering will be less than the measure of the object. If there are overlaps, then Property 3 is not satisfied, so we cannot count/add the unit measures to find the measure of the object.

Spatial-Numerical Linked Structuring

Beyond the basic measurement properties, linking spatial and numerical reasoning in geometric measurement requires use of what we call *spatial-numerical linked structuring* (SNLS). *Spatial structuring* is the mental act of constructing a spatial organization or form for an object or set of objects, imagined or real (Battista, 1999, 2007, 2008; Battista et al., 1998; Battista & Clements, 1996). *Numerical structuring* is the mental act of constructing an organization or form for a set of computations. A correct *spatial-numerical linked structuring* is a coordinated process in which a numerical measurement operation is performed along with a linked spatial structuring in a way that is consistent with the above measurement properties. Incorrect student enumeration is generally based on SNLS that violates at least one of the measurement properties. Note that each measurement property expresses a spatial-numerical linked structuring. For instance, putting one angle inside another to decide which is bigger spatially organizes the two angles with respect to each other. In this paper, we give examples of correct and incorrect spatial-numerical linked structuring.

Methods and Data Sources

The data we analyze comes from individual interviews and one-on-one teaching experiments with elementary and middle school students from several NSF-funded geometry projects awarded to the first author.

Sample Results and Discussion

To illustrate our results and analysis, we provide examples of spatial-numerical linked structuring for angle, length, volume and area. The examples (a) describe student actions, (b) discuss what students did, and (c) interpret what students did using the spatial-numerical linked structuring conceptual framework.

Spatial-Numerical Linked Structuring for Angles

For the computer-presented problem in Figure 1, KS employed several spatial-numerical linked structurings to find the angle that rotates the green point onto the red point.

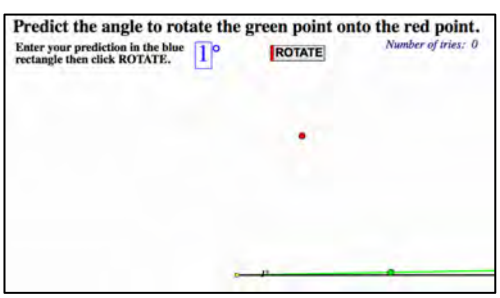

Figure 1.

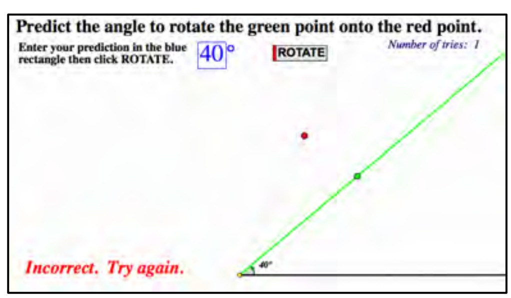

Figure 2.

KS: I think it may be 40 [enters 40; green ray rotates to the 40° position Figure 2].
Int: So what are you thinking?
KS: So if this is 40 [angle in Figure 2], I may have to go up maybe *20 more*.
Int: Okay, why 20 more?
KS: Cause, if this was 40 [pointing at the interior of the green 40° angle], then half of it is this [pointing to the interior of the angle between 40° and the target angle; enters 60°; Figure 3].

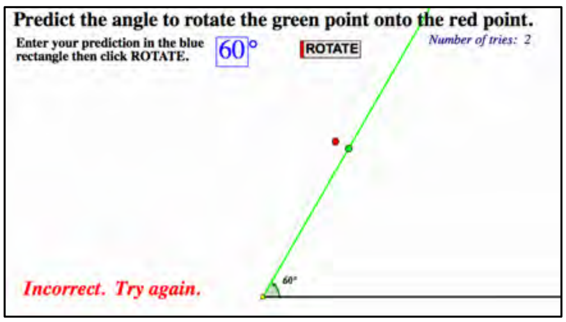

Figure 3.

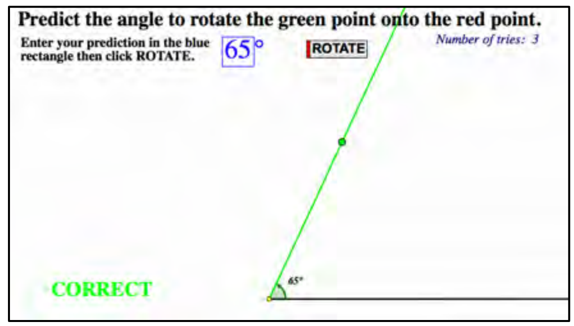

Figure 4.

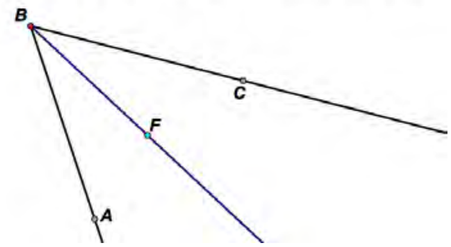
Int: Very close, what are you thinking?
KS: Hum. So maybe with the other [computer page showing 5° iterations of a ray] it shows that they were really close together, so maybe it'd be 65 [enters 65°; Figure 4].

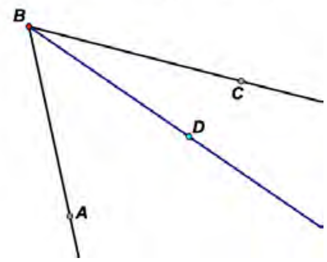
Discussion. KS used a sequence of spatial-numerical linked structurings (SNLSs) for solving this problem (see Table 1). After viewing the result of her first estimate, which is quite a bit off, KS reasoned that her original estimate was too small. This is an example of SNLS 1, in which KS recognized the smaller-than spatial relationship between the angle she made and the target angle. KS then, using SNLS 2, spatially compared the angle between the green ray and the black ray from her 40° estimate as half of the 40° angle. Then, using SNLS 3, she added 20° to 40° to produce a second estimate of 60°. Finally, in her third estimate, KS used SNLS 4 followed by SNLS 3 to recall a previously viewed 5° angle and add that to her estimate of 60°.

Table 1: Definitions of Types of Angle Spatial-Numerical Linked Structuring

SNLS 1. [Bigger Angle ⇔ Greater Measure; Property 2]: If Angle X is bigger than Angle Y, then the measure of Angle X is greater than the measure of Angle Y. Definition/Spatial Structuring: Angle X is spatially "bigger" than Angle Y if the angles have the same vertex and Angle Y fits in the interior of Angle X.	**∠ABC is bigger than ∠DBE.** 
<table>
<tr><td>SNLS 2. [One-half angle ⇔ One-half measure] If Angle X is one-half of Angle Y, then the measure of Angle X equals one-half of the measure of Angle Y.

Definition: Angle X is one-half of Angle Y if the initial side of Angle X coincides with the initial side of Angle Y and the terminal side of Angle X is in the interior of Angle Y and is halfway toward the terminal side of Angle Y.</td><td>∠ABF is half of ∠ABC. ∠CBF is half of ∠ABC.


</td></tr>
<tr><td>SNLS 3. [Add angles ⇔ Add measures; Property 3] If Angle X equals Angle Y plus Angle Z, then the measure of Angle X equals the measure of Angle Y plus the measure of Angle Z.

Definition: If point D is in the interior of Angle ABC, then Angle ABC equals Angle ABD "plus" [joined with] Angle DBC.</td><td>∠ABC equals ∠ABD plus ∠DBC.


</td></tr>
<tr><td colspan="2">SNLS 4. [Compare perceived angle to recalled angle; Property 1] The student compares a perceived angle to the recalled visual image of a previously seen angle, and says that the two angles are congruent so their measures are equal.</td></tr>
</table>

Spatial-Numerical Linked Structuring for Length

To examine the way students use spatial-numerical linked structuring with length, we consider a student's work in a computer golf game (Figure 5). Students "putt" a ball by entering a distance and angle. When students click the *PUTT* button, the ball travels to the right the entered distance, then arcs around counterclockwise as it sweeps out the entered angle, which is a multiple of 5° (Figure 6). Students receive visual feedback on each of their estimates until they determine a correct putt angle and distance. SJ is doing the problem in Figure 5.

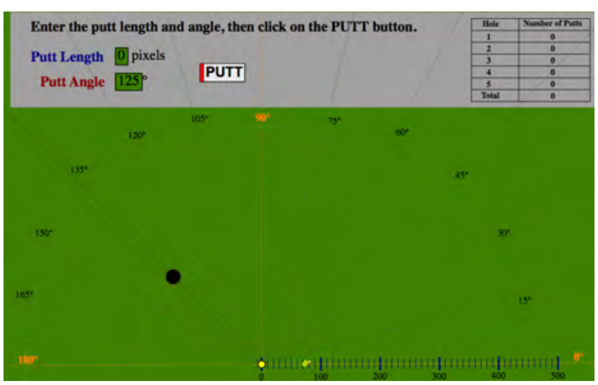


Figure 5.

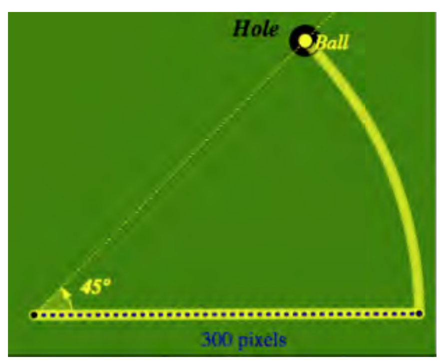

Figure 6.

Example 1:

SJ: [Pointing along hash marks 0-140 on the number line with the cursor] These lines are the pixels right?

Int: Yep. So this [pointing with a finger] is 100 pixels. That's 200 [pointing]. So they might be counting by, what do you think, in those little ones [points to hash marks between 100 and 200 on the number line]?

SJ: 25s?

Int: So let's see. If this is 100 [pointing to 100]. That'd be 125 [pointing to 110], 150 [pointing to 120], 175 [pointing to 130], 200 [pointing to 140].

SJ: Aw, never mind.

Int: So what do you think?

SJ: 10, 15, [points along hash marks 110 to 190 on the number line] 45. No [goes back to 110 on the number line]. *Oh, tens!*

Discussion: SJ understood that each hash mark represents the same amount of space (Measurement Property 1), but she could not immediately determine the correct numerical value for the distance associated with the space between each hash mark. When she estimated 25 as the distance, the Interviewer iterated by 25 starting at the landmark for 100 so that SJ recognized that the numerical value of 25 for each hash mark was too large. After choosing a smaller value of 5 and realizing it was too small, she correctly concluded that 10 was the distance between each hash mark. This is an example of a student using the measurement properties and the iteration spatial-numerical linked structuring to develop an understanding of the coordinate system inscription embedded in the game. The mistakes she made with the 25 and 5 estimates for hash-mark values seem to arise from not coordinating the number iterations of the hash-mark interval with the beginning and end values of the 100-to-200 interval. In essence, she violated Measurement Property 4.

Example 2:

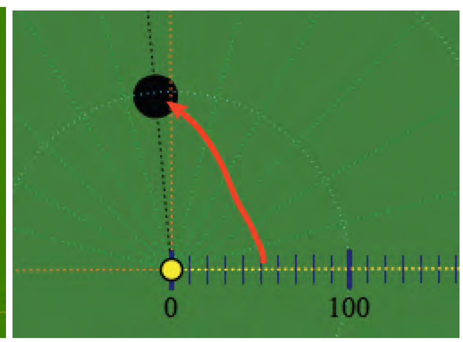

Figure 7. **Figure 8.**

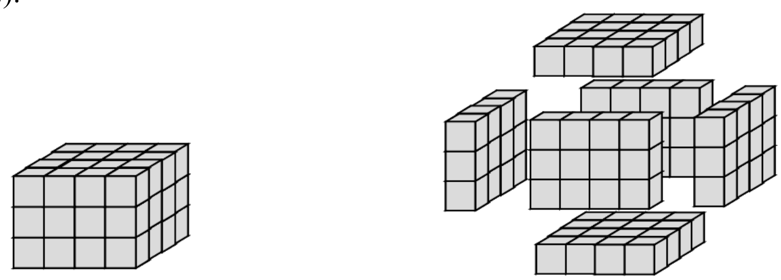
SJ: [For the problem in Figure 7] Okay. This one is probably going to be 50 [points the cursor at 50 on the number line]. Because like 10, 20, 30, 40, 50 [counting on the 10-50 hash marks with the cursor]. Here's the 50 [moves from 50 towards the hole; Figure 8]. Maybe even 60.

Discussion: In this example, SJ's spatial structuring of the rotation path of the ball is incorrect. Because of this incorrect spatial structuring, her numerical choice for the length of the putt was incorrect—her spatial structuring violated Measurement Property 2. Importantly, note that SJ does not understand the meaning of the distance-arc inscriptions for the embedded coordinate system. Because of her incorrect structuring of a point rotation, she does not recognize that every point on a distance arc is the same distance from the origin as the reference measurement on the number line.

Similar to many elementary students using rectangular coordinates (Battista, 2007; Sarama et al., 2003), SJ does not conceptualize the spatial-structural metric properties of the coordinate system. In order to accurately recall spatial relations, students must abstract not pictures but mental models that have encoded spatial properties of objects (e.g., Hegarty & Kozhevnikov, 1999).

Spatial-Numerical Linked Structuring for Volume

In the complex context of enumerating unit cubes in rectangular boxes, students must link their numeric structuring to their spatial structuring. For instance, consider the following example (Battista, 2004, 2012).



a b

Figure 9.

For the building shown in 9a, Fred counted based on the spatial structuring shown in 9b. He said that there are 12 cubes on the front, then immediately said there must be 12 on the back; he counted 16 on the top, and immediately said there must be 16 on the bottom; finally, he counted 12 cubes on the right side, then immediately said there must be 12 on the left side. He then added these numbers. Fred's numerical structuring of *12 + 12 + 16 + 16 + 12 + 12* corresponded to his spatial structuring of *(front + back) + (top + bottom) + (right side + left side)*. So his spatial structuring of the building into composite units of cubes violated Measurement Property 3—the cubes that he double-counted occupied the same space.

Below we see two alternative SNLSs for the same cube building. On the left, the spatial structuring of *front + what's left on right side + (9 columns of 3)* corresponds to the numerical structuring of *12 + 9 + (repeat 9 times counting 3 cubes in a column)*. In Figure 10b, we see a column spatial structuring that a student numerically structured as *3, 6, 9...45, 48*. Another spatial structuring is horizontal layers (Figure 10c) which students variously structure numerically as *16 + 16 + 16*, *3 x 16*, or *skip counting 16, 32 48*.

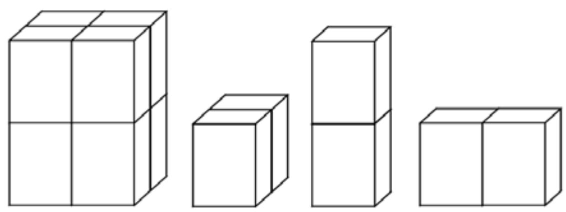
Figure 10.

Galindo, E., & Newton, J., (Eds.). (2017). *Proceedings of the 39th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* Indianapolis, IN: Hoosier Association of Mathematics Teacher Educators.

Note that, unlike the first SNLS in Figure 9b, the last three SNLSs produce correct answers. Given that there are multiple correct SNLSs for this cube building enumeration task, part of SNLS reasoning is consideration of enumeration efficiency. The SNLS in Figure 10a is correct but too cumbersome to be efficient and too unwieldy for large arrays. The SNLS in Figure 10b could be conceptualized in terms of 3 cubes in each column times 4 columns in a horizontal row times 4 horizontal rows, leading to the standard volume formula, as could the layer structuring SNLS (Figure 10c). So part of SNLS reasoning is metacognitive consideration of enumeration efficiency. Furthermore, using SNLS reasoning to make sense of the volume formula illustrates how SNLS reasoning can be used for generalization, not just enumeration.

SNLS reasoning as sense making for volume. The next example further illustrates how SNLS reasoning can be used to make sense of geometric measurement problems that deal with generalizations rather than enumeration. Consider the following problem (Battista, 2012). *The dimensions of a box are 3 cm by 2 cm by 4 cm. Give the dimensions of a box that has twice the volume.* The most common error that students make on this problem is to multiply all three dimensions by 2. SNLS reasoning can help students understand why the numerical structuring of *multiply all the dimensions by 2* is incorrect and what correct numerical structurings are possible. For instance, Figure 11a shows that doubling all the dimensions of a *3 cm by 2 cm by 4 cm box* gives 8 times the original box volume, whereas Figures 11b, c, d show that doubling any one of the dimensions of the box doubles its volume.

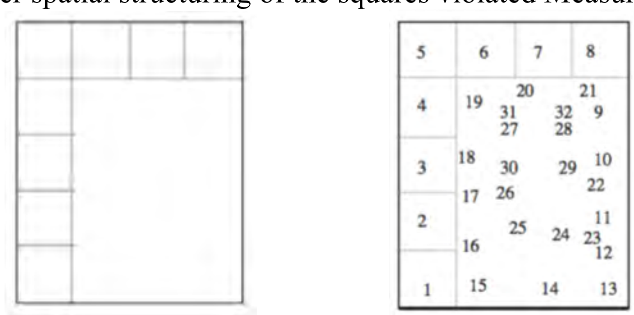


a b c d

Figure 11.

Spatial-Numerical Linked Structuring for Area

The ability to mentally construct an accurate spatial structure for rectangular arrays is a critical reasoning process for students determining area. But this process is surprisingly difficult for students to construct (Battista, et al., 1998). For example, student CS was asked to determine the number of squares required to completely cover the inside of the rectangle in Figure 12a (Battista, et al., 1998). CS counted in a non-random way as shown in Figure 12b. She counted the pre-drawn squares first, then she counted 9, 10, 11, 12, 13 down the right side and an equivalent number (15, 16, 17, 18, 19) up; overall counting in a clockwise spiral (Battista, et al., 1998). Because of the overlapping positions of CS' squares, her spatial structuring of the squares violated Measurement Property 3.



a b

Figure 12.

Significance

In addition to helping us untangle the complicated nature of students' coordination of spatial and numerical reasoning, this research helps us decompose the basic mental processes that students use in geometric measurement. It therefore helps us understand, for one content area, more precisely how spatial reasoning is related to numerical reasoning in geometry, which in turn helps us start penetrating why spatial reasoning has been found to be related to mathematical reasoning in so many correlational studies.

TIME AS A MEASURE: ELEMENTARY STUDENTS POSITIONING THE HANDS OF AN ANALOG CLOCK

Darrell Earnest

acgonzales@umass.edu

Anna M. Plant
University of Massachusetts at Amherst
aplant@umass.edu

Time is an area of measurement that is difficult for children. This interview study addresses the question: What are children's solution approaches to position the hands of an analog clock? To explore this, we investigated problem solving when using a clock manipulative with mechanically linked hands. We compare overall success rates among students in Grades 2 (n=24) and 4 (n=24) in positioning hour versus minute hands. We then present a qualitative analysis of solution approach for both hour and minute hands. Results indicate successful students may use the linked hands without overt consideration of the measurement structure of the clock.

Objective

Children have difficulty with the topic of time (Earnest, 2017; Kamii & Russell, 2012; Williams, 2012). Despite the fact that this topic is a staple of early grades mathematics instruction (NGA Center & CCSSO, 2010), little empirical research exists that documents problem solving in the context of common tools for telling time. Because time measure underlies mathematics of change in later grades as well as serving as an independent variable for STEM-related investigations, the present study seeks to reveal how younger students make meaning of units and unit relations on an analog clock, a prevalent cultural tool for time. In the present analysis, we investigate children's strategies for positioning hands on an analog clock to indicate particular times. The objective of our investigation is to reveal patterns across children's strategies and, because time is an area of measure, to consider how different strategies reflect measurement ideas related to unit and scale (Lehrer, Jaslow, & Curtis, 2003).

Theoretical Framework

We frame our study with two lenses. First, we consider mathematical aspects of time units as related to children's developing *theory of measure* (Lehrer et al., 2003). Second, we consider the mediating role of the clock manipulative itself. First, children develop a theory of measure through everyday examinations of the attributes of objects or events (Lehrer et al., 2003). In investigating the world in such a way, children gradually attend to such attributes as length, area, weight, and duration, each of which may be measured formally or informally. As children compare and contrast and, eventually, quantify such attributes, they grapple with mathematical ideas particular to measure (Lehrer et al., 2003). These ideas include conceptions of unit (such as the need for identical or equal units) as well as conceptions of scale (such as any point serving as an origin or zero-point).

As a measurement tool, the analog clock features 12 equal hour intervals, with the numeral 12 marking both a zero-point and ending point depending on that to which a user attends. As with any standard tool for measure, the analog clock provides equal intervals that are arranged end-to-end without gaps or overlaps. Of course, the clock does not represent only hours; rather, the same 12 intervals reflect both minutes and seconds. As in other areas of measure, individuals may draw upon tools for measure in procedural ways unrelated to their mathematical properties (Moore, 2013; Stephans & Clement, 2003). One concern in the present study was not only to identify students' approaches as they position the hands, but to understand them in relation to ideas related to unit and scale.

Galindo, E., & Newton, J., (Eds.). (2017). *Proceedings of the 39th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* Indianapolis, IN: Hoosier Association of Mathematics Teacher Educators.

Second, the present study positions thinking and learning as inextricably linked to cultural practices (Cole, 1996; Earnest, 2015, 2017; Sfard, 2008), with conventional tools (i.e., a digital or analog clock) serving a mediating role in problem solving. Analog and digital clocks represent time and its properties in different ways, with the analog clock's intervals of time translating duration into spatial distance (Lakoff & Nuñez, 2000; Williams, 2012). Digital time provides a precise time to the minute without reflecting part-whole relations of minutes and hours. The digital time 2:50, for example, provides a quick and precise numeric representation of time. In contrast, for the analog clock's hour hand to show 2:50, one may interpret its position as not just showing the "2" as with digital notation, but its displacement from 2:00 to 2:50 as well as the length remaining length for the ten minutes from 2:50 to 3:00. Our study involved a particular clock manipulative featuring mechanically linked hands; based on our perspective of thinking and learning, this material property is consequential to children's solution approaches.

Related Research

Classrooms in the United States typically feature classroom clock manipulatives for teaching time, though the functionality of clock features—and how unit relations are thereby supported—vary. Of two common clock manipulatives, one features mechanically linked hands such that movement in one hand provokes the proportional shift in the hour hand; this specific clock is the focus of our study below. For example, on a clock displaying 7:00, if one were to move the minute hand clockwise to show 7:30, the hour hand would proportionally move as well (see Figure 1). With this tool, a user may note the proportional shift in hand movement; alternatively, one may not attend to this particular feature at all, as such proportional movement is not dependent on the user's intentions in hand positioning. A different clock manipulative features independent hands, such that a user must deliberately position each of the two hands to indicate a particular time. On this clock, given 7:00, if one were to move the minute hand clockwise to reflect 7:30, the hour hand would remain at the 7 and thereby reflect a time that does not exist in our system (Figure 1b). In particular, we seek to understand if one manipulative is more helpful for children in terms of connections to measurement (not necessarily just in terms of accuracy).

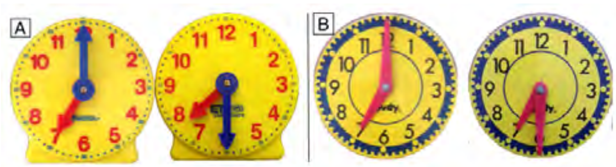

Figure 1. Manipulatives with (a) mechanically linked hands or (b) independent hands.

Given our concerns related to a theory of measure together with how tools mediate thinking and communication, our work has investigated problem solving related to time in the context of the two clocks in Figure 1. A recent analysis revealed that elementary students performed differently as a result of the clock available to them (Earnest, 2017), and in particular students were more successful when the hands were mechanically linked. To understand why students may have performed more poorly when the clock featured independent hands (Figure 1b), we further analyzed students' performances with this specific tool. We found that students' incorrect approaches often did not overtly reflect concerns for unit and/or a continuous scale (Earnest, Gonzales, & Plant, 2017). One such approach included treating intervals as containers; for example, treating the 2-3 interval as representing a container for the 2 o'clock hour (see also, Williams, 2012). In another approach, students matched a number from the digital time (i.e., the 2 of 2:50) to the numeral on the clock (i.e., positioning the hour hand on the 2).

Although less common, approaches reflecting concern for unit and scale often led to success (Earnest et al., 2017). One approach involved treating the two hands—functionally independent on the clock manipulative (Figure 1b)—as coordinated; for example, to show 2:50, one student explained how the hour hand would be in the 2-3 interval but close to the 3 because the minute hand was only ten minutes from the top of the hour. Other students identified a zero-point on the clock. For example, to position the minute hand for 2:50, students began with the 12 as a zero-point and counted by 5s to reach the accurate position; such a concern for zero-point has been identified as a key idea related to scale (Lehrer et al., 2003). Overall, students were statistically more successful with the minute hand as compared to the hour hand, which, because hands were not linked on the manipulative, each student had to deliberately position.

Research Questions

Our prior analysis focused on a manipulative with independent hands (Figure 1b), yet we found students were more successful overall when using the clock with mechanically linked hands (see Figure 1a) (Earnest, 2017; Earnest et al., 2017). We wondered if the success among students using linked hands reflected different solution pathways for students as compared to those using independent hands. If so, results could illuminate how the linked hands support disciplinary ideas related to time. Alternatively, the linked property of the hands may support pathways towards accurate hand placement through mechanically accomplishing this mathematical work on behalf of the user.

The present study investigates the questions: Are children more successful positioning one hand over the other? And, what are the solution approaches children apply to position each hand? In particular, we were concerned with how such strategies reflected treatments of unit and interval consistent with geometric measure.

Methods

Participants included students in Grades 2 (n = 24) and 4 (n = 24) from six elementary schools in diverse areas (urban and rural) of western Massachusetts. All schools were identified as having a high percentage of children from low-income families. Interviews were conducted in 2015. Grade 2 students were selected because standards indicate children in this grade have already mastered time to the hour and half hour and are currently working on time at the 5 minutes (NGA Center & CCSSO, 2010). Grade 4 students were selected because, according to standards, time concepts including elapsed time have been mastered in prior grades, and their performances therefore illuminate any persisting differences in performance on problems involving time.

Based on an assessment administered to a larger group of students in the six focal schools, we identified a range of students with permission in each classroom and assigned them to one of three clock conditions; our focus in this paper is on the condition featuring an analog clock with mechanically linked hands (Figure 1a; see Earnest et al., 2017, for a similar analysis involving an analog clock with independent hands).

Interviews lasted approximately 30 minutes. Our analysis here focuses on seven particular tasks specific to positioning hands on the clock, as these tasks reveal students' treatments of unit and interval (see Earnest, 2017, for all interview tasks). Hand Positioning tasks were designed based on prior literature (Kamii & Russell, 2012; Williams, 2012) and ongoing piloting of tasks. The seven times included in tasks were: time to the hour (7:00), time to the half hour (4:30), time on the first half of the clock (10:10), time on the second half of the clock (2:50), and time with a minute value less than 10 (9:03), along with two relative time tasks using hour units only (half past 11, quarter past 8). To present tasks, the interviewer provided the clock positioned to an unrelated time and asked the student to show the target time (e.g., "Show me what 2:50 looks like on this clock."). The interviewer also turned over a card on which the same question was printed (Figure 2). Once the student positioned the hands, the interviewer asked that student to explain her/his thinking.

Show 7:00 on the clock.	Show 4:30 on the clock.	Show 10:10 on the clock.	Show 2:50 on the clock.	Show 9:03 on the clock.	Show *half past 11* on the clock.	Show *quarter past 8* on the clock

Figure 2. Playing cards for administering the Hand Positioning tasks.

We conducted both a quantitative and qualitative analysis. First, using video and transcript, we coded each hand position separately as correct (1) or incorrect (0) for placement, enabling a comparison in performance between the two hands. To do so, we identified an interval for the two hands for each problem (i.e., 4.3-4.7 for the hour hand for 4:30), outside of which a response was considered incorrect. All responses were double coded, and any discrepancies in hand positioning accuracy were resolved in team meetings. Second, we open coded video and transcripts using the constant comparison method (Corbin & Strauss, 2008). Based on rounds of coding to identify particular solution strategies in data, we generated a codebook. Three coders then double-coded all data, with any discrepancies discussed until reaching consensus on a final code.

Analysis and Results

The analysis is presented in two parts. We first present quantitative results speaking to whether students had similar success at positioning hour and minute hands. Following this, we present a qualitative analysis to identify strategies students applied.

Performances on Hand Positioning Tasks

We first compared performances for hour and minute hands: Were students more successful at one hand over the other? Means and standard deviations are provided in Table 1, and in general mean performances out of 7 problems show that students were quite successful. A Two (Hand) ✕ Two (Grade) repeated measures analysis of variance (ANOVA) revealed a main effect for Hand, $F(1, 46) = 11.560$, $p = .001$, with better performance with the minute hand as compared to the hour hand. A main effect also emerged for grade, $F(1, 46) = 7.676$, $p = .008$, with Grade 4 students outperforming Grade 2 students. There was no significant Hand ✕ Grade interaction, suggesting that the discrepancy in performance was roughly equivalent across grades ($p = .168$). A post hoc Tukey's HSD showed that the difference for Grade 4 students in hand positioning was not significant ($p = .135$) and with a low effect size ($d = .194$) (Cohen, 1988). For Grade 2 students, the difference was found to be significant ($t(23) = 3.14$, $p = .005$), yet with a low to medium ($d = .338$) effect size, suggesting only a low or low to moderate practical significance of the result.

Table 1: Means and Standard Deviations for Each Grade for Correct Performance on the Seven Hand Positioning Tasks

	Grade 2	Grade 4
	Mean (SD)	Mean (SD)
Hour Hand	5.04 (1.681)	6.17 (1.129)
Minute Hand	5.54 (1.250)	6.37 (0.924)

This finding is different than the comparable analysis for the analog clock with independent hands, for which both grades were more successful with the minute hand and both with a large effect size (Earnest et al., 2017). In the present analysis, when using the clock with linked hands, there was little detectable difference in students' positioning of hour versus minute hands. Given our interest in children's approaches to showing time on the clock, we question how the linked hands may differently support such accuracy and whether such success owes to conceptual understandings students applied or, alternatively, the mathematical achievements underlying the manipulative's functionality. To address this, we turn to our second question; given the high level of success with this clock, what are students' strategies when positioning the hands, and how are such strategies related to key ideas within measurement?

Children's Strategies to Position Hour and Minute Hands

In this section, we provide an overview of solution codes that emerged in our analysis for the seven Hand Positioning tasks (Figure 2). The role of qualitative data analysis involving children's strategies is to further contextualize performance results above that suggests there was little difference in the challenge of placing the two hands and high overall accuracy in hand positioning. We first present the six codes that emerged from analysis of video and transcript. After this overview, we present our analysis of strategies for each hand across all Hand Positioning tasks in both grades among the 48 students using the clock with mechanically linked hands.

Our analysis of the 48 students' solutions resulted in six strategy codes (Table 1): Container, Number Matching, Hand as Lever, Number as Floor, Origin, and Coordination, with idiosyncratic or unclear strategies coded Other. Table 1 features code names with examples as well as the frequencies across the 672 possible instances (7 problems with 2 hands per problem for 48 students) and, given all instances for just that code, the percent correct for each of the two hands. We first consider four strategies that (in our determination) did not overtly relate to unit or scale followed by two additional strategies that reflected some aspect of these measurement ideas.

First, 50 responses were coded as Container. Consistent with Williams (2012), children treated a particular interval as a container, with any point in that interval the same as any other point (see examples in Table 2). Second, Number Matching refers to a strategy to match the number from the time in the prompt with a number on the clock (e.g., "It's 2:50, so the hour hand goes on the 2.". At times, this included the application of a fact that remained unexplained in the interview (e.g., "I know 6 is 30"). Third, Hand as Lever involved children treating the focal hand as a mechanism to move the other hand; only nine students applied such a strategy, and in all cases this involved treating the minute hand as a lever to move the hour hand. Fourth, Number as Floor involved students finding the position of the hour hand for the top of the hour (e.g., when solving for 2:50, first finding 2:00 so the hour hand points to 2) and then applying continued movement to the minute hand clockwise resulting in further movement of the hour hand. In these cases, after finding time to the hour, students focused exclusively on positioning the minute hand without any overt further consideration of the hour hand. Unlike Number Matching, for which students' goals involved positioning the hour hand as close as possible to the target number (e.g., indicating 1:50 on the clock when matching the hour hand as close to 2 as possible), students found the top of the hour and then relied on the functionality of the linked hands. This occurred 65 times in interviews.

We identified two strategies related to key ideas of measurement (Lehrer et al., 2003): Origin and Coordination. Origin involved strategies in which a student identified a zero-point on the clock—typically the 12—with the target position as a path from that starting point. Unlike Number as Floor, which involved finding the top of the hour to locate the hour hand and then (based on available data) turning their attention to the minute hand, Origin involved a starting point with an explicit follow-up strategy (see example in Table 2). This code was applied 76 times, yet we note that it was applied only for the minute hand and not once to the hour hand. In almost all applications (96.1%) of this strategy, students were accurate. We also coded strategies as Coordination (n = 105), which involved treating the position of the focal hand as dependent or related to the position of the other hand. In doing so, such cases involved the proportional relationship of hours and minutes. These two measurement strategies were more successful than the prior four strategies, yet arose less frequently in our data.

Table 2: Strategy Codes for Positioning Hour and Minute Hands (N = 672)

Strategy (frequency)	Example
Container (n = 50)	*To position the hour hand for 4:30.* "It's 4, so the hour hand is in the 4-space.
Number Matching (n = 263)	*To position the minute hand for 4:30.* "I know 6 is 30."
Hand as Lever (n = 9)	*To position the minute hand for half past 11.* "I placed this here because I wanted this hour hand to be between 11 and 12."
Number as Floor (n = 65)	*To position the hour hand for 2:50.* "I first found 2:00, and then I knew that the hour hand would be after the 2."
Origin (n = 76)	*To position the minute hand for 4:30.* "I started here [at 12] and counted by 5s until I got to 30.
Coordination (n = 105)	*To position the hour hand for 2:50*. "I know this goes there because it's close to the 3, and the minute hand is only 10 minutes away from 3:00."
Other (n = 104)	Idiosyncratic or did not respond.

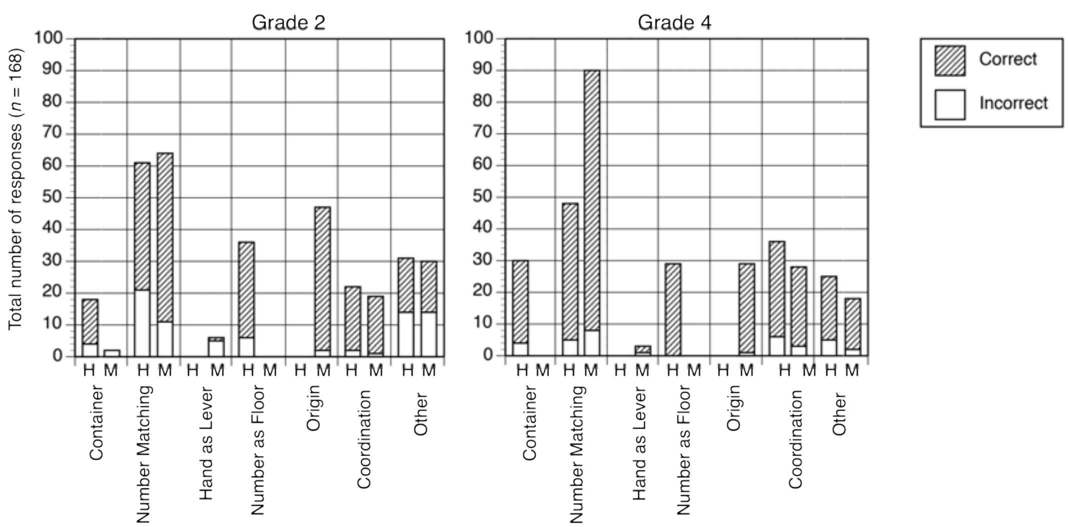

Figure 3. Strategy use for hand positioning when using clock with linked hands.

Figure 3 displays bar graphs for each grade to indicate frequencies of particular strategies for each hand along with whether such uses were correct or incorrect. Despite quantitative results above indicating little difference in success between the two hands, the strategies behind their positioning were often different. In particular, students' application of Container and Number as Floor were almost always for the hour hand. Although we would expect in general that strategies reflecting unit and scale would lead to greater accuracy (see Earnest et al., 2017), the material properties of the tool might have accomplished important mathematical work on behalf of the users applying Container, Number Matching, Hand as Lever, or Number as Floor strategies. We further note that the Origin strategy was applied exclusively to the minute hand. Such a result leads us to question whether, for children, the hour hand has an obvious zero-point like the minute hand does. We also note here that Hand as Lever was employed only in the context of relative times (i.e., half past 11) and, although we did not consider this to reflect unit or scale, any problem in which a student's minute hand position was coded as Hand as Lever received a Coordination code for the hour hand.

Concluding Remarks

With limited existing research focusing on children's understanding of time, we contend that the results of the present analysis are an indication that children may be developing an understanding of the inner workings of the clock—specifically how it reflects units and unit relations—in ways that are unrelated to mathematical properties of unit and scale. Further data is required to examine the extensiveness of these implications. Based on available data, if we were to look at overall performances among students using the clock with linked hands (Table 1), we may have concluded that this clock is a useful and productive manipulative for children to learn about time; however, our present analysis suggests that the material properties of the tool may be doing some important mathematical work on behalf of students.

Broadly speaking, what are our instructional goals related to time, particularly given that digital clocks are pervasive? We contend that instruction ought to move beyond procedures of clock-reading. Considering the role of time as a parameter in later mathematics, children ought to engage more deeply with the underlying meaning of clock features related to unit and scale. This research identifies a potential change in route with respect to how the field has framed learning and instruction related to time. We contend that more research is necessary in the area of how children come to understand time and common representations and tools for time. Although clocks are certainly pervasive in culture, results of this study underscore that children's ideas of time may be unrelated to the mathematical ways in which we measure it.

EXPLORATIONS OF VOLUME IN A GESTURE-BASED VIRTUAL MATHEMATICS LABORATORY

Camden Bock
University of Maine
camden.bock@maine.edu

Justin Dimmel
University of Maine
justin.dimmel@maine.edu

A room-scale virtual-reality environment was used to investigate students' conceptions of the volume of a pyramid. Participants controlled the virtual environment with a gesture-based interface that converted movements of their hands into actions on mathematical figures. Two students in graduate programs leading to certification in secondary science education investigated how the volume of a pyramid is affected by horizontal (i.e., shearing) or vertical (i.e., elongation) movements of its apex. Participants' actions within the environment were analyzed using the conceptions-knowing-concept (cK¢) *model of student conceptions. Both participants used an analogy of volume to surface area and area to perimeter to make sense of the effects of the shearing operator.*

Keywords: Geometry and Geometrical and Spatial Thinking, Technology, Teacher Education-Preservice

Introduction

New modes of interacting with virtual objects (Hwang & Hu, 2013; Kaufman 2011) can facilitate new ways of engaging with mathematical ideas (Abrahamson & Raúl Sánchez-García, 2016). Students today have a considerable advantage over the ancients: Instead of making do with crude, fixed diagrams sketched in sand, they can hold virtual mathematical objects in their hands and use intuitive, gestural interfaces (Goodman, Seymour, & Anderson, 2016; Zuckerman & Gal-Oz, 2013) to translate their instincts to explore different shapes (Hwang & Hu, 2013) into dynamic investigations of geometric structure (Duval, 2014; Sinclair & Bruce, 2015).

In this study, we report on two graduate students' explorations of the volume a pyramid in a virtual mathematics laboratory. We asked: How do students use virtual operators (e.g., the ability to dynamically elongate or shear a figure) to make and test conjectures about the volume of a pyramid? We use the cK¢ model (Balacheff & Gaudin, 2010) to describe two cases of students' explorations in the volume laboratory.

Theoretical Framework

Design of the Environment

The HandWaver environment (Dimmel & Bock, 2017) we developed was designed to create a space where learners could train their dimensional deconstruction skills (Duval, 2014)—the capacity to see representations of geometric objects as figures that can be resolved into components rather than as whole shapes (Laborde, 2008)—by using their hands to act directly on mathematical objects. The virtual tools were designed to provide various operators (Balacheff & Gaudin, 2010) participants could use to solve problems, such as that of relating the volume of the pyramid to the volume of a unit cube. For example, users could modify the (x,y,z) position of the apex of a pyramid by pinching and moving it in space, thereby changing the height of the pyramid by elongating (z-axis) or shearing (x-, y-axes).

The Conceptions-Knowing-Concept (cK¢) Model

Balacheff and Gaudin (2010) define a conception as a quadruplet (P,R,L,Σ): a set of problems (P), a set of operators (R), a representation system (L), and a control structure (Σ) (Balacheff & Gaudin, 2010; Balacheff, 2013). In this model, conceptions are not mental entities that belong to particular learners but are rather emergent, observable states of dynamic equilibrium between learners and their actions in an environment (i.e., a milieu). A conception is a "system of relationships" between the four components of the model. The set of problems for our study pertained to exploring the volume of a pyramid. A prototypical problem (Balacheff, 2013) was: How does the volume of the pyramid change as the position of its apex changes?

The environment provided various operators for participants to work on this problem. In addition to the elongating and shearing operators (Dimmel & Bock, 2017), the environment allowed users to constrain the elongate and shear operators by locking the apex of the pyramid in space along axes determined by the user. For example, users could lock the *z* coordinate of the apex, allowing them to move the apex in an *xy* plane without changing its height. Alternatively, users could lock its *xy* position and vary the pyramid's height while keeping its apex in its current vertical position. We report below on how participants used the shear and elongate operators to investigate volume.

Method and Participants

We investigated how pre-service teachers explored the volume of pyramids in the environment by conducting task-based interviews using a semi-structured protocol. Participants were asked to describe their thinking out loud (Fonteyn, Kuipers, & Grobe, 1993) as they navigated the environment and worked on the tasks. Participants were visually immersed in room-scale virtual reality for the duration of the interview. There was at least 2.5 meters x 3 meters of clear floor space for participants to move. All manipulatives were contained within the 2.5-meter x 3-meter virtual space. However, the virtual environment was unbounded such that participants could see to the horizon. Participants were recruited from a cohort of graduate students who were completing a Master's of Science in Teaching program. The two participants were given pseudonyms: Abe and Brendan.

Data

A 60-minute interview was conducted with each participant. A participant's first-person view of the virtual world was displayed and screen recorded on a monitor that was visible to the researchers throughout the interview. A third-person view of the participant navigating the virtual environment was also screen captured. A separate audio recording captured the conversation between the investigators and the participant.

Analysis and Results

After conducting three recorded interviews, each interview was transcribed and partitioned into episodes by task, differentiated by the operators common to each task (González & Herbst, 2009). Transcriptions included references to direction and geometric figures indicated by hand gestures. We consider here a task where participants investigated the volume of the pyramids by manipulating its apex. Episodes were partitioned by the type of manipulation (vertical or horizontal) of the apex during the participants' inquiry. We differentiated horizontal manipulation (shearing) from vertical manipulation (elongating).

Episodes of Exploring Volume

At the beginning of the task, Abe stated that he believed "moving the apex increases the volume" when the apex is restricted to vertical movement (elongating). As Abe began to experiment with horizontal motion, shearing the pyramid, he claimed that "[the surface area is] probably balancing out, so the total volume isn't changing, it's just redistributing where the volume is." After he was asked what tool exists or could be built that would increase his confidence in his claim, Abe first suggested that if "each side of the pyramid could be a different color, then…you might be able to visualize the changing of the area." Abe then suggested applying a "cube grid" (a graph-paper material seen on the unit cube) to each face. The measurement tools Abe wanted were absent from the environment by design, to discourage empirical discussions of volume (Herbst, 2005).

Reaching a Contradiction

The investigators prompted Abe to investigate the changes of the heights of the triangles and to use greater than or less than statements if measurement was not possible. Abe then attempted to use relative changes in the perimeter of each face of the pyramid to gauge relative changes in area. Abe acknowledged that the length of each edge of the square base was equal and constant when the apex of the pyramid was sheared. Abe used the changes in lengths of the two remaining sides to determine if a face was increasing or decreasing in area. Abe concluded that the net surface area was increasing, thus the volume was increasing. However, Abe stated that "It just doesn't feel like it is," and that it "seems weird to...say that ...the volume of [the sheared pyramid] is larger." The interview concluded shortly after Abe reached this contradiction, so we were unable to observe Abe attempt to resolve the contradiction.

Connection to Perimeter and Area

Brendan used an argument that related area to perimeter as he explored the relationship between surface area and volume. Brendan suggested that there is a relationship between the structure of perimeter and area, and surface area and volume. He appeared to be using the connection between perimeter and area as a control to work on the problem of describing how volume is affected by shearing or elongating. This aspect of his control structure could be described as follows: Volume is the 3D analog of area and surface area is the 3D analog of perimeter. So, if a change in perimeter implies a change in area, then a change in surface area implies a change in volume.

This control is a component of a conception of volume equality that could be described as follows:

- *Problem (P):* How is the volume of a pyramid affected when the position of its apex changes?
- *Operators (R):* Elongate (xy axis lock) or shear (z-axis lock) the pyramid. Use one's gaze or one's position in the environment to make a visual comparison.
- *Representation (L):* A dynamic pyramid in an immersive virtual space.
- *Control Structure (Σ):* Analogy between the relationships of volume to surface area and area to perimeter.

Conclusions & Scholarly Significance

We anticipated participants would use an available cross section tool (not described) to effect side-by-side comparisons of sheared and non-sheared pyramids of equal height. Participants' uses of the analogy between perimeter/area and surface area/volume as a control on the shearing operator was unexpected. The participants that used this control did not recognize that the perimeter of a figure can increase while its area remains constant and that the surface area of a figure can increase while its volume remains constant. Even though participants arrived at a conception of volume we had not intended, the environment we designed facilitated participants' use of dimensional deconstruction to reason about plane and solid figures. The use of physical manipulatives has previously been proposed to address conceptions in 3-D geometry, particularly in investigations of shearing (Fischman & McMurran, 2011). Our study highlights how virtual manipulatives in immersive spaces can be used to explore how learners reason about volume.

Our study is significant because mathematics education is at a technological crossroads. The virtual reality technology we used to conduct this study is commercially available, inexpensive, and will be as ubiquitous as mobile phones in the coming decade. How will classroom instruction adapt to strategically harness the vast potential of these new systems of representation and interaction to positively affect student experiences in mathematics? This is an urgent question. Studies like ours demonstrate what the potential of these new instructional technologies look like in practice.

MIDDLE AND HIGH SCHOOL STUDENT UNDERSTANDING OF HEIGHT OF A TRIANGLE

Davie Store
Central Michigan University
store1d@cmich.edu

Jessie C. Store
Alma College
storejc@alma.edu

This study focuses on geometry, one of the under researched studies in mathematics education. Based off national and international tests, it is also the least understood areas of mathematics. Geometry teaching and learning should be at the center of reform policies. To contribute to understanding of this issue, in this study we conducted clinical interviews with 25 students from 13 middle and high school students. The results reveal misconceptions that are likely to hinder development of geometric understanding.

Keywords: Geometrical and Spatial Thinking

Objective

Educators contend that Geometry is one of the critical areas in mathematics education. It is foundational to higher-level mathematics, to understanding space in our world, and many other science disciplines. Several studies have shown student difficulties with geometry. Usiskin (1982) after a study with 2700 students on geometric thinking concluded "half the students who enroll in a proof oriented course experience very little or no success with proof" (p. 99). These difficulties have persisted over decades. Several studies (E.g., Stylianides & Silver, 2014), and achievement tests such as NAEP and TIMMS have shown geometry to be the weakest area for students compared to algebra, number, data, and chance. Secondary school mathematics teachers also report students' difficulties with high school geometry.

In light of these difficulties, standards for mathematics teaching (ex. Common Core States Standards, 2011) are targeting deeper and connected ways of understanding geometry from elementary school. In these standards, six grade students should be solving geometry problems that include volume and area. Seventh grade geometry standards include constructing geometric figures, and eighth grade students should be learning Pythagorean theorem, and congruence and similarity of geometric figures. One of the underlying concepts that affect depth of understanding in the geometry domains in the standards is the concept of height, for instance height of a triangle. Understanding height of a triangle pulls from understanding what a triangle is and feeds into conceptual understanding of area, volume, Pythagorean theorem, and congruence and similarity.

Clearly, it is critical to explore students' understanding of height of a triangle. Moreover, there is scarcity of literature on students' geometric thinking after implementation of Common Core 2010 standards. Furthermore, Bergstrom and Zhang (2016) in their meta-analysis of studies on geometric thinking and interventions reported that "compared to the rich literature on numerical instruction, research investigating students' development of geometric thinking is rather limited" (p.2). For these reasons, the objective of this study is to explore how middle and high school students understand height of a triangle.

VanHiele Theory of Geometric Thinking

This study is informed by Van Hiele theory of geometric thinking. This theory was developed in response to the need for improving secondary students geometric thinking (Van Hiele, 1959) and has been used as a model for geometry curriculum (Burger & Shaughnessy, 1989). Drawing from Jean Piaget's theory on cognitive development and other theories, Van Hiele theory organizes geometric thinking into five levels namely visualization, analysis, abstraction, rigor, and deduction.

At visualization stage, students focus on the orientation of geometric shapes. Their focus when identifying shapes is not the explicit properties of the shapes. Even for those beginning to use properties, the properties used are very imprecise as they compare drawings, sort, or characterize shapes. For example "a child recognizes a rectangle by its form and a rectangle seems different to him than a square" (Van Hiele,1959, p.62). The vocabulary for figures is present, but the definitions for such vocabulary are not understood.

Analysis stage follows visualization stage. At this stage, students analyze the shapes, discern properties, and are even able to make generalizations about those properties. Given the properties, students can draw the corresponding shapes. However, they are not able to see relationships between those properties. They are still unable to see a square as a rectangle (Van Hiele, 1986). Once children reach abstraction level, they are able to make informal deductions about properties and see their relationships. These informal deductions allow children to identify interrelations of properties both within and between shapes, enabling them to identify squares as rectangles. In the later levels, students are able to work with axioms and write formal proofs, and later work within abstract non-Euclidian geometry.

Methods

Data were collected from 13 female and 12 male students from 13 schools from Midwestern US. Ten participants were in grade 6, 7, and 8 while the rest were either freshmen or sophomores in high school. These students had participated in a one-week college residential camp conducting research in STEM fields. Students were given written questions that asked them to define height of a triangle, draw heights to given triangle bases, and write how many heights each triangle may have. Clinical interviews (Piaget, 1983) were conducted with each student to understand students' reasoning for their responses. The interviews were video recorded and lasted 30 minutes on average.

A line by line coding of the interview transcripts and student worksheets was conducted in Nvivo to identify themes for developing categories of student reasoning. NVivo coding helped to check how robust the themes were and to identify relationships between themes, and between verbal and written reasoning. Multiple coders built in the trustworthiness of the analysis (Creswell, 2007). The results are presented in the following section.

Results

Defining Height of a Triangle

From our sample, only three students who had just finished 10th grade were able to define height correctly and could identify heights that were either horizontal or vertical without changing the orientation of the triangle. For the rest of the sample, height of a triangle was how visually tall a triangle is. Some explained that a triangle can have up to three heights, but needed to rotate the triangle to explain that the height would change depending on which leg was the base. Some differences were observed between grades.

None of the ten students who had just finished sixth and seventh grade were able to correctly define height. From the interview and written transcripts, to identify height of a triangle, one simply needs to pick one corner of a triangle with a line (leg) that looks taller, and follow that leg to the top corner. They interpreted height as how visibly tall a triangle is as judged from "the bottom" of that triangle. When asked what happens to the height when the triangle is rotated, they believed that there is a need to consider the bottom line again and choose the longest line to the top. Only four of these sixth and seventh graders believed a triangle could have up to 3 heights while the others believed the maximum number is 2 or 1. Notably, this group of participants did not use any formal vocabulary during the interview or in their written work.

Eighth graders were using formal vocabulary (ex. hypotenuse, base). Although their definitions of height were incorrect and also viewed height as how tall a triangle is, they were able to talk of heights meeting the base, and that height did not necessarily have to be one of the legs. In general, the ninth and tenth graders had similar understanding but also talked of other factors such as the type of triangles. They tended to default to discussing height of a right-angled triangle as being the opposite of a hypotenuse, but their understanding was limited to right-angled triangles where the right angle was on one of the bottom vertices.

Drawing Height of a Triangle

Participants were also asked to draw a height to a given base *b.* Analysis of the heights they drew correlated with their description of height during the interview. There were four common misconceptions for the students who seemed confident in their definitions and drawing of heights.

The most common misconception was believing that the height of a triangle is the leg that looks the tallest. Students with this misconception, in line with their definitions of triangle, always used one of the legs that looked taller from the bottom to the top to draw the height. Because they believed that rotating the triangle would change the base and therefore which side looked the tallest, they were convinced that a triangle has three possible heights. However, they were confused when prompted to think whether *every* triangle would always have three heights. They thought number of heights depended on the relative sizes on the legs. It became very difficult for them to give a convincing argument on determinants of number of heights of a triangle.

A second misconception was that the height always bisects the base. With this misconception, students always drew a height starting from the middle of one of the legs. Some perceived heights were from the given bases and others from the bottom leg. They did not necessarily go to the vertex opposite the base, some legs were drawn from the mid point of the perceived base and to middle of the triangle, and others left randomly outside the triangle.

Another misconception was that the only triangles with heights or whose heights can be identified are right-angled triangles whereby the leg opposite the hypotenuse is the height. Interestingly, students with this view easily identified the height of right-angled triangle when the height was vertical and on the left, but almost always never identified such edges as heights when the edges did not look 'vertical enough' even on triangles labeled as right-angled.

Lastly, students had a misconception that the height of a triangle can only be drawn if the triangle measurements are known. The measurements that students mentioned were the formula for area of a triangle (A= b x h), angle measurements, and types of a triangle (ex. isosceles, acute, equilateral, e.t.c). These students focused on trying to recall computational geometry ideas and trying to figure out how they could use those ideas to draw heights. They discussed triangle properties at length but could not draw any height because drawing heights without measurements included in the triangles did not make sense to them.

Only three students were able to draw heights for any given triangle correctly, and their discussion was consistent with the mathematical definition of height. These students had just finished 10^{th} grade at different high schools.

Significance

Based off these data, students' reasoning with height of a triangle is within visualization and analysis levels. From different theoretical perspectives, development of geometric thinking is sequential; students cannot achieve higher-level thinking without the basic understanding. Any high level mathematics such as calculus builds on geometry concepts some of which are heights of figures. To reason with measurements in our world, for instance volume, require understanding height of objects. Students who do not fully comprehend the height of a triangle lack mathematical empowerment. The results of this study show students are not well prepared to do high school geometry or college mathematics. By sixth grade, geometry domains require understanding of height of a triangle and yet in our sample only three students could define and draw height of a triangle. This calls for rethinking geometry curriculum, and/or pedagogy.

MOTIVATING THE CARTESIAN PLANE: USING ONE POINT TO REPRESENT TWO POINTS

Hwa Young Lee
University of Georgia
Hylee00@uga.edu

Hamilton L. Hardison
University of Georgia
Ham42@uga.edu

The Cartesian plane is often used as a representational tool in high school mathematics and beyond. Often, the Cartesian plane is taken as a given, and little research has examined students' constructions of the Cartesian plane. We present data from a teaching session focused on two ninth-grade students' activities during the Ant Farm Task—a task we designed to motivate students' construction of the Cartesian plane. We describe three elements of the students' constructive activity that we view as critical for constructing the Cartesian plane.

Keywords: Geometry and Geometrical and Spatial Thinking, High School Education, Cognition

Using the Cartesian plane, students are expected to represent and reason about various mathematical ideas (e.g., characteristics of geometrical shapes, functions, etc.). Consider the following statement in the Common Core State Standards for Mathematics (CCSSM) regarding the Cartesian plane:

> Use a pair of perpendicular number lines, called axes, to define a coordinate system, with the intersection of the lines (the origin) arranged to coincide with the 0 on each line and a given point in the plane located by using an ordered pair of numbers, called its coordinates. (NGACBP & CCSSO, 2010, p. 38)

Descriptions of the Cartesian plane like the one above are common in textbooks and other curricular materials. In short, students are given the rules of "generating" a Cartesian plane and plotting points within it. We are aware of no curricular materials designed for high school students that attend to students' conceptions of coordinate systems or why we construct and use the Cartesian plane in this manner. In this report, we present how two ninth-grade students described the location of two points using a single point by constructing a Cartesian-like coordinate system. More specifically, we will present the Ant Farm Task, analyze the two students' strategies in the task, and consider educational implications.

Theoretical Framework

Based on our conceptual analysis (Thompson, 2008), we distinguish between two different uses of coordinate systems: spatial coordination and quantitative coordination (Lee, 2016; Lee & Hardison, 2017). Spatial coordination refers to the use of coordinate systems to re-present space by establishing frames of reference to locate points within the space (e.g., a map). Quantitative coordination refers to the use of coordinate systems to coordinate sets of quantities in a representational space. We are unaware of any curricular material which address our distinction between these two uses of coordinate systems, including the CCSSM.

Saldanha and Thompson (1998) explained thinking covariationally as "holding in mind a sustained image of two quantities' values (magnitudes) simultaneously" (p. 298). Often, curves in the Cartesian plane are used as static representations of the mental covariation outlined by Saldanha and Thompson. Previously, we have argued that spatial coordinations are necessary (i.e, a barrier) if Cartesian coordinate systems are to be productive tools for students' quantitative coordination and subsequent covariational reasoning (Authors, year). In this paper, we present data and analysis of students' constructive activities in a task we view as a bridge between spatial coordination and quantitative coordination. We propose three features of students' constructive activities that may be critical for fostering students' transition from utilizing one number line to represent a single quantity to developing the Cartesian coordinate system to represent covariation in two quantities.

Methods

We conducted a yearlong teaching experiment (Steffe & Thompson, 2000) with ninth-grade students Kaylee and Morgan to investigate their constructions of coordinate systems (Author, year). The first and second authors served as the primary teacher-researcher and witness respectively for the teaching experiment. We collected video recordings and student work from each of the 20–25 minute teaching episodes. We conducted both on-going and retrospective analyses and oriented our work in modeling students' constructive activities (Steffe & Thompson). In this report, we discuss a single task: The Ant Farm Task (AFT). The goal of AFT was to engender students' creation of a space that would allow them to describe the location of two points simultaneously, with one possible solution being the standard Cartesian system. Providing the students with two plastic tubes that represent ant farms, we asked students to pretend there were two ants: one moving around in each tube. The task was accompanied by a model of this situation in a dynamic geometry environment (DGE) as shown in Figure 1.

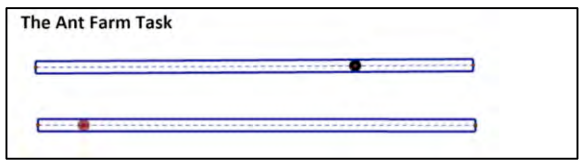

Figure 1. Ant Farm Task dynamic geometry environment model.

We asked the students to imagine the computer screen to be the floor of a room on which two ant farms—long, thin rectangles within the DGE—were resting. Each ant farm contained a single ant—a point that moved along the longest segment connecting midpoints of opposite sides of each rectangle (the dashed lines in Figure 1). The rectangular-shaped models could be translated and rotated in the DGE by dragging the end points. The ants' movement was designed so it appeared to move haphazardly along the interior of the tube. Additionally, in the DGE, there was an action button that allowed students to stop/activate the motion of the ants and one to hide/show the ants in each tube to encourage students to attend to both static and varying locations of the points. We asked the students to devise a way to represent the location of both ants using a single point so that if we were to hide both ants, they would be able to use their new point to determine the location of the two hidden ants. We presented the situation absent of any quantitative measurements (e.g., an ant's distance from the end of the tube).

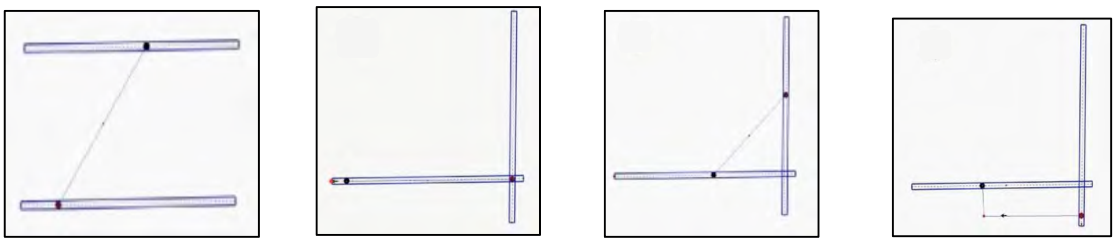
Results

As the students worked together, Kaylee first suggested connecting the two ants and marking the midpoint of that line segment as their point, as shown in Figure 2a. As such, Kaylee constructed a new point outside of the ant farms in two-dimensional space to coordinate the location of both points simultaneously. Morgan animated the ants to explore if Kaylee's idea would work for any location of the ants. As the ants moved, Morgan attended to the line segment and midpoint Kaylee constructed and claimed, "This only shows where the middle of [the ants] are. It doesn't actually show us where they are." We consider Morgan's remark to indicate that she viewed Kaylee's solution as insufficient for determining the location of both ants

Moments later, Morgan suggested positioning the tubes perpendicularly, with one of the ants at the intersection, as shown in Figure 2b. The two ants were still connected by a line segment which

Galindo, E., & Newton, J., (Eds.). (2017). *Proceedings of the 39th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* Indianapolis, IN: Hoosier Association of Mathematics Teacher Educators.

contained its midpoint (Figure 2c). Morgan then animated the ants and observed various "triangles" formed by the two ant farms and the line segment connecting the two ants (e.g., one instance captured in Figure 2c). Morgan explained that she thought of "axes, like a *x* and *y*" and triangles formed by the axes with the connected segment. The researcher hid the two ants and the connecting segment, leaving only the midpoint left on the screen, and asked the students to anticipate the locations of the two ants based on the visible midpoint. Testing several different locations, Kaylee and Morgan concluded that the midpoint of the line segment connecting the two ants was insufficient for locating both hidden ants by noting that multiple lines could pass through this midpoint. Although we consider their midpoint coordination valid, Morgan and Kaylee did not find their midpoint sufficient for reliably locating the two hidden ants.



(a) (b) (c) (d)

Figure 2. Kaylee and Morgan's activities in the dynamic geometry environment. (a) Kaylee connects two ant points and marks midpoint (b) Morgan re-positions the two rectangles (c) One instance of perpendicular rectangles with midpoint coordination (d) Kaylee's box coordination.

After discarding their midpoint coordination, Kaylee and Morgan sat in silence for approximately 40 seconds until Kaylee came up with the idea to make a rectangular "box" as shown in Figure 2d. Kaylee said, "I was thinking like putting a point right here so I can make a box," as she indicated the point that would be the intersection of lines perpendicular to the tubes through the ants. Then she made a rectangular motion connecting the two ants to this point and the intersection of the tubes. In subsequent activities, Kaylee and Morgan tested their approach by moving, hiding, and predicting the locations of the ants. Both students appeared very surprised when their predictions were accurate. In checking each prediction, they revealed the ants using the hide/show button and both exclaimed, "Wooo!" "What?!" "Gosh!" as they saw the ants were located where they predicted.

Next, Morgan posed the question, "But wait, what if we move this down more?" as she pointed to the vertically positioned tube and moved her finger as if to drag the tube downwards. She continued, "Would it change our answers?" Kaylee responded, "No, because it's still in line with it," as she moved the vertically positioned tube up and down. They were able to see the point in the plane move in accordance with the movement of the tube. When the researcher asked if that will work no matter where the two tubes were, Morgan explained using the plastic tubes, "Say these are the two tubes and make sure they're crossing somewhere and then wherever that dot is, it will go." Through their activities, the students had spontaneously constructed a (non- quantitative) Cartesian-like coordinate plane in order to coordinate the location of two points using a single point.

Discussion

Although Morgan and Kaylee had formal instruction in using the Cartesian plane, devising a system to coordinate the location of two points using a single point appeared novel to the students and neither student associated the activity with the Cartesian plane during the teaching session. Morgan described the configuration of tubes as similar to *x* and *y* axes; however, other than this figurative association, neither student mentioned the way in which points are coordinated in the

Cartesian plane. Furthermore, we consider the task non-trivial for the students as they spent 24 minutes working on the task before reaching what they considered to be a satisfactory solution. In a later teaching session, one student explained how in school they were told “this happens and that happens” on the coordinate plane but that “they never really gave us real world examples like [the Ant Farm Task].” Looking across the activities of Kaylee and Morgan in AFT, we highlight three features of their activities that we see as critical for fostering students’ transition from utilizing one number line to represent a single quantity to developing the Cartesian coordinate system to represent covariation in two quantities.

First, the students’ use of space outside of the ant farms suggests that the Cartesian coordination of two quantities represented on independent number lines requires an *awareness of two-dimensional space* outside of the one-dimensional number lines. Second, the students’ *attention to variability* in both ants’ locations motivated a particular spatial coordination (e.g., perpendicular lines through the ants) that would enable holding a sustained image of two locations simultaneously (Saldanha & Thompson, 1998) for arbitrary positions of the ants.

Having students move the tubes themselves, rather than pre-constructing them perpendicularly on the screen, and having the ants move haphazardly allowed the exploration to be novel for the students. Finally, the students’ decision to reorient the ant farms in the dynamic geometry environment suggests that developing the Cartesian coordinate system is supported by students *viewing number lines as objects* that can be rotated and repositioned in two-dimensional space.

To modify AFT to provide students with an opportunity to engage in quantitative coordination, we recommend asking students to represent each ant’s distance from one end of its ant farm via a variable point on a number line; we would then ask students to represent these variable points on two independent number lines using a single point. AFT and the findings from this study can provide insight for mathematics educators and researchers who are interested in engendering productive meanings for the Cartesian coordinate system.

PUTTING OUR BODIES ON THE LINE: MATHEMATIZING ENSEMBLE PERFORMACES

Lauren Vogelstein	Corey Brady	Rogers Hall
Vanderbilt University	Vanderbilt University	Vanderbilt University
lauren.e.vogelstein@vanderbilt.edu	corey.brady@vanderbilt.edu	r.hall@vanderbilt.edu

All humans have bodies. Our bodies profoundly affect our perspectives and understandings of the world. Today's schools neglect the body as a resource for mathematical thinking and learning. Recently this changed and researchers are putting the body back into the equation. Recent research explores changes in the modality and scale of mathematical activity, putting the power of paper and pencil into whole-body coordinated movements in open spaces. This study designs and studies learning in new forms of mathematical activity that involve multiple, moving bodies. This paper reports on the first phase of a two phase project in which we use interviews with experts in a variety of disciplinary fields, asking people to find and make sense of emergent mathematics in choreographed, ensemble performances from the opening ceremony of the 2016 Rio Olympic Games, to design and study experimental mathematics learning.

Keywords: Cognition, Geometry and Geometrical and Spatial Thinking

Introduction

Our bodies profoundly affect our perspectives and understandings of the world. However, today's schools neglect the body as a resource for mathematical thinking and learning. Recently researchers are putting the body back into the equation (Lakoff & Núñez, 2000; Stevens & Hall, 1998). Research on embodied mathematics learning has shown multiple affordances of gesture use (Goldin-Meadow, 2005), but these investigations tend to focus on stationary, individual bodies with an emphasis on hand and arm movements. More recent research explores changes in the modality and scale of mathematical activity, putting the power of paper and pencil into whole body coordinated movements in open spaces (Hall et al., 2014; Ma, 2016). This study investigates learning in new forms of mathematical activity that involve multiple, moving bodies. In this paper, we share initial findings from interviews with experts from various disciplines, asked to find and make sense of emergent mathematics in choreographed, ensemble prop-based performances from the opening ceremony of the 2016 Rio Olympic Games (Table 1) when they are given similar props to think with. Findings from these interviews will inform future designs and studies of experimental mathematics teaching and learning at the crossroads of embodied ensemble learning and mathematics.

Background and Framework

During the opening ceremony of the 2016 Rio Olympic games, billions of people worldwide watched over 6,000 performers execute large-scale choreographed routines with dynamic geometric forms that were viewed at local and global scales (Table 1). In this emerging genre of theatrical production, viewers are invited to engage with a performance that is mathematically complex in design and appearance (Lakoff & Núñez, 2000; Ma, 2016) and are able to see close up views of the local organization of bodies as well as aerial shots that show the global organization of bodies in space. We argue that these performances hold rich relations to mathematics. The performer-plus-prop ensemble covers the enormous stage, exhibiting tessellation after tessellation; local organization becomes global in emergent complex systems; performers turn straight chords into curved cones. However, we do not know, whether or how viewers, particular professionals with different disciplinary backgrounds (e.g., a choreographer or mathematician), might make sense of these performances mathematically. Thus, the first phase of this project examines how people with different disciplinary backgrounds find patterns, articulate how they see these patterns being assembled in the performances (e.g., repeating shapes as tessellations), and use their own bodies (as well as other representational forms such as written diagrams and the use of embodied props) to demonstrate and communicate their understandings. Selections from the opening ceremony of the Rio games provide rich material for probing these understandings, since the video record involves hundreds of performers, who create complex dynamic formations by using their bodies and other tools (e.g., folding and rotating square panels and moving cords hanging from above into cones and triangular prisms).

Our focus in these interviews is (1) to understand a new theatrical genre composed of units of props plus bodies, which expresses something important in the present cultural moment, (2) explore what is compelling for viewers, and (3) to ask participants to use their own most "powerful tools" (including mathematics, if they find it relevant) for interpreting these performances, probing how participants make sense of their own role within the local organization of bodies-with-props in relation to global orders of repeated groups of bodies and props in space.

Table 1: Local and Global Orders in Opening Ceremony Clips

Name of Routine	Local Order	Global Order	Props Plus Bodies
Solar Panel People			The square solar panels plus the four performers that hold each one at a time afford different local folding symmetries and grid like global formations and tessellations
Spaghetti			The cords plus the performers holding them are able to create cones, where the cone point expands to a dorsal line suspended across the center of the performance space

Methods

In these interviews, participants are shown two clips from the opening ceremony of the 2016 Rio games (Table 1). After each clip, participants are engaged in a dialogue guided by the researcher. This discussion follows a line of inquiry structured by three primary questions. Participants are first asked to describe what they saw or heard in the clip. They are then asked what they think performers would need to know or be able to do to in order to create the performance. Finally they are asked how they would describe the performance mathematically. Participants are given control of the computer so that they can rewind to any part of the clip and rewatch for further, iterative analysis (Hall & Stevens, 2016; Jordan & Henderson, 1995). They are also supplied with paper, pencils and similar props to think with such as a square made of silver mylar to reenact aspects of the performances and test their own thoughts on how these performances are enacted. Preliminary interview sessions have been conducted at the focus group level (about 10 participants) and at the smaller scale of one and two interviewees at a time.

Through iterative analysis of interview recordings, we are developing grounded theoretical categories to describe similarities and differences in how participants make sense of these spectacular choreographed performances, both as a form of cultural expression (including the expression of mathematics) and as something that people learn to do together (i.e., as embodied, ensemble performances). We are also interested in exploring the bodies of the performers and participants as a *technology* to enact mathematical forms and processes, something that the performers are clearly doing and that interview participants may explore with their own bodies.

These performances and viewing sessions provide an opportunity to "restore" whole bodies as a sensible topic and medium for understanding things from a mathematical perspective. In this sense, local orders and how these "parts" add up to emergent "wholes" in the performance *necessarily* involve bodies, moving in coordination together. We also want to investigate the use of "props" that support both part and whole aspects of ensemble performance (i.e., performances that require many, coordinated bodies) as a technological tool for mathematics thinking and learning because they constrain the movement of bodies in ways that are able to systematically organize bodies in time and space. These performances thus involve *tools* that performing bodies manipulate as props to express visually regular motion at the scale of "parts" (or local orders). Assembling local orders at a broader scale (e.g., creating a matrix with either a static of moving structure for the entire field), and how these forms are made depends equally on technologies.

Preliminary Analysis and Findings

Thus far, participants have noticed two important aspects of these performances: (1) the narrative affordances of these performances and (2) how they relate to mathematical descriptions of them.

Many participants seem to expect different narrative elements in these performances and their sense making comes from either interpreting these expected narrative elements or dealing with an absence of these narrative elements. For several participants latching onto narrative elements and symbolic representations in these performances seems to be one way that they can start to make sense of these performances. These participants may begin by identifying familiar elements of the performance and the enable them to construct meaning in the performance. Alternatively, they may discard any narrative meaning and view the performance as pure entertainment, either when the performance lacks a clear narrative structure or the narrative elements are ambiguous. Both interpreting expected narrative elements and attempting to make sense of the absence of narrative elements has led some participants to question the relevance of mathematically describing these performances and has led others to eagerly explore mathematical descriptions. While some participants were resistant to describing the performances mathematically, claiming that mathematics was not relevant, others were able to share mathematical elements that they saw in the performance such as recognizable two and three dimensional shapes, symmetries, isometries, and wave patterns.

As we have begun to conduct these interviews we have also noticed the importance of getting participants to think with props similar to those used in the clips shown. Participants in our first focus groups were hesitant to engage with these props, but through encouraging our smaller interview groups and explorations ourselves, we have found that allowing participants to stand up and move under the constraints of these props has proven to be an effective means of getting people to explore the complexity of simple performance elements such as maintaining alignment with respect to multiple moving bodies, moving while keeping a piece of mylar taut, and folding a square into a right triangle. Participants have shared how the coordination of multiple bodies in space is deceivingly deceptive and very complex in execution.

In addition, asking performers to move under the constraints of props has also brought in their ideas about how time and rhythm and marked time are used as another tool to organize bodies in space. For example when one group was working with the square prop and trying to figure out how the performers in the Solar Panel People clip were able to fold a square into a right isosceles triangle, they discovered that if they stepped in synch to an agreed upon rhythm they were able to traverse equal distances and thus come together at the same time. Then if they took the same number of steps backwards, to the beat, they would form a taut triangle at the same time as well (Figure 1). The first image in Figure 1, shows remnants of the participant in the upper left corner moving his right arm up and down as he counts "1, 2, 3, 4" before the group moves on the same rhythm into the center as depicted in the second image in Figure 1. He embodies the rhythm in his arm before embodying it in his feet.

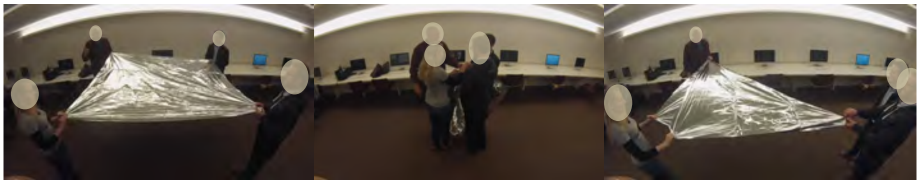

Figure 1. Quartet of participants folding a Mylar square into a triangle.

Preliminary Discussion and Conclusion

Our examination of these interview and analysis sessions has developed our understanding of how people use different resources to make sense of choreographed performances. It has also highlighted the role that mathematics plays in understanding the constituent structures of these performances. We have begun to see a relationship between recognizable narrative elements and mathematical elements to these performances. We have also identified affordances in having participants physically put their bodies on the line to reenact different elements from the performance, allowing them to get a better understanding of the choreographic rules at the local level. The number of participants in these interviews, however, does not afford many of our participants without performance experience with ways to think about how their local movements would need to be organized to produce visible global orders such as a grid. Nonetheless, this project is important for understanding how highly visible cultural events are (or can be) understood mathematically (i.e., extending how mathematics forms a significant component of culturally powerful and meaningful events), and also for understanding how human bodies can be used as a medium for creating and expressing these structures.

A TEACHER'S GEOMETRIC CONCEPTUALIZATION AND REASONING IN TERMS OF VARIANCE AND INVARIANCE IN DYNAMIC ENVIRONMENT

Gili Gal Nagar
UMass Dartmouth
gnagar@umassd.edu

Purpose and Background

Developing sophisticated and abstract spatial thinking about figures, in terms of variance and invariance underlying mathematical structures that represent concepts and relationships between them, are critical for learning and teaching of mathematics at all levels (e.g Hadas, Hershkowitz, & Schwarz, 2000; Hegedus and Moreno-Armella, 2011; Sinclair, Pimm, & Skelin, 2012). This study uses a dynamic environment (Geometer's Sketchpad® (Jackiw, 1991, 2009) for iPad - Sketchpad® Explorer) to examine: (a) what conceptualizations and reasoning about the concept of circle, an in-service mathematics teacher demonstrate, in terms of variance and invariance?, (b) what are the key elements of such conceptualizations?

Framework & Methods

Invariant Property (IP) denotes to geometrical properties that remain unaltered when transformations on the geometrical object are enacted (e.g. Hadas et al., 2000). Data were collected from 90-minutes videotaped task-based interview with one certified 9th-11th grades teacher with five years of teaching experience from the U.S. (David - pseudonym). Task 1 was designed to explore ways to enable the existing of a circle, that passes through A and B and its center is C, by dragging point C (A and B are fixed). Point C leaves a trace that can be deleted by clicking a button (see Figure 1 that presents David's response to Task 1).

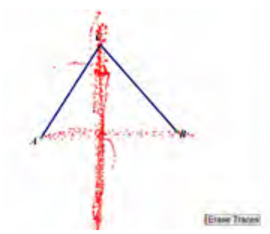

Figure 1: Task 1

Results

David offered different conceptualizations and reasoning of multiple circles. David offered to reflect point C with respect to AB and to keep the distance of C from AB equal and to keep AC and CB as equal distances (invariant properties) so that there would be exist a desired circle. Later on in the interview, David focused on continuous variation to conceptualize and to reason that under translation of point C along the perpendicular bisector of AB (maintaining dragging) it is possible to generalize that there are infinity many circles that exist and these circles are of different sizes.

BERTIN'S RIGHT (ABOUT) ANGLE MEASURE: WE DON'T NEED TO BASE DEGREES ON 360

Hamilton L. Hardison
University of Georgia
Ham42@uga.edu

Keywords: Geometry and Geometrical and Spatial Thinking, Cognition, High School Education

The fourth-grade Common Core State Standards for Mathematics describe a one degree angle as "an angle that turns through 1/360 of a circle." Degrees are often introduced in this manner in terms of a 360-unit composite. In this poster, I question this normative approach to developing degrees as a unit of angular measure and illustrate that students can develop coherent conceptions of degrees without leveraging a 360-unit composite. I draw on data from a yearlong teaching experiment (Steffe & Thompson, 2000), which was informed by the principles of quantitative reasoning (Thompson, 2011) and focused on students' understandings of angle measure. Here, I focus on Bertin, a ninth-grade student who participated in 15 thirty-minute sessions, and his ways of reasoning with two tasks (making a one-degree angle and the partitioned plane) involving degrees as a unit of angular measure.

When I asked Bertin how he'd make a one degree angle, he explained, "… if you get a 90-degree angle, you can divide that into nine. So it would be like 10 degrees each…and then you can divide each one of those into 10." In his explanation, Bertin indicated that he recursively partitioned a mental re-presentation of a right angle to produce 90 one-degree angles. Bertin's method for producing these one-degree angles incorporated a three-levels-of-units structure (i.e., a right angle partitioned into 9 ten-degree units, each of which contained 10 one-degree units).

Later, I presented Bertin with *The Partitioned Plane*—a dynamic geometry sketch wherein Bertin could set a whole-number parameter, n, to partition the screen into n equiangular parts. When I asked Bertin to produce one-degree angles, Bertin quickly set $n = 1$ and explained this gave "almost a straight line; I guess there's like one, small little degree somewhere in there." Moments later, I asked Bertin to set n to produce 90-degree angles. In sequence, Bertin set $n = 10, 2, 6, 7, 5$, and finally 4. Bertin explained that he settled on $n = 4$ because it looked like the edge of a square. When tasked with producing a 90-degree angle, Bertin did not anticipate a split of the plane into four equiangular parts. Instead, he resorted to a trial-and-error approach and stopped when he reached a perceptual configuration that was like "a square or a rectangle." Bertin's actions within the partitioned plane sketch indicate that he did not view the plane as a 360-unit composite angle that could be partitioned to produce other angles.

In conclusion, students can construct degrees as a unit of angular measure by taking a right angle as a 90-unit angular composite without viewing the plane as a 360-unit angular composite. Additional studies are needed to determine the prevalence of this conception of degree measure.

In the mathematics education literature, there is little research specifically on how learners understand geometric reflections. Recent studies, such as Yanik (2006, 2011), have investigated PTs' learning and understanding of geometric translations in a dynamic geometry environment. His findings revealed that PTs have motion view based on their understanding of parameters and domain because use of dynamic geometric software (DGS) (e.g., GeoGebra, Geometer Sketchpad) may have some limitations for promoting PTs' understanding of geometric reflections as a mapping view. For instance, when they click on the "reflect about line" to perform a reflection, it is possible that they think of the line of reflection as a tool rather than a geometrical object. In other words, when students use features of dynamic geometric software such as the dragging modality, they may focus on as physical representations of the figures (e.g., movement of figures). Taken together, these empirical studies show that learners usually have a motion view of geometric reflections, which prevents their development of a mapping view. To help students develop a mapping view of reflection as a transformation, teachers need to know what factors are effective in facilitating the students' transition from motion view to mapping view (Hollebrands, 2003; Yanik, 2006).

The purpose of my study is to explore and investigate pre-service teachers' (PTs') understanding of the geometric reflections. To do this, I aimed to develop a model, a genetic decomposition of PTs to identify how schema development occurs between motion understanding and mapping understanding, what factors are effective to facilitate this development. To conduct this investigation, I created an environment in which I can explore PTs' schema development on geometric reflections paper-pencil. I will use clinical interviews to collect my data since it is difficult to observe PTs' understanding with direct observation. To explore PTs' understanding, I will use the Action-Process-Object-Schema (APOS) theoretical perspective as the conceptual framework. The research questions that will guide this study are as follows:

1. How does PTs' motion view of geometric reflections develop into a mapping view?
2. What factors facilitate PTs' motion view of geometric reflections into a mapping view?

Addressing the research questions of this study will be useful for teaching geometric reflections in the K-12 mathematics curriculum. More importantly, the findings and conclusions of this study will answer questions raised by the research community in regard to how motion view evolves and generate mapping view.

GEOMETRY REPRESENTATIONS: WHICH ONES AND WHY DO TEACHERS USE THEM?

Waldemar W. Stepnowski
Temple University
wstepnowski@temple.edu

Keywords: Geometry and Geometrical and Spatial Thinking, Mathematical Knowledge for Teaching, High School Education

Understanding representations and their place in the high school mathematics curriculum is vital to the study of geometry. Duval (2006) examined representations in a theoretical manner dividing them into four categories of a two-by-two matrix of discursive/non-discursive and mono-functional/multi-functional. Ainsworth (2006) devises a more practical approach in her DeFT framework. Pimm (2002) explored representations in a different manner, more specific for math education than Ainsworth; his descriptions of the many different representations are detailed and exhaustive.

In the presnt study, I follow Pimm's (2002) example, and list and analyze the representations presented in high school geometry classrooms. I observed five public school teachers in the Northeastern US during regular lessons on various content in geometry. After the observations, teachers shared their reasons for choosing the representations during recorded interviews. I analyzed the observations and the interviews looking for how often teacher used representations and common reasons for choosing them.

The teachers used many of the representations Pimm (2002) described like algebra, language, and coordinate grid. From the observations and interviews, I divided the geometry representations into thirteen categories: (1) spoken language, (2) written language, (3) gestures, (4) sketches/diagrams, (5) symbols in statements (e.g. $\angle A \cong \angle B$), (6) numerical, (7) algebraic expressions, (8) graphs on coordinate grid, (9) constructions with compass, straightedge, and other tools (10) physical objects, including manipulatives, (11) tables, (12) construction in dynamic geometry software, and (13) animations. Some representations were used more often than others; for example, spoken language and gestures were used by all teachers during all lessons, while animations and physical objects rarely and by only some teachers. Teachers had a hard time explaining the reasons for using certain representations. During the interviews, they often said that they did not think about it, that it was in the textbook, that it motivated students, that it was what the content required at the time, or that it was spontaneous.

Such results require more studies on representations and how they are taught in geometry. It seems that teachers do not have the background to discuss representations and to determine which ones are most useful in teaching certain concepts. They often rely on the textbook, spontaneity, or prior experience, and not on theory, which needs to be taught to pre-service teachers.

We present data from a semester-long teaching experiment (Steffe & Thompson, 2000) examining preservice secondary teachers' covariational reasoning (Saldanha & Thompson, 1998). We use Piaget's (2001) distinction between figurative thought and operative thought to characterize the circle concept of one participant, Lydia. We define a figurative circle concept as an individual's ability to recognize or re-present a circle as a static form. In contrast, an operative circle concept includes an individual's mental image of a segment rotating about a fixed endpoint while the other endpoint traces out a circular path. We analyze Lydia's activities in two tasks—Going Around Gainesville (GAG) and Where Did They Go? (WDTG). In GAG, Lydia observed an animation of a car driving along a path from Atlanta to Tampa; a semi-circular portion of the path was centered about the city of Gainesville. We asked Lydia to create a graph relating the car's total distance traveled to the car's distance from Gainesville during the trip. In WDTG, we provided Lydia with a Cartesian graph displaying a car's distances from two cities, A and B. We asked Lydia to produce a path that the car could traverse to satisfy the graph.

Lydia exhibited a figurative circle concept in both tasks. Upon recognizing a semi-circular path in GAG, she drew in radii before concluding that the distance from Gainesville was invariant; this invariance was not available to her without carrying out the sensorimotor activity. As Lydia considered a horizontal segment on the WDTG Cartesian graph, she recalled that the curved path in GAG resulted in an invariant distance; however, the invariant distance did not necessitate a circular path in WDTG for Lydia. Instead, she relied on drawing particular curves and judging viability based on perceptual instantiations of the relevant distances. We hypothesize that an operative circle concept might have supported Lydia's covariational reasoning on these two tasks.

MOVING BEYOND THE MORE A–MORE B CONCEPTION OF THE RELATIONSHIP BETWEEN AREA AND PERIMETER

Jane-Jane Lo
Western Michigan University
jane-jane.lo@wmich.edu

Keywords: Geometrical And Spatial Thinking, Middle School Education

Area and perimeter are important geometrical measurement concepts in school curricula. They build upon the ideas of linear measurement in the early grades and serve as the basis of topics such as fractions and multiplicative reasoning in the middle grades as well as the 3-D geometrical measurements in the upper grades. Prior studies have found the relationship between the area and perimeter to be a challenging topic (Battista, 2007). Often, students believe that an increase in area for a given shape results in an increase in perimeter of that shape, or vice versa. Tirosh and Stavy (1999) suggested that this misconception is rooted in the More A–More B intuitive rule. The goal of this study was to explore the visual and intuitive reasoning behind seventh-grade students' conceptions of area and perimeter. Particularly, this study sought to identify the concept definitions and images (Tall and Vinner, 1981) middle school students had about area and perimeter that could be used to build rich tasks that can further their development.

This study was conducted in a rural school district in a Midwestern town. The participants included 17 seventh-grade students. Each student was interviewed individually at the school, for 45 to 60 minutes, on a variety of measurement topics, including a task that asked students to find ways to cut a piece a piece off while making the perimeter bigger, stay the same or smaller. While the majority (13 out of 17) of the students initially believed that the shape with smaller area would have a smaller perimeter, 12 of them came up with some examples of shapes that would have smaller areas but either the same or a longer perimeter. Their examples and the reasoning provide a much richer set of concept definitions and images than have been documented in previous studies. For example, the idea that more turns or more segments would create a longer perimeter generated similar concept images for many students, but some students created a longer perimeter, while others did not.

Based on the concept definitions and concept images identified by this study, I proposed an instructional sequence to help students get a deeper understanding of the concepts of area, perimeter, and their relationship. Future study is needed to examine the effectiveness of such activities in helping students build a more solid understanding of area, perimeter, and their relationship. It would also be interesting to see if the effect of this sequence of activities can be transferred to the relationship between surface area and volume.

AFFORDANCES OF THE CULTURAL INQUIRY PROCESS IN BUILDING SECONDARY MATHEMATICS TEACHERS' CAPACITY FOR CULTURAL RESPONSIVENESS

Frieda Parker
University of Northern Colorado

Over the last couple of decades, there has been a growing call for teachers to become more responsive to the increasing cultural diversity of students as a means of improving students' experiences in school and their learning outcomes. Challenges exist in working with secondary mathematics teachers due to the common belief that math is culture-free and the lack of images of culturally responsive teaching in secondary mathematics classrooms. In this research, we explored the affordances of the Cultural Inquiry Process project in building inservice secondary mathematics teachers' capacity for cultural responsiveness.

Keywords: Equity and Diversity, Teacher Beliefs, Teacher Education-Inservice/Professional Development

Over the last couple of decades, there has been a growing call for teachers to become more responsive to the increasing cultural diversity of students as a means of improving students' experiences in school and their learning outcomes (Banks, 2001; Gay, 2010; Nieto, 2004). Studying culturally responsive teaching specifically within secondary mathematics education is important because mathematics education is its own cultural system (Nasir, Hand, & Taylor, 2008) and understanding that system is necessary for the types of awareness teachers need to be culturally responsive. In addition, supporting secondary mathematics teachers to be culturally responsive holds particular challenges. Mathematics is often seen as "culture-free" (Bishop, 1988), which can make the role of culture in the teaching and learning of mathematics more difficult to envision, especially as compared to language arts and social studies content. Related to this, there are few images of what culturally responsive teaching looks like in mathematics classrooms (Leonard, Napp, & Adeleke, 2009), which may contribute to the struggles mathematics teachers have in operationalizing cultural responsiveness in their practice (Morrison, Robbins, & Rose, 2008). Furthermore, secondary students often have particularly negative attitudes towards and low engagement with mathematics (Nardi & Steward, 2003), which can make it more challenging for teachers to interest students in the content.

In this study, we explored the nature of teachers' perspective changes that resulted from their completion of the Cultural Inquiry Process (Jacob, Johnson, Finley, Gurski, & Lavine 1996) project. The goals of the study were to describe teachers' perspective changes, relate these changes to how the teachers engaged with their CIP project, and analyze how this engagement may reflect a process of learning to be culturally responsive.

Rationale for Implementing the CIP Project

The purpose of the CIP project is "to broaden teachers' understanding of culturally diverse students and to maximize these students' success" (Jacob et al., 1996, p. 30). In the CIP project, teachers select a student whose behavior is puzzling, hypothesize potential cultural influences on the student, gather information about the student, design an intervention to support the student, and evaluate the intervention outcomes. Once the project is completed, the teacher turns in a report describing their work and reflecting on the experience.

We chose to use the CIP project with teachers because it is a form of action research. Action research has generally been established as a viable means of supporting teachers in improving their practice, understanding better themselves and their students, and developing dispositions to continue studying their practice (Zeichner, 1993). Also, because action research is situated in the teacher's setting, teachers can generate images of what a particular change looks like. Furthermore, action research can support teachers in co-developing their beliefs and practices. While debate exists whether to prioritize building teachers' beliefs or behaviors, Gay (2010) argues that, "The more important issue is that examining beliefs and attitudes about cultural diversity, *along with* developing cognitive knowledge and pedagogical skills, are included as essential elements of teacher education" (p. 151).

Besides being a form of action research, we valued the CIP focus on exploring cultural influences on students' engagement in school. Jacob suggests that teachers in the United States tend to develop tacit knowledge of students in terms of psychology, thus leaving teachers less equipped to understand students in terms of culture. The goal of the CIP project is to "provide teachers with new ideas and approaches they can use in the future in culturally diverse classrooms" (Jacob et al., 1996, p. 32). We also valued the CIP's focus on specific students, which as Jacob et al. (1996) argue, provides an opportunity for teachers to consider culture at a personal level rather than relying on cultural generalities. Lastly, we appreciated the CIP website (http://cehdclass.gmu.edu/cip/g/gs/gs-top.htm) created by Jacob to support teachers in conducting the CIP.

Theoretical Perspectives

We drew on two theoretical perspectives for our research.

Cultural Responsiveness

In order to analyze the degree to which teachers' perspective changes aligned with being culturally responsive, we used a framework we developed in related research (Parker, Bartell, & Novak, 2015). We view cultural responsiveness as dispositions grounded in cultural awareness to work to know, understand and support the engagement and learning of all students. Culturally responsive teachers, then, work to understand students' cultures and backgrounds and using such knowledge to support students' learning and cultural competence. Additionally, these teachers develop supportive student-teacher relationships based on culturally responsive care, have positive attitudes toward students' knowledge and experiences (i.e., reject deficit perspectives), and hold high expectations for student learning and achievement.

Critical Perspective

Another disposition scholars have identified as important to cultural responsiveness is being able and willing to employ a critical perspective to surface, question, and, when appropriate, change the normative beliefs and practices that may influence students' engagement and success in school (Bartolome, 2004; Valencia, 2010). Bartolome (2004) has described two aspects of this critical perspective: political clarity and ideological clarity. Political clarity includes being able to understand the influence of the broader culture, such as political, economic, and social variables, on subordinated students' academic performance. Ideological clarity includes being able to explore the ways in which one's own beliefs uncritically reflect those of the broader culture. With political and ideological clarity, teachers are able to understand the role of culture in creating a status quo and to make visible the beliefs and practices embedded in that status quo as a means of questioning how normative beliefs and practices may be limiting some students' access to school success.

In order to analyze how teachers' engagement with the CIP project might support teachers in developing cultural responsive dispositions, we analyzed the degree to which the teachers were able to surface, question, and ultimately change their beliefs and practices around normative practices when these practices appeared to be hindering students' success in school. We focused on examining how teachers critically examined the beliefs and practices related to their expectations for student behavior since perspective changes teachers described in their projects mostly related to their expectations of student behavior. This likely occurred because the project involved teachers selecting students about whom they were puzzled and this puzzlement invariably involved why students were not behaving in desirable ways, with "desirable" being a value embedded in school culture. Attending to student expectations is important because it is an aspect of school culture that commonly influence student success - particularly underserved students (Lane, Wehby, & Cooley, 2006; Valencia, 2010). To understand whether teachers were able to enact the process of exploring normative practices with respect to their influence on student success, our data analysis involved juxtaposing teachers' perspective changes with their self-described normative beliefs and practices related to their expectations for students' behavior. Finally, to understand the nature of the teachers' perspective changes, we analyzed the perspective changes against our framework for cultural responsiveness.

Data Collection and Analysis

The course that served as the context for this study was called *Culture in the Math Classroom* (CIMC). It was a required course that was part of a graduate program for practicing secondary mathematics teachers at a public doctoral-granting university in the Rocky Mountain region. The data we collected were 58 CIP projects submitted by teachers over four semesters of the CIMC course. The mathematics teaching experience of the teachers ranged from 2 to 22 years, with an average of 7 years. Almost all of the teachers identified as white. About 60% were women and 40% were men. The teachers taught in suburban or rural schools that typically had 27-35% minority students. Hispanic students were the largest minority group in most schools. The schools had 7-10% of students classified as English language learners and between 26-43% classified as low-socioeconomic status.

Our research questions were:

1. How did teachers' perspective shifts relate to their normative beliefs and practices about student expectations?
2. To what extent did the teachers' perspective shifts indicate a building of capacity to engage in culturally responsive pedagogy?

For data analysis, we drew on narrative inquiry, which is a set of tools and perspectives based on the idea that it is possible to explore how people make sense of their experiences through the stories they tell (Clandinin & Connelly, 2000). We chose narrative inquiry because 1) we wanted to understand teachers' perspective shifts in terms of their experiences conducting the CIP project and 2) the CIP project reports typically were written as stories.

The first step in analyzing the project was to identify projects with valid perspective changes. To do this, we included in the data analysis pool only those projects in which the teachers 1) followed the CIP project guidelines, 2) wrote reflections that appeared to align with their project activities, and 3) included in their reflections a description of a perspective change likely to influence their practice. Thirty of the 58 projects met all three of these criteria. The focus students in the 30 projects consisted of 12 girls and 18 boys. Four of the students were identified as white and in 12 cases, the student's race or ethnicity was not specified by the teacher, likely because the focus student was white. In 14 projects, the teachers identified their focus student as being of mixed race/ethnicity (N=3), Hispanic (N=8), African-American (N=1), or Native American (N=2).

The next step in the data analysis was to identify the student expectations the teachers' perspective changes related to. In 28 of the 30 projects, the teachers explored one or more of the following student expectations:

- Students should seek help if they are struggling (N=8).

- Students should complete their homework (*N*=14).
- Students should engage in class discourse (*N*=8).
- Students should value learning mathematics (*N*=6).

For each student expectation, the set of projects involving this expectation were analyzed to discern the normative beliefs and practices the teachers associated with the expectation, the types of interventions the teachers implemented to address their focus student's behavior, and the nature of the perspective changes the teachers described.

Normative Beliefs and Practices about Student Expectations and Perspective Shifts

For each of the four normative student expectations we identified in the teachers' CIP projects, we illustrate the beliefs and practices associated with them by describing how the teachers identified the expectation, why they believed the expectation was important, and how they typically responded to students who did not comply with the expectation. We then describe the types of interventions the teachers implemented and the perspective shifts the teachers had with respect to the student expectation.

Students Should Seek Help if They Are Struggling

Eight projects focused on the expectation that students should seek help if they are struggling. Half of these teachers mentioned that they thought the struggling student should seek help because not seeking help was limiting the student's success. Seven of the teachers provided some indications of how they would normally respond to struggling students who did not actively seek help. Four teachers suggested they would have responded in a limited way. For example, one teacher said he would invite students in for assistance outside class, but if they did not take him up on his invitation, he would not pursue the issue further. Another teacher said she would help the student pass the course, but would not think more broadly in terms of getting the student support outside of class. Statements made by three teachers indicated they would not actively respond to the student. For example, one teacher wrote that initially he had assumed that his focus student did not care about learning. Another teacher wrote that at the outset of the project he did not know how to support shy, low-achieving students.

The intervention teachers often selected for their focus student involved additional tutoring outside class. Sometimes the teacher did the tutoring and sometimes another tutor was found. Another intervention was changing seating arrangements in class so the student was more comfortable talking to at least one classmate. Other interventions were particular to the focus student's needs. For example, one teacher wanted to build the focus student's confidence in discussing mathematics and arranged for the focus student to be a tutor.

Themes in the teachers' perspective shifts included 1) the teacher needed to be proactive in finding additional supports for the struggling student and 2) in order to provide appropriate supports, the teacher needed to communicate with the student to understand the student's perspectives, issues, and goals.

Students Should Complete their Homework

Students needing to complete their homework was addressed in almost half (*N*=14) of the analysis pool projects. Seven of these teachers focused exclusively on supporting their student to complete homework and another five teachers focused on homework as well as the student's participation in class discourse. Typically, homework completion, and sometimes correctness, was part of the course grade, so when students did not complete their homework, their course grade suffered. However, the teachers believed that doing homework improved a student's learning of the mathematics, and this in turn, affected how well students performed on assessments, which also affected the course grade. The majority of teachers (*N*=10) made statements suggesting they did not initially have a way of responding to students who do not complete their homework. Four of these teachers attributed a student not completing homework to characteristics of the student and/or their family.

Teachers created different types of interventions to support their focus student with completing homework. Six teachers focused on the student feeling more comfortable and successful in class, such as by interacting with the student more often. Four teachers focused on helping the student be more organized to know what the homework assignments were, when they were due, and what materials were needed. Two teachers found time for their student to start homework in school. Two teachers changed their homework policies to accommodate their students. One of these teachers decided to grade only the homework the student completed in class, as long as the student did well on assessments. The other teacher disallowed partial credit for late homework for the focus student as he admitted he postponed doing homework if he knew he had some leeway.

Teachers indicated that they learned that a student not completing homework was not necessarily because the student was lazy or did not value their learning, but instead may be due to psychological or logistical issues that could be addressed at school. One teacher found out his focus student had experienced a trauma the previous year for which she had kept silent and therefore had not received any support. Once that was addressed, her school engagement, including homework completion, improved. Besides the two teachers who elected to change their homework policy, two other teachers questioned how they were approaching what they assigned for homework and even the necessity of homework. While these teachers decided to retain homework in the short run, they indicated they thought that homework merited further consideration. Most of the other teachers indicated that they could influence a student's tendency to complete homework by building a better relationship with the student so that the student felt cared for by the teacher and so the teacher better understood the student's needs.

Students Should Engage in Classroom Discourse

Eight teachers expressed concern that their focus student did not engage appropriately in classroom discourse, such as contributing to whole class discussions or engaging productively with group members. Only one teacher focused exclusively on this normative expectation. Other teachers lumped this with one or more other behaviors, such as not completing homework. Two teachers described reasons for students to engage in classroom discourse other than it generally supporting student learning. One teacher explained that the curriculum she used included an expectation that students discuss their ideas with each other. The other teacher cited research that reported good social skills were valued by employers. The teacher believed that high school was a good time for students to develop these skills. None of the teachers indicated ways in which they would normally respond to students who did not engage in classroom discourse. One teacher noted, "As a staff we have focused on the students that are culturally different for more visual reasons (e.g., race, clothing, etc.) but we haven't focused on the other students who are culturally different for less obvious reasons such as beliefs about social interactions."

Teachers' interventions for addressing this normative expectation included redirecting off-task behavior, changing the student's seat assignment, assigning competence to the student (Horn, 2012), speaking directly with the student about what behavior is desired and why, providing positive reinforcement for the desired behavior, and developing a closer relationship with the student.

Teachers' reflections focused on what they had learned about their ability to influence the classroom culture, which in turn could influence student engagement.

Students Should Value Learning Mathematics

Instead of focusing on the student's behaviors, six teachers ended up attempting to address their student's lack of interest in learning mathematics. In all but one case, the teachers' puzzlements were focused on their students' behaviors, but after speaking with their students during data collection, they decided to address their students' motivation to learn mathematics. These teachers did not provide much detail on why the students should value learning school mathematics, although, in the context of the project, there was an implicit assumption that students valuing learning mathematics would lead them to be more successful in class and even in completing high school. The teachers did not indicate they had particular ways of addressing their students' lack of interest in learning mathematics. One reason for this is captured in a teacher's question: "How do you reach a student who does not see value in mathematics?" which suggests readily available methods of approaching this issue were not known.

All of these teachers included as part or as the entirety of their intervention creating one or more lessons they believed incorporated context that would have more meaning for their focus student and possibly the class as a whole. In their project reflections, all six teachers indicated they felt more empowered to influence students' interest in mathematics by introducing context in their instruction that related better to students' lives.

Perspective Shifts and Cultural Responsiveness

The normative expectations teachers focused on in their projects were behaviors and attitudes teachers believed students should comply with to be successful in school. Teachers who reflected on their own beliefs and lived experiences found the normative expectations so obviously appropriate that they had a hard time imagining why someone would not follow them, except if the person were somehow "faulty," such as being lazy or not caring about their education. When the teachers attributed non-compliance to a student's inherent characteristics, the teachers typically did not feel able to address the mismatch between students' behaviors and what was expected of them.

While the teachers tended to focus on one, or at most two, of the four identified normative expectations of students, the teachers typically expressed perspective shifts in more general terms about how to approach supporting students. We found that overall, teachers' perspective shifts aligned with some aspect of the following narrative:

> I need to be proactive in knowing my students' backgrounds, perspectives on school, and goals. This process of knowing my students allows me to understand how to meet my students' needs and helps me to build better relationships with my students. Often, my assumptions about the student, such as that they do not care about their education or are lazy, are incorrect. Instead, school policies and the classroom culture can be negatively impacting students' engagement. Working on making the classroom a safe place, creating lessons that are meaningful to students, and implementing supports outside the classroom are within my power as a teacher.

No teacher expressed a perspective shift that encompassed the entirety of this narrative. However, most teachers emphasized one or two elements of the overall shift. This narrative contrasts with the teachers' normative beliefs and practices as it expresses:

- A stronger sense of responsibility for getting to know their students and responding to their needs
- An awareness that their assumptions about their students' perspectives and capabilities might not be accurate
- More self-confidence in their ability to design effective interventions for students

- More open-mindedness in considering the need to change their practices or school policy to better support students

The perspective shifts indicated by the teachers suggest they built their capacity for being culturally responsive in that teachers were more willing to take up the work of understanding and supporting students, less likely to engage in deficit thinking, and more confident and open in their thinking about ways to support students' school engagement and achievement.

In terms of developing a critical perspective, the teachers in this study appeared to exhibit more ideological clarity than political clarity in that they questioned their personal normative beliefs and practices related to the expectations they held for students, but did not reflect on the influence of the broader school and societal cultures. This could be a function of the CIP project or the way it was facilitated. It could also be representative of the way in which people's cultural awareness evolves "from a self-centered state to identification with society and eventually to the larger global community" (McAllister & Irvine, p. 18, 2000).

Discussion

The nature of the perspective changes teachers expressed aligned with being culturally responsive in that teachers indicated an increased willingness and confidence in reaching out to, understanding, and supporting students they initially find puzzling. We cannot make definitive claims about what aspects of the CIP project might be responsible for the ways teachers engaged with and learned from the project, but we do believe that the project characteristics we identified in our rationale to implement the CIP are likely mechanisms. Another factor might have been teachers' propensity to be empathetic towards their students. Teachers sometimes wrote about their experiences with their students in moving and passionate ways. Goodman's (2000) research suggests that empathy is often one of the orientations that can move people from privileged groups to take action towards social justice. It is possible many of the teachers in the CIMC course had this orientation, which contributed to their engagement with and learning from the CIP project. Understanding what teachers may bring to the work of building cultural awareness can support teacher educators in conceptualizing teachers as "competent learners who bring rich resources to their learning" (Lowenstein, 2009, p. 187).

Additional factors may have influenced teacher engagement with the CIP project. First, during the project implementation, the instructors offered feedback to the teachers at several points, which may have also influenced teacher thinking. Second was their participation in the CIMC course. The course content and other activities may have supported the development of knowledge and skills that pre-disposed teachers to explore the role of culture more successfully than they would have otherwise. The beginning of the course delved into theoretical foundations by asking: What is culture? How can examining students' home culture influence their experiences at school? Is mathematics culture-free? What are the central tenets of culturally relevant pedagogy? The remainder of the course explored issues involving culture and student learning including student motivation, status and small group work, language in the classroom, the purpose of mathematics education, and teaching math for social justice. Teachers also completed projects analyzing case studies, exploring an aspect of their local community, and implementing a change in their instruction to improve student motivation.

A limitation of our work is that we did not follow the teachers into their schools and classrooms after they completed the course, so we cannot describe what teachers brought into their ongoing practice. An area of further exploration would be to explore the impacts on teachers' cultural awareness and cultural responsiveness in the projects where teachers did not indicate a perspective change. In half the projects, though, teachers' engagement with the CIP project indicated they created experiences in their practice that modeled being culturally responsive and developed their own perceptions about how this would influence their practice going forward. The CIP project, then, appears to have affordances for building the capacity of secondary mathematics teachers for being culturally responsive.

With online learning becoming a more viable option for teachers to develop their expertise, our report shares one such effort focused on improving the teaching of statistics. We share design principles and learning opportunities, as well as discuss specific impacts evident in classroom teachers' course activity concerning changes to their beliefs and perspectives about statistics. Specific course experiences that served as triggers for critical reflection are discussed.

Keywords: Teacher Education-Inservice/Professional Development, Teacher Beliefs

Statistics has gained a prominent place in middle and high school curricula through the National Council of Teachers of Mathematics (2000), Common Core State Standards (National Governors Association Center for Best Practice & Council of Chief State School Officers, 2010), and recommendations endorsed by the American Statistical Association (Franklin et al., 2007; Franklin et al., 2015). Professional development (PD) for secondary teachers to develop their statistical content and pedagogy are being offered across the country, typically on a small local scale, and these often include focused evaluation and research efforts to document impacts. However, the need for preparing teachers to teach statistics is much bigger than what can be addressed with small local programs. In this paper, we discuss a way of leveraging the internet to assist in a solution that is free, open access, and can reach many more teachers across geographic boundaries (Kim, 2014). With an online solution at a much larger scale, methods for examining impacts must also evolve. We offer a glimpse at one effort to use course participants' online activity, forum discussions, and self-reported changes on surveys as a way to measure impact.

For a "massive" and "open" course, there are many design challenges to meet the needs of participants with varied backgrounds. Massive Open Online Courses (MOOCs) are designed and delivered in a variety of ways, depending on learning goals for participants, to serve different target populations and provide diverse experiences for learners. In recognizing the potential for MOOCs to serve as large-scale PD, some are crossing local boundaries to design MOOCs specifically for Educators (MOOC-Eds, Kleiman, Wolf, & Frye, 2014). Those that engage in and study impacts of professional development for mathematics and statistics teachers must consider how this new frontier can potentially assist in developing teachers' content understanding and pedagogical strategies for improving practice, and forming global communities of educators. To contribute to the synergistic discussion needed at this crossroad, our focused question for this report is:

> *How can the experiences in an online professional development impact participants' perspectives about the nature of statistics and teaching statistics? Which resources and experiences in the course seem to influence any changes in perspectives?*

Literature and Framework

Beliefs and perspectives about statistics include a teacher's ideas about the nature of statistics, about oneself as a learner of statistics, and about the classroom context and goals for students' learning statistics (Gal, Ginsburg, & Schau, 1997; Pierce & Chick, 2011; Eichler, 2011). Certain beliefs would likely lead to different teaching practices. For example, if a teacher believes that statistics is a way of quantifying data and that the many procedures available in statistics for computing measures lead to such quantification, his or her teaching practices may favor a focus on statistical procedures and have less emphasis on the context of the data, the process of ensuring good data is collected and available (sampling methods), and making claims about data that are uncertain in nature (Pierce & Chick, 2011). Eichler (2011) further discusses how the focus of teachers' intended curriculum in statistics can be considered on a continuum from traditionalists (focused on procedures absent of context), to those wanting students to be prepared to use statistics in everyday life (focused on engaging in an investigative process that is tightly connected to contexts of real data). A goal in statistics teacher PD is to move teachers along this continuum towards a focus on investigative processes, which requires impacting teachers' beliefs about the nature of statistics and learning goals for students related to statistics.

Professional development that includes accessible, personalized, and self-directed elements can provide increased opportunities for sustained, collaborative and meaningful work among teachers that can affect their knowledge, beliefs and practice (e.g., Vrasidas & Zembylas, 2004). Researchers have found that online professional development (OPD) that addresses the varied needs and abilities of its participants can be effective in changing teachers' instructional practice (e.g., Renninger et al., 2011; Yang & Liu, 2004). Designers of OPD should be especially mindful that activities are meaningful, accessible and relevant so that participants can apply their learning to their educational context (Ginsburg, Gray, & Levin, 2004; Vrasidas & Zembylas, 2004).

Just as communities of practice can exist in face-to-face PD, OPD should facilitate development of an online community of practice (CoP). Researchers have highlighted benefits of such communities that are not always afforded in traditional face-to-face PD. For example, Mackey and Evans (2011) argued that online CoPs provide members with "extended access to resources and expertise beyond the immediate school environment" (p. 11), thereby offering ongoing PD and the potential for increased application in their classroom. Designers of OPD should build infrastructure to support such communities across geographic and time zone boundaries. Asynchronous discussion forums, for example, provide opportunities for participants to reflect on practice, exchange ideas, and discuss ways to improve on their own schedules with colleagues with whom they may not otherwise interact (Treacy, Kleiman, & Peterson, 2002).

While making changes in teachers' statistics teaching practices and ultimately changing students' learning of statistics is a major goal, we are guided by the integrated model for PD proposed by Clark and Hollingsworth (2002). In this model, they represent the change process for teachers through PD as being one that includes reflection and enactment among an external domain and a teacher's professional world that includes domains of personal, practice, and consequence. The external domain includes information and resources often experienced through a PD, including interactions with others. In our study the external domain includes the resources in the OPD and the discussions with others in forums. The personal domain includes one's knowledge beliefs and attitudes. The practice domain includes any professional experimentation, with content or instructional strategies, and the domain of consequence is concerned with salient outcomes that result in practice. Because of the massive size of our OPD about teaching statistics, we are most concerned with the reflections and enactments between the external domain (experiences and resources in the OPD) and the reflections and enactments we can discern concerning their beliefs and perspectives about statistics and teaching statistics. Though some teachers may be able to engage in professional experimentation during the course, this is hard to examine given everyone's different curriculum and timing of when statistics units may be taught. To aid us in considering how PD experiences may have an impact on teachers' beliefs and perspectives related to statistics, we draw upon Mezirow's (2009) theory of transformational learning in adult education. Specifically, we are interested in what stimulus in the OPD (external domain) may act as triggers to evoke dilemmas (or cognitive dissonance) for teachers where they question their understandings or perspectives that have been formed from prior experiences.

Online Professional Development Context

The MOOC-Ed effort at the Friday Institute for Educational Innovation includes several courses built using research-based design principles of effective PD and online learning (Kleiman, Wolf, & Frye, 2014) that emphasize: (a) self-directed learning, (b) peer-supported learning, (c) job-connected learning, and (d) learning from multiple voices. One such course, *Teaching Statistics Through Data Investigations* [TSDI], aimed to have participants think about statistics teaching and learning in ways likely different from their current practices and past experiences. The course did not focus on a particular grade band or specific statistical content. A major goal was for teachers to consider statistics as an investigative process, promote statistical habits of mind, and view learning statistics from a developmental perspective.

The TSDI course consisted of an orientation unit and five units (http://friday.institute/tsdi). The course was open for about 15 weeks to allow for flexibility for participants to engage while managing their busy professional lives. Units began with an Introduction video of the instructor highlighting critical aspects of teaching and learning statistics in the unit. The Essentials included materials to read or watch. The design principle of learning from multiple voices guided the decision to include many videos of Expert Panel discussions with the instructor and three experts in statistics education. Multiple voices were also present in many classroom videos with teachers and students working on statistics tasks using various technology tools, as well as, animated illustrations of real students' work were created (using tools like Go Animate or Powtoon) that represented students' statistical reasoning and use of technology tools.

Self-directed and job-connected learning opportunities included Dive Into Data experiences in each unit for participants to use a variety of free technology tools (e.g., Gapminder, Tuva, CODAP, GeoGebra simulations) or import data into their own data analysis tool (e.g., Fathom, StatCrunch). These experiences allowed teachers to use tools accessible in their schools and connected them to relevant and free sources of data that can be useful in their lessons. For example, in Unit 4, the Dive Into Data used the Census at Schools website and asked teachers to download data and engage in statistical investigation. Extensions in each unit include extra resources (e.g., data sets, lesson plans, brief articles, java applets, additional videos) and provide self-directed opportunities to explore resources that may be useful in their educational context.

Peer-supported learning is a cornerstone of the MOOC-Ed experience. Since participants are geographically dispersed, it is important to provide focused and ample opportunities for them to connect with and support one another in learning and applying the material in the course. Each unit contains two discussion forums: 1) a forum focused on discussing a specific pedagogical investigation about aspects of teaching statistics (e.g., analyzing statistics tasks, considering students' approaches to statistics tasks through video clips), and 2) a forum where participants start their own discussions about unit materials or other ideas related to teaching statistics.

Building upon an existing framework (GAISE, Franklin et al., 2007), the development team incorporated recent research on students' statistical thinking and productive statistical habits of mind into a new framework, Students' Approaches to Statistical Investigations [SASI]. There were several learning opportunities for participants to develop an understanding of its importance and potential ways it can influence teaching. The diagram in Figure 1 shows the investigative cycle, reasoning in each phase can occur at three levels of sophistication, and productive habits of mind. Two brief PDF documents described statistical habits of mind and the framework. In a video, the instructor illustrated the framework using student work from research, and another video featured an expert illustrating development of the concept of mean across three levels. Participants could watch two animated illustrations of students' approaches to an investigation using different levels of statistical sophistication and then discuss students' work. More details about the design of the TSDI course can be read in Lee and Stangl (2015).

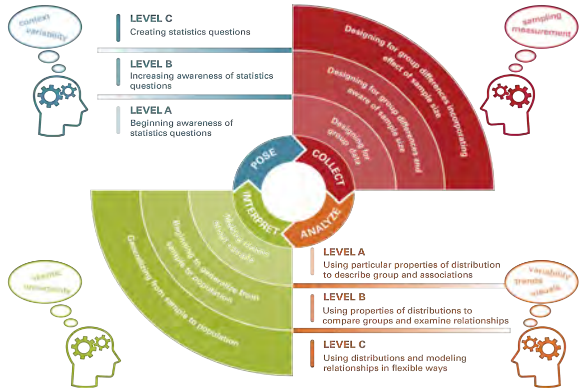

Figure 1. Framework for supporting students' approaches to statistical investigations.

Methods

Participants

Though the course is offered several times per year, we focus here on Fall 2015, the second run of the course. The course was advertised through many different organizations (NCTM, ASA, CAUSEweb), social media posts, state-level leaders in mathematics education, and personal contacts. Enrollment was free and open. For the purpose of this paper, we are only interested in how course experiences could be impacting beliefs and perspectives of K-12 classroom teachers. From registration (n=827), we discerned demographic characteristics and focused on those participants self-classified as classroom teachers (n=489). The classroom teachers resided in 46 states and 29 countries, with majority in the US (n=380) and New Zealand (n=48). The majority were female (67.5%) and 72.8% had a master's degree or above. Their years of experience in education were evenly distributed, creating a diverse community with varied teaching experiences that impact their starting perspectives and growth opportunities. Of those 489 self-identified classroom teachers, we confirmed 412 were actively working in K-12 contexts (e.g., some classified themselves as classroom teachers but taught community college).

Data Sources and Analysis Methods

Aside from registration data, four other data sources were used. Course activity was tracked through click logs that allowed us to examine trends in participants' engagement with material. Qualitative data was collected from three sources: 1) posts in discussion forums (two per unit, for a total of 10 forums), 2) open-ended responses to end-of-unit and end-of-course surveys, and 3) a follow-up survey sent 6 months after the course to inquire about how participants may have applied their learning and what they considered the most impactful ideas from the course.

All registration and click log data was merged and displayed in a dashboard in Tableau that allowed investigators to visualize participants' engagement over time and with certain types of resources. The dashboard facilitated the ability to filter by role of classroom teacher, so that we could examine and report on trends of the 489 participants classified as classroom teachers. Descriptive statistics and graphical displays were used to examine engagement patterns. All discussion forum log data was filtered to only include posts from those classified as classroom teachers. Because our research question was focused on how K-12 classroom teachers' beliefs and perspectives may be impacted by course experiences, it was important to maintain information about which activity and unit the discussion forum was embedded in, but not information about all posts from all participants. For the results reported in this paper, we are not discussing the impacts of particular ideas posted by participants or the social networks that formed in the forums as an indication of a community of practice (this is part of a larger study). The 977 discussion forum posts were analyzed using open coding guided by our focus on change in beliefs and perspectives related to teaching statistics. Each post was considered a unit of analysis and we were specifically coding instances where teachers self-reported changes or shifts in their beliefs and perspectives. The coded posts were sorted until four themes emerged. Within the themes, the posts were re-examined and tagged for evidence of what seemed to be triggering the change in perspective. We documented which triggers were most prevalent and only kept triggers associated with many instances of impacts on perspectives and beliefs, and discarded those only occurring once or twice. These themes and triggers were then used to examine responses on the end-of-units, end-of-course, and follow-up surveys. While we were looking for confirming and disconfirming evidence of themes and triggers, disconfirming evidence was not evident and no new themes or triggers were documented.

Results

Engagement

When registration opened, participants could enroll and engage in the Orientation unit that included an overview video, survey to self-assess their confidence in teaching confidence, and an introduction forum. Each unit opened in weekly intervals for 5 weeks, with earlier units always accessible when later units opened. This allowed for participants to start and engage in course material on their own time and pace, which is part of the self-directed design principle. Once Unit 5 opened, the entire course remained active for seven more weeks. After the course closed, participants could still access course material and read discussion forums in a read-only format (no new posts allowed in forums). In this way, the course site remained an open resource.

Overall, a majority (n=370) of enrolled classroom teachers engaged in various aspects of the course. Thus, we use 370 as the number of classroom teachers who began the course. With respect to accessing the course by units, the greatest number of classroom teachers accessed Unit 1 followed by Unit 2. In Unit 1, 293 classroom teachers engaged, but by Unit 5, only about 25% (n=92) of the classroom teachers that began the course had accessed material. The number of classroom teachers accessing the course in Units 3-5 was relatively the same, indicating that most classroom teachers who engaged through Unit 3 finished the course in its entirety.

The most accessed resources were discussion forums and videos (instructor videos, expert panel, and classroom and student work videos). 206 of the classroom teachers who began the course (56%) posted to a forum. The frequency of posts per teacher who engaged in forums is a skewed distribution (Figure 2), with 57% of teachers posting 1-3 times (typically in Units 1-2), 38% posting 4-14 times across several units, and 11 very active teachers posting 15-45 times. The levels of engagement in discussion forums and videos were highest in Units 1 through 3. Teachers' highest level of engagement with videos was in Unit 3 where 93 teachers took advantage of the video-based learning opportunities related to the SASI framework.

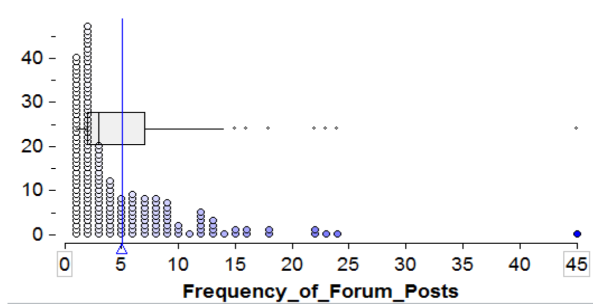

Figure 2. Frequency of posts per teacher across all discussion forums.

Impact on Perspectives and Beliefs

Looking carefully at themes from our coding, we saw four major ideas emerge related to how teachers' beliefs and perspectives may have changed:

1. engaging in statistics is more than computations and procedures and should include investigative cycles and habits of mind;
2. engaging in statistics is enhanced by the use of dynamic technology;
3. engaging in statistics requires real (and messy) data; and,
4. statistical thinking develops along a continuum.

Due to space limitations, we only elaborate on the first and last with examples from teachers.

We noticed a shift begin in Unit 1 with participants thinking about statistics as *more than computations and procedures*. This was expanded by posts in later units and evident in the survey responses. There were two aspects to this shift in perspective. The first seemed to be a realization that the statistics they experienced and that they tend to teach was too focused on procedures, and that this focus was not aligned with what they were experiencing in TSDI. For example, a teacher started a discussion thread detailing a dilemma because of points made in a video by statistics education experts in Unit 2. The extensive post began as:

> I had a "lightbulb moment". Although I have been teaching HS math for 24 years, I have never actually taught "statistics" as defined by the members of the expert panel. I have taught units that I THOUGHT were statistics, but I was merely providing students with a few mathematical tools that statisiticians [sic] can use (e.g. finding a mean, making a histogram, calculating a standard deviation, etc.)...(female, 24 yrs experience)

Twelve participants joined that discussion, 10 of which were teachers. They echoed that they were "guilty" of teaching statistics this way and that their own prior experiences in learning statistics treated the subject in a procedural manner. Similar discussions and replies about this issue were also started by several others. Teachers also recognized that attending and engaging in all parts of an investigation would give students opportunities to make sense of how statistics is used to answer questions and how important data collection (or experimental design) is to the process. Many admitted they spent little time on this with students and aimed to improve.

Related to the final idea that emerged, teachers seemed to realize that statistical thinking and understanding develops across a continuum and that they can use this to think about instructional decisions and assessment of students. "The idea of the 4 process cycle and the different levels for different ages of each process, has helped me lot. I understand more and feel I am a better teacher to my students" (female, 15 yrs experience). Considering statistics as developing across levels seemed to impact many teachers. For example, after commenting on students' work in a video and describing what levels she thought students may be working at, a teacher (10 yrs experience) noted, "with the SASI framework, I like how it never mentions age or grade level. I feel it's a continuum that students, depending on the context, can move back and forth between. If they get to a harder problem, they may not know how to exactly collect the data without bias and ensuring randomness. But with an easier experiment, that may be more obvious to them."

Triggers for Dilemmas

Four elements emerged as often cited for triggering critical reflection that had impacts on beliefs and perspectives about statistics and teaching statistics. By far, the *SASI framework* (and associated documents and multimedia) was the most dominant trigger for change. The *expert panel video discussions* and the *videos of students and teachers* engaged in statistics tasks were also dominate triggers to assist teachers in reconsidering their prior experiences in learning and teaching statistics, and help them envision a different outcome for their students if they change their practices. The *use of technology for visualizing data with real data* that are multivariable and “messy” was an additional trigger that seemed to impact perspectives. The technology experiences directly influenced their ideas that engaging in statistics is enhanced by using dynamic technology tools and real world messy data. These triggers came from learning opportunities that included videos of students and teachers engaged with messy data using technology, discussions in expert panel videos, and opportunities to Dive into Data. Two frequently referenced experiences were using the Gapminder tool, and engaging with Census at School. When asked the most valuable thing they learned on a follow-up survey, a teacher responded as follows, with triggers bolded that may have sparked her learning.

> “The most valuable aspect of the MOOC was obtaining **resources for the improved use of technology** to make instruction come to life and be more meaningful to students. I was able to **see the statistical process in action** and now have an idea of **what it should look like in the classroom**.” (female, 19 yrs experience)

Discussion

One of the challenges in designing OPD for teachers is identifying how to leverage stimuli that has the potential to act as triggers to impact teachers’ beliefs about teaching. For those who are at a crossroads facing this challenge, whether face-to-face or online, our identification of triggers can provide guidance as they embark on PD efforts for teachers. While we have no evidence (yet) that teachers experiences in a brief OPD in teaching statistics has impacted actual teaching practices and students’ learning, our research indicates that the purposeful design elements of the course were successful in causing critical reflection through certain triggers. Many teachers appear to have moved along the continuum described by Eicher (2011) towards beliefs that we should engage students in doing statistics through investigations, not merely teach them mathematical tools to apply to numbers devoid of context.

Teachers are attracted to and can make sense of how frameworks apply to their practice and within the context of their learning environments. In addition, they learn a lot from expert opinions (beyond just a single PD instructor), as well as from the voices and experiences of other teachers with whom they collaborate with as part of the course. These voices act as additional resources outside of their physical school environment (Mackey & Evans, 2011) to impact their perspectives about statistics and teaching statistics. In accordance with other researchers, the discussion forums indeed provided opportunities for critical reflection about teaching statistics.

Teachers also learn a lot about what it means to engage in statistics, by doing it, as well as from examining students’ thinking. Is any of this a big surprise? Perhaps not to experienced teacher educators. However, the key is to include these types of learning opportunities and potential triggers in professional development that occurs online, whether it is to a local group or massive and open to teachers around the world. Our research also supports the idea that online professional development that emphasizes: (a) self-directed learning, (b) peer-supported learning, (c) job-connected learning, and (d) learning from multiple voices can be effective for areas in mathematics education (e.g., teaching statistics) that need wide-scale efforts.

The following research report documents a professional development that focused on promoting understanding of algebraic learning progressions across vertical teams of elementary and secondary teachers. Analyzing quantitative data from the pre and post MKT assessment and qualitative data from lesson reflections and final course reflections, revealed multiple outcomes for teachers. More specifically, elementary teachers had lower MKT than the secondary teachers in both pre and post assessment, and teachers exhibited a significant increase in their MKT as a result of the program. Further, all teachers gained more in depth knowledge about the learning progression of algebra through collaboration in vertical teams and revealed a focus on improving pedagogy through the use of high leverage teaching practices.

States and districts often have to realign their curriculum when standards are revamped. In fact, forty-two states, the District of Columbia, four territories, and the Department of Defense Education Activity have adopted the Common Core State Standards and had to undergo realignment with their curricular standards (NGACBP & CCSSI, 2010). Although our state did not adopt the Common Core State Standards, the state standards were revised and realigned with some standards expanded to bring more rigor, depth, and breadth to the learning objectives. As district leaders, mathematics educators, and teacher leaders worked with classroom teachers to unpack the standards, we designed professional development that focused on helping teachers learn the mathematics concepts more deeply by mapping out the learning progressions that will guide the sequence of concepts crucial in building mathematical understanding. The importance of this knowledge for teachers leads to a critical, practical question: what professional development experiences are necessary for teachers to develop an understanding of the learning progression in algebraic thinking?

This study is aimed at examining the ways in which the designed professional development can engage teachers in deepening their understanding of algebra. Further, we wished to explore how engaging in vertical teams for collaborative planning of lessons can help teachers at different grade levels better understand students' learning progression of algebraic thinking.

Theoretical Framework

In the math community, the term "learning progression" has been used to describe the vertical articulation of standards with an emphasis on conceptual understanding (Confrey, 2012; Confrey, Maloney, & Corley, 2014; Wilson, Mojica, & Confrey, 2013). Understanding of learning progressions is important for teachers; they serve as the guidepost for analyzing student learning and tailoring their teaching sequence (Wilson et al., 2013). A research-based learning progression also informs how mathematical content knowledge and conceptual understanding for students develop over time.

Understanding How Vertical Knowledge of the Curriculum Contributes to Teachers' Mathematical Knowledge for Teaching

Mathematics knowledge for teaching (Hill, Sleep, Lewis & Ball, 2007) includes understanding of general content but also having domain specific knowledge of students. Teachers with mathematical knowledge for teaching must have an extensive and complex set of knowledge and skills that facilitates student learning across the learning progressions so that they learn the structure and relationship of students' understandings about a particular mathematical concept, teach specific strategies to elicit student thinking, strategically evaluate students' responses, and move the mathematical agenda forward (Wilson et al., 2013).

An example of the importance of learning progressions is found in the research on developing algebraic reasoning in the earlier grades through problem solving which requires depth of understanding. Blanton and Kaput (2008) reported that teachers become better at teaching algebraic reasoning when the teachers' own mathematical knowledge and understanding was increased and their algebra "eyes and ears" allowed them to bring out the algebraic reasoning while looking at student work and listening to their discussions and questions. To know what to look and listen for in the classroom, teachers must have a deep and profound understanding of the foundational concepts for algebraic reasoning through patterning, relations, functions, and representations using algebraic symbols and utilizing mathematical models to represent relationships (NCTM, 2000).

The knowledge of learning progressions is vertical knowledge. Vertical knowledge includes "familiarity with the topics and issues that have been and will be taught in the same subject area during the preceding and later years in school, and the materials that embody them" (Shulman, 1986, p. 10). This vertical knowledge can be supported through knowledge of learning trajectories and vertical teaming by teachers. Confrey states that using learning trajectories, teacher can "plan their instruction based on how student learning progresses. An added strength of a learning trajectories approach is that it emphasizes why each teacher, at each grade level along the way, has a critical role to play in each student's mathematical development" (Confrey, 2012, p. 3). However, teachers do not have frequent opportunities to work with teachers from different grade bands. Understanding the learning progression across grade levels requires the collaboration of teachers through meaningful vertical articulation and PD.

Context: Detailing Our PD Design and Activities

The designers and instructors of this project included a university mathematics educator, a mathematician, teacher leaders from the districts, and doctoral students in mathematics education. This PD was conducted as year one of a three-year Mathematics Science Partnership grant focused on algebraic thinking and proportional reasoning during the transition years from fifth grade into high school. We based this project's design on the current research and needs in mathematics education with a specific attention to creating opportunities for vertical articulation focused on algebraic learning progressions as students move into high school algebra. We considered all the core features of effective mathematics PD which includes having content as the focus, being sustained over time, collective participation of teachers working together on issues central to instruction, and focus on instructional materials that teachers use in their classrooms (Desimone, 2009).

To focus teachers' work with content, we used NCTM's standards (2000, p. 39) and explored the algebraic learning progression beginning with recursive patterns, representing mathematics situations with quantitative relationships, multiple representations of functions, including numeric, graphic, and symbolic, since the representational fluency develops a deeper understanding of functions (Moschkovich, Schoenfeld, & Arcavi, 1993). Weekly activities in content-based class sessions included modeled lessons using rich tasks combined with in-depth conversation about both the algebra content and the pedagogical strategies employed by facilitators. In addition, a centerpiece of the PD experience was having teachers learn about the high leverage practices outlined in the *Principles to Action* (NCMT, 2014), and asking teacher teams to select a goal that they wanted to focus on for improving their practice. Many of the teacher teams selected goals of facilitating meaningful discourse and posing purposeful questions. In addition, we shared Smith and Stein's (2011) *5 Practices for Orchestrating Productive Mathematics Discussions* with the PD participants and guided their use of the five practices in the planning and implementation of their lessons.

We conducted two iterations, each with a different cohort of teachers, of the content-focused course which included either a follow up Lesson Study or participation in a video-based teacher study group in school based vertical teams. We focused on engaging teachers in active learning through algebraic problem solving tasks and exploring pedagogical strategies. Our goal was to deepen teachers' algebraic thinking, encourage vertical articulation, and develop a productive disposition towards teaching through problem solving. The follow-up sessions were designed to provide teachers with continued support in professional learning implementing algebraic content, as well as providing opportunities for vertical articulation between and among grades levels.

Methods

For our study, we used a mixed methods approach to examine the outcome of the PD focused on learning progressions and vertical teaming of teachers. The quantitative research focused on examining teachers' content knowledge and the qualitative research focused on professional growth as identified by teachers' reflections.

Participants

The data were collected from the teachers who participated in the two cohorts. A total of 54 teachers participated in the study, 23 of whom were in Cohort 1 and 31 in Cohort 2. Most teachers worked in public schools (N=51 from seven school districts). A total of 35 schools were represented with 21 schools being represented by one teacher, nine schools by two teachers, and five schools by three teachers. The teachers also held various positions at their schools: elementary school teachers (N=22), secondary teachers (N=25), special education teachers (N=3), ELL teachers (N=1), and coaches (N=1). Two teachers did not report their positions. Specifically, the participants taught Grade 2 (N=1), Grade 3 (N=2), Grade 4 (N=3), Grade 5 (N=11), Grade 6 (N=11), Grade 7 (N=9), Grade 8 (N=3), and Grade 9 (N=6). Eight teachers did not indicate which grade they taught. On average, the teachers (N=52) had 9.42 years of teaching experience (SD=7.42) with a minimum of 0 and a maximum of 30 years.

Data Sources

Quantitative data. Prior to the beginning of the PD program, the Mathematics Knowledge for Teaching (MKT) of the participating teachers was assessed (Learning Mathematics for Teaching, 2007). Specifically, they completed the 2007 Middle School Patterns Functions and Algebra – Content Knowledge instrument, administered in two forms (N=24 for Form A; N=30 for Form B). At the end of the program, the same assessment was administered again (N=30 for Form A; N=24 for Form B). All teachers completed different forms for the pre and posttest. The forms were assigned to the teachers randomly. Due to non-equivalence of the test forms, teachers' raw test scores were converted into IRT scores, which were used in the analysis.

Qualitative data. The qualitative data sources included final course reflections, teacher reflections from lessons, video clips from the research lessons. To delve in deeper into the nature of the collaborative exchange, we collected a final course reflection, that the researchers created for the second PD cohort, which asked teachers to reflect on the nature of the vertical professional learning and how the focus on an instructional practice by the team contributed to their professional learning.

We chose one of the video-based teacher study groups as a case that provided us the best opportunity to learn about how team members exchanged professional knowledge within the video lesson analysis.

Research Questions

1. What differences did we see in content knowledge of teachers at different grade levels?
   - Do the two cohorts of teachers differ in their MKT over the PD program?
   - Do elementary and secondary teachers differ in their MKT over the PD program?
2. What did teachers identify as areas of professional growth from their vertical teacher study groups focused on algebraic thinking and enhancing their instructional practices?
   - How did vertical teaming enhance teacher's planning and instruction?
   - What is the nature of the collaborative learning that teachers identified through their work with peer study groups?

Data Analysis

The quantitative data were statistically analyzed using IBM SPSS Statistics 22. To begin analyzing the themes in the qualitative data, we systematically analyzed the data by developing initial codes and used the method of axial coding to find categories in such a way that drew emerging themes (Miles, Huberman, & Saldaña, 2013). To verify and compare recurring themes and categories, the research team worked individually on coding the documents before comparing preliminary codes in order to agree upon recurring themes from the reflections. Dedoose, an internet-based data management tool (Dedoose Version 6.2.7) was used to code and analyze the data. Initial codes reflected specific teacher practices and actions (e.g., posing purposeful questions, learning content from peers, anticipating student responses). As codes were categorized, several main themes emerged: improved pedagogical practice due to instructional strategies, improved content knowledge; supporting student thinking in algebra; improved pedagogical practice resulting from collaboration, and gaining vertical knowledge of content from peer collaboration.

Results

Quantitative Results

The descriptive statistics for the pre and posttest IRT scores are presented in Table 1. In addition to the total, descriptive statistics by Cohort and Position at school are also presented. Due to the sample size restrictions, only elementary and secondary positions are considered (secondary teachers include both middle and high school teachers).

To further explore teachers' MKT, we conducted a comparative analysis for the cohorts and teachers' positions (a Bonferroni correction was employed). First, to determine if there was a difference between the two cohorts on the pre and posttest, we conducted independent-samples t-tests. The results showed that the cohorts did not differ in MKT either on the pretest *($t(52)=0.741$, $p=0.462$)* or on the posttest *($t(52)=0.428$, $p=0.670$)*. Second, to determine if there was a difference between the pre and posttest for the two cohorts, we conducted paired-samples t-tests. The results indicated that teachers in Cohort 2 scored higher on the posttest than on the pretest *($t(30)=-2.546$, $p=0.016$)*; however, no difference was observed between the pre and posttest scores for Cohort 1 *($t(22)=-1.219$, $p=0.236$)*.

Next, to determine if there was a difference between elementary and secondary teachers on the pre and posttest, we conducted independent-samples t-tests. The results showed that the elementary teachers scored lower than secondary teachers on the both pre *($t(45)=-3.948$, $p=0.000$)* and posttest *($t(41.811)=-3.785$, $p=0.001$)*. Finally, to determine if there was a difference between the pre and posttest for the elementary and secondary teachers, we conducted paired-samples t-tests. The results indicated no difference between the pre and posttest scores of either elementary *(t(21)=-2.248, p=0.035)* or secondary *(t(24)=-1.060, p=0.300)* teachers.

Table 1. Descriptive Statistics for the Pre and Posttest of MKT

Measure	Mean (SD)				
	Total (N=54)	By Cohort		By Position	
		Cohort 1 (N=23)	Cohort 2 (N=31)	Elementary (N=22)	Secondary (N=25)
Pretest	-0.049 (1.000)	0.068 (0.918)	-0.137 (1.063)	-0.532 (0.749)	0.497 (1.000)
Posttest	0.185 (0.917)	0.248 (0.936)	0.139 (0.915)	-0.244 (0.632)	0.645 (0.962)

Research question #1a. First, we aimed to determine whether the two cohorts differed in MKT over time. To answer this research question, we conducted the two-way mixed design ANOVA with Cohort (Cohort 1 and Cohort 2) as a between subject factor and Time (pre and post) as a within subject factor. The results indicated the main effect of Time *(F(1, 52)=6.502, p=0.014)*, i.e., teachers' scores, averaged across cohorts, were higher on the posttest than on the pretest. However, there was no main effect of Cohort *(F(1,52)=0.393, p=0.534)*, i.e., teachers' scores, averaged across time, did not differ between the cohorts. Additionally, no interaction effect of Time and Cohort was observed *(F(1, 52)=0.289, p=0.593)*. Thus, considering these results and comparisons above, we decided to combine the two cohorts for the further analysis.

Research question #1b. Next, we aimed to determine whether elementary and secondary teachers differed in MKT over time. To answer this research question, we conducted the two-way mixed design ANOVA with Position (elementary and secondary) as a between subject factor and Time (pre and post) as a within subject factor. The results indicated the main effect of Position *(F(1, 45)=17.084, p=0.000)*, i.e., elementary teachers had lower scores on MKT, averaged across time, than secondary teachers. The comparisons above also suggest that elementary teachers had lower MKT on both pre and posttest. Additionally, there was the main effect of Time *(F(1, 45)=5.187, p=0.028)*, indicating that teachers' scores, averaged across positions, were higher on the posttest than on the pretest. However, according to the comparisons above, when the teachers are split into elementary and secondary levels, the effect of time does not hold for either level. This finding is also consistent with the absence of the interaction effect of Time and Cohort *(F(1, 45)=0.532, p=0.470).* Larger sample sizes may be needed to determine differences within the levels (i.e., elementary vs. secondary).

Qualitative Results

While the MKT results showed that teachers overall made gains in their content knowledge as a result of the PD, they also reported, universally, through the qualitative data that the PD led to improvement in their understanding of algebraic content and pedagogy for math instruction. We will next examine reflections of the teachers from the second cohort to identify which particular benefits the teachers gained from the PD.

Vertical teaming and its impact on teacher's planning and instruction of algebra across the learning progression. All of the second cohort teachers who completed the final reflection indicated that they learned from their peers and found added value in that learning because the teams were made up of teachers from multiple levels (i.e., elementary and secondary). Barbara, an algebra teacher, described the benefit of working in vertical teams:

> There really should be more collaboration between elementary, middle, and high school. I loved hearing from the elementary teachers because of all their use of manipulatives and their different approaches can also work for high school and be helpful, especially for low level students.

By working together in vertical teams, the teachers built a broader foundation of both personal understanding of content and knowledge of how students at different levels (both in age and readiness) approach algebraic thinking. Ralph, a 5th grade teacher stated:

> The wide-range of grade levels that are taught within our group served as a catalyst for a deeper understanding of the levels of reasoning and problem-solving students are at and what can be achieved during those levels and what can be and needs to be done for those that may be behind developmentally.

Finally, teachers indicated that they had a firmer grasp of the learning progression necessary for students to succeed in algebraic thinking at all levels. Rebecca, a 4th grade teacher shared:

> I really was able to open my eyes to how the ideas that start in early elementary are so foundational to how students think when they get to their algebra class. The connections that can be built through patterns and being able to recognize them is so valuable.

Collaborative professional learning through teacher study groups. Consistent with the quantitative results, almost all participants (30/32) specifically indicated that working with their peers improved their knowledge of math content. More than half (18/32 total teachers) identified that they learned math content from their colleagues: elementary teachers learned to see equations and formal algebra from their secondary colleagues (10/18 elementary teachers) and secondary teachers learned to utilize manipulatives and visual models from their elementary colleagues (8/14 secondary teachers). In fact, most teachers indicated that working with peers expanded their knowledge of diverse strategies and the use of varied representations when solving problems (29/32). Jan, an 8th grade math teacher elucidates this idea:

> Being able to see how others approach problem-solving was very enlightening. It was so interesting to me to see that there are so many different ways of solving problems. I was never taught and haven't felt comfortable using manipulatives, etc., but I really appreciated seeing this strategy being used. Now when I look at a problem, I am able to see different ways of approaching it.

Teachers also learned to improve their pedagogy through collaboration with their peers. Half the teachers made specific comments that their pedagogical practice improved due specifically to their interactions with their peers (16/32). Elizabeth, a 5th grade teacher, stated, "I liked brainstorming with my group members and thinking outside of my box. I realized that anticipating the questions that students might ask prior to the lesson is very helpful!" Further, Jocelyn, a middle school math teacher reflected that, "Working with the group helped frame the plan of what ideas to share and how to make those mathematical connections between the students' strategies and the 'Big Ideas'."

While teachers' reflections offered insights into their thinking, their video discussions allowed us to view their practice. We selected one case study that we felt demonstrated notable exchanges among team members in regards to the benefits of collaboration. The team was composed of five teachers, ranging from 2nd grade to 8th grade algebra. The study group chose a growing toothpick pattern task which they modified for implementation at each grade level. We coded the commentaries from the collaborating teachers on each video. These exchanges revealed ways in which peers exchanged their knowledge for teaching and assisted one another. One of the major themes was how peers validated each teacher's instructional practices.

Ann, a 4th grade teacher presented the Hexagon Pattern. A peer-teacher, Karen, commented that Ann did not jump in to tell a student she had the wrong number of toothpicks for two hexagons. Instead, Ann allowed the student to discover the error when building the pattern.

> *Karen:* I love how you didn't originally tell her that 12 was wrong, she noticed it was wrong when she got up to place the toothpicks!

Another peer-teacher, Holly, viewing Ann's lesson commented on Ann's use of posing purposeful question to follow up on the student's discovery:

> *Holly:* Purposeful questions - "If we know that hexagons have 6 sides and we are building 2 then why do we have 11 toothpicks instead of 12?" Great job!

In another notable exchange, two teachers share the challenge of knowing and gauging the right balance between allowing students to experience "productive struggle" and knowing when to ask a probing question while commenting on a lesson taught in Micki's classroom.

> *Micki:* Another moment where a purposeful question would have been helpful. This student got stuck and I gave her time to think, believing I was supporting productive struggle, but I should have left her with a question to help move her thinking along.
> *Sara:* Sometimes it is really hard to find that balance of when to let them keep going with the productive struggle and when would it be better to give them a purposeful question to help them along. Remember hindsight is 20/20 and it is why we should always reflect on our lessons. If you do another activity with your class before the end of the year, you will know this student needs a little more support.

Conclusions and Implications

For several decades, the mathematics education community has focused their attention on the importance of the *Mathematical Knowledge for Teaching* (Hill et al, 2007) that defines the deep, broad, and well connected knowledge that is needed to decompose and unpack content to make it comprehensible by students. In addition to conceptual understanding of the knowledge needed for teaching, teachers must have command of high leverage teaching practices. Our PD design focused on the task of exposing teachers to the complexity of ambitious teaching. To examine the benefits of participation in our PD, we conducted a mixed-methods study.

With our quantitative analysis, we found that teachers were able to gain significant knowledge during the PD course. Our qualitative results supported the increase in teachers' content knowledge and also indicated learning benefits beyond the content knowledge; the teachers content scores did not tell the whole story. In particular, perhaps the most encouraging result from our study is the notion that PD utilizing collaborative, vertical teams of teachers can contribute to teachers' professional learning as they examine their practice and work to improve their pedagogical skills. The evidence also suggested that validation from their peers supports teachers' continued growth. As we consider Synergy at the Crossroads, mathematics educators and researchers may consider providing more opportunities for teachers to work in vertical professional learning communities focused on understanding the mathematics learning progressions in future PD offerings to increase teachers' MKT and improve their practice.

Acknowledgments

This PD was supported by the TRANSITIONS grant from the Virginia Department of Education Mathematics and Science Partnership.

MATHEMATICS TEACHERS' TAKE-AWAYS FROM MORNING MATH PROBLEMS IN A LONG-TERM PROFESSIONAL DEVELOPMENT PROJECT

Serife Sevis

rhudson@usi.edu

Considering the role of mathematics-focused professional development programs in improving teachers' content knowledge and quality of teaching, we provided teachers opportunities for dealing with mathematics problems and positioning themselves as students in a large-scale long-term professional development (PD) project. In this proposal, we aimed to understand the impact of engaging in morning math problems on teachers in terms of their mathematical understanding and teaching practices. Both written work and interviews showed that solving open-ended problems helped teachers better understand the mathematics content and students' challenges as they solve problems; thus, suggested an effective means of PD for teachers.

Keywords: Teacher Education- Inservice/Professional Development, Problem Solving

As many teacher education researchers highlighted, mathematics-focused professional developments play a central role in efforts to improve teachers' knowledge base (Ball, 1990; Hill, 2007; Moss, 2006). Through encountering mathematics problems and positioning participating teachers as students, we sought to improve not only the teachers' mathematical content knowledge but also pedagogical knowledge, pedagogical content knowledge, and beliefs about what it means to 'do' mathematics. Considering this role, we aimed to provide teachers opportunities of dealing with mathematics problems and positioning themselves as students in a large-scale long-term professional development (PD) project. Each professional development session started by asking teachers to work on authentic and challenging mathematics problems. We also interviewed teachers at the end of the project to learn their thoughts about morning math sessions, the nature of the math problems they worked on, and what they learned about mathematics and mathematics teachers. We particularly focused on the following research questions:

1. What do teachers think about the role of morning math sessions on their improvement as mathematics teachers?
   1.1. What did teachers gain in terms of mathematical content from morning math sessions?
   1.2. What did teachers gain in terms of mathematics teaching from morning math sessions?

We found these questions significant to investigate to better understand the role of teachers' solving math problems and experiencing student position as a means of professional development. Thus, this study links to the conference theme, *Synergy at the Crossroads: Future Directions for Theory, Research, and Practice*, in that it introduces a promising component of professional development for mathematics teachers, discusses the role of morning math sessions in improving teachers' mathematics teaching practices, and makes suggestions for future directions to develop more effective professional development sessions for mathematics teachers.

Theoretical Framework

Teacher Knowledge and Role of PD in Teachers' Knowledge Development

Over the last 40 years, understanding what teachers need to know has become one of the most important concerns in the field of education (Cochran-Smith & Lytle, 1999). While some studies have focused on the knowledge that teachers need to know as professionals (Grossman & Richert, 1988; Shulman, 1987), others have aimed to understand the knowledge that teachers need to know for the practice of teaching (Hiebert, Gallimore, & Stigler, 2002). Cochran-Smith and Lytle (1999) took this distinction between professional and practitioner knowledge further and suggested three conceptions of knowledge: (1) knowledge-*for*-practice, (2), knowledge-*in*-practice & (3) knowledge-*of*-practice. Among these three conceptions, knowledge-*for*-practice referred to the formal knowledge that teachers gained in teacher education and professional development programs. In this vein, in the mid-1980s, Shulman (1987) had proposed seven categories of teacher knowledge: (i) content knowledge; (ii) general pedagogical knowledge, with special reference to those broad principles and strategies of classroom management and organization that appear to transcend subject matter; (iii) curriculum knowledge, with particular grasp of the materials and programs that serve as "tools of the trade" for teachers; (iv) pedagogical content knowledge, that special amalgam of content and pedagogy that is uniquely the province of teachers, their own special form of professional understanding; (v) knowledge of learners and their characteristics; (vi) knowledge of educational contexts, ranging from the workings of the group or classroom, the governance and financing of school districts, to the character of communities and cultures; and (vii) knowledge of educational ends, purposes, and values, and their philosophical and historical grounds. (p. 8)

Shulman argued that these categories constituted a teacher knowledge base which was supported by both theoretical and empirical sources of knowledge. Shulman's perspective viewed the teacher as a trained professional who could learn about subject matter, curriculum, educational philosophy and history and as an active member of a scholarly community, who could pursue and help others pursue intellectual development.

Understanding those categories of teachers' content knowledge provides a strong basis for designing effective teacher education and professional development opportunities. Especially, mathematics-focused professional developments play a central role in efforts to improve teachers' knowledge base (Ball, 1990). As argued by Moss (2006, p.97), "In order to encourage their students' mathematical thinking, teachers must be able to appreciate and evaluate the reasonableness of their thinking. However, to be able to do this, they must have for themselves a deeper understanding of mathematics." Thus, providing teachers opportunities of evaluating their understanding of mathematics is important for teacher development.

Five Practices for Orchestrating Productive Mathematics Discussions

The PD sessions at the focus of this study were designed using the five practices for orchestrating productive mathematics discussions (Stein & Smith, 2011); therefore, PD trainers demonstrated these five practices during morning math sessions. Stein and Smith (2011) developed these five practices to help teachers design and implement lessons involving mathematically rich discussions and enhancing students' mathematical understanding. Stein and Smith (2011) summarized these five practices as follows:

1. anticipating likely student responses to challenging mathematical tasks;
2. monitoring students' actual responses to the tasks (while students work on the tasks in pairs or small groups);
3. selecting particular students to present their mathematical work during the whole-class discussion;
4. sequencing the student responses that will be displayed in a specific order; and
5. connecting different students' responses and connecting the responses to key mathematical ideas (p. 8).

In addition to those, Stein and Smith (2011) proposed that setting instructional goals and selecting appropriate tasks could be viewed as the practice zero, which had to be ensured before five practices. It is important to note that these practices do not serve as a manual but suggest an effective way for teachers to characterize their work of orchestrating student-centered discussion by ensuring they make sense of students' work and connect students' thinking to the big mathematical ideas.

Mode of Inquiry

Professional Development Project and Participants

Approximately twenty-two elementary teachers from across three school districts participated in the two-year professional development program focused on preparing mathematics teacher leaders. The professional development program consisted of monthly sessions and intensive summer PD workshops. All sessions were focused on engaging teachers' in activities to develop their teachers' mathematical knowledge for teaching and leadership skills. They were involved in 16 monthly 8-hour workshops and 80 hours (10 days) of PD over two summers for a total of 26 workshops days. The sessions involved in a range of activities (e.g., video discussions, math content sessions, rehearsals etc.) and teachers were engaged in coaching sessions (McGatha, 2009) with the professional developers. In this study, we focus on the activities involved in one regular PD session we called *Morning Math*. During each Morning Math session, teachers were given a problem (or two) to solve. These problems were selected to not resemble typical textbook tasks; rather, they represented true problems for the teachers.

Data

In this proposal, we focused only on teachers' work on morning math problems during two summer PD sessions; a five-day PD in June 2015 and a five-day PD in July 2015. In particular, we examined teachers' work on four mathematics problems in June PD and five mathematics problems. The names of the problems that teachers worked during each PD session are given in the table below.

Table 1: Morning Math Problems

Name of the Math Problem	PD Session
Darts Remainder 4 Milk Chocolates Painted Cubes Rocket Science	June PD
Marbles Gum Drops The Sheep Activity Coin Sums	July PD

Although teachers worked on these problems in groups, they recorded their thinking on provided worksheets, and regularly recorded their work on large flipchart paper to share with peers. Furthermore, their group discussions were video recorded. In addition, teachers were individually interviewed. Thus, data set also consisted of transcriptions of teachers' interviews.

Data Analysis Process

In the initial round of data analysis, teachers' written work on math problems were analyzed based on content analysis for understanding the range of solutions (Neuendorf, 2016). Then, the video records of group working were analyzed using more focused coding about the ways in which teachers approached these problems. In the final round of data analysis, the teachers' interviews were examined using thematic analysis to understand whether teachers thought the morning math sessions impacted their practice as mathematics teachers (Clarke & Braun, 2013).

Findings

In this proposal, we only present teachers' work on the Milk Chocolates problem. To introduce the Milk Chocolates problem, we showed a box of chocolates as shown in Figure 1. We also provided a model of this chocolate box and asked whether they could find the number of milk chocolates in the box without counting. Moreover, we explained to the teachers that we were not only interested in the correct answer to the problem but also the ways in which they got the answer. Therefore, we asked them to find the answer in as many different ways as they could and record a numerical expression that modeled their thinking.

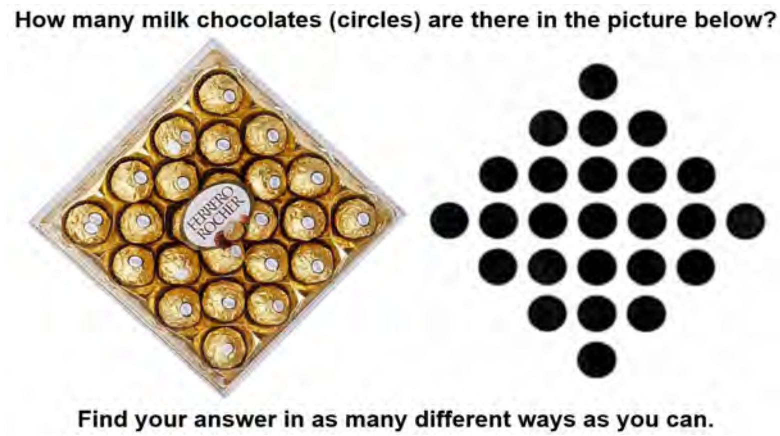

Figure 1. Milk Chocolates Problem (adapted from Balka & Hull, 2012).

Teachers' Content-Related Take-Aways

Teachers worked in groups of 2-3 and produced fifteen different solution methods as shown in Figure 2 below. As demonstrated by these solutions, teachers developed different ways of counting the chocolates in the box. When they started to work on this problem, they had not anticipated that there would be fifteen different solutions. As they solved the problem, we observed that they were changing their perspectives: "Ohh, okay. There might be a couple other ways to get the answer." As the discussion ensued and additional solutions were shared, they were very excited and engaged as they saw many different ways that their colleagues shared on the board.

This is also evident in their interviews that most of the teachers mentioned about more than one solution method when they were asked about morning math problems. The following excerpts illustrate this issue:

> Teacher A: I just learned different strategies during morning math and I learned, you know, not to give up and continue to keep trying.
>
> Teacher B: Well, there's definitely more than one strategy. One way to think about something that everybody takes a different way, and, um, it seems that when you work in groups, um, with the teacher walking around and kind of, like, monitoring.
>
> Teacher C: Just how many different ways people approach things. Because I try to think-- well, I seem to think kind of 1, 2, 3 stepwise. And then people are pulling out all this other stuff that I've never even dreamed of thinking of. So it's good to see all the different ways that people approach things.

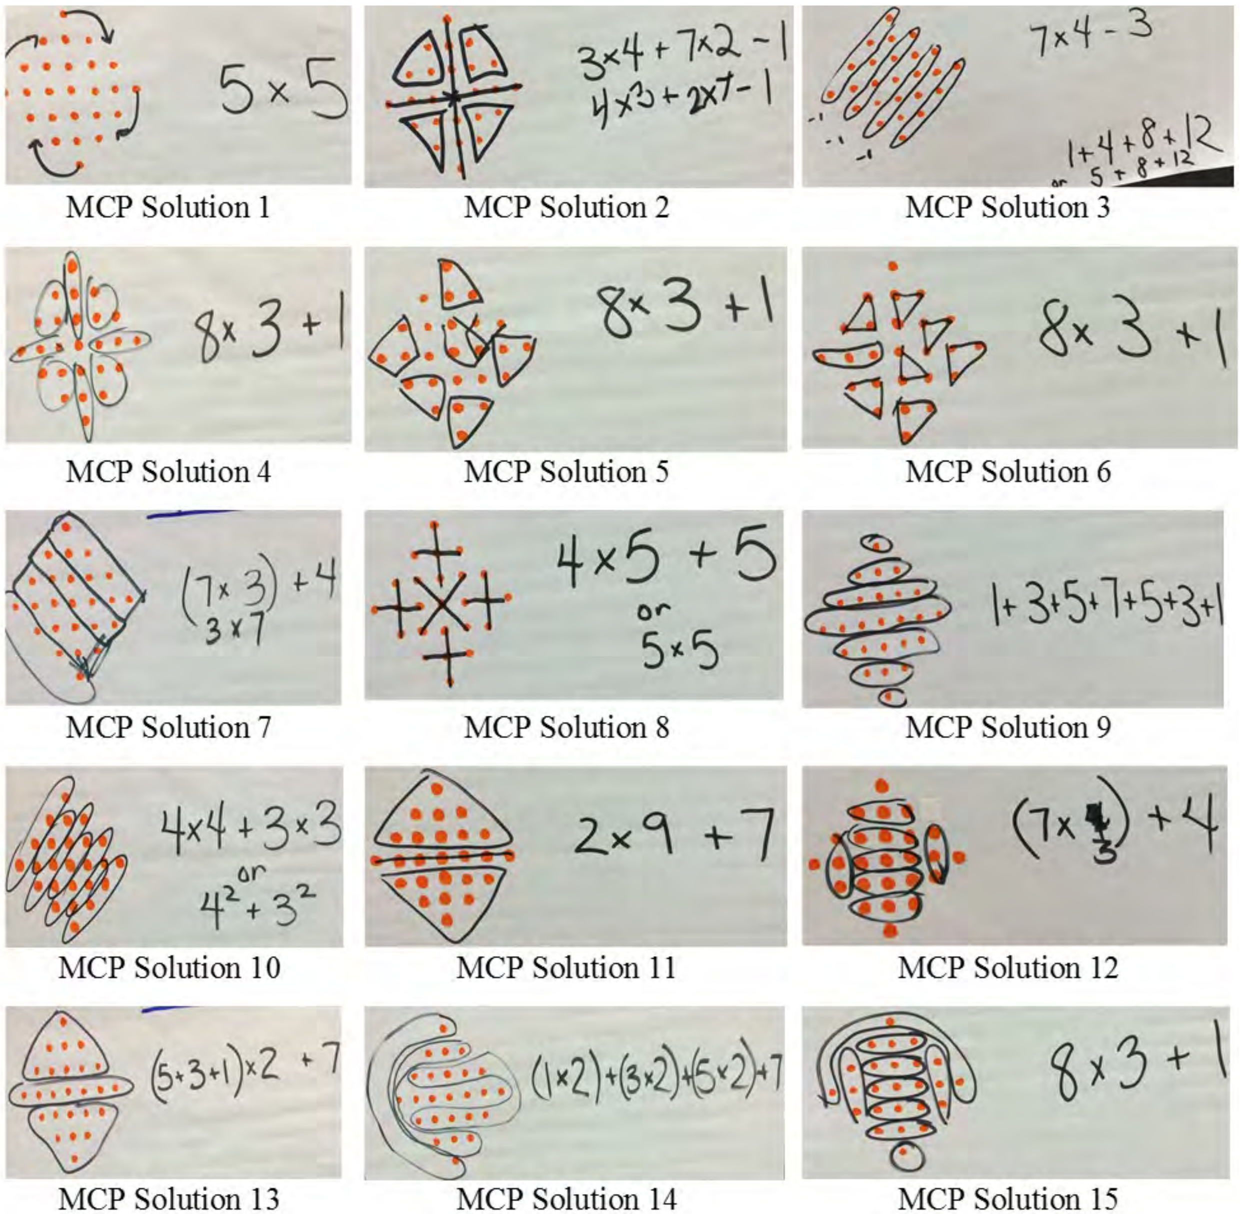

Figure 2. Teachers' solutions on Milk Chocolates Problem (MCP).

Like many other teachers, these three teachers highlighted different solution methods that were developed by other teachers and that they would not have anticipated otherwise. After sharing fifteen solutions to the milk chocolates problem, we asked teachers an extension question:

- What if the size of the box changes?
- Which method would you use to find the number of chocolates in these boxes (see Figure 3 below)?

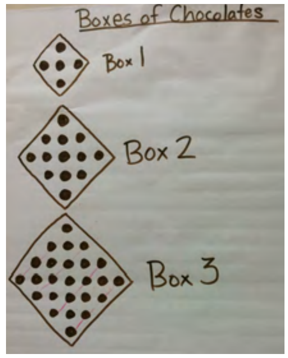

Figure 3. Milk Chocolates Problem Extension Part 1 (adapted from Goldenberg et al., 2015).

- If the pattern (shown in figure 3) continued, how could you find the number of chocolates in the box of any size? (i.e., Milk Chocolates Problem Extension Part 2)

In this extension part, teachers picked the method they thought to be more efficient to find the number of chocolates in Box n. It was challenging because not all of the solutions shown in Figure 2 led to a more general solution. Figure 4 presents four of the fifteen methods that teachers utilized to develop algebraic expressions.

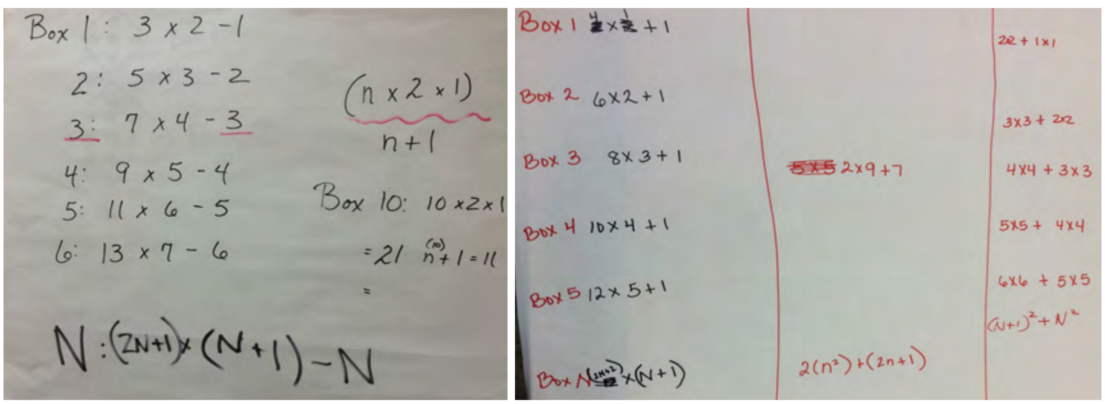

Figure 4. Teachers' Solution to the Milk Chocolates Extension Problem

After this work was shared by teachers, they engaged in a discussion about how they found different algebraic expressions and whether each of these expressions was a different one. During this discussion, teachers reached a conclusion that each of the methods showed them a pattern in counting, but these patterns resulted with the same simplified algebraic expression (i.e., $2n^2+2n+1$). Similarly, teachers had not thought that they would reach an algebraic expression with one unknown at the end of this problem, and they did, in fact, find the same expression even though they developed different solution methods.

Teachers' Teaching Practices-Related Take-Aways

During the interviews, teachers mentioned about morning math problems in relation to the 'selecting' and 'sequencing' practices:

Teacher D: Well, we worked on--there's usually--definitely there's more than one way to answer the problems and all of them and the way that he [*PD trainer*] just placed them is all--generally, the concept--the overall concept that he's trying to get everybody to see, the real wow moment, he saves for the end, like when there's a formula, he saves them for the end, so he's working simplest to most complex is what it looks like in, uh, showing the students work and that is a good strategy that I feel I could benefit from.

Teacher E: Well, it really has helped me to, um, well, learn that, uh, there's different ways that people think about a problem and that, um, you have to help, uh, persevere through some of the problems because they really help you to really think and make connections to other, um, other math concepts that you weren't even thinking at first.

Those teachers described that the morning math problem sessions went beyond only showing that multiple solutions existed. The multiple solutions were discussed, compared with one another and through engaging in the 'connecting' practice, wisely connected to a mathematical big idea. In fact, the open-ended nature of the problem (i.e. involving more than one answer), the potential for multiple solutions, and the opportunity to build understanding of an underlying math idea were three characteristics named by teachers as they describe the nature of the morning math problems and the quality of math problems in general.

Another important role of the morning math was that it required teachers to engage in productive struggle and that perseverance is important in the problem-solving process. The excerpt of a teacher below illustrates the sentiments of several teachers' in terms of the impact of morning math sessions in that the struggle and perseverance were necessary for learning new mathematical ideas.

Teacher F: Uh, I've learned--actually one, it's taking me back to, like, what children experience and how they have to persevere and just struggle through and go back--and go back to all those ideas and teachings that you learn from the past. So, it brought me back to that and understanding what they have to experience. … And then also, with the right coaching, with the right assistance through those tests, I think that that's been a really big eye-opener, um, made me think past first-grade math.

Interviewer: (laughs) and that's good or bad or…

Teacher F: Oh, that's good because, I mean, I like Math so I try to refresh and keep myself as, I want to say up-to-date as I can. Because not too long ago, I was looking at some Algebra II books and just, you know, just for the sake of time, just messing around and just refreshing it. … knowing how to persevere and understanding what children feel. … I think it makes anyone a better teacher because the more you see it, the more you understand that person's experiences, the better you're able to actually help them through their experiences.

Having first-hand experience of what students were experiencing while learning new mathematical knowledge helped teachers think more about how they could support students differently; thus, this experience helped them to improve their understandings and skills for "monitoring" practice. As many teachers also pointed out, one of the ways of enhancing student learning is by selecting good problems which are challenging but attainable and which will allow making real-life connections. In this vein, we could observe that teachers understood the importance of the practice zero, "setting goals and selecting tasks." To sum up, morning math sessions of the PD not only provided teachers direct experience with mathematical ideas but also demonstrated the ways in which such problems enhance students' learning.

Conclusions

Our aim in this particular study was to understand the role of morning math PD sessions on teachers' understanding of mathematics content and mathematics teaching. As illustrated with the data shared in this proposal, we argue that providing teachers direct experiences with mathematics problems is important for them to learn mathematical ideas conceptually, to understand the challenges that students experience as they learn, to appreciate the effectiveness of challenging, open-ended, and sense-making problems in learning mathematics, and to understand the role of cooperative learning in teaching mathematics. These findings are important for teacher educators and teacher education researchers since they indicate morning math problem-solving sessions as an effective means of professional development for mathematics teachers. However, the role of morning math sessions did not solely result from teachers' solving *any* mathematics problems. In fact, the problems which connected with real life situations, which had multiple solutions and sometimes multiple answers, and which were challenging but attainable, help teachers improve themselves in terms of mathematical content and mathematics teaching skills, particularly around five practices for orchestrating productive mathematics discussions because teachers also observed PD trainers as they monitored their work, selected and sequenced the solution methods, and connected with the big mathematical idea (Stein & Smith, 2011). By presenting teachers' take-aways from morning math sessions of this PD project, we provide insight to teacher educators and teacher education researchers for improving professional development sessions designed for mathematics teachers, which we expect to result in improvement in teachers' mathematics teaching practices.

Math Teachers' Circles (MTCs) bring math teachers and university mathematicians together to engage in collaborative mathematical activity. Currently there are over 110 MTCs across 40 states. A key claim is that MTCs are "communities of practice." However, to date there has been no research to substantiate this claim. In this paper, we explore the ways in which participants in an MTC negotiate aspects of community formation.

Keywords: Teacher Education-Inservice/Professional Development, Teacher Beliefs

Founded in 2006 by the American Institute of Mathematics, Math Teachers' Circles (MTCs; www.mathteacherscircle.org) bring K-12 math teachers and research mathematicians together to engage in collaborative mathematical activity. Unlike traditional professional development, which tends to foreground pedagogical practice, MTCs focus on engaging participants in mathematical activity. Notably, the model:

> emphasizes developing teachers' understanding of and ability to engage in the practice of mathematics, particularly mathematical problem solving, in the context of significant mathematical content. The core activity of MTCs is regular meetings focused on mathematical exploration, led by mathematicians or co-led by mathematicians and teachers (White, Donaldson, Hodge, & Ruff, 2013, pp. 3-4).

MTCs have expanded rapidly, and currently, there are over 110 MTCs in 40 states. As MTCs have expanded across the country, a small amount of research has begun to explore MTCs as a form of professional development for teachers. One significant finding is that MTCs can increase teachers' mathematical knowledge for teaching (White et al., 2013). This is an important result, as mathematical knowledge for teaching (Ball, Thames, & Phelps, 2008; Hill & Ball, 2009) is associated with effective math teaching (Hill, Rowan, & Ball, 2005). Further, surveys of MTC participants have suggested that teachers who participate in MTCs begin to identify more strongly as mathematicians (Fernandes, Koehler, & Reiter, 2011; White & Donaldson, 2011).

Finally, an often-stated claim is that MTCs are *communities of practice* that support sustained teacher learning. For teachers, communities of practice help to support intellectual renewal and provide a sustained venue for new learning (Grossman, Wineburg, & Woolworth, 2001). However, there is currently no research-based evidence to support the claim that MTCs are—or develop into—communities of practice. This is important because communities are not created by fiat, and not all groups of teachers are communities of practice in the way that the term has been used in the anthropological literature (e.g., Lave & Wenger, 1991; Wenger, 1998).

Given the importance of communities of practice to teacher professional development, it is crucial to understand the ways in which MTCs are—or are not, or develop into—communities of practice. In this paper, we explore the ways in which participants in an MTC negotiate aspects of community formation.

Conceptual Framework

A community of practice is defined by three features: mutual engagement, joint enterprise, and shared repertoire (Wenger, 1998). Mutual engagement refers to the requirement that participants jointly participate in the practice(s) that binds and defines the community. Joint enterprise refers to the purpose of the community. Shared repertoire refers to the objects that are naturalized in the community—those objects that are so natural to members so as to be taken-for-granted, but which may seem foreign or strange to outsiders (Bowker & Star, 1999).

In this paper, we pay particular attention to the negotiation of joint enterprise by focusing on the *essential tension in teacher communities*: the tension between focusing on pedagogical practice on the one hand, and engaging in subject-matter disciplinary practices on the other (Grossman et al., 2001). This is an important consideration with respect to MTCs. Primarily, MTCs are meant to engage participants in mathematical practice. The improvement of pedagogical practices is not a "core" activity (White, et al., 2013). However, Grossman et al. (2001) contend that both foci are essential elements in the joint enterprise of a teacher community:

> We contend that these two foci of teacher learning must be "brought into relation" in any successful attempt to create and sustain teacher intellectual community... Teacher community must be equally concerned with student learning and with teacher learning. (p. 952)

Grossman et al. (2001) suggest that the negotiation of the essential tension will go through three ordered stages as a group develops into a community. A "beginning" group demonstrates a lack of agreement around whether the joint enterprise ought to be one focus or the other, and there is often opposition tension between the two foci. An "evolving" group maintains the opposition between the foci, but begins to demonstrate a willingness to allow different people to pursue different foci. Finally, a "mature" community holds the two foci in productive relation, recognizing that "teacher learning and student learning are fundamentally intertwined" (Grossman et al., 2001, p. 988).

Research Questions

On the one hand, pedagogical practice is officially backgrounded in MTCs so as to maintain a focus on engagement in disciplinary practice. On the other hand, "for a group of teachers to emerge as a professional community, the well-being of students must be central" (Grossman et al., 2001, p. 951). This makes us wonder, even if the stated goal of an MTC is to engage participants in mathematical activity, *what actually happens when a group of math teachers gets together to do mathematics?* Do teachers simply engage in mathematical activity? Do they focus on pedagogy? Or some combination? Our study is the first to employ anthropological methods to answer anthropological questions about math teachers' circles—in particular, just *what is* the joint enterprise, as it is negotiated by participants? Our research questions are:

1. In what ways, if at all, are the two foci of the essential tension—mathematical activity and pedagogical practice— manifested in MTCs?
2. When pedagogical practice is invoked, how is it treated by participants?

Materials and Methods of Analysis

Our data come from the initial gatherings of a newly-inaugurated statewide MTC. The gatherings include two after-school gatherings from each of five state-wide locations and a 3-day "summer retreat." These were the first gatherings for the statewide MTC, although two locations had previously hosted MTC gatherings.

Local gatherings were facilitated by "lead teams" composed of 3-5 local teachers and university mathematicians. These lead teams attended a group training session facilitated by the American Institute of Mathematics, the organization that created and currently disseminates the MTC model. The lead teams designed and conducted their gatherings independently of each other. The summer retreat was organized and facilitated by the coordinators of the statewide MTC, four of whom are also authors of this paper (Peck, Erickson, Roscoe, and Wu).

Gatherings were organized around "activities"—mathematical problems that participants worked on groups of 3-6 people, followed by large group discussions of the problem. There was 1 activity in each of the 10 local gatherings, and 9 activities in the summer retreat. In all, the data encompass 11 gatherings and 19 activities. Across all sites, there were 177 participants: approximately 80% were practicing teachers (20% elementary, 30% middle school, 30% high school), approximately 10% were post-secondary mathematics faculty, and approximately 10% were pre-service teachers (these percentages are approximate because there are some participants for whom we do not have demographic data).

Communities develop via engagement in joint activity. Participants interact with each other and with artifacts, and through this interaction norms of engagement, joint practices, and a shared repertoire emerges; a community develops and people become part of it (Bowker & Star, 1999; Dean, 2005; Lave & Wenger, 1991). Because community development occurs in interaction, we used video and audio recorders to capture the naturally-occurring interactions of participants as they engaged in activity during the gatherings. For each of the 19 activities, we have video and audio recordings of 2-6 problem-solving groups. Additional data include:

- Participants' notebooks from the summer retreat. Participants used these notebooks for jottings and work space during the retreat. They also used the notebooks to provide written responses to a series of reflection prompts at the end of the retreat.
- Interviews with 10 participants from the summer retreat. This represents a selective sample of all participants. We invited all participants to be interviewed. From the set who agreed to be interviewed, we chose interviewees selectively in order to achieve a diverse sample with respect to gender self-identification, level taught (elementary, middle, high), and region of the state.

Our initial analysis focused on the recordings of MTC activities. We used a cyclical data analysis method, which relied on both inductive and deductive approaches (Miles, Huberman, & Saldaña, 2014). First, we developed a list of deductive codes based on our conceptual framework. We then engaged in the following process for each activity. Members of the research team each watched/listened to a different group engaging in the same activity. The team member created a content log (Maxwell, 2013) of the recording and coded the log according to the codebook, allowing new codes to emerge from the data. We then met to discuss our observations and coding. We refined our codebook and then used the refined codebook to code the next activity. We proceeded in this fashion, with inductive codes emerging from the data and subsequently undergoing refinement, for all 19 activities.

We used these coded content logs to identify key segments in which participants negotiated the two foci of the essential tension (mathematical activity and pedagogical practice). We transcribed these key segments and analyzed them using multi-modal interaction analysis (Erickson, 1992; Goodwin & Heritage, 1990; Streeck, 2009).

We employed a similar procedure to analyze the participants' notebooks and interviews.

Findings

We present our findings organized around our two research questions.

RQ 1: In What Ways, if at all, Are the Two Poles of the Essential Tension Manifested in MTCs?

Perhaps unsurprisingly, we found that the majority of activity in MTCs involved engaging in disciplinary (mathematical) practices. Pedagogical concerns occupied less than 5% of the "official" activity. We gloss an activity as "official" if it was introduced by the facilitators as the focal activity of the group.

Pedagogical concerns were sometimes explicitly backgrounded by facilitators. For example, in the introduction to the one of the initial spring gatherings, a facilitator explained the goals for the gathering:

> You shouldn't feel like there's any expectation to be walking away this evening with anything other than a good feeling, alright? We're not trying to prove anything, this is just for us. We're not trying to say, "and now, fourth-grade math achievement will go up because-" ((laughter)). That has nothing to do with it. You see, we're just- what we're trying to do is just, be a group that likes mathematics.

In this turn, the facilitator invokes both pedagogical concerns ("fourth-grade math achievement") and disciplinary activity ("be a group that likes mathematics"). The turn is designed such that the two foci are put into opposition with each other. This can be seen in the use of the adverbs "not" and "just" to modify the verb "trying" in the second half of the turn ("*not* trying," and "*just* trying"). In particular, the use of the word "not" in "we're not trying to say" negates the pedagogical focus. This is reinforced with the exclusionary "just" in reference to mathematical activity.

This finding—that the primary activity of an MTC is mathematical, not pedagogical, activity—is not surprising, given that engagement in mathematical activity is the explicit purpose of MTCs. Furthermore, the finding that the two foci were treated oppositionally is also not surprising due to the "beginning" nature of these teacher groups.

However, we also found that pedagogical concerns were invoked in multiple, interesting—and sometimes surprising—ways during MTCs.

Pedagogy was rarely the official topic of activity. Most commonly, if pedagogy was the official activity of an MTC gathering, it happened in the final phase of the gathering. This phase was framed as a "reflection" time, and pedagogy was a topic for reflection. For example, at the end of the 3-day summer retreat, the group met all together, and reflected on what it meant to *do* mathematics, based on their experience in the summer retreat. After the group generated a list of attributes associated with doing mathematics, the facilitator (Peck) referenced the list and said:

> So if we think about all this stuff that doing mathematics <u>is</u>, um, take a moment and write just a couple ideas about how you might incorporate some of this into your classroom.

Both the design of this turn, and the subsequent uptake by participants provide evidence that pedagogy has become the official activity. By employing the imperative mood (*take* a moment and *write* just a couple of ideas…), and applying it to pedagogical concerns (…about how you might incorporate some of this into your classrooms), the facilitator signals that the official activity is now related to pedagogy. Participants' uptake confirms this. After the facilitator's turn ended, participants began writing and there is silence on the video and audio recordings. Analysis of participants' notebooks confirms that each response involves pedagogy.

Notice also how this turn brings pedagogy into a productive relationship with mathematical activity. Rather than treating pedagogy as separate from the mathematical activity of the retreat, the facilitator, through the use of the word "incorporate," suggests that the mathematical activity of the retreat can productively be brought to bear on classroom pedagogy.

More commonly, pedagogy came up informally in relation to the concurrent mathematical activity. As participants engaged in mathematical activity, they often related the activity to pedagogy. For example, the strip of dialog in Table 1 occurred while participants were exploring the question, "can any number be written using only powers of 2?" The three participants, Amy (5-6th grade teacher), Diane (3rd grade teacher), and Patty (7-12th grade math teacher) discuss the mathematical question in turns 1-17. In turns 18-20, they transition to a pedagogical discussion related to the mathematical activity, which they continue for the remainder of the strip.

Table 1: Doing Mathematics and Talking Pedagogy

Turn	Speaker	Talk[1]
1	Amy:	I think, I mean-
2	Diane:	Well we have to be able to because how else- That's how binary works.
3	Amy:	How else could we-
4	Diane:	They have to-
5	Patty:	Make every number?
6	Diane:	Yeah, binary's gonna work every time.
7	Patty:	mmm-hmm
	((Amy looks at notebook, where she has written a list of powers of 2.))	
8	Amy:	How do you get 127?
9	Diane:	((points to notebook)) There's your two, 16 – ((moves finger along notebook, where Amy has written successive powers of 2)) That's gonna be… one hundred… [twenty seven!
10	Amy:	[twenty seven! Okay…
	((Talk continues in this fashion, for turns 11-17, with Amy suggesting an number, and Diane showing how to make the number)).	
18	Amy:	Two:::: f::::- ((smiling))
19	Diane:	You little pain in the butt! ((laughing))
20	Amy:	Hmmm… I'm trying to think like a f-
21	Diane:	Trying to think like a sixth-grader?
22	Amy:	Yes!
23	Diane:	They are difficult little critters, but they're adorable!
24	Amy:	"well what if you want to do this? What if you want to do this?"
25	Diane:	"So tell me how. What's the pattern you're seeing?"
26	Patty:	So what grade do you start doing these problems?
27	Amy:	Binary?
28	Patty:	No-
29	Diane:	Exponents!
30	Amy:	[Oh exponents
31	Patty:	[Yeah, just- just exponents?
32	Amy:	Fifth- fifth grade.

33	Patty:	Well, we talk about squaring (crosstalk) not- not square roots-
34	Diane:	Just squared?
35	Patty:	Just squared. So I [sh-
36	Amy:	[I don't even talk about square roots, until-
37	Patty:	So I show the kids that notation ((draws a "2" in the air)), and I talk to them about how if it's 54 square units, I show them how you can write 54 units squared ((draws "2" in the air)) [with a-.
38	Amy:	[yeah
39	Patty:	with a- with an exponent two… so what grade do you start talking about, "what does that exponent MEAN?" ((draws 2 in the air)) and-
40	Amy:	I do fifth and sixth grade, and in fifth grade I introduce it to them-
41	Patty:	Okay.

[1] In general, talk is transcribed using standard punctuation, so that a comma denotes a short pause, a period denotes a longer pause after a falling intonation, and a question mark denotes a pause after a rising intonation. Ellipses ... denote a long pause. Underline denotes vocal emphasis, co:::lons denote a drawn-out sound, and a hyphen- denotes a restart. Vertically-aligned open brackets [denote overlapping speech. ((Double parentheses)) denote non-vocal action.

Because participants often invoked pedagogy even when it was not the "official" topic, we found that participants were engaged in pedagogical conversations or activity approximately 15% of the time—3 times more than that which was accounted for in the official activity.

RQ 2: When Pedagogical Practice Is Invoked, How Is It Treated by Participants?

We found that pedagogical practice was treated as a normative topic of discussion in MTCs. The strip in Table 1 is representative of this. Notice the framing of the turns where pedagogy is first evoked, and the response to these turns:

20	Amy:	Hmmm… I'm trying to think like a f-
21	Diane:	Trying to think like a sixth-grader?
22	Amy:	Yes!
23	Diane:	They are difficult little critters, but they're adorable!
24	Amy:	"well what if you want to do this? What if you want to do this?"
25	Diane:	"So tell me how. What's the pattern you're seeing?"
26	Patty:	So what grade do you start doing these problems?
27	Amy:	Binary?
28	Patty:	No-
29	Diane:	Exponents!
30	Amy:	[Oh exponents

In particular, notice the absence of an account for why pedagogy is being introduced. Neither Amy nor Patty provides a rationale for why they are introducing pedagogy, and subsequent turns do not hold them to account for such an introduction. Together the design of turns 20-30 can be taken as evidence that for these participants, pedagogy is normative topic of discussion (consider how these turns would be designed differently in a situation where pedagogy was not normative, say at an adultleague softball game). This finding is somewhat surprising, considering the "official" framing of MTCs as primarily focused on engaging in disciplinary practice.

Even though pedagogy was a normative topic, the way that it interacted with disciplinary practices varied. In some cases, these two foci were treated oppositionally, as would be expected in a "beginning" group like the ones that we studied. The first facilitator quote given above is one example of this. A second example comes from the reflections of participants in the summer retreat, one of whom wrote,

> Some of the activities were good, but others were not helpful. I guess I was looking for more options to take back to my classroom.

Using the word "but," the participant contrasts "good" activities with those that were "not helpful." She goes on to identify "helpful" activities as those that could be used in the classroom. This comes even after the participant discussed how much she had learned about doing mathematics from the activities. This suggests that, for this participant, "engaging in disciplinary activity" and "improving pedagogical practice" are two *separate* foci.

However, we also found multiple times where the two foci were held in "productive relation," which would be evidence of a more mature community. The strip of talk in Table 1 is one example of this, where the content of the activity spurred a conversation about pedagogy related to that content.

We also see evidence for the "productive relation" in participants' reflections. For example, a different participant reflected:

> Working together to solve problems reminds me how important and fun it is, and I need to do that as much as possible in my class!

Here the participant uses a different conjunction: "and" instead of "but." In doing so, she brings disciplinary activity ("working together to solve problems") into a productive relation with pedagogy ("I need to do that… in my class").

Conclusion and Significance

Math Teachers' Circles have exploded in popularity since their introduction in 2006. A key claim is that MTCs constitute *communities of practice.* However, this claim has not been subjected to analytical scrutiny. In this paper, we take a step towards such scrutiny by employing anthropological methods to analyze the ways that participants in MTCs negotiate their joint enterprise.

We found evidence that both disciplinary practice *and* pedagogical practice are part of the joint enterprise. This is a surprising finding because the groups are "officially" framed around disciplinary practice only, and are represented as such in the published literature (e.g., the excerpt from White et al, 2013, in the introduction). This supports Grossman et al.'s contention that teacher communities must include a focus on pedagogical practice.

We also found that, in negotiating the joint enterprise, MTC groups display hallmarks of both "beginning groups" and "mature communities." This complicates the claim that all MTCs are communities of practice: our findings suggest that a beginning MTC, at least, may not be a mature community of practice. Participants are still negotiating the essential tension, and some participants struggle to hold the two foci in productive relation.

However, what is perhaps our most striking finding is that, most often, when pedagogy was invoked, it was treated as normative by participants. Most of the time, when the "essential tension" manifested itself, there was no *tension* at all. This finding complicates the model of Grossman et al. (2001) in which communities must go through ordered stages of oppositional tension between mathematical activity and pedagogical practice, before they can hold the two in productive relation. This finding should be explored and elaborated in future research.

STEM AND MODEL-ELICITING ACTIVITIES: RESPONSIVE PROFESSIONAL DEVELOPMENT FOR K-8 MATHEMATICS COACHES

Courtney Baker

Sara Birkhead
George Mason University
sbirkhea@gmu.edu

This research highlights a university-school division collaboration to pilot a professional development framework for integrating STEM in K-8 mathematics classrooms. The university researchers worked with mathematics coaches to construct a realistic and reasonable vision of STEM integration built upon the design principles of model-eliciting activities (MEAs). Analysis of participant reflections after they experienced two MEAs as learners in mixed grade-level teams suggests an evolving conceptualization of STEM integration with an explicit connectedness to mathematics content. Mathematics coaches valued the potential for MEAs to provide multiple entry points to open-ended problem solving, but they articulated a sense of vulnerability as they contemplated the challenges of time and teacher buy-in within the contextual realities of curriculum pacing and standardized test preparation.

Keywords: Teacher Education-In-service/Professional Development, Modeling, Instructional Activities and Practices, Problem Solving

Introduction

School divisions across the United States have "embraced" the slogan of STEM (Bybee, 2010), but there is limited evidence of theoretical frameworks for the design and development of sustainable STEM integration in K-12 education [National Academy of Engineering (NAE) & National Research Council Committee (NRC), 2014]. Mathematics may be relegated to a supporting role in STEM integration (Fitzallen, 2015) when it is characterized as the calculations or the data representations in science classrooms, technology labs, or outside-of-school programs. To bring mathematics content to the forefront in STEM integration, designers must attend to "learning goals and learning progressions" within mathematics (NAE & NRC, 2014, p. 148) and avoid a dilution of mathematics content (Shaughnessy, 2013). Without specific connections to mathematics content, teachers may perceive STEM integration as an additional instructional requirement that is placed on top of the existing curriculum (Wang, Moore, Roehrig, & Park, 2011).

The university researchers reflected upon these challenges as they collaborated with a school division to develop a STEM integration professional development (PD) framework for mathematics coaches. They hypothesized that model-eliciting activities (MEAs) offer a vehicle for *reasonable and realistic* STEM integration in K-8 mathematics classrooms by providing open-ended problems within a client-driven, real-life context. With mathematics coaching support and explicit connectedness to content, teachers can use MEAs to engage students in both collaborative mathematical thinking and productive engineering design processes.

In this paper, we describe preliminary findings from our exploratory study during a STEM integration PD initiative in a mid-Atlantic school division. The mathematics coaches experienced two MEAs as learners and collaborated to envision MEAs as an instructional vehicle for integrating STEM within the bounds of their coaching contexts.

Conceptual Framework

STEM integration should offer students and teachers the opportunity to engage in "real-world, rigorous, and relevant learning experiences" (Vasquez, Sneider, & Comer, 2013). For many mathematics teachers, this conceptualization of STEM integration is so distant from their daily understandings of content, curriculum, and pacing that implementation becomes unrealistic. STEM may be perceived as a project or activity that is ancillary to content-specific instruction and may become an unintended barrier to richer opportunities to learn. Although reform curricula have emphasized the need for problem-solving opportunities in mathematics, many teachers still perceive problem solving as an elite activity, accessible only to students who have mastered essential mathematical skills and formulas (Crespo, 2003). This perception impedes conceptualization of mathematics content instruction through STEM activities. In addition, mathematics students in underperforming populations are often denied access to opportunities to practice 21st century skills as they are instead provided with remediation and extra support to gain computational fluency in preparation for standardized assessments.

Drawing from Stohlmann's (2013) definition of STEM integration as "an effort for mathematics teachers to use the engineering design process as the structure for students to learn mathematical content along with science concepts through technology-infused activities," the researchers designed a PD structure that would support teachers in incorporating MEAs within existing mathematics curriculum. The research team's goals were to: 1) explore participant understanding of mathematics within STEM integration; 2) use hands-on MEA experiences to elicit a more accessible classroom implementation of STEM aligned with coach and teacher beliefs; and 3) build coaching capacity to use MEA design principles to develop STEM tasks with a specific focus on keeping the mathematics content explicit.

MEAs were originally conceptualized as a device to help mathematics education researchers elicit student modeling and to develop expertise about cognition and problem-solving behavior. They have since become a tool that can also be used to help teachers and students develop their own competencies (Hamilton, Lesh, Lester, & Brilleslyper, 2008). MEAs support the learning of mathematics within STEM by integrating other content areas found inside and outside of mathematics, by encouraging learning through discovery, and by promoting problem-solving dispositions (Magiera, 2013) with a specific focus on accessibility to varied learning styles and experiences (Stohlmann, 2013). MEAs offer teachers a contextual and content-focused lens on student mathematical thinking (Chamberlin & Moon, 2008; Stohlmann, 2013) that yields explicit evidence of student learning that is needed to ensure the mathematical rigor in STEM integration.

Because educator expertise may be the "key factor" in STEM integration (NAE & NRC, 2014, p. 115), PD is needed to support teachers who did not learn mathematics in STEM contexts to build a working knowledge of what STEM integration can look like (Stinson, Harkness, Meyer, and Stallworth., 2009). PD that is both "site-based" and "curriculum-linked" (Penuel, Fishman, Yamaguchi, & Gallagher, 2007, p. 928) is theorized to improve teacher enactment of reform-oriented instruction, and prior research has shown that ongoing mentoring and support (p. 124) and teacher collaboration (p. 125) increase the likelihood of successful STEM integration (NAE & NRC, 2014). The university researcher-school division partnership offered a bridge between research with MEAs and the practical demands of existing curriculum and standards. As the division mathematics coaches experienced MEAs as learners, they could begin to conceptualize STEM integration built upon engineering design and real-world contexts with an explicit connectedness to mathematics content. The research question which guided this study was as follows: How do iterative experiences with MEAs during a university-facilitated PD help mathematics coaches to envision STEM integration in K-8 classrooms?

Methodology

Design-based implementation research (DBIR) is an emerging methodology in which stakeholders are committed to iteratively developing an educational innovation with a goal of broader and sustainable impact (Penuel, Fishman, Cheng, & Sabelli, 2011). This collaborative PD connected research on MEAs which "engage learners in productive mathematical thinking" (Hamilton, et al., 2008, p. 5) to STEM integration efforts within one school division. The university-school division partnership drew upon studies of specific enactments of MEAs as tools in mathematics and engineering education and theorized a STEM PD structure to explicitly focus on instructional coaching and mathematics content. The team worked to construct coaching expertise that schools would need to broadly implement MEAs as a vehicle for STEM integration.

Setting and Participants

The university researchers and the division mathematics supervisor collaborated to create a longitudinal PD structure in response to a district directive to integrate quarterly STEM tasks at each grade level. Within this school division, 73% of students were traditionally underserved and 53% were economically disadvantaged students (State Department of Education, 2015). The division had five elementary schools, each with Title I designation, one intermediate school, one middle school, and one high school. The supervisor sought to leverage the university's mathematics education and instructional coaching expertise to bring mathematics to the forefront of STEM integration. She allocated time for mathematics coaches from the seven K-8 schools to explore and design MEAs with university facilitator support during their monthly academic year coaching meetings.

The Professional Development Context

The university researchers developed resources aligned with the partnership's PD goals and piloted a four-day summer institute for eight aspiring STEM teacher leaders to engage with MEAs and plan for use within their classrooms. Two of the participants were mathematics coaches. The summer institute participants explored their perspectives on STEM, engaged with MEAs as learners, evaluated the affordances and challenges of implementing MEAs in their classrooms, and adapted existing curricular materials and online resources to design MEA instructional materials for their schools. The university researchers drew upon participant reflections and questions from the summer institute as they designed ongoing PD for the mathematics coaches during monthly academic year meetings. The evolving PD structure was purposefully adapted to support coaches in seeing the possibilities of MEAs, first through the eyes of students, then as teachers, and finally as coaches.

Month 1. The university researchers asked the coaches to reflect on the meaning of STEM in order to situate their existing understandings before introducing MEAs. The definition of MEAs offered by Maiorca and Stohlmann (2014) provided an accessible set of four design features (open-ended, client-driven, mathematics similar to real-life, and engineering design process) to help coaches as they began to build a working knowledge of model eliciting. These practitioner-friendly constructs were a crucial bridge from the researcher language of MEA design principles (Hamilton et al., 2008) to coach envisioning of MEAs in classrooms.

Teams of coaches engaged with the Survivor MEA (Maiorca & Stohlmann, 2014) to explore the affordances and challenges of MEAs from a student perspective. Although the Survivor MEA offered an engaging, relatable context for the participants as they experienced their first mathematics-focused STEM integration task, the research team observed that the physical construction of the weather-resistant shelter model became the primary focus of iterating and refining. The coaches required additional hands-on experiences to see the potential for explicit mathematics content instruction within this type of engineering activity.

Month 2. Before the coaches engaged in a second hands-on MEA experience, they needed time to make sense of MEAs and connect them to their own K-8 educational contexts. The university researchers offered a task adaptation template based upon the four MEA design features to support coaches in thinking critically about MEAs and in exploring online resources. This space for exploration allowed the coaches to purposefully think about not only the teachers they would support and the classrooms in which they would pilot MEAs, but also to build important contextual knowledge that would prepare them for their second hands-on experience.

Month 3. The university researchers selected the Pelican Colonies MEA (see Figure 1) as a second hands-on experience because the mathematics content could be more flexibly connected to K-8 standards and there were more varied opportunities for use of manipulatives. The coaches were purposefully grouped to offer mixed levels of content expertise and grade-level experience. The goal of this second exploration was to allow the coaches an opportunity to not only analyze their own collaborative engagement with the MEA as learners but also to reflect on transferring these ideas to their coaching practice.

Data Collection

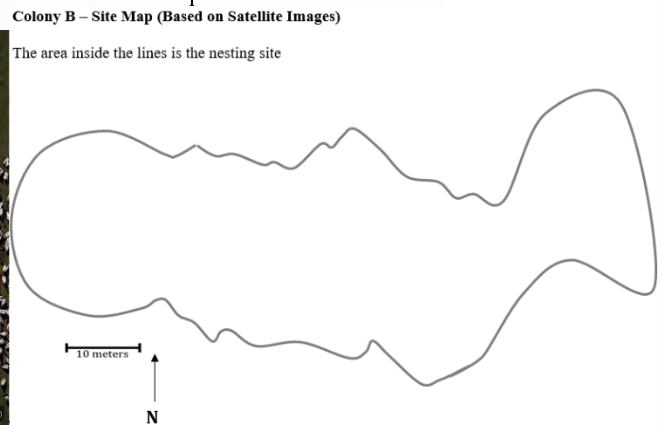
Multiple qualitative data sources were used to characterize the envisioning and enactment of MEAs as vehicles for STEM integration. Written reflections were centered on the participants' perceptions and understandings of STEM integration and the affordances and challenges of using MEAs in mathematics teaching and coaching. Additionally, discussions during and after MEA problem-solving experiences were audio recorded to capture the dynamic nature of conversations and preserve the integrity of the participants' experiences and perceptions. Finally, PD artifacts, mathematics task adaptation charts, and modified curriculum materials provided evidence of the evolution of participant thinking on specific strengths of MEAs and the contextual challenges of implementing MEAs.

Data Analysis

Data gathered was qualitatively analyzed to inform real-time changes in the PD structure and to support longitudinal evaluations of changing conceptualizations of STEM integration. The university researchers examined participant writing prompts at the end of each session as they modified each iteration of the PD to maximize stakeholder involvement and negotiation in design decisions (Fishman, Penuel, Cheng & Sabelli, 2013; Penuel et al., 2011). Group discussions and written reflections provided evidence of beliefs about the potential role of MEAs in mathematics instruction and the emerging challenges of using MEAs to integrate STEM in their classroom contexts. Sample codes that emerged from the analysis of audio recordings and reflection prompts included: reasonable, realistic, teacher buy-in, appreciation of PD design, need for collaboration, student readiness, and time. The reduction of all codes into categories led to the emergence of themes which illuminated the role of PD design decisions in both evoking and alleviating coaches' concerns about introducing and supporting MEA enactments.

Pelican Colonies MEA - Excerpts from Client Memorandum

"The U.S. Fish and Wildlife Service needs a procedure to estimate the number of nests at each pelican colony...We are enlisting your team's help to create a procedure that will allow us to estimate the number of nests in a pelican colony, based on the photograph that shows a sample of the colony, and a map that shows the size and the shape of the entire site."



MEA Design Features	Affordances of Pelican MEA for PD for Mathematics Coaches
Client-Driven	Request from U.S. Fish and Wildlife Service; Context activated by one-page newspaper article; connection to scientific research
Open-Ended	Variety of relevant manipulatives: ruler, tape measure, small beans, transparencies, and markers
Mathematics Similar to Real Life	Multiple K-8 entry points: Multiplication; decomposing area of a polygon into rectangles; measurement; estimation; ratios and proportions; unit rate; random sampling and inferential statistics
Engineering Design Process	Iterative refining and testing

Figure 1. Pelican Colonies MEA Summary and Design Features (Adapted from http://wordpress.unlvcoe.net/wordpress/wp-content/uploads/2013/01/Pelican-Colonies-MEA-Teacher-Materials.pdf.

Findings

Because mathematics coaches have varying school contexts and administrator expectations, the university researchers needed to be responsive to the changing needs of the participants as they engaged in a collaborative journey toward envisioning MEAs as a vehicle for STEM integration with a specific place for K-8 mathematics content. The PD design decisions to provide time and space for peer exploration of MEA resources and to offer a second hands-on experience with an MEA were critical moments in the collaborative journey toward STEM integration in mathematics classrooms. While coaches expressed enthusiasm about the problem-solving potential of MEAs, they also became more fully aware of the pedagogical and leadership challenges they would face in bringing MEAs to classrooms.

Affordances of a Second Hands-On Experience

As the coaches discussed their experiences with the Survivor MEA during Month 1, they initially focused on the relatability of the context to their lives. They also adopted a teacher lens as they discussed the possibilities of tailoring the context, introducing mathematical language, and completing the written component of the task outside of mathematics instructional time. However, there was no organic discussion of possible application of grade-level content. One of the university researchers needed to prompt the coaches to specifically think about the mathematics content within this MEA.

In contrast, the coaches' second hands-on experience with the Pelican Colonies MEA during Month 3 elicited deeper mathematical thinking that aligned with familiar standards. The centrality and potential flexibility of mathematics application elicited by the Pelican Colonies MEA encouraged the coaches to draw on their content knowledge and past teaching experiences. Mathematics coaches looked at engagement with the MEA through a different lens than Month 1 as they initiated discussions on the multiple mathematical entry points and their grade-level expectations. In Group 1, the district math supervisor acknowledged that her problem-solving approach was consistent with her secondary math experiences. "I thought unit rate, others on the team thought ratio." The other two K-6 mathematics coaches in her group connected to content by drawing on their most recent classroom teaching responsibilities. "Amy said 60 x 19 because that's what we would do in 3rd grade, while I was still thinking ratio because the last grade I taught was middle school." (Jill, K-6 mathematics coach)

Because the previous monthly PD sessions built working knowledge of MEA design features and task design, coaches were able to reflect on the MEA from a teaching perspective centering on mathematical implementation. Yet they also maintained an important attentiveness to client-driven, open-ended, real-world aspects of the MEA. Although the coaches in Group 2 did not progress as far into the task as Group 1, they engaged in an engineering design process. "We did not finish because we took time to think, which the kids need to do" (Mia, 6-8 mathematics coach). Mia also wondered if middle school students would question the purpose of the MEA. "Why are we trying to save the pelicans?" Anticipating potential student responses to the MEA context was essential for the mathematics coaches to think about the future enactments in K-8 classrooms. "Real world to kids is something they can activate - something they can be interested in doing. In middle school it's hard to get them engaged to think something is important."

The university researchers had selected the Pelican Colonies MEA because of its broad potential for K-8 mathematical thinking and for use of manipulatives. The mathematics was more accessible to the coaches than it had been with the Survivor MEA, and the coaches responded by discussing the explicit use of mathematics content without specific prompting by the university researchers.

Coaching Challenges

During Month 3, the coaches transitioned from acting as students to anticipating the unique demands of implementing MEAs in their own schools. Their critical thinking about the potential of MEAs to improve student opportunities to learn was accompanied by a vulnerability they would feel as they introduced MEAs to K-8 mathematics teachers and students. They shared their anxieties about advocating for the use of a resource that they were still exploring.

> Because I am new to MEAs, I feel like I will be entering uncharted territory where I will no longer be the 'knowledgeable other' or expert... It's hard to walk into someone else's classroom. If [the experience] is perceived as a waste, what is the fall out for that? (Jill, K-6 mathematics coach)

The concern about consequences of failure extended beyond elementary contexts. Mia, the middle school mathematics coach, worried that an unsuccessful MEA could harm her ongoing efforts "to get kids to do more than the teachers." She further wondered how teachers would see MEAs connecting to math, specifically standardized tests and other accountability measures.

> The math piece of it is where I think the teachers will struggle as much as the kids do when we talk about there not being [one] answer. They are at that level where they think there should be [one] answer or [the task] needs to look like the [standardized test] questions. (Mia, 6-8 mathematics coach)

Finally, the coaches articulated concern that students would not be able to make the important "connection between what they are doing and the content that they know" (Jess, K-6 mathematics coach). They also speculated that teachers would assume that the MEA would be too hard for their students.

While the coaches expressed vulnerability with respect to student and teacher readiness, they believed that opportunities to collaborate with other coaches and teachers could build their confidence in addressing these challenges. In her written reflection at the end of the Month 3 PD, Jill described her planned collaboration with another mathematics coach, a STEM coach, and a 3rd grade teacher to "help build buy-in with other teachers, provide more adult support with students, and increase excitement/engagement of the students." Three of the coaches expressed a need for more time to collaborate to develop their MEAs. These needs were shared with district mathematics supervisor as the university-school division partnership planned future directions for the STEM integration PD.

Conclusions

The construction of a *reasonable* and *realistic* STEM orientation for teachers is critical as the education community looks toward connecting STEM integration and mathematics learning. At the beginning, the coaches were challenged to reevaluate their conceptualizations of STEM from prior PD experiences. The university facilitators engaged in real-time iterations of planning, reflecting, and revising as they gauged participant perceptions and responded to participant challenges to connect research to practice. As the coaches iteratively engaged with MEAs, they envisioned multiple entry points within these problem-solving structures with respect to grade-level content and student readiness.

School contexts, administrator expectations, and assessment-driven cultures must inform the ongoing negotiation of STEM implementation. The challenges that the coaches articulated in bringing their MEA designs to the classroom is consistent with prior research on the need for ongoing school-based support. Coaches, teachers, and researchers will continue to engage in this STEM integration design and development process as they reflect upon prototype MEA enactments and redesign resources for wider implementation. Their shared investment in realizing classroom and school STEM integration capacity with a specific focus on mathematics outcomes and coaching contributions will offer a model for STEM integration that challenges "one-size-fits-all" PD, defines a new role for mathematics coaches and teachers as STEM instructional leaders, and promotes meaningful readiness for STEM citizenship and careers for their students. The district supervisor articulated the student-centered possibilities of MEAs that continue to motivate the work of the team. "The kids are acting as mathematicians instead of learning about math."

Acknowledgments

Our research team members experienced the Pelican Colonies MEA as learners during a mathematical modeling working group at an international education conference. We appreciate the continuing collaboration with the facilitators as we refine our PD framework.

TEACHER PERCEPTIONS ABOUT VALUE AND INFLUENCE OF PROFESSIONAL DEVELOPMENT

Tami S. Martin
Illinois State University
tsmartin@ilstu.edu

Gloriana González
University of Illinois at Urbana-Champaign
ggonzlz@illinois.edu

We used a situative perspective to examine teachers' perceptions of a professional development intervention that integrated lesson study, video clubs, and animation discussions. The analysis of interviews with the five geometry teachers who participated in the intervention during two consecutive years showed three characteristics of professional development that were valuable: designated time to collaborate, focus on student mathematical thinking, and use of animations to represent practice. A fourth characteristic, accountability for implementation, is also discussed. The findings have implications for designing professional development, because participants cited links between their experiences and changes in their practice.

Keywords: Teacher Education-Inservice/Professional Development, Geometry and Geometrical and Spatial Thinking, High School Education

Perspectives

Putnam and Borko (2000) cited the importance of creating situative learning experiences for inservice teachers and described aspects of such experiences that promote growth in teacher learning and practice. In a situated learning experience, teachers engage with others (e.g., in a discourse community) both within their own classrooms and outside their classrooms (Putnam & Borko, 2000). Although familiar contexts may help teachers make connections to their daily practice, there are limitations to professional development that occurs exclusively in a teacher's own classroom. Comfortable habits, supported by a local culture, are difficult to break. Discussions with others may serve as disruptors to entrenched patterns of behavior which may then spark reflection and change. Putnam and Borko described how discourse communities can help teachers face the risks entailed in making meaningful change. When a group explores new materials and strategies in a forum that draws on different perspectives and expertise, practice may become the subject of critical reflection. As a result, teachers may be empowered by knowledge drawn from and trust in the group to try new ideas that were previously seen as too unfamiliar and, thus, risky to use with students.

Lesson study (Lewis, Perry, & Murata, 2006) is one example of a professional development model that is both classroom-centered, and considers teaching and learning as objects of reflection by a community of practitioners. Hiebert, Gallimore, and Stigler (2002) concurred that effective professional development should be centered in the classroom, part of a long-term collaborative process, and focused on student learning and curricula. These perspectives frame our investigation of teachers' perceptions about valuable characteristics of professional development.

Purpose and Research Questions

The purpose of this study was to determine what teachers valued about a professional development experience that was designed to create a situative learning experience. In other words, we looked at ways that teachers might justify the value of different aspects of such an experience, including components of that experience that were both centered on their own practice, yet occurred away from their classroom in the context of a discourse community. Given that such situative learning experiences have been shown to induce powerful teacher learning, we examined the extent to which teachers reported such learning and the factors to which they attributed that learning. The following research questions guided our analysis:

1. Which aspects of the professional development intervention did teachers find most valuable and how did they justify that value?
2. What changes did teachers note in their practice and to what factors did they attribute those changes?

Methods

The teachers in this study were participants in a larger study focused on promoting teacher noticing and use of students' prior knowledge to inform lesson design, implementation, and reflection on implementation (González, Deal, & Skultety, 2016). The five participants were all high school geometry teachers, with 4–26 years of teaching experience, who taught in high-need schools in the Midwestern United States. Teachers participated in two iterations of a lesson study process. The teachers met in 3-hour monthly sessions that teachers called study groups. Each year, participants watched and discussed animated, cartoon depictions of several versions of a geometry lesson (i.e., animations; Chazan & Herbst, 2012), collaboratively planned and implemented a lesson on the same topic, watched and discussed videos of their own students participating in the planned lesson (in a video club; van Es, Tunney, Goldsmith, & Seago, 2014), revised the lesson they developed, and repeated the process.

The lessons topics (i.e., dilations and perpendicular bisectors) were predetermined by the research team. Because the focus of the lesson development and analysis was on identifying and building upon students' prior knowledge during instruction, the focus of study group discussion was on student understanding, rather than on the teacher actions during lesson implementation. Participants constituted a discourse community, as they worked together to plan the lessons and analyze video clips of students' work during the lessons.

The data for this paper are teacher self-reports from 20–60 minute individual interviews that the first author conducted at the end of each of the two years of the professional development experience. Teachers were asked to describe strengths and weaknesses of the study group, their perceptions about the goals of the study group, and the relative value of each aspect of the study group (e.g., animations, collaborative planning, analysis of student thinking). Participants were also asked to comment on whether the experience had an impact on their teaching.

The first author audio recorded and transcribed the interviews, using pseudonyms for each teacher. Transcripts were analyzed for common themes mentioned by participants using a grounded theory approach (Corbin & Strauss, 2008). In the first iteration, we used an open coding process, identifying any significant aspects that the participants noted, regardless of the question that they were addressing. In a second iteration, we looked more closely for participants' justifications for significant aspects of the professional development and examples participants provided of how their practice changed as a result of the professional development.

Results

The resulting themes from the open coding process are listed in Table 1, by teacher and year. Themes are grouped in broad categories: (a) aspects of the professional development that were significant for teachers in their own right (e.g., designated time to collaborate, forum for reflection, authentic to my curriculum or students, focus on one thing over time), (b) outcomes of the professional development (e.g., change in teaching practices), and (c) mechanisms that were inherent in the professional development that may have led to perceived outcomes (e.g., focus on students' mathematical thinking, focus on students' prior knowledge, accountability for implementation, use of animations to represent practice). Students' prior knowledge and students' mathematical thinking were related, and, indeed overlapped on occasion, but teachers were more likely to refer to students' prior knowledge when discussing lesson planning and students' mathematical thinking when describing making sense of student ideas retrospectively (e.g., when reflecting on videos).

Table 1: Significant Aspects of the Professional Development by Teacher and Year

Theme	Year	Teacher 1	Teacher 2	Teacher 3	Teacher 4	Teacher 5
Designated time to collaborate	1	X	X	X	X	X
	2		X	X	X	X
Authentic to my curriculum or students	1	X	X			X
	2		X			
Focus on one thing over time	1	X			X	
	2			X	X	
Forum for reflection	1					
	2			X	X	X
Change in teaching practices	1	X	X	X	X	X
	2	X	X	X	X	X
Focus on students' mathematical thinking	1	X	X	X	X	X
	2	X	X	X	X	X
Use of animations to represent practice	1	X	X	X	X	X
	2		X		X	
Students' prior knowledge	1	X		X		X
	2	X		X		X
Accountability for implementation	1			X	X	X
	2					X

Note: Themes addressed in this paper are in bold. An "X" in the cell at the intersection of that teacher and the year within a theme, indicated that the theme was mentioned by that teacher at least once during the interview.

There were two themes that were mentioned both years by every teacher: (a) change in teaching practices (an outcome of their participation) and (b) focus on student mathematical thinking (a mechanism inherent in the learning experience that may have contributed to the outcome). A third theme, designated time to collaborate, was mentioned by every teacher in year 1, and by all but one teacher in year 2. A fourth theme, use of animations to represent practice, was also a potential mechanism for allowing change to occur, and was noted by every teacher in year 1 and reiterated by three of the teachers in year 2. We discuss each theme in more detail below and provide examples of teacher utterances that are representative of how teachers expressed each idea. Although a fifth theme, accountability for implementation of the new lesson, was not mentioned by all teachers, the three who did mention it were adamant about the importance of this factor in accounting for the effectiveness of the professional development. Results are organized by the two research questions.

Significant Aspects of the Professional Development

Teachers uniformly valued a focus on student mathematical thinking, and one justification for that choice was its role in sparking change in practice. There was also broad agreement on the value of designated time to collaborate, although justifications were a bit more diffuse. The use of animations was frequently cited and valued for its effect on the process.

Focus on students' mathematical thinking. The teachers named a focus on students' thinking as a beneficial aspect both years, and they attributed that value to video analysis, more so than to the animations. Teachers justified that a focus on student mathematical thinking was significant due to three main factors: (a) focusing on the student's role in instruction was novel to them, and it was something they did not believe was a focus of their teacher preparation programs; (b) listening to student thinking helped teachers understand why students respond as they do so that they can act on that information; and (c) knowledge of student thinking sparked changes in their practice. In the excerpts below, teachers' justifications are highlighted (in italics) within their claims about the significance of a focus on student mathematical thinking. The year during which the claim was made is identified after the teacher number (e.g., year 1 is represented as Y1). Further details about changes in practice are detailed in a subsequent section.

Teacher 1 (Y1): But I think the discussions that helped me the most were when we broke down what the kids did… That to me was huge, because, like I said, I've never thought about that part of it. *I've never thought about the kids being part of the process*. I thought about "I'm the teacher, I know everything." You know, so I thought that was the biggest thing there. When we really analyzed the kid's thought process that was huge.

Teacher 2 (Y1): So, [I think the goal of the study group was] to help support me as a teacher *to create those [problem-based tasks]* and then from there then look at the student thinking to help *create better tasks* or help improve that specific task.

Teacher 4 (Y1): The beneficial aspect is when we're sitting around the table and we're analyzing, so we're trying to get into the students' shoes and try to figure out what they're thinking during it. And then, it's not just how I think they're thinking, but I get to hear everyone else's thinking that they're [the students are] thinking. So it kind of *broadens my perspective of what I'm thinking about students' thinking*.

Teacher 1 (Y2): And then if you go to the discussion on the student thinking, that was such a *foreign concept*. Like I said before, nobody talks about that. You're the teacher. I'm going to impart my wisdom on you and you're going to absorb it in like a sponge. And, unfortunately, that's the way a lot of education classes were. You were taught in the way the professors were taught in the way they were taught in the way they were taught. And it was all just teacher is the expert; they lecture; you get the material; you test over the material; you move on. It was never, *there was never discussions about, "Well why did this kid do this first?* Let's look at their paper. Let's look at the their steps."

Teacher 3 (Y2): But it's still good to hear how students are thinking differently. So then *as a teacher I can be aware of how my students might approach problems*. So, that can either *change how I teach it* or just when I'm working with them and I see them doing this I can think, "*Oh, maybe this is how they're thinking I need to redirect them that way*."

Teacher 5 (Y2): I feel like as a professional, we, other than this study group, we've never necessarily just sat down and been like, "Let's look at student work and try to think of what they were thinking?" You never get time to practice that…. And generally you're just thinking Johnny's crazy and has no idea what he's doing. *But maybe secretly he just has a different frame of reference. And what he's saying actually makes sense to him.* And in his frame of reference makes sense. But *you're so clueless to his frame of reference that you just think he just doesn't make sense*. And I feel like that misunderstanding between student and teacher, is sometimes what turns kids off of math altogether.

Designated time to collaborate. All teachers indicated that they valued having a designated time to collaborate with other professionals, specifically geometry teachers. The teachers justifications were (a) they were able to see other teachers in action via excerpts of video-recorded lessons that were shared during the study group, and (b) they provided an opportunity to share ideas. In the excerpts below, teachers' justifications are highlighted (in italics) within their claims about the value of teacher collaboration. At times, teachers attributed their growth to collaborations, specifically, and these instances are highlighted, as well.

Teacher 1 (Y1): Because to me that's the biggest advantage of things like this is when you *get to steal ideas* from people that are specifically doing what you're doing.

Teacher 2 (Y1): I just think overall it was a really great experience, especially being able to talk to other teachers that are teaching geometry but in other buildings, I think was really valuable.

Teacher 3 (Y1): That's how I feel like *I have been able to grow the most professionally is just through the collaboration* with other professionals.

Teacher 4 (Y1): I feel like having to talk about specifics like as far as teaching geometry on like a regular basis has been really good for me and keeping me kind of like inspired, to fix things and do more and whatever. Because I feel like a lot of times when you are kind of like on your own, you kind of get in a rut and you start teaching the same things and you kind of no one really stirs the pot or makes you think, you know, unless you're like super self-motivated, like, to do that [laughter]. So it's kind of nice to be able to get together with professionals who are not necessarily at my school but are teaching the same concepts, same standards. And be able to *bounce ideas off* and *see what other people are doing* has been very good for … the teaching act. It's … kept a lot of my stuff fresh.

Teacher 5 (Y2): But then it was also *giving each other ideas* of … you know because it's the same problem they did in their class, and they probably ran into the same misconception. But they handled it differently than I did. And it was *nice to see different people handling them in different ways*. And I feel like that's part of practicing is seeing it done different ways, but you never get to see each other's classrooms like that. So, it was just really neat to see.

Use of animations to represent practice. Teachers noted two reasons that animations were valuable: (a) it was more comfortable to critique the practice of an animated, cartoon image of a teacher, rather than a real teacher, because the anonymity of the teacher created a safe space for honest dialogue; and (b) there were fewer distractions (e.g., background noise, student offhand comments, or off-task behavior) than would be inherent in a video of real people.

Teacher 1 (Y1): At first I was like, "Are you kidding me?" But I think the good thing about it was you weren't looking at a specific real person. It made you focus, *it made me focus on the content*. Because it was a cartoon setting and you knew it was scripted. So, you weren't looking at "Okay, how did the teacher say this?" You were looking at what did they say and how did the kids receive it and what did they say. So, *it really made me focus on what was being taught and what was being heard and what was being learned*, rather than "What kids were talking in this corner?" and "What was the teacher doing?" and that kind of thing.

Teacher 4 (Y1): I think those are really helpful because I think what happens there is the focus is… you're not like … as a teacher or as a classroom *you don't feel at all defensive because it's not like... you're not being analyzed*. You're analyzing a student's thinking. So, it's easier to be more open and share that information.

Teacher 5 (Y1): You know, you're looking at it and it's a cartoon guy. So you don't feel, *you feel very free to kind of like have criticism of it.* You know what I mean? It's like, you don't feel like your watching your buddy teach and you're like, "Why did you do that? That makes no sense." You know what I mean? So it's like… *it's not as personal*.

Teacher 2 (Y2): Well first, the [animated] vignettes, I think, provided a good opportunity. We didn't use them as much. But, it provides *a good opportunity to look at something without the bias of certain groups of students or looking at the teacher* or … It kind of *takes away more of the personal aspect* of it, when *you're just looking at the vignettes*. So I think that was kind of nice. Especially as would like at the beginning when we were kind of getting to know each other or starting to kind of feel out what this process whole… was all about.

Accountability for implementation. Although only three of the teachers addressed this issue, we found it compelling and have included it here. Teachers stated that a significant aspect of the professional development was the fact that there was accountability for implementing a practice (i.e., teaching the collaboratively developed lesson) that was a product of the study group. Often, this claim was made in response to a question in which teachers were asked to compare the study group with other professional development experiences. Teachers justified this claim by stating that being forced to attempt something new meant that they could not easily ignore the ideas that arose in the study group, as they might otherwise do after a professional development.

Teacher 3 (Y1): So, like, and the fact that it's like I'm held accountable for it. It's not like I'm sitting in some like even a full day, a full professional development day maybe by my district or whatever. And like we could come up with some good ideas, like "we could do this and that." And maybe we'll throw something in the air, but sometimes like once teaching…Like once the year starts, once the… *we kind of can fall back into that same old grind*.

Teacher 5 (Y1): So it's like very much like, "Here's some skills, now we're going to put them into practice. And, I'm coming to your school on Tuesday to see it being done." And you're like "Okay." So *it like forces you to like really do things*. Whereas a lot of PD is like, "They paid me to do this, here's a bunch of stuff, and I'm never going to see you again. So, use it or don't use it. I don't care." And then it's like not as effective. There's no follow up."

Teacher 5 (Y2): And then they hold you accountable *because they're coming to your room with cameras*! So you can't just tell them you're going to do it and then go and not do it. You, like, *you gotta do it*!

Changes in Teaching Practices

Teachers identified several specific changes in practice, even though study group facilitators focused specifically on helping teachers analyze students' prior knowledge, and not on any of the participants' teaching practices. Changes in practice that were cited were (a) increased focus on how to launch a problem (b) increased focus on effective implementation of wait time, including anticipating student responses and formulating next steps; and (c) increased skill in implementing problem-based tasks or discovery activities. Launches were mentioned more often by teachers in year 1, which was the year during which they were a focus of the study group. Although a common launch was developed during group planning, during implementation, teachers tailored their launches to their own talents and knowledge base or to what they perceived would be more motivating for their students. The excerpts illustrate the types of changes teachers reported in their practices.

Teacher 1 (Y1): One of the things that I think I've taken from this is that, we talked about a lot, kind of like *launching a problem*, and kind of how you'd build up a problem at the beginning. And, often times, I just kind of roll through, "Alright let's go, here's the paper, here's the materials, make it happen." Where I don't necessarily think about how to build that up or how to get those kids involved or kind of hook the students. And so, *that piece, kind of made me think overall, in my other courses, too, how can I try to get the hook involved more*.

Teacher 1 (Y1): I think it goes back to thinking about what kids bring to the table. It made me stop and think about that when I was planning things, when I was presenting things, when I was doing my *wait time*, y'know. "*Don't just ask a question and wait. Think about their response, and formulate the next questions.*" So, I think just forcing me to think about what kids bring to the table was the biggest positive.

Teacher 5 (Y1): I feel like it's *made me more thoughtful in how I go about presenting topics*. Especially something like in the first time. Like, *how do we discover this*? *How should I present it*? What's the *launch* gonna look like?

Teacher 2 (Y2): And then I think I'm starting to do a better job of kind of *managing that bigger group, bigger task ideas*. And then, I want to do more of just creating more of these task oriented. So that's my goal. I'm not there yet…. I think what I really appreciated and I think will benefit most from my teaching is really *looking at if it's more of these hefty problems*, like what are the *anticipated responses*? And then kind of game planning how I might do that.

Teacher 4 (Y2): I mean, so *you are thinking about the way the kids are thinking about it which changes the way that you're writing the lesson*.

Discussion

Teachers identified several significant aspects of the learning experiences, situated both in their classrooms and in a context removed from those classrooms, that were consistent with claims in the literature about effective professional development. Specifically, teachers valued the opportunity to participate in a discourse community (Putnam & Borko, 2000), especially when members of that community were teaching peers. Teachers' justifications about the value of those discourse communities were fairly general (e.g., share ideas, seeing other teachers in action), and they may not have recognized the affordances of collaborating in that way. Putnam and Borko (2000) claimed that having the support of a discourse community can support the risk taking that is necessary changing practice. Although none of the teachers made explicit claims connecting their changes in practice to the discourse community, they did claim to have made such changes. The teachers did argue that accountability requirements of participation in the study group enabled them to take the risk of implementing a lesson that they may have otherwise left unimplemented. Perhaps this need for accountability could also be characterized as a disruptor to the teachers' existing practice (Putnam & Borko, 2000).

The teachers stated that they valued a focus on student thinking, rather than on teaching. Teachers noted that understanding students' logic (even if it was not correct) was an impetus for changes in teaching practice. Although this may seem counterintuitive, creating the need for change by seeing classroom events through the students' eyes was a more powerful motivator, and perhaps less intimidating than having a direct focus on the actions of the teacher. As one teacher implied, there is a tendency to be defensive, when one's work is the object of scrutiny. Thus, protecting teachers from a perceived vulnerability, by limiting discussions of teaching to those based on animated representations, encouraged dialogue and may have built the trust that was needed to sustain interactions later in the study group process, when videos from participating teachers classroom were analyzed.

Finally, the changes in teaching practice reported underscored the value of a focus on students' mathematical thinking in the study group. The changes reported (e.g., focus on the lesson's launch, increasing wait time, or listening carefully to what students say before responding) were indicative of an increased interest in student-centered learning. Thus, a focus on making sense of students' prior knowledge, encouraged teachers to reflect on how to modify their practice to find more opportunities to listen to students.

Overall, identifying characteristics of professional development programs that teachers find valuable is important because teachers may persevere in long-term, or time-consuming professional development if they see the inherent value. In our case, the teachers established the importance of having authentic experiences connected to their students and their curriculum. At the same time, the opportunities to collaborate with teachers from other schools and districts prompted them to discuss important problems of teaching. Resources used in the program such as the animations served as important vehicles for helping the teachers extend and connect their knowledge of their context (e.g., the geometry curriculum and their students) and their knowledge of teaching. The teachers' analyses of student mathematical thinking opened the door to examination of their own practices and moved them closer to the goal of effecting robust mathematical understandings in their students.

Acknowledgment

The research described in this article was supported by a National Science Foundation grant to Gloriana González for the project entitled "CAREER: Noticing and Using Students' Prior Knowledge in Problem-Based Instruction," Grant No. DRL-1253081. ATTITUDES/BELIEFS OF EARLY CAREER SECONDARY MATHEMATICS TEACHERS IN REGARD TO THEIR SUPPORT SYSTEMS

Lisa Amick	James Martinez	Megan W. Taylor
University of Kentucky	CSU Channel Islands	Trellis Education
lisa.amick@uky.edu	james.martinez@csuci.edu	megan@trelliseducation.org

This study describes the data from a series of national surveys of mathematics teachers in their first three years of teaching. The initial, pilot survey was created by a team of researchers and educators from 13 universities and four K-12 school districts and involved a year long study of 41 teachers. The final survey, devised as a result of data gleaned from the pilot, was administered in December of 2016, with 141 participants responding. The main objective of the final survey was to gather information about how these teachers perceive they were being supported and inform initiatives aimed at improving teacher retention rates. The survey focuses on what types of professional activities and communities in which teachers are participating, their perceptions of these activities, and how practice is influenced. Additional questions focused on administrative and university support, job satisfaction, and anticipated longevity in the field.

Significance/Purpose of Study

We are in the midst of a crisis in math teacher education that has a critical effect on how prepared our students are to be successful in high school, college and beyond. Half of all teachers leave the profession within the first five years, and this rate is highest for math positions in high poverty schools (Goldring et al, 2014; Fantilli & McDougall, 2009). Furthermore, with half of all current teachers in the U.S. retiring in the next five years (Foster, 2010) and enrollment in many teacher preparation programs declining, the teacher turnover is expected to cost $7.3 billion annually (National Math + Science Initiative, 2013).

Theoretical Framework

Research has defined key components of a more cohesive and effective system of mathematics teacher preparation and development that facilitates teacher growth and retention. Our theory of action focuses on one of these components: ensuring early-career mathematics teachers have high-quality, content-specific professional support. Targeted mentoring by experienced teachers, for example, especially as part of a long-term arc of teacher learning, has a dramatic impact on a new teacher's beliefs, practices, effectiveness, reflectiveness, satisfaction, and likelihood to stay in the profession (Ingersoll & Strong, 2011; Oh, Ankers, Llamas, & Tomyoy, 2005; Ronfeldt & Reininger, 2012; Walkington, 2005), and ultimately affects student achievement (Strong, 2006; Strong, Villar, & Fletcher, 2008). Effective support is especially critical and impactful in a teacher's pre-service year before entering the classroom full-time, and in his or her first few years of teaching (EdSource, 2014). Additionally, when teachers participate actively in professional learning communities, the likelihood they remain in the teaching profession and become more effective at teaching mathematics increases (Fulton, Yoon, & Lee, 2005).

Methodology

In 2016, STRIDES researchers designed a pilot survey of early-career secondary mathematics teachers to identify potential mismatches between the kinds of support research has shown are important for early-career teachers and the support early-career teachers are actually receiving. The researchers distilled three change ideas with which they developed a revised survey and an early set of interventions. These ideas were:

1. Build professional learning communities (PLCs) of early-career mathematics teachers.
2. Ensure early-career mathematics teachers and mathematics teacher PLCs have effective mentors.
3. Bolster administrative support for early-career mathematics teachers and teacher PLCs.

The STRIDES researchers developed the “Reflection on Professional Activities” survey in iterative cycles of survey design, implementation, and data analysis, including a year-long pilot with 41 early-career mathematics teachers. The survey was designed to gather semi-annual information about the three change ideas that would support the researchers implementing the change ideas more effectively.

Participants

The pre-service and early career teacher participants were solicited via electronic means by MTEP partnership university faculty. Twelve percent of the respondents designated themselves as pre-service teachers, twenty-six percent in their first year, twenty-six percent in their second year and thirty-six percent in their third year of teaching. An overwhelming number (94%) of these teachers were serving in public secondary schools in rural (13%), suburban (32%), and urban (23%) settings, and teaching in a full range of classes from 6th grade general math through calculus. The schools they were serving were characterized by their teachers as low-SES (26%) and high-SES (9%). Most (72%) of the pre-service and early career teachers surveyed stated that between five and twenty percent of the students they were teaching had Individual Educational Plans (IEPs), fifty-nine percent stated that between five and twenty percent of their students were designated as English Language Learners (ELLs) and fifty-five percent of them reported that between forty to one hundred percent of their students qualified for free and/or reduced lunch. The map below shows the locations of the teachers who participated in this study.

Findings

Several questions were posed to participants that asked them to select their answers from a given list of choices. These questions focused on career choice, job satisfaction, anticipated longevity in the field, and estimated weekly time spent on teaching, planning, and professional activities. Other questions asked participants to choose professional activities in which they had recently participated and select to what extent those activities impacted their enthusiasm for teaching. The final quantitative questions asked participants who supports them, the depth of that support, and what type of support they get from those people.

Initial data analysis shows that most of the pre-service or early career teachers surveyed (81%) "certainly" or "probably" would become a teacher "if (they) could go back and start college again" and nearly half (46%) of them would remain in teaching "as long as (they) were able". The majority of teachers (53%) say that they spent between one and two hours a week involved in professional learning activities and another eighteen percent say they spend three to five hours a week. Teachers reported spending a large chunk of their weekly time planning with colleagues (56% spend 1-2 hours, another 27% say 3-5 hours) and another large amount of time planning alone (35% spend 6-10 hours, another 30% say 3-5 hours). Sixty three percent of respondents claim to spend more than 20 hours a week teaching. With regard to professional learning activities that "increase their enthusiasm for teaching mathematics", working/communicating with a mentor or coach rated the highest among all choices (83% responding that it was either moderately or very influential). In terms of support from administrators in a variety of areas (curriculum, classroom management, course assignments, assessment, instruction, collaboration and affirmation), the respondents relied to a much larger degree on those who were on-site (principals and assistant principals) rather than university professors and district office personnel. The three graphs below depict some of our findings.

When teachers were asked what they wish was different about their job, the words that were mentioned the most frequently were support, non-teaching duties, class size, collaboration, student behavior, and pay. Participants also reported that the most used online forums for professional use were blogs and Twitter. When asked to describe a professional learning opportunity the teachers participated in that had a positive effect on their ability to facilitate student learning, teachers described a huge variety of activities, some of which were embedded in formal or informal professional learning communities. For example, one teacher described a community of first-year teachers the school district created, and many described their departments as versions of PLCs that supported their teaching practice. Few teachers described formal professional learning communities created or facilitated by their university teacher preparation program or school district, but many teachers reported access to mentors or coaches (e.g., “I am currently participating in an Algebra 1 blended learning pilot being conducted by the state department. I meet bi-weekly with an coach online to discuss teaching practices and strategies.”). The “positive effect” of the support teachers described tended to be either related to a change in a planning or teaching strategy, move or structure (e.g., [I learned] “the regal look - a look you give your students when you want them to be quiet”) or to feeling generally “prepared” to teach. Few teachers described changes in student learning related to changes in teaching supported by professional learning communities, mentors, or administrators.

Lastly, participants were asked to describe how a professional learning activity increased their enthusiasm for teaching mathematics. The majority of the responses fell into two categories. The first category is teachers who are inspired and rejuvenated by working with someone who has an infectious, enthusiastic attitude about teaching. Participants described listening to a presenter who was like this, reading testimonials online, or working with colleagues such as math coaches or department members who have this passion for teaching. For example, one participant wrote, “I participated in a conference call with colleagues from across the nation. Every time we chat, I am reminded of why I love to do what I do. Their enthusiasm definitely rubs off on me.” The second category of responses was enthusiasm gained by trying out new ideas in the classroom and seeing their students succeed with them. Teachers learned of new activities via conferences, blogs, meetings with colleagues and various other ways and described how invigorating it was to customize these ideas to fit the needs of their students, try them on using their own teaching style, and see their students succeed.

Conclusions

The MTEP STRIDES team is not comfortable at this time to draw conclusions or suggest possible interventions based on this initial data. Our one-year study is only halfway complete, with the second survey administration set to happen in April of 2017. Once these same teachers complete the survey a second time, detailing how they were supported for a full school year early on in their career, the research team will meet in the summer to fully analyze the data and propose interventions. These targeted interventions will be implemented during the 2017-2018 school year with a goal to expand meaningful support for early career mathematics teachers and to increase teacher retention at large, serving as proof of principle for more wide-scale efforts.

While professional development (PD) provides an opportunity for teachers to cultivate skills that are consistent with best practices in the field, it is their buy-into the PD that ultimately determines the effectiveness of the PD. We examined how teacher buy-in affected the classroom habits and practice of four elementary teachers who took part in a district wide PD. Using baseline and first-year implementation video recordings, in conjunction with frameworks for discourse analysis, cognitive demand, and tools built specifically to measure PD implementation, we found that varying combinations of teachers' beliefs served as a mitigating factor for PD implementation.

Keywords: Teacher Education-Inservice/ Professional Development, Teacher Beliefs

In this report, we explore the effect of teachers' buy-in for a high-quality, sustained, district-wide professional development (PD), Mathematics Studio PD (Foreman, 2013), on improving their classroom habits and practices. Systematic change requires coordination and cooperation between the system (school and PD program) and the participants (teachers). Without high buy-in, teachers will likely implement little of what they learn in even the strongest of PD programs. We present four divergent cases to illustrate the relationship between the exhibited level of buy-in and how it affected their mathematics teaching practice in their elementary classrooms.

Background and Theoretical Framing

Field-endorsed best practices for PD often exist at the program level with recommendations like "intensive, ongoing, and connected to practice; focuses on the teaching and learning of specific academic content; is connected to other school initiatives; and builds strong working relationships among teachers" (Darling-Hammond et. al, 2009, p. 5). We challenge that program level recommendations are insufficient without looking at individual participating teachers. As PD represents an appeal to change, the inclination of a teacher to making said changes in their teaching practice is an important factor in the success of the PD. We capture this inclination using the construct of *buy-in* from the management and leadership field (Thomson et al., 1999). We adopt Thomson et al.'s two types of buy-in: *intellectual* and *emotional*, where intellectual captures the degree of understanding and emotional the degree of commitment. We treat belief alignment between teacher and PD as an (intellectual) indicator of buy-in, and seeing a need for change as an (emotional) indicator of buy-in.

Teacher Beliefs and Classroom Practice

To address belief alignment, we both identified teacher beliefs from their discussion contributions in PD sessions and explored related factors of their classroom practice. In this context, our focus is on beliefs about mathematics, teaching, and learning. The principles underlying the PD focus on mathematics as a sense-making activity where are all students are capable of deep engagement in meaning-making via justifying and generalizing. To explore belief relationships and their classroom practice we used cognitive demand and patterns of discourse. Henningsen and Stein

Galindo, E., & Newton, J., (Eds.). (2017). *Proceedings of the 39th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* Indianapolis, IN: Hoosier Association of Mathematics Teacher Educators.

(1997) defined cognitive demand as, “The kind of thinking processes entailed in solving the task as announced by the teacher and the thinking processes in which students engage” (p. 529). When teachers engage students in high cognitive demand tasks, it is an implicit reflection of a belief that students can do highly demanding mathematics and that mathematics is richly connected (Wilhelm, 2014). A second way beliefs may manifest in observable classroom actions can be seen in patterns of discourse. We leverage Scott, Mortimer, and Aguiar’s (2005) interaction and authority framework to address the balance of student and teacher engagement in doing mathematics. In this report, we focus on the authority dimension where discourse is classified as *authoritative* or *dialogic.* An authoritative classroom has only one acceptable solution path and correct answer versus a dialogic classroom allows for multiple solution paths.

Critical Components and Measuring Fidelity of PD Implementation

We also examined teacher’s classrooms for explicit implementation of the PD measured as *degree of implementation* to capture “the extent of change that has occurred at some particular time toward full, appropriate use of the target innovation” (Scheirer & Rezmovic, 1983, p. 601). We analyzed the *critical components* (O’Donnell, 2008) of our PD and developed a classroom observation tool, *The Mathematically Productive Habits and Routines* (MPHR) to measure the implementation of the PD components in classrooms (see Melhuish & Thanheiser, 2017).

Methods

Data for this project was taken from a large-scale study aimed at discerning the efficacy of a 3-year PD program in an urban school district in the Northwestern United States. Our data consist of classroom video recordings (two lessons before PD and two lessons after PD), as well as video recordings and detailed field notes from five PD sessions across the year at two schools.

Identifying Teacher Buy-In

Researchers observed and video-recorded all PD sessions taking detailed field notes which were analyzed using thematic analysis (Braun & Clarke, 2006). The themes were informed by the need to identify important factors that relate to the efficacy of the PD program. We identified four case study teachers to further analyze. They were selected based upon their variations in terms of belief alignment and perceived need to grow.

Analyzing Classroom Change

Each year, two lessons were recorded for all participating teachers. For our case study teachers, we focus on their baseline videos (prior to any PD) and their year 1 videos (after a year of PD). To facilitate in the process of scoring and coding, each video was segmented into episodes; each episode representing a portion of the lesson where the curricular goal/aim was consistent throughout. Each episode was then scored and coded according to the frameworks for the discourse analysis and cognitive demand analysis (i.e. 1-memorization, 2-procedures w/out connections, 3-procedures w/ connections, 4-doing math). Each lesson was given an overall degree of PD implementation score based on the MPHR.

Results & Discussion

In this section, we provide an overview of our four case study teachers and focus more extensively on our most extreme cases: Cora and John. The buy-in level was based on two factors: perceived need to grow in teaching practice and belief alignment with the PD. A summary of the four cases in terms of: (1) 2 factor buy-in, (2) belief and classroom practice alignment, and (3) PD Implementation can be found in table 1. For a more nuanced discussion of their buy-in see Fasteen, Melhuish, and Thanheiser (2015).

Table 1: Degree of Implementation Growth and PD Buy-In for Case Study Teachers

Case Teacher	John (Low)	Nina (Mid)	Kim (Mid)	Cora (High)
Belief Alignment with PD	No	No	Yes	Yes
Need to Grow in Practice	No	Yes	No	Yes
Beliefs Aligned with Classroom Practice	Yes	Yes	Inconsistent	No
PD Implementation	No	Yes	No	Yes

Case 1 & 4: John (Low-level buy-in) & Cora (High Buy-In)

Cora and John were at opposite end of their careers. John was preparing to retire while Cora was in her second year of teaching. During the PD, Cora displayed indicators of high-level emotional and intellectual buy-in while John displayed low levels of both.

Baseline lessons. Prior to involvement with our PD, Cora's classes had a high number of student contributions, but the tasks were often low-demand (see Table 2). Her lessons tended to include majority authoritative discussions. In John's baseline lessons, his class had minimal student interaction with most interaction consisting of pro forma call and response leaning heavily authoritative. The task demand was low with heavy focus on procedures (see Table 2). John's traditional beliefs aligned with his classroom practice. In contrast, Cora's beliefs that students are capable and that mathematics is a rich subject was reflected only in her students having opportunities to contribute while the mathematics remained procedural.

Table 2: Cora & John's Lessons in Terms of Cognitive Demand and Discourse

Lesson / Teacher	Cognitive Demand (% of time High)		Authority (% of time Dialogic)	
	Cora	John	Cora	John
Baseline 1	Varied (40%)	Low (0%)	Authoritative (32%)	Authoritative (0%)
Baseline 2	Low (12%)	Low (12%)	Authoritative (31%)	Authoritative (32%)
Post-PD 1	Varied (40%)	Low (0%)	Dialogic (72%)	Authoritative (12%)
Post-PD 2	High (85%)	Low (13%)	Dialogic (85%)	Authoritative (31%)

After one year of PD. After involvement with the PD, Cora's classroom came into closer alignment with her beliefs. The level of cognitive demand increased. The discourse moved from authoritative to largely dialogic reflecting the acceptance and discussion of multiple strategies and viewpoints. The nature of John's class changed little after the PD. His lessons remained predominately low cognitive demand and authoritative in nature (see Table 2). Cora's implementation of the PD rose after a year of sustained support. This growth reflects her students engaging in mathematical habits of mind and interaction and her use of teaching habits and teaching routines. The tools provided through the PD may have allowed Cora's beliefs and classroom actions to more closely align. As John had low buy-in for the PD, and had beliefs that may limit growth both in terms of his own need to grow, student capabilities, and the nature of mathematics, his degree of implementation score did not rise despite a year of PD.

Conclusion

A teacher's beliefs and disposition towards the subject area, learning, and their own practice play an important factor promoting teacher change through PD. We use the buy-in construct to explore alignment or misalignment of these beliefs and the PD's principles. The literature has established that teacher beliefs and classroom actions are related, but the relationship is often complex. Our cases illustrate some of the complexities. Cora's case is particularly compelling as she has aligned beliefs (and subsequently high buy-in to the PD), but prior to the PD intervention, the beliefs alone were insufficient to promote high level reasoning in her mathematics classroom. When provided with the tools, Cora's classroom became more in-line with her beliefs. John, who did not perceive a need to grow, implemented little work from the PD into his teaching. Cora and John each represent very different types of teachers that may participate in PD. As providers of development and researchers on innovation, attending to beliefs and belief-alignment in classroom actions, may provide a starting ground for addressing the variance in individual PD participants.

This study explores mathematics teachers' participation in a series of virtual sessions focused on implementation of new state mathematics standards and promoting more equitable learning opportunities for students. Our findings indicate that teachers' preferred the use of text-based chat features for interactions. Further, their emerging participation practices focused on task implementation, student work, and mathematical content.

Keywords: Teacher Education-Inservice/Professional Development, Technology, Standards

Introduction and Background

Mathematics education researchers have built a strong body of research that continues to move the fields of both research and teaching forward; however, a divide continues to exist between research and practice (Battista, 2007; Cai, et al., 2017) and issues of implementation at scale (Cobb & Jackson, 2011). Responding to this challenge, researchers and funding agencies are encouraging research-practice partnerships where researchers and practitioners work together to iteratively design and research problems of practice (Kane, 2016; Penuel & Farrell, in press).

As part of a statewide research-practice partnership between a state education agency, district leaders, teachers, and mathematics education researchers at several institutions, our work draws upon Design-Based Implementation Research (DBIR) (Fishman et al., 2013) as an approach to facilitate the design of intervention efforts related to new state mathematics content standards and efforts to promote more equitable learning opportunities for students. These efforts include many spaces for engagement, one of which is a weekly virtual session designed to be "just in time" regarding the new standards and related mathematics topics addressed in each of the three integrated and sequenced high school mathematics courses, Math 1, Math 2, and Math 3.

Theoretical Perspective

Central to a DBIR approach are key principles of drawing upon multiple stakeholders' perspectives; collaborative and iterative design; a commitment to developing both theory and knowledge; and developing sustainable practices (Fishman et al., 2013). The focus of this paper is the design-research efforts related to the nature of mathematics teachers' participation in the virtual sessions. We conceptualize virtual sessions as an affinity space (Gee, 2005) where teachers come together to engage in the common activity of sense making around statewide implementation of new mathematics content standards in ways that promote more equitable teaching and learning. Viewing the virtual sessions as an affinity space is helpful because it frames both the design of the space and the ways in which participants interact with both the space itself and with one another.

Fundamental to affinity spaces are the constructs of what Gee (2005) calls a generator, portals, and internal and external grammar. A generator represents the focus of the space; portals represent the various ways in which participants can engage in the space; internal grammar represents the design of the space; and external grammar represents the ways in which participants behave and interact. In this study, the generator is a statewide effort to support teachers in student-centered implementation of new mathematics content standards through weekly virtual sessions. The portals for this space include registration (which provides access to documents to be shared in the session), attending, chatting using a text-based feature, and speaking aloud. Using a DBIR approach to this work, we iteratively design the internal grammar of the space while studying the external grammar of the ways in which participants engage within the space. Specifically, our research is guided by the questions: (1) *In what ways do teachers use the portals for participation within the space?* and (2) *What is the nature of teachers' participation evidenced by their external grammar within the space?*

Design of the Affinity Space

The online platform used to conduct the virtual sessions, *GoToWebinar* (https://www.gotomeeting.com/webinar), was the contracted platform of the state agency partner. Only teachers were invited to take part in the space, as we hoped to create a safe place for open discussions. The platform allows for participants to chat via a text feature and speak aloud for those with microphones. The sessions ran approximately one hour each and were offered the first three Thursdays of each month in the order of Math 1, Math 2, and Math 3. The design of the sessions was initially informed by our initial learning conjectures and joint design work with teacher and state agency partners, and was continuously revised based on our ongoing analysis and teacher feedback within the space and through surveys. Over the first few iterations a "typical" session design emerged. Sessions were typically hosted by two teachers/leaders with a focus on implementation of a task related to the mathematics standards of focus for that month and included samples of student work.

Methods

Qualitative methods were used to understand the nature of mathematics teachers' participation in the Math 1, Math 2 and Math 3 virtual sessions. Participants in this study included teachers across the state who taught Math 1, Math 2, or Math 3. All teachers were invited to participate through email announcements and at state, regional, and district level face to face meetings. Twelve virtual sessions were held and approximately 350 teachers participated at least once over the course of the semester. Participants represented 70 school districts (out of 115) spread across the state, with many being from rural areas.

Data for this study includes text of participants use of the text-based chat feature and video recordings of virtual sessions. Video recordings were viewed by members of the research team and all participants' talk was transcribed verbatim. To understand the ways in which teachers were participating, frequencies related to portal use were calculated. To understand the nature of teachers' participation, all chat and verbal transcripts were open coded to identify themes. We used a constant comparative method (Strauss & Corbin, 1998) to identify emerging categories and refine these categories as they contrasted with data.

Findings

The ways in which teachers participated in the virtual sessions varied from month to month and across courses. There were four portals within the virtual session platform: 1) *registering* provided access to the tasks that were the focus of each session; 2) *attending* in which participants could listen to (and read) the interactions of others; 3) *chatting* in which participants could interact through text; and 4) *speaking* aloud during the session. A summary of the use of each portal appears in Table 1. Attendance in the sessions decreased each month across all three courses, with the Math 1 sessions having significantly higher attendance than the other two courses. The most common mode of interaction during the sessions was the use of the chat feature. This suggests that the chat feature was the easiest or most comfortable mode of interacting within the session platform. In addition, the amount of interaction among participants increased, as is seen by the increased trend of growth in the ratio of attendees to total chats until the drop off in attendance in December.

Table 1: Virtual Session Portal Use

	Sept			Oct			Nov			Dec		
Math Course	1	2	3	1	2	3	1	2	3	1	2	3
registered	255	162	182	216	136	133	99	32	30	42	28	18
attended	132	74	77	61	49	38	43	11	11	16	15	7
total chats	19	63	82	74	52	38	45	8	4	69	27	3
total talks	n/a	10	6	14	4	14	2	4	1	0	2	0

Analysis of participants' chat text and transcribed talk revealed that interactions fell into the following categories: *general about students* (i.e. comments about students in general, not specific to the context of the task being discussed), *general about teaching* (i.e., about teaching unrelated to the task being discussed), *general about standards tools* (i.e., about other project spaces and tools), *task discussion* (i.e., focused on the mathematics of the task itself), *pedagogical decisions related to task* (i.e., focused on suggested pedagogical decisions, shared pedagogical ideas, or pedagogical questions related to the task of focus), *student thinking* (i.e., analysis of student work or anticipation of student thinking), and *technical issues* (technological issues with the virtual session platform). Below we discuss the most commonly used codes to illustrate the nature of the participants' discussions. All examples are pulled from the text-chat data as they tended to be more succinct.

Focusing on Task Implementation (43.3% of all quotations)

When participants discussed pedagogical decisions related to the implementation of the task their contributions included questions about implementing the task or suggesting questions to pose to students (e.g., "I might ask: Do you see a pattern with the change in time leaking?"). However, the majority of their contributions regarding pedagogical decisions related to sharing ideas with one another for implementing the task. For example, when multiple examples of student work had been shared, a teacher used the chat feature to conjecture an instructional decision to support students' mathematical engagement in the task, stating, "The student whose work is currently shown should be paired with the previous student. They should discuss how their tables are connected." Additionally, while listening to one teacher sharing a task another teacher chatted, "This is a good place to discuss inverse relationships."

Focusing on Student Thinking (23.4% of all quotations)

When discussing student thinking participants tended to anticipate student thinking when presented with an instructional task. For example, "I think students may struggle with the three variables (price, # of boxes, and revenue) when they are only used to an input/output, and identifying which is the input and output." In addition, when presented with student work samples the participants showed evidence of critical analysis of that work. For example, as a sample of student work was shared one teacher noted, "This table doesn't completely show understanding of the repeated multiplication aspect of exponential functions, just that they know they are multiplying answers by 3."

Focusing on Mathematics (21.9% of all quotations)

Each session was designed around a specific mathematical task that allowed for a focus on mathematics related to the new standards. Within the virtual sessions participants discussed ways that the task addressed the new standards (e.g. “It seems to fit nicely with the set of G.CO group. Ideas about transformations, congruence, similarity, changes in area and space.”) and characteristics/purpose of the task itself (e.g. “I think that the task really allows students with different methods to solve the problem. They can use the properties studied. They can use models. They can use tools such as rulers, protractors, and folding paper.”). Furthermore, in each session there was evidence of discussion around the specific mathematics related to the task. This included asking other participants for help with the mathematics (e.g., “Can you re-explain how you developed the quadratic to solve for the min?”) and sharing their own solution strategies (e.g., “I see that the rate of change in the table is not constant, but it has linear scatter plot. So, use the model to see if the y-intercept is 400?”).

Conclusion

The purpose of the virtual sessions was to provide a space for mathematics teachers across a state to engage with new state mathematics standards and a pedagogy centered on student thinking. The virtual sessions were successful in that approximately 350 teachers chose to enter the space at least once. These teachers were mostly from rural areas of the state, which is important as they often noted that they did not have others to interact with at their schools. While it is promising that participants’ interactions focused on important instructional issues, we are also encouraged by the mathematical nature of their interactions. Teachers not only discussed mathematics, but also some went as far to admit uncertainty and ask for help. Overall, we feel as if the design of the space is meeting teachers’ needs, however, the drop off in attendance and focus on the use of the chat feature suggests that revisions are needed.

Creating spaces in which teachers feel safe to take mathematical and pedagogical risks is important for teachers as they work toward implementing mathematics standards in ways that provide more equitable learning opportunities for students. As we consider the conference theme, “Synergy at the Crossroads”, we are confident that research-practice partnerships can provide a productive and fruitful space for researchers and practitioners to work together on challenging issues of implementation at scale and the development of theories of implementation.

This early-stage design and development project combines formative assessment, learning trajectories, and professional development to improve mathematics teaching and learning in grades K-3. Formative assessment items relating to addition, subtraction, and number have been developed based on current research, learning progressions, and the Common Core State Standards. These items are being piloted by teachers and validated to determine the utility of items in eliciting student thinking and informing instruction. Early analyses of piloted items have revealed the effectiveness of items in revealing a range of student strategies and levels of understanding, as well as challenges in capturing the thinking of very young learners.

Keywords: Assessment and Evaluation, Elementary School Education, Learning Trajectories (or Progressions), Number Concepts and Operations

Introduction

This project is an early-stage design and development study extending the Ongoing Assessment Project (OGAP), a project that combines formative assessment, learning trajectories, and professional development to improve mathematics teaching and learning in elementary and middle school. OGAP has previously focused on multiplicative reasoning, proportional reasoning, and fractions for grades 3-8; the goal of the current project is to broaden this focus to include formative assessment tools and routines for addition, subtraction, and number for grades K-3. These tools and routines include: (1) a collection of formative assessment items that vary by characteristics such as problem context, situation, number complexity, and representation of operation; (2) a set of frameworks for addition, subtraction, and number that illustrate a progression of student strategies that increase in depth of understanding and sophistication of strategies; and (3) grade-level professional learning communities (PLCs), in which teachers collaborate to examine student work on formative assessment items, analyze students' strategies, and determine next instructional steps based on the learning trajectory frameworks. The OGAP formative assessment system lies at the crossroads of theory and practice by distilling research in early number and operations into illustrative frameworks and formative assessment items that allow teachers to make research-based instructional decisions on an ongoing basis. This paper will focus on the formative assessment item bank development and validation process.

Conceptual Framework

Classroom formative assessment is a process in which information is gathered regularly from students to provide feedback and inform the adjustment of teaching and learning (Black & William, 1998). The formative assessment item bank development and validation process employed in this project is shown in Figure 1.

The item bank development process began with a review of the research on the three areas of focus for the project—addition, subtraction, and number (e.g., Baroody, 1987; Carpenter, 1985; Clements & Sarama, 2009; Cross, Woods, & Schweingruber, 2009; Fuson, 1988, 1992; Ginsburg, 1983). The existing research, learning progressions, and common core standards on these topics were utilized to create an item bank blueprint. The item bank blueprint includes content, concepts, problem structures, number complexity, strategies, and representations for the three topics across grades K-3.

Galindo, E., & Newton, J., (Eds.). (2017). *Proceedings of the 39th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* Indianapolis, IN: Hoosier Association of Mathematics Teacher Educators.

Frameworks illustrating the learning progressions for addition, subtraction, and number were also created based on the research and standards review.

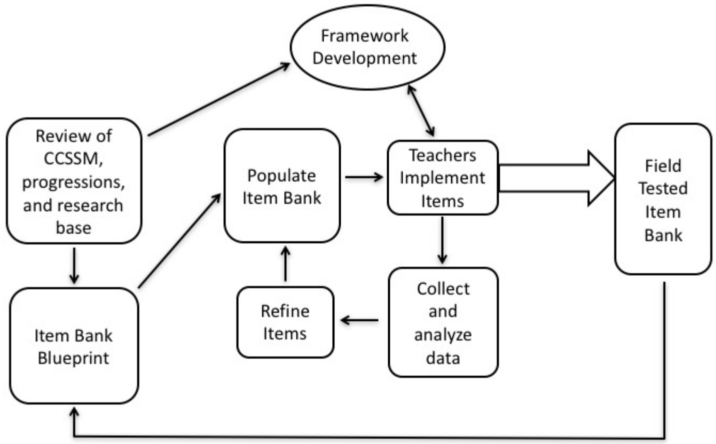

Figure 1. Formative assessment item bank development and validation process.

Formative assessment items were developed based on the item bank blueprint. The items are written tasks that can be administered to a whole group, small group, or individual. Items were created to address each of the characteristics identified in the item bank blueprint for the three content areas. Typical developmental level of a child in the grade in which a topic is taught was considered when writing problems. For example, a kindergarten counting problem would be written in simple, brief language and may contain a counting situation that could be represented easily with a small number of objects or a drawing, while a third grade problem could contain an addition situation involving distance that would lend itself to a number line representation.

Items were then distributed to teachers to implement in classrooms. Teachers collected their students' work and used the framework to sort the work by strategy use. In PLCs, teachers collaboratively sorted student work using the framework and determined next instructional steps based on the strategies and understandings demonstrated in the work.

The item validation employed in this project focuses on Stobart's (2012) recommended area of emphasis for validation in formative assessment: "Validity is based on the purpose(s) of an assessment and how effectively the interpretation and use of the results serve each purpose…effective formative assessment will do this and the 'threats to validity' are those things that get in the way" (p. 233). Through both PLCs and student work sorts conducted by the researchers, items were validated based on how students performed on the items, whether the items elicited a range of student strategies, and if the items provided information that would be useful to teachers in guiding future instruction. Sorting and discussing student work has informed both item refinement and framework development.

The first round of item development, validation, and refinement has been completed, and we will continue to validate and refine items in preparation for field testing of the fully developed item bank in a larger number of schools in year 2 (2017-2018). After field testing is complete, the item bank will be mapped back to the item bank blueprint to ensure that all characteristics and learning targets of the three content areas have been sufficiently addressed in the item bank.

Research Questions

The research questions guiding the development and validation of the formative assessment item bank are as follows: (a) What information is elicited by the formative assessment items? (b) What information is not revealed by the formative assessment items? (c) What characteristics make items useful for formative assessment?

Pilot Data Collection and Analysis

Formative assessment items have been piloted by 21 teachers in 5 public schools located in a city in the Mid-Atlantic region of the United States during year 1 of the project. Student work has been collected for 103 items. Items on addition, subtraction, and counting/number have been collected across grades K-3. Items have been piloted in two ways: in schools where teachers meet regularly in PLCs to sort and discuss items, and in schools where teachers are not implementing PLCs. In addition to the student work sorts that have been conducted in PLCs, the research team has been sorting student work to validate items and inform framework development. The data that have been collected in year 1 include student work on formative assessment items, PLC summary records, and researchers' notes on student work sorts. The data have been analyzed by reviewing the student work and sort records to determine whether students were able to answer the question, whether a range of strategies was elicited, and whether the student responses were useful for making subsequent instructional decisions.

Early Results from Item Bank Validation

In initial analyses of the data collected in year 1, two types of information elicited by the items have been identified: addition/subtraction/number strategies and concept understanding. On problems that can be solved in a variety of ways, such as an add to problem with a missing addend, a range of solution strategies was generated. These strategies can be mapped to the framework to determine subsequent instructional steps. Concept problems assess understanding of an idea relating to addition, subtraction, or number (e.g., the commutative property of addition). Though student strategies on these problems cannot be mapped to the framework, these problems reveal understanding—or lack thereof—of key concepts and properties.

Data analyses have also revealed that some information is not being elicited by the formative assessment items. Metacognition—or awareness of one's own thought process, self-regulation, and beliefs about mathematics—is a cognitive behavior that is developing in children (Schoenfeld, 1987), making it challenging for children to identify and represent mental solution strategies. When a single piece of student work contains multiple solution strategies, it may not be evident which strategy was used by the student to solve the problem. A particular challenge has revealed itself during piloting of items in kindergarten classrooms—for children who are in the process of learning to read, write, and draw, representing a solution strategy, or even writing an answer, can be a difficult task.

Three primary characteristics that make an item useful for formative assessment have been revealed through item bank validation. First, an item must draw out student thinking. For example, if an item can be answered easily with a known fact such as a double addition fact, the item may not generate much student thinking, whereas an item that incorporates a "near double" or "double +1" allows students to demonstrate whether they can use the known fact to solve a related problem, thereby calling for more complex thinking. Second, an item should generate a *range* of strategies. If most students in a class solve a problem similarly (e.g., most students accurately use the U.S. addition algorithm), the information obtained from the student work may not help the teacher to make instructional decisions, indicating that the item may not be an appropriate formative assessment item (or perhaps not appropriate for that grade level or time of year). On the other hand, if a problem generates a limited range of strategies that differ significantly in sophistication (e.g., an addition problem that generates only the counting all strategy and the addition algorithm), this may indicate that intermediate strategies that facilitate students' development of understanding of the topic should be introduced through classroom instruction. The framework plays an important role in helping teachers identify appropriate transitional strategies based on evidence of understanding present in the students' work. The third characteristic that makes an item useful for formative assessment is accessibility. The structure and number complexity of an item needs to be appropriate for the grade level and time of year, the item context should be familiar to students, and the language and vocabulary contained in the item needs to be clear and easily understood by students.

The Future of OGAP

We will continue to develop and validate items with the following questions in mind: (1) When a problem does not generate a range of student strategies, does this indicate that the problem is not valid and should not be used in the item bank? Does this indicate that the problem is not appropriate for the grade level/time of year/group of students but would produce a wider range of results in another context? Does this indicate a need for instruction on intermediate strategies so that students can move from using early counting strategies to transitional strategies and eventually to additive strategies? (2) Is there a way to collect written information from young children, or do we need to add a verbal component or observation checklist to our formative assessment items? We will then move from item development and validation to field testing, in which teachers will use formative assessment items in their daily instruction.

EXAMINING THE EFFICACY OF SIDE-BY-SIDE COACHING FOR GROWING RESPONSIVE TEACHER-STUDENT INTERACTIONS IN ELEMENTARY CLASSROOMS

Jen Munson
Stanford University
jmunson@stanford.edu

Learning to respond to student thinking in the moment is challenging precisely because responsiveness cannot be scripted in advance. In this study, I situated teacher learning opportunities within teachers' daily instruction to support learning to respond during teacher-student interactions. This embedded professional development - side-by-side coaching - was found to have a significant positive impact on teachers' ability to respond to and advance students' mathematical thinking in the moment through the practice of conferring.

Keywords: Classroom Discourse, Teacher Education-In-Service/Professional Development

Ambitious teaching practices are difficult to learn because they often require responsiveness to student thinking in the moment that cannot be pre-planned. Professional learning opportunities often focus on learning in the absence of students, for example, in workshops or collaborative planning. But teachers need opportunities to learn to respond to student thinking as it emerges. In this study, I examine the effects of using side-by-side coaching, a professional development structure situated directly in teachers' practice, to grow teachers' capacity to respond to student thinking in the moment in ways that advance students' thinking.

Prior Literature

Responding to student thinking in the moment requires teachers to orchestrate a variety of skills, capacities, and knowledge. While teachers can prepare for such moments by anticipating student thinking in advance, they cannot plan how these instructional moments will unfold. In previous work (Munson, 2016, 2017), I have described a type of responsive instructional interaction – conferring – in which teachers and students work together to uncover and advance student thinking. Conferring requires two essential types of instructional work: *eliciting* student thinking and then *nudging* that thinking along a productive avenue. A nudge is an instructional response to the elicited student thinking which advances that thinking while maintaining sense-making. Nudging is challenging; teachers who start by eliciting student thinking do not always nudge that thinking forward. In a previous study of teachers who were learning to confer, I found that fully two-thirds of the time they began to confer by eliciting student thinking, they did not end up nudging. Others have similarly found that opening questions are easiest to learn, while advancing the instructional conversation beyond initial elicitation is far more challenging (Franke et al., 2009). However, when teachers did nudge, advancement of students' mathematical thinking, engagement in mathematical practices, or productive collaboration was evident in the discourse (Munson, 2016, 2017). Given the instructional advantage of nudging, how can teachers learn to engage in this responsive practice?

Teacher educators have developed pathways for teachers to learn in, through, and from teaching, where these complex moments of instruction emerge (e.g., Ball & Cohen, 1999; Lampert et al., 2013). Grounding teacher learning in the particulars of practice allows teachers to grapple with particular challenges, such as specific misconceptions or individual student needs, rather than speaking in generalities. One possible platform for locating teacher learning directly in practice is coaching. Gibbons and Cobb (in press) identified several "potentially productive coaching activities," one of which, co-teaching, is a fruitful activity situated in instruction. When the coach and teacher are side-by-side during instruction, opportunities to reflect, seek input, and make decisions can be

Galindo, E., & Newton, J., (Eds.). (2017). *Proceedings of the 39th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* Indianapolis, IN: Hoosier Association of Mathematics Teacher Educators.

created. Further, both modeling and observing and offering feedback have been shown to be effective coaching activities. In side-by-side coaching, leadership of instruction can be handed off between the teacher and coach in the moment, rather than fixing each in the role of teacher and observer for an entire lesson, so that modeling and feedback can be embedded in the activity. Opportunities for teacher learning can then be as responsive as the instruction they aim to promote. In this study, I ask, can side-by-side coaching support teachers in learning to respond to student thinking when conferring?

Methods

Participants

The teacher participants included three elementary classroom teachers (grades 1, 2, and 4) from the same school in an urban area of northern California. The school serves predominantly bilingual Latino and Pacific Islander students from a low-income neighborhood. The teachers are part of a larger, teacher-initiated research-practice partnership, and were selected based on their interest in engaging in coaching and learning to confer. Through participant observation, the author served as the coach and shaped the coaching provided in partnership with the teachers.

The teachers all taught by launching each lesson with a task for which students were actively developing strategies. Students worked in partnerships for the bulk of the lesson, with the teacher supporting student work through conversations. Typically, lessons would end with a whole class discussion of the strategies or mathematical ideas that emerged during worktime.

Data Sources and Collection

Data was collected in three periods: pre-coaching, during coaching, and post-coaching. For the purposes of this analysis, I focus on comparing the pre- and post-coaching data. Pre-coaching, I videoed 4-6 math lessons, of approximately one hour each, over a two-week period for each participating teacher; post-coaching, I recorded a similar number of lessons for each teacher. The camera was positioned high and in one corner of the classroom. The teacher wore a lavalier microphone and a back-up audio recorder; the audio, thus, followed the teacher as she moved interacting with students.

Side-by-side Coaching Model

The coaching period for each teacher lasted approximately four weeks. During each week, the teacher and I conferred with students side-by-side for two days. Each teacher received 7-8 days of coaching in total. On each coaching day, I spoke with the teacher before each lesson about the students' mathematical goals and the teacher's own learning goals for the day. We negotiated how we wanted to work together based on these goals.

Coaching took place during the students' worktime. During this time, we would approach students at work to confer together. Conferring unfolded as co-facilitated by the teacher and the coach, with each taking the lead at different times during the interaction. During most interactions, I would pause the conversation at some point and ask the teacher to think aloud with me about what she was noticing about student work, how she interpreted what she noticed, and how she might respond. These time outs were brief and served to create space for reflection and decision-making in the moment. At times, the teacher would ask me to lead the interaction so she could observe. After each conferring interaction, we would reflect briefly on the course and outcome of the conversation and consider anything we could learn from it before moving on to confer with the next group. At the end of each lesson, the teacher and I would debrief the lesson overall and consider next steps for students and for the teacher's own learning.

Analysis

Video records of each lesson were analyzed in Studio Code, a qualitative video analysis software. In each pre- and post-coaching lesson, I identified conferring interactions based on the following criteria: (1) the interaction took place during student mathematics worktime; and (2) included elicitation of student thinking. Such interactions exclude exchanges regarding simple directions, materials, or matters of classroom management.

Each conferring interaction was then coded as either including a nudge or not. Nudges, a series of talk turns within conferring that advance student thinking, were defined based on prior research (Munson 2016, under review) as fulfilling four criteria: (1) initiated by the teacher to advance students' mathematical understanding, engagement in mathematical practices, or productive collaboration; (2) contingent on elicited student thinking; (3) taken up by students; and (4) maintained student ownership and sense-making of the work. If a conferring interaction contained a series of talk turns after eliciting student thinking that met these criteria, the interaction was coded as a *conferring interaction with a nudge*. All other conferring interactions were coded as *conferring interactions without a nudge*. These two types of interactions were then counted in the pre- and post-conferring periods for each teacher.

To determine the effects of coaching on getting to a nudge in conferring interactions, I analyzed the pre/post data using a linear mixed-effects regression (LMER) using the lmer4 package version 1.1-12 in R (Bates, Maechler, Bolker, & Walker, 2015). Interactions (n=105) were nested within teachers (n=3), with fixed slope and random intercepts to address the variation in initial teacher practice. Binary variables were coded as follows: condition: pre-coaching= -1, post-coaching = 1; interaction: conferring interaction without a nudge= 0, conferring interaction with a nudge= 1. I obtained a p-value for the regression coefficient using the lmerTest package version 2.0-33 in R (Kuznetsova, Brockhoff, & Bojesen, 2016).

Results

Conferring interactions that included a nudge, and thus advanced student thinking, significantly increased after coaching. The total number of conferring interactions in the pre- and post-coaching period varied by teacher, but a meaningful shift from interactions without a nudge to interactions with a nudge can be seen in Table 1.

Table 1. Number of Conferring Interactions With and Without a Nudge, By Teacher, Pre- and Post-Coaching

	Teacher 1		Teacher 2		Teacher 3	
	Pre	Post	Pre	Post	Pre	Post
Conferring Interactions (No Nudge)	21	0	9	3	15	2
Conferring Interactions (With Nudge)	1	7	5	17	15	10

Overall change can be seen by examining the proportions of conferring interactions with and without a nudge for each of the three teacher participants pre- and post-coaching, as shown in Figure 1. Condition (β=0.25, SE=0.04, t=5.79, p<0.001) had a significant effect on nudging. The slope indicates that the likelihood of conferring with a nudge after coaching increased by a full 50%. Increases in the rate of nudging were seen across the three teacher participants, as can be seen in Figure 1.

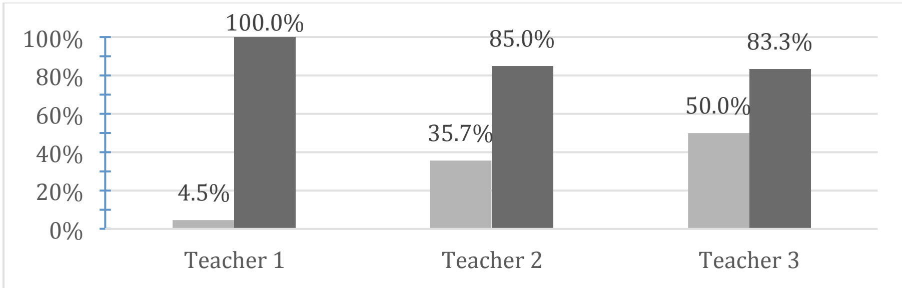

Figure 1. The proportion of conferring interactions that include a nudge, pre- (light gray) and post-coaching (dark gray) by teacher.

Significance

This study has implications for both research and practice by providing a promising intervention and by offering an underexamined way coaches can support teacher learning. Ambitious practices, particularly those demanding in-the-moment responsiveness such as conferring, are challenging for teachers to learn. Some strategies have shown promise in promoting such learning, typically outside of instructional time. This study shows one new pathway for embedding professional learning of responsive practice directly within teaching and adding to the potentially productive coaching activities (Gibbons & Cobb, in press).

How did side-by-side coaching achieve these effects? Ongoing analysis indicates that by surfacing teacher thinking in the moment, considering alternate interpretations together, and co-constructing a response, the coach and teacher can grow instruction as it happens. Additional research is needed to unpack how the coach and teacher co-constructed moments of teacher learning while engaged in the act of teaching. Side-by-side coaching is a promising avenue for future research in in-service teacher professional development of ambitious teaching practices.

HOW URBAN MATHEMATICS TEACHER SELECTION, TRAINING AND INDUCTION AFFECT RETENTION

Andrew Brantlinger
University of Maryland
amb@umd.edu

Laurel Cooley
Brooklyn College
lcooley@brooklyn.cuny.edu

Selective alternative teacher certification programs like the New York City Teaching Fellows (NYCTF) have trained thousands of mathematics teachers for urban school districts. This study draws survey and administrative data to examine the retention of 620 selective route mathematics teachers who entered teaching through the NYCTF program in 2006 or 2007. It uses logistic regression to estimate how teacher selection, training, and induction in NYCTF shapes mathematics teacher retention in New York City schools.

Keywords: Teacher Education-Inservice/Professional Development

Selective Alternative Teacher Certification Programs

Selective alternative teacher certification programs (ATCPs) like the New York City Teaching Fellows (NYCTF) actively recruit high-achieving graduates from the nation's most selective colleges and admit very few applicants (Clark, Chiang, Silva, McConnell, Sonnenfeld, Erbe, & Puma, 2013). These programs currently recruit thousands of teachers in dozens of U.S. districts In New York City alone since 2000, approximately three-quarters of all new secondary mathematics teachers in the city's public schools have entered through selective ATCPs. There is much to learn from selective ATCPs in spite of the mixed record (see Clark et al., 2013; Darling-Hammond, Holtzman, Gatlin, & Vasquez Heilig, 2005; Meagher & Brantlinger, 2011).

Research Methods

We adopt a teacher preparation program perspective to examine how mathematics teacher turnover is influenced by the major components of selective ATCPs, namely, their: (1) selection, (2) training, (3) first schools, and (4) induction. This perspective reflects research on teacher preparation by Humphrey and Wechsler (2007), Susan Moore Johnson and her colleagues (e.g., Johnson & Birkeland, 2003) and Richard Ingersoll (e.g., Ingersoll & May, 2012). Informed by this perspective, the study uses logistic regression to examine how the features of these program components shape mathematics teacher turnover in urban schools.

Research question. What is the association between SMTF turnover and their *selection* (i.e., teacher characteristics), *training,* and *induction* as part of NYCTF?

Participants. The study includes data on 620 prospective secondary mathematics Teaching Fellows (SMTFs) who entered teaching through NYCTF in either June of 2006 or 2007. SMTFs attended one of four NYCTF university partners for secondary mathematics certification.

Data. We linked data from three sources. *Survey data* on participant backgrounds and first-year induction support collected in three waves: 2006-07, 2007-08, and 2016. *Service history* data from the NYCDOE that provided information on how long individual SMTFs worked in their first school and also in the district through the spring of 2015. And, *first school data* (i.e., school climate and demographic data) for every school in the NYC school district is collected and published annually by New York state and the NYC Department of Education.

Logistic Regression. To explain how the major components of selective ATCPs affect secondary mathematics teachers district and school retention, we calculated the coefficients of four logistic regression models (Table 1). These models were estimated as:

$$ln\left(\frac{\hat{p}}{1-\hat{p}}\right) = \mathrm{B}_0 + \mathrm{B}_1\mathrm{X}_1 + \mathrm{B}_2\mathrm{X}_2 + \mathrm{B}_3\mathrm{X}_3 + \mathrm{B}_4\mathrm{X}_4$$

The coefficients B_i are in log-odds units and predict the retention outcome (i.e., the natural log of the odds ratio) for each participant provided measures of their teacher (selection) characteristics (X_1), university-based training (X_2), first school contexts (X_3), and induction (X_4).

Results

The descriptive statistics (not shown) show that the majority of the SMTFs were white, young, and graduated from a selective college and most were outsiders to the district (as judged by their high school). Fewer than one-in-six majored in mathematics or had completed the equivalent in coursework prior to beginning NYCTF. Approximately 26.8% of the SMTFs leave their first school within a year of starting teaching and, of these, about half (13.1%) move to another district school. Just over half have left the district within five years and less than 15% remain in their first school for eight years or more. These rates are much higher than national averages (Goldring, Taie & Riddles, 2014; Ingersoll & May, 2012).

Math teacher selection significantly shapes retention. Different SMTF characteristics became salient in explaining school retention in different Table 1 models. Graduates of the most selective colleges had the worst district retention. When compared with SMTFs from the most selective colleges, those SMTFs from other selective institutions were estimated to be 2.1 times more likely than those from the least selective colleges remain in the district beyond eight years. Where SMTFs went to high school (as students) was predictive of their district and school retention. Specifically, SMTFs who graduated from an NYC high school were estimated to be at least 1.5 times more likely than other SMTFs to remain in the district over time.

University training was predictive of SMTF retention. SMTFs trained at UnivB had the best estimated odds of retention. As shown in Brantlinger and Smith (2013), UnivB (and UnivD) training included a focus on mathematics teaching methods whereas UnivA and UnivC did not. Moreover, school characteristics like student race and poverty levels shape turnover, but school leadership also was impactful. In particular, SMTFs were estimated to be much more likely to return to placement schools with the most supportive principals and, surprisingly, less likely to remain in placement schools led by principals who were seen as particularly effective managers.

First-year induction also mattered. In particular, the quantity of professional interactions that SMTFs had with (1) mentors, (2) administrators, and (3) other math teachers during the first-year significantly influenced their school and district retention. For example, SMTFs who received the most mentoring (i.e., 13 professional interactions or more with their mentor during the first year) were estimated to be 9.1 times more likely to remain in their placement school for eight or more years than those who received least (i.e., 4 or fewer interactions during the first year) and 4.8 times more likely to remain in the district for eight or more years.

Discussion

This study illustrates how the major components of such programs *combine* to shape secondary mathematics teacher turnover in urban schools. We believe findings about secondary mathematics teacher training and selection are applicable to other programs that prepare mathematics teachers to teach in urban schools. The results also point to several things district and program leaders can do to improve the retention of secondary mathematics. In particular, the use of college selectivity as a screen for teacher selection, a hallmark of selective ATCPs, does not fare well in this study. Second, if retention is the goal, mathematics teacher training in selective ATCPs should include a greater focus on mathematics content and mathematics teaching methods. Third, the induction results have clear implications for how urban district and school leaders could provide better support to early-career teachers.

We share the case of one teacher engaged in professional development (PD) designed to improve collective argumentation. We present an analysis of two lessons in her classroom, one before and one after her engagement with the professional development. Findings show that the classrooms differ across both teacher support for collective argumentation (requesting ideas and elaboration vs. requesting facts and methods), and student contributions (justifications vs. procedures and facts).

Keywords: Teacher Education-Inservice/Professional Development, Instructional Activities and Practices, Classroom Discourse, Reasoning and Proof

Objective

In this paper, we explore the change in one teacher's classroom after participating in a professional development (PD), Mathematics *Studio PD* (Foreman, 2013), designed to improve collective argumentation in the classroom. More specifically we examine the question: "How does engagement in *Mathematics Studio PD* play out in one individual teacher's classroom?"

Background and Theoretical Framing

We leverage frameworks related to contributions from students and supportive questions and actions from teachers for collective argumentation to make sense of the totality of a lesson. The PD is designed to address these constructs using mathematically productive habits and routines. We begin by describing the underlying principles of the PD and describe each construct.

Underlying Principles of the *Studio PD*

The *Studio* PD advocates for student-centered classrooms where all students engage in and contribute to discourse that focuses on mathematical sense making, justifying, and generalizing mathematical ideas. A constructivist theory of learning (Von Glasersfeld, 1995) underlies these tenants where students are meant to engage in cognitively demanding tasks (Smith & Stein, 1998) providing opportunities for productive disequilibrium leading to deep mathematical learning. All students are viewed as capable mathematical thinkers with the PD's focus on growth mindset (Dweck, 2007). In this way, mathematics is not treated as a set of rules, but rather as an interconnected and logical structure (Hiebert, 1986) and the authority lies within the mathematics rather than the teacher or the textbook.

Teacher Support of Collective Argumentation.

Teachers support such mathematics by orchestrating the classroom discussion towards collective argumentation focused on justification and generalization. We use the construct of collective argumentation to describe discussions which "involve[s] multiple people arriving at a conclusion, often by consensus." (Conner, Singletary, Smith, Wagner, & Francisco, 2014, p. 401). Teachers facilitate collective argumentation through their questions (requests of action or information) and other supportive actions (directing, promoting, evaluating, informing, and repeating). The quality of these questions and support impacts the students' contributions to collective argumentation occurring in the classroom.

Contributions Types

We use the term contribution to define statements made by the students in support of collective argumentation. In the PD, student contributions are categorized into *procedures and facts (PF), justifying (J),* and *generalizing (G)* (Foreman, 2013) (see Figure 1 for a description of each category). To engage in meaningful mathematical discourse contributions should include justifications and/or generalizations.

PF USING PROCEDURES/FACTS	**J** JUSTIFYING	**G** GENERALIZING
No evidence of reasoning • Short answer to a direct question • Restating facts/statements/rules • Showing or asking for procedures *Uses meanings, definitions, properties, known math ideas to describe reasoning when:* • Explaining ideas & methods • Questioning to clarify • Noticing relationships/connections But ***doesn't show why*** the ideas/methods work	*Reasons with meanings of ideas, definitions, math properties, established generalizations to:* • Show why an idea/solution is true • Refute the validity of an idea • Give mathematical defense for an idea that was challenged	*Reasons with math properties, definitions, meanings of ideas, established generalizations, and mathematical relationships as the basis for:* • Making conjectures about what might happen in the general or special cases or • Justifying a conjecture about what will happen in the general or special cases

Figure 1. Contribution types.

Methods

The setting for this study is an elementary school in a mid-sized school district in the Pacific Northwest. This school has an enrollment of approximately 580 students with a 73% minority enrollment and 79% of children enrolled in free and reduced lunch. At this school 53% of 5th graders were meeting the math standards. The school is participating in a 3-year district-wide professional development program focused on improving instruction in mathematics. This PD uses the *Studio Model* of PD combined with summer workshops on best practices for teaching mathematics (Foreman 2013). Data collected includes 2 lessons videotaped at the end of each year, starting with a baseline video (Year 0) before engagement with PD as well as after the completion of each full year of the PD (Years, 1, 2, and 3). In addition, researchers observed and video recorded each PD session and took detailed field notes.

For this study, we focus on one fourth-grade teacher (Hannah – all names are pseudonyms) and analyze two lessons, one from before her engaging with the PD (Year 0) and one after (Year 3). We highlight the changes in her classroom and share some of Hannah's reflections throughout the PD to give insight into her engagement with the PD. Hannah was a participating teacher in the PD in Year 1, and the studio teacher in Years 2 and 3. Each lesson analyzed was transcribed and watched by two researchers multiple times.

To code student contributions and support for collective argumentation, talk turns supporting or contributing to collective argumentation were identified in the transcript. Each talk turn was coded as a direct contribution or question/supportive action. Direct contributions were coded as *procedures and facts, justification,* or *generalization* (see Figure 1). For example, a student working on the claim that 24/42 > ½ stated, "she divided 42 divided by two and she got 21. And since 24 is greater than 21, than it's over- the half. It's greater than half." This statement was coded as a justification as the student was "reasoning with meanings… of math properties" (Figure 1). Questions and other supportive actions were coded with the framework in Table 1. For example, the teacher asking a student "How do you write ten cents?" was coded as r*equesting a factual answer* as the request only

Galindo, E., & Newton, J., (Eds.). (2017). *Proceedings of the 39th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* Indianapolis, IN: Hoosier Association of Mathematics Teacher Educators.

included a how. The teacher question “Why does it work mathematically?” was coded as *requesting elaboration* as it requested the student to elaborate further on their response, justifying their answer using mathematical reasoning. For supportive actions, a talk turn including the teacher statement “OK guys, let's see if they fixed it in the right way,” was coded as *evaluating* as it centered on the correctness of the mathematics.

Results & Discussion

Hannah’s lessons in Year 0 and Year 3 differed across the constructs listed above. Next, we discuss these observed changes and connect them to Hannah’s statements throughout the PD, illustrating her intentional engagement with the PD.

Collective Argumentation.

From Year 0 to Year 3 a shift occurred in terms of *teacher questions* and *supportive actions*, captured by the collective argumentation framework (Conner et al. 2014). In Year 0 most teacher questions focused on requesting facts (58%) or methods (21%). In Year 3 most of the teacher questions focused on requesting ideas (24%) or elaborations (58%) (see Table 1). In terms of *teacher supportive actions,* promoting actions increased (1% to 30%) while evaluating actions decreased (32% to 4%). Additionally, we saw an increase in informing actions (20% to 26%) and a decrease in repeating actions (24% to 5%) (see Table 1).

Table 1. Categorization of Teacher Questions and Teacher Supportive Actions

Teacher Questions			Teacher Supportive Actions		
	Year 0	Year 3		Year 0	Year 3
Requesting Fact	58%	3%	Directing Action	23%	35%
Requesting an Idea	4%	24%	Promoting Action	1%	30%
Requesting a Method	21%	8%	Evaluating Action	32%	4%
Requesting Elaboration	12%	58%	Informing Action	20%	26%
Requesting Evaluation	5%	7%	Repeating Action	24%	5%

The change in focus is correlated with changes in the quality of student contributions. In Year 0 most of those contributions were categorized as procedures and facts (96%) while in Year 3 42% were categorized as justification (see Table 2).

One of the foci of the PD is on questioning to research children’s mathematical thinking so the teacher can build on their understanding. At the beginning of her engagement with the PD, Hannah’s questioning did not model this focus. In the initial year she began as the studio teacher (Year 2, Studio 1) she reflected on questioning, stating the realization that “The questions are [asked] to give you [the teacher] ideas where they [the students] are at and not to teach them. That is something I never thought of.” In Year 2, Studio 3 Hannah responded to the prompt *What are key elements of your professional learning from today’s collaborative inquiry?* Her response included “Plan on asking specific questions during conferring [with the students] – research first and then advance their thinking.” In Year 3, Studio 2 Hannah responded to the prompt *What is it that you know about the HOM now that you didn’t know at the beginning of studio?* Hannah responded, “Pushing students to show their thinking rather than just having a correct answer.” Additionally, she shared that she “found it interesting because I started to use more visuals when I started training with the math studio model. Math Studio really brought more of the visual, justifying with the visual.”

Table 2. Categorization of Contributions from students (columns represent 100%)

Contributions	Year 0	Year 3
P/F	96%	58%
Justification	4%	42%
Generalization	0%	0%

Conclusions/Take-Away

In the context of this three-year PD, Hannah made significant changes, bringing her teaching in line with the goals and philosophy of the PD. Throughout the PD, Hannah's reflections, goals for next steps, and remarks made during the studio days captured her intentional implementation of this PD. These comments align with observed changes from Year 0 to Year 3. The focus in the classroom shifted from mostly focusing on procedures and facts to including justifications. Students were credited with (re)inventing mathematics and student strategies were shared with the class. Being able to justify was the ultimate authority. This change is exemplified in the following excerpt from the Year 3 lesson analyzed for this paper.

Hannah: How do you know that this is right?
Student: Because I am smart
Hannah: That is not math reasoning. Math reasoning is the authority in this classroom. *I am smart* does not tell me anything. *I am smart* tells me that you think too much of yourself. So mathematically why does this make sense? And what strategy did you use to solve it?
Hannah: [to S's partner] you hold him accountable to explain to you.

These changes in Hannah's teaching practices and in her students and their contributions are an inspiring example of changes that can occur in a long-term PD. Her example of growth illustrates the many strengths of this PD and informs teacher educators, PD providers, and school administration and leadership of the potential benefits of a PD of this nature.

INTERACTION OF PROFESSIONAL DEVELOPMENT SUPPORT ON CO-TEACHING HIGH QUALITY MATHEMATICS TASKS

Stefanie D. Livers

We illustrate a professional development design focused on infusing high quality mathematics tasks within inclusive elementary mathematics classrooms. Our design supported teams of general education and special education teachers with integrating tasks and differentiation strategies into co-taught mathematics lessons to meet the unique needs of all students. We highlight the interaction between the professional development activities and the actions of the teachers. Analyzing, creating, and implementing tasks was the process used with teachers with thoughtful consideration for differentiation and co-teaching strategies.

Keywords: Teacher Education-Inservice/Professional Development, Equity and Diversity, Instructional Activities and Practices, Elementary School Education

Rigorous standards and a heterogeneous student population are characteristics in today's classrooms that make continued professional development essential for high quality mathematics teaching. National organizations expect equitable, accessible, and quality instruction for all students (e.g. NCTM, AMTE, CEC, TODOS), yet without professional development and on-going support teachers may struggle to meet the needs of students with varying instructional needs as noted in the persistent achievement gap between typically achieving students and students with identified disabilities (NCES, 2015). It is critical that general and special education teachers collaborate and develop a common vision for effective and equitable instruction that requires teachers to eliminate the "one size fits all" approach (Gregory & Chapman, 2002; Tomlinson, 2003). Meaningful learning of mathematics includes a shift from procedural instruction to instruction focused on understanding and reasoning. This instructional shift creates a crossroads of uncertainty, as teachers may not be prepared for changes in content and practice. Teachers are often dependent on textbook scripts and controlled formulas for solving problems, and their content knowledge may be lacking (Ma, 1999). To assist teachers with this shift, professional development and support of teachers' instructional practice are necessary.

Professional Development Design

To provide the needed support to establish and maintain effective collaboration between general and special education teachers, we designed a longitudinal professional development plan based on Guskey's (2000) recommendation for effective professional development that included infusing multiple formats of professional development delivery. Our design included both synchronous (face-to-face) and asynchronous (independent) opportunities with on-site coaching sessions to enhance instruction in inclusive elementary mathematics classrooms. Our hybrid approach addressed teachers' beliefs, misconceptions, and practices regarding high quality mathematics teaching, co-teaching, and differentiated instruction in order to positively influence instructional practices and student learning. Intentional planning based on teachers' needs, goals, and interests was a key component of the hybrid professional development, in lieu of a prescribed, one-dimensional design. The current description highlights the integration of high quality mathematics tasks into instruction, which was one aspect of the larger professional development project designed for co-teaching teams of general and special education teachers.

Teacher Application and Actions of High Quality Tasks

Recognizing the difficulty in the shift from typical problems to high quality tasks, planning was very deliberate within the professional development. High quality tasks require a high cognitive demand from students and are an essential staple in good mathematics teaching (Stein, Smith, Silver, & Henningson, 2001). Therefore, teachers must focus on building conceptual understanding through problem solving which requires providing an instructional environment to develop the behaviors presented in the Standards for Mathematical Practices (CCSSM, 2010), instead of using rote memorization tasks that only require procedural knowledge.

Differentiation of the task is also critical for successful implementation in inclusive mathematics classrooms. Differentiation can be thought of as a pedagogical approach in which teachers modify and adapt curricula, instructional practices, support, and assessments in order to maximize learning based on student needs (Algozzine & Anderson, 2007; Tomlinson et al., 2003). The progression of high quality task support within our professional development was carefully planned and scaffolded to ensure effective understanding and application. The sequence of support followed these steps: analyzing sample tasks, creating tasks from simple word problems, and implementing high quality tasks in a co-taught setting.

Analyzing Tasks

One of the first sample tasks presented to teachers was *Danny Dinosaur's Designer Coat* (see Figure 1). Teachers worked individually and then in teams (co-teaching partners: at least one general education and one special education teacher) to analyze and solve the *Danny Dinosaur's Designer Coat* task in ways that made sense to them; this included some teachers using manipulatives, such as color tiles, some drawing pictures or tables, and a few using symbolic representations. Group discussions on how the problem was solved provided opportunities for teachers to share ideas and learn from their peers. This discussion generated discourse around this open task with multiple solution paths.

Danny Dinosaur's Designer Coat
Danny Dinosaur's designer coat is missing 5 buttons. How many ways can you use blue and red buttons to fix is coat?

Figure 1. Examples of high quality mathematics task.

Next, we posed the question about how to differentiate the task to students with varying learning styles and ability levels. Teachers generated adaptations and modifications, and used differentiation strategies to implicate how this single task could be used in a variety of grade levels and settings. Teachers suggested: requiring a red button to be first, incorporating patterns, and changing the number of buttons from five to ten. Thinking ahead to more advanced mathematics, we explained how this task can be extended by asking how many different patterns of blue and red buttons can be created where the order matters, which builds the knowledge of permutations and combinations. Next, teachers brainstormed how to implement the task in a co-teaching setting. Teams discussed how the use of tasks would be put into action in their classrooms, with conversations about the roles of each adult, the flow of a lesson built around the task, as well as specific differentiation strategies to use with their students in their actual mathematics classrooms. By providing time for each team to discuss how they would use the *Danny the Dinosaur* task, teachers were able to relate the general instruction from the professional development sessions into a specific plan for classroom implementation.

Creating Tasks

Teachers were given examples of word problems and tasks to classify in order assist them in recognizing the differences between the two and the differences in cognitive demand required by students to solve them. Problems and tasks were selected from Stein et al., (2001, p. 9) classifying activity. Next, teachers selected one of the word problems from the classifying activity to revise and transform into a high quality task, focusing on the level of cognitive demand needed for the solving process. Teacher teams pasted the original task on chart paper and then wrote their newly created task. Once teams were finished and chart papers were posted around the room, teachers individually gave feedback on each teams' work (see Figure 2).

• Excellent.
• Graphic organizer!
• I LOVE the table!
• Students have to work around limitations. Great job!
• Excellent due to different possibilities and diagram.</td></tr>
</table>

Figure 2. Creating tasks.

Implementing Tasks

As teams became more comfortable with analyzing and creating tasks, they began to implement tasks into their classroom instruction. A group of fourth-grade teachers (two general education and one special education teachers – two teams of teachers) developed and implemented a task to focus on addition, subtraction, and multiplicative thinking called "Chartable Giveaway." In this task, small groups of students were awarded different amounts of money to "help purchase toys for children in need." Students worked together to decide which toys (from a sheet designed with various toys and prices) to purchase and how many of each toy they wanted to purchase, while keeping in mind how much money they had spent and had left over to spend. Student groups recorded their selections on a teacher created table to show their decision-making process throughout the task. Differentiation was a key component in the successful implementation of this task. Students were purposefully grouped together to support one another and meet the needs of all learners. Student groups received monetary values ranging from $500 to $20,000. As the students worked, both the general education and special education teachers together monitored students' progress and provided prompts to support student thinking and learning. Monetary values were changed as needed. For instance, one group of students successfully completed working with $1,000 and was then given a larger amount of $5,000 in order to provide students with an extension. After the lesson, the teachers reflected on the successes implementation of the lesson, including positives about the mathematics instruction, differentiation strategies used, and co-teaching components. The teachers believed this was a highly successful lesson with all of their students and expressed that incorporating more task-based lessons would be a goal of their future instruction.

Summary

The implementation of this professional development design created a positive and visible interaction between the teacher learning and instructional practices creating a synergy between general education and special education teachers. This project took the theoretical model of best practices of professional development and put it into meaningful practice focused on the differentiation of high quality tasks in inclusive mathematics classrooms.

Acknowledgments

This project was funded with a 2015 Mathematics and Science Partnership grant from the Alabama State Department. Dr. Jim Gleason is the principal investigator on this grant.

LEADERS HELPING LEADERS: BUILDING LEADERSHIP CAPACITY TO SUPPORT STANDARDS IMPLEMENTATION

Kimberly Kappler Hewitt
University of North Carolina Greensboro

This exploratory study examines how leaders across a state take up and engage in webinars designed to build leadership capacity to support teachers' implementation of new mathematics standards. Leaders Helping Leaders monthly webinars served as a space through which the community embodied mutual engagement, joint enterprise, and shared repertoire. Findings indicated that tensions among the design principles undergirding the webinars surfaced, raising questions about how to prioritize limited resources for continued support of leaders.

Keywords: Design Experiments, Policy Matters, Standards

Introduction

Statewide implementation of new mathematics standards is no small feat. Successful implementation that promotes mathematics teaching focused on students' thinking requires concerted efforts by classroom educators and educational leaders alike. Indeed, district leaders (Lawrence et al., 2011), principals (Desimone, 2000), and instructional coaches (Neufeld & Roper, 2003) are all critical to implementing and sustaining instructional change. This study addresses a gap in the literature about how to cultivate leadership capacity amongst district mathematics leaders, principals, and instructional coaches for implementation of new high school mathematics standards. Specifically, the North Carolina Collaborative for Mathematics Learning (NC^{2}ML) partnership described below used a design-based implementation research (DBIR) (Fishman et al., 2013) approach to iteratively design and study the implementation of capacity-building opportunities for leaders related to the new standards.

North Carolina Collaborative for Mathematics Learning

NC^{2}ML is a statewide research-practice partnership involving the state education agency, educational researchers from multiple universities, teachers, and leaders from across the state engaged in a complex research endeavor to examine and learn from the implementation of North Carolina's new high school mathematics standards. NC^{2}ML engages and supports multiple constituencies, including teachers, educational leaders, and parents/community members. This paper focuses on educational leaders and examines the ways in which they participate in an online community of practice (CoP) – a "space where learning takes place and [sic] where learning is the practice itself" (Savard, Lin, & Lamb, 2017, p. 42). This paper examines the use of monthly Leaders Helping Leaders (LHL) webinars and is guided by the questions: (1) *What can be learned from patterns of participation in LHL?* (2) *What are participants' perceptions of LHL?* and (3) *How do leaders take up and engage in a* CoP *around implementation of high school new mathematics standards?*

Conceptual Framework: Communities of Practice

Three dimensions of practice characterize what brings coherence to a CoP – mutual engagement, joint enterprise, and shared repertoire (Wenger, 1998). Mutual engagement signifies that communities are developed and maintained through engagement in a shared set of practices valued by a community. Respectively, joint enterprise and shared repertoire denote communal goals and viewpoints, and use of a shared set of tools. CoPs can work to solve problems of interest to the group, foster best practices, and develop skills; serve to build members' capacities and create and exchange knowledge; and are bound not by formal membership structures but rather by affinity.

Methodology

NC^{2}ML draws upon DBIR (Fishman et al., 2013) as an approach to facilitate the design of implementation efforts related to new state mathematics content standards. DBIR transcends traditional research-practice barriers by applying design-based principles to address and study problems of practice. The four core principles of DBIR include: 1) attention by teams of researchers and practitioners to persistent problems of practice; 2) use of iterative, collaborative design; 3) development of knowledge and theory through systematic inquiry around learning and implementation; and 4) emphasis on cultivating sustained change at scale. The focus of this study is on how educational leaders engage in a CoP within the Leaders Helping Leaders space.

Design of the Affinity Space

Leaders Helping Leaders (LHL) is a monthly virtual session hosted by the NC^{2}ML team, with agendas informed by an advisory board comprised of math leaders from across the state. LHL sessions were facilitated by members of NC^{2}ML and focused on three overarching objectives: 1) Provide support to math leaders as they support teachers; 2) Provide space for leaders to share and problem solve together (collaborate); and 3) Cultivate community amongst math leaders. LHL agendas were informed by the interests and stated needs of participants and guided by a consensual set of norms. LHL sessions typically consisted of a review of the norms, a community-building activity, and focused on a specific topic (e.g. parent resources for mathematics learning, tools to support teacher learning and instructional planning).

Methods and Analysis

The NC^{2}ML team analyzed three datasets for the September 2016, October 2016, and November 2016 LHL webinars: webinar analytics (registration, attendance, and participation data), post-webinar survey results, and webinar transcripts and chat comments. Participant perceptual data were collected via an online survey tool. The response rate for each survey was low: 18.5% in September (n = 10/54), 5.7% in October (n = 2/35), and 11.1% in November (n = 3/27). As such, it is important to keep in mind that these data are unlikely to be representative of the full population of LHL attendees. We conducted content analysis of transcript and chat data, leveraging open and deductive coding.

Findings

Participation Patterns: Leaders Helping Leaders Webinar Analytics

Overall, 116 leaders attended the sessions, representing 40 (34.8%) of the 115 districts across the state. Attendance fell each month from September (54) to October (35) and November (27). Active participation, defined as speaking or using the chat feature, was highest in September and inconsistent across months. High level activity, defined as speaking or using the chat feature multiple times, while also inconsistent across months, was highest in November, when attendance was lowest, raising the question whether settings with fewer participants allow more space for high level activity.

Attendance patterns across sessions. Of the 54 participants who attended in September, 30 (55.5%) did not return (Disengagers), while 11 (20.4%) attended all three fall sessions (Stayers). Seventeen participants were new in October and eight were new in November (Entrants). These data reflect the idea that even with a substantial number of Disengagers, the Stayers and Entrants fostered a viable CoP that can sustain over time, suggesting that the CoP can remain viable even as attendees differ.

Participant's Perceptions: Post-Webinar Survey Results

On a 1-5 Likert scale for four items regarding respondents' perceptions of the LHL webinars, means increased from the September session (3.6 across items) to October (5.0) and November (4.7). There are multiple possible explanations for the apparent increase in perceived quality from the first to second/third sessions: LHL sessions became more polished and fine-tuned with experience. Also, it appears that LHL webinars benefit from having a focused topic(s) that includes explicit resources/tools that leaders can use in their districts. Noteworthy is the disconnect between plans to attend future sessions and aforementioned data regarding high numbers of Disengagers versus Stayers. This suggests that the moniker Disengagers might be a misnomer. Perhaps it is less a desire or decision to disengage and more a function of other factors, such as schedule conflicts or competing demands on leader attention and time.

Open-ended survey items indicated that respondents find collaboration, networking, and the focused specific topics/tools most helpful. A few respondents indicated that providing input on future sessions would be helpful. Specifically, respondents would like future webinars to provide space for sharing ideas regarding implementation of the new standards, collectively identifying solutions to challenges, and finding ways to help teachers with standards and pacing guides. Overall, respondents have positive views of LHL webinars, plan to attend future webinars, prefer the live version, and seem to appreciate a focus topic/tool for each webinar.

How Leaders Take Up and Engage in a CoP: Webinar Dialogue

In this section, webinar dialogue – spoken comments and use of the chat feature – is examined using the concepts of mutual engagement, joint enterprise, and shared repertoire.

Mutual engagement. This construct involves ways in which participants engage with one another and interact. At the beginning of each webinar, facilitators shared a community-building prompt. In each webinar, 11-12 participants responded to these prompts. During the November session, 12 of 27 (44.4%) of participants responded.

Mutual engagement, however, also involves "implied competency" (Savard, et al., 2016), the notion that participants have expertise that allows for interactions that are thoughtful and meaningful. Participants have responded to prompts by facilitators that ask participants to share experience and examples from their school/district related to the topic. For example, during the October session, participants shared what they are doing to inform parents about the implementation of the new mathematics standards. For example, one participant shared:

> I love what some high school mathematics teachers are doing …creating videos to answer questions that students send them! We have teachers who are considering this concept in our district.

This example illustrates sharing out as well as considering implementing ideas, and it also represents the type of affirming comments that are common in LHL sessions. In response to the aforementioned comment, a participant responded, "great idea." These comments contribute to mutual engagement.

Joint Enterprise. Also common to the chat conversation are posts through which participants networked and collaborated with one another. For example, during the September session, one participant asked the group, "Is there anyone creating benchmarks that would be willing to co-author them with other districts??" Several other participants responded in the affirmative to this request. During the same session and based on the robust conversation amongst participants, the facilitator (a state department of education math coordinator) offered to send out an initial group email to those interested that could then be used as an informal listserv by which leaders could communicate directly with one another. Twenty-seven participants asked to be included on the email and continue to communicate with one another. In these ways, participants are engaging in joint enterprise: They collaborate on shared interests, learn from one another, and go beyond these to develop a collective sense of shared practice and work.

Shared repertoire. CoPs coalesce around tools, artifacts, ideas, and routines. A number of the tools discussed and used within LHL were created by collaborative writing teams facilitated by the state agency partner, including a pacing guide and curriculum guide that expands upon the mathematics standards, provides aligned mathematics tasks, and offers instructional ideas related to mathematics teaching and student learning. As previously detailed, some leaders from LHL worked together to create common assessments aligned to the new standards. During the October session, which focused on informing parents about the implementation of the new math standards and building bridges with parents, five participants chatted about the ideas they wanted to try in their own school/district, such as: "Looking forward to sharing these videos via Facebook – parents will check out Facebook." Their shared repertoire is a reflection of – as well as a means of – knowledge-sharing and learning within the CoP.

Conclusions

While the data collected thus far are limited, they provide valuable insights for iterative design through DBIR. First, while participation in LHL webinars fell markedly with each webinar, and participation rates have been uneven across sessions, these findings do not mean that the CoP is anemic. Wenger (1998) argues that participants may move in and out of the CoP through its porous periphery and move towards and away from the core at different points. The richness of the CoP itself can be maintained or even expanded. The data suggest that the leaders' CoP embodies the key constructs of mutual engagement, joint enterprise, and shared repertoire.

As we continue our efforts in supporting stakeholders in implementation of new mathematics standards, we are excited about the possibilities of research-practice partnerships and CoPs, and we see DBIR as a productive approach to jointly working on problems of implementation at scale and developing theories that lay the groundwork for future crossroads or intersections between theory, research, and practice.

As part of a larger project aiming to develop a framework of competencies for mathematics teacher educators by utilizing a Delphi approach, the purpose of this study was to investigate what a group of experts think about the competencies that mathematics teacher educators should possess. The data were collected in a workshop with 10 experts coming from mathematics teacher education programs and non-governmental organizations. Findings revealed a set of competencies about the works and identities of university-based mathematics teacher education faculty as teachers, researchers, and community leaders.

Keywords: Instructional Activities and Practices, Teacher Beliefs

Despite the efforts to define competencies of qualified teachers throughout the world, studies regarding the competencies of teacher educators who play a key role in training teachers and researchers are limited (Goodwin & Kosnik, 2013). In recent years, a few institutions throughout the world attempted to identify the competencies that qualified teacher educators should possess. While some of these efforts encompass the competencies for all teacher educators (e.g., Association of Teacher Education [ATE], 2008; Koster, Dengerink, Korthagen, & Lunenberg, 2008), some are focused on competencies within specific disciplines competencies (e.g., see Association of Mathematics Teacher Educators [AMTE], 2002 regarding qualifications for mathematics education doctoral students).

Given the importance of reflective inquiry in developing as a mathematics teacher educator, studies focusing on mathematics teacher educators' professional education and development are rare and those available are mostly self-studies of university-based teacher educators (e.g., Chauvot, 2009; Williams, Ritter, & Bullock, 2012). Lack of a framework for the professional knowledge base and competencies that mathematics teacher educators should possess might be useful for the education and professional development of teacher educators and to assess the effectiveness of teacher education programs. It would also be useful to identify the mathematics teacher educator competencies using a research based empirical approach. Thus, the purpose of this study was to investigate what a group of experts involving mathematics teacher educators and representatives of educational non-governmental organizations think about what competencies mathematics teacher educators should possess.

Even though the term "teacher educator" might refer to those who are involved in training prospective teachers and/or practicing teachers (Even, & Krainer, 2014; Krainer, Chapman, & Zaslavsky, 2014), in this study, it is conceptualized from a broader perspective as comprising those who also do research, train prospective teacher educators (i.e., graduate students), and are engaged in institutional and community work. Moreover, within this study the term "competencies" is used when referring to the knowledge, skills, attitudes, motives and personal characteristics that mathematics teacher educators should possess in order to act effectively in a particular situation (Spencer & Spencer, 1993).

Method

Context and the Participants of the Study

The study reported here is part of a larger project aiming to (*i*) identify the competencies that mathematics teacher educators in Turkey should possess; (*ii*) investigate the self-efficacies of mathematics teacher educators in meeting these competencies. The data reported in this paper were collected from a three-day workshop which was the first step of a four-step Delphi method (Landeta, 2006) utilized in order to develop a develop a framework of competencies for mathematics teacher educators. The participants of the workshop were 10 experts representing middle school and high school mathematics teacher education programs from six different universities and four different educational non-governmental organizations.

Data Collection and Analysis

Prior to the workshop and on the first day, the participants/experts were briefed about the larger project, the purpose of the workshop and what is expected from them during the workshop using situations and vignettes designed to help them think about the qualifications a competent mathematics teacher educator should have. The two overarching questions that the participants were asked to answer were as follows: “What duties and responsibilities do mathematics teacher educators have?” and “What knowledge, skills and attitudes do they need to have in order to fulfill these responsibilities?” The participants were divided into two groups and worked separately. In each group, a researcher acting as moderator and a research assistant for taking detailed notes of the deliberations were present. The groups worked to produce a draft list of competencies in the first two days. In the third day, the two groups joined together and made presentations of their draft competency lists. They further discussed the similarities and differences between the frameworks that came from the two groups.

For data analysis, in addition to field-notes, video and audio-recordings of the discussions in the two groups were coded and then compared in order to highlight the participants’ emerging thoughts about competency areas and competencies.

Results

Focusing on qualifications they would seek when hiring a mathematics education faculty for a hypothetical open position, Group-1 suggested the following competency areas: *Mathematical Knowledge and Skills; Knowledge for Teaching the Subject (i.e., Mathematics); Professional Development and Social Responsibility (Service); General Pedagogical Knowledge; Mentorship; General Knowledge; Attitudes and Values; Knowledge of Programs for Mathematics Teacher Education and Faculty Development*. Somewhat different from Group-1, Group-2 focused on duties and responsibilities of a university-based mathematics teacher educator and identified the following competency areas: *Teaching; Academic Work, and Service to Society*.

One of the major issues participants discussed during the workshop was the definition of a mathematics teacher educator. After intense debates about who a mathematics teacher educator is, it was decided that a mathematics teacher educator is someone who received his/her doctorate in mathematics education, have continuing scholarly work in mathematics education and/or teach courses on mathematics education. On the other hand, particularly in Group-2, one of the initial concerns was whether the competencies should aim for the minimum or a higher level of competencies. Through deliberations, they decided that the competencies should be descriptive of a mathematics teacher educator who is capable of educating qualified mathematics teachers.

Another issue that was the subject of long and dense debates in both groups was the extent of mathematical content knowledge that a mathematics teacher educator should have. Knowledge, skills, and attitudes related to mathematics and its teaching were discussed as essential components of mathematics teacher education competencies. In Group-1, it was decided that a mathematics teacher educator should at least have the knowledge and skills to be able to analyze mathematical concepts in the school mathematics curricula and their connections to the connected concepts and topics at the post-secondary level mathematics. On the other hand, Group-2's dilemma was whether a mathematics educator should be competent enough to be able to teach all of the undergraduate level mathematics courses. Their conclusion was that having such level of advanced mathematical knowledge is not realistic for all mathematics teacher educators and thus there needs to be a boundary depending on the similarities and differences between mathematicians and mathematics educators. Similar to Group-1, they adopted the idea that a mathematics educator should possess sufficient knowledge of mathematics in order to be able to make connections among concepts and topics in school mathematics. According to Group-2, a mathematics teacher educator must have deep knowledge of mathematics taught from kindergarten to the first year of university (K-13). They also argued that having experience in teaching mathematics would contribute to a deeper understanding of mathematics; thus, having teaching experience would be desirable and be considered as an indicator of mathematical content knowledge.

Another important discussion point was about who would be responsible for teaching mathematics (content courses) to the teachers. In Group-2, while some participants indicated that it is mathematicians' responsibility, others argued that it should be mathematics teacher educators' responsibility because the ultimate purpose in teaching mathematics to teachers is directly related to teaching how to teach the content. Group-2's major emphasis was on the fact that the nature of mathematical knowledge of a mathematics teacher educator should be different than that of a (research) mathematician in the sense that it should focus on how to teach it or help students learn it. This view led to another discussion that the knowledge about learning and understanding mathematics is as important as the knowledge of mathematics and content knowledge for teaching mathematics. Thus, the ability to produce knowledge regarding teaching and learning of mathematics should be an integral part of mathematics teacher educator competencies.

Another topic of discussion in Group-2 was about in-service teacher education. While some of the participants argued that in-service teacher education is a direct responsibility of mathematics teacher educators and thus it should go under the competency area "Teaching", others argued that such activities are not among official requirements and duties of the universities or related governmental bodies and thus it needs to be under "Service to the Society". After some discussion, even though all agreed that in-service mathematics teacher education is among the responsibilities of a mathematics teacher educator, it needs to be considered as part of "Service to the Society". A similar discussion was held in Group-1. They concluded that whether mathematics teacher educators feel responsible or not, they should be competent in designing and managing in service teacher training programs and they thought it fell under "Mentorship."

Discussion

Involving a group of professionals/experts into a process of active discussion, and establishing consensus using Delphi procedures with a focus on mathematics teacher educators' competencies make the present study different from the other studies focusing on standards and competencies of teacher educators. Findings showed that developing a framework of professional competencies for mathematics teacher educators is a challenging task and different parties would have their own priorities. Based on the findings of this study in the Turkish context, the priorities are addressed from the perspective of professional identities of university-based mathematics education faculty mainly as teachers and researchers. This implied that a balance between research and teaching is needed as part of being a competent mathematics teacher educator. Additionally, the extend of mathematical content knowledge that a mathematics teacher educator should have and who would be responsible for teaching mathematics (content) courses to prospective teachers seemed to be important in defining the duties and responsibilities of mathematics teacher educators and the competencies they need to have.

We believe that this study contributes to the international debate in professional development of (mathematics) teacher educators. It is important for other contexts for stimulating teacher educators towards reflection. It is considered that the results of this study, as part of developing a framework for mathematics teacher educator competencies, would provide mathematics teacher educators with opportunity to reflect on, serve as a guide for understanding the development of professional competencies, and provide insights into the nature of mathematics teacher educators' expertise.

QUANTITATIVE LITERACY IN MIDDLE SCHOOL MATHEMATICS: A TEACHER'S IMPLEMENTATION

Diana L. Moss
Appalachian State University
mossdl@appstate.edu

Heather Crawford-Ferre
University of Nevada, Reno
hcrawford@unr.edu

This study draws on critical pedagogy to frame and interpret the investigation of a teacher's implementation of quantitative literacy in a middle school mathematics classroom after taking a graduate education course on numeracy. We provide a brief overview of elements of critical pedagogy and discuss how we used this theory to explore how a middle school teacher implemented quantitative literacy instruction in her classroom. Finally, we present the first theme, authentic application of mathematics concepts, which emerged from the data.

Keywords: Teacher Beliefs, Equity and Diversity, Instructional Activities and Practices

Theoretical Framework

Critical pedagogy was first used by Henry Giroux in 1983 (Wink, 2011) and involves identifying and naming power structures and examining the role schooling plays in reproducing hegemony (Allen & Rossatto, 2009). Critical pedagogies posit that the goal of education is to train every student to be a productive member of a democratic society (Erikson, 2016). This is accomplished through valuing students' lived experiences and voices (Cho, 2010). The goal for social institutions is to reform systems based on predetermined principles such as equality, democracy, emancipation, common good, social justice, and equal rights (Cho, 2010). Critical pedagogy closely relates to quantitative literacy (QL) instruction in middle school. Literacy is a form of power that "naturally breaks down barriers of time, space, and culture" (Wink, 2011, p. 70). Literacy goes beyond just reading and writing and includes multiple types of literacies, such as academic, functional, constructive, critical, financial, and quantitative (Wink, 2011). QL instruction empowers students in that it operates only in the context of real-world applications and, therefore, provides students the ability to draw upon their own real-world experiences to problem solve.

Background and Purpose

QL is different than typical school mathematics. School mathematics tends to focus on abstract, procedural knowledge with little problem-based, investigative thinking. In contrast, QL involves the use of mathematics in the context of real-world scenarios. QL is supported by the National Council of Teachers of Mathematics (NCTM, 2014) and the National Governors Association Center for Best Practices and Council of Chief State School Officers (2010), who have established national standards that advocate for use of "real-world" mathematics. However, "real-world" mathematics is typically implemented in the form of story problems that involve hypothetical stories rather than authentic tasks (Wiest, Higgins, & Frost, 2007). For true implementation of QL, students must apply fundamental mathematics to genuine, real-world, interdisciplinary situations (Yarnall & Ranney, 2017).

Unfortunately, many people do not fully understand how mathematics relates to the real world (Erikson, 2016). For example, pre-service teachers tend to exclude real-world information, such as tax in solving shopping problems, and thus preference non-realistic answers to real-world problems (Verschaffel, Greer, & DeCorte, 2000), indicating that pre-service teachers tend not to approach problems from a QL standpoint. Further, Gutstein (2006) found than many teachers do not appreciate the practical utility of the mathematics they teach. Moreover, in a survey of 62 teachers found that teachers reported giving real-world examples, rather than engaging students in tasks with real-world data (Gainsburg, 2008). Gainsburg recommends professional development to address teachers' lack of appropriate QL implementation.

Tunstall et al. (2016) supports this post-secondary need stating "the value of QL (QL) for college graduates is well documented…to empower students to feel confident in quantitative situations (p. 2). This lack of confidence, due to a lack of training and experience, for teachers might result in teachers limiting or omitting QL topics in their instruction. Thus, mathematics education for teachers should include exploration of QL to increase implementation of QL instruction in K-12 education (Garii & Okumu, 2008). Given the lack of teachers who implement QL and the connections between training/education and implementation, this study explored the implementation of QL in one teacher's classroom instruction.

Context and Methods

The teacher selected for this research was chosen because she was a middle school mathematics teacher who was enrolled in a QL course, Critical Numeracy Across the Curriculum (offered at a land grant university located in the western United States). She had taught mathematics for four years, was in her second year teaching middle school, and was in her first year teaching at her current school. The teacher had earned a bachelor's degree in discrete mathematics, a master's degree in applied mathematics, and a secondary teaching license program, and she was currently enrolled in a doctoral program in mathematics education. The teacher taught at a small parochial school with an enrollment of 288 students, including 35 eighth graders. The teacher's math class took place three days each week for a total of five hours. Twenty-two of the eighth graders were enrolled in algebra and were taught by this teacher. These students were 12 to 13 years old and included 12 female and 10 male students. Most were from middle-to-upper-class families, and all were Caucasian.

Initially, we conducted an interview with the teacher, asking her to describe QL. Additionally, the teacher was asked to identify ways she implements QL in the classroom. We then observed the classroom instruction three days a week for two months, conducting observations as described by Florio-Ruane (1999), mapping the classroom, making a classroom log, and collecting field notes. After the observations, we conducted a second interview to ask questions prompted by the observations. Additionally, lesson plans and assignments were collected and analyzed for consistency with the observations of teaching and the teacher's reports of quantitative-literacy implementation in the classroom.

We employed grounded theory for data analysis (Glaser & Strauss, 1967) and simultaneously collected and analyzed data (Lichtman, 2011). The analysis was a part of the research design with the coding of the first data set serving as a foundation for future data collection and analysis (Corbin & Strauss, 2008). We adjusted additional data collected based on analysis of the first data set (Corbin & Strauss, 2008) by deriving the interview questions on analysis of the initial data. We proceeded through the coding process by analyzing the data line by line and paragraph by paragraph and then coding the deconstructed fragments (Lichtman, 2011). Codes were compared, renamed, added, or deleted as we constantly compared them (Corbin & Strauss, 2008). We constructed conceptual categories based on multiple re-readings and re-coding of the data. "This 'checking back' is a method of confirming or disconfirming that ensured that the categories were grounded in the theory rather than 'flights of fancy' or pet ideas" (Lichtman, 2011, p. 63).

Results

The results are categorized into the following themes: authentic experience, connection to mathematics standards, teacher knowledge, and student engagement. This paper reports on the first theme, authentic experience.

Authentic Application of Mathematics Concepts

The teacher reported a goal of using mathematics authentically as her primary reason for implementing QL in her teaching. She stated that it was important that her students know how to research real data, represent it using graphs and charts, and analyze it. Further, she indicated that it was important for her students to know mathematics rules and have the ability to apply them in their daily mathematics encounters, saying, “I use QL in my class because it is important for students to be able to apply their mathematical skills to the real world. Applying their knowledge to solve a problem in a different context involves a deeper level of thought.”

This perception of authentic instruction was supported frequently in the teacher’s teaching. The teacher’s lessons, homework assignments, and assessments could be categorized into four levels:

1. Students research authentic data to analyze and respond to a question(s).
2. Students are provided authentic data to analyze and respond to a question(s).
3. Students use hypothetical data to respond to a question(s) set in a real-world context.
4. Students use no QL.

The majority of the lessons fell into categories 1-3. Lessons that were not based on QL occurred only on days that were dedicated to review for a state assessment and one day when technological problems prevented the planned lesson from being implemented.

The teacher had students use laptop computers to research authentic data and provided instruction on identifying reputable Web sources. Many lessons required students to find their own data to analyze. For example, in one lesson students were asked to apply their knowledge of graphing systems of equations to research the cost of two gym memberships, create equations for both, graph the system of equations, and write a conclusion regarding which membership they would choose and why. When the students were not researching their own data, they were frequently analyzing authentic data provided to them, such as data on the average unemployment rates and salaries of individuals with different levels of educational attainment.

The assessments and homework assignments, however, tell a different story. No assessment was given during this study that evaluated any QL skill or task. Further, the only required written QL homework assignments were incomplete class work that students were asked to complete as homework. Typical homework included worksheets of algebra problems. The students also had electronic homework on a class web page. Approximately one-quarter of the online assignments had a QL component, requiring the students to discuss or comment on the QL activities that were completed in class.

Discussion

These results indicate that taking a teacher education course in numeracy increased this teacher’s QL instruction in her middle school mathematics teaching. This supports the call for QL instruction in college (e.g., Tunstall et al., 2016) and, in particular, teacher education (e.g., Garii & Okumu, 2008). Further, the teacher asserted that the course was practical in terms of QL implementation, stating that she used complete lesson plans and lesson plan ideas directly from the course. This might help inform design of an effective teacher education course in QL. The role of a specific course in QL rather than increased requirements in mathematics is supported by Gutstein’s (2006) plea that teachers need to learn how to read and write the world with mathematics in addition to possessing both disciplinary mathematics content knowledge and pedagogical content knowledge.

Although the course provided the teacher who participated in this study with the resources to implement QL instruction in her classroom, she did not conduct QL assessments. When asked about this in a follow-up interview, the teacher indicated that she was not sure how to assess this knowledge and did not feel she needed to assess QL since it was not a required standard. Lack of assessment in QL is noted by Pugalee, Hartman, and Forrester (2008), who state, "Despite the importance of such skills, assessment of QL has not been a focus in education and there is a lack of assessment tools that specifically address these skills" (p. 35). There is both a need for research and development in the area of formalized QL assessment and a need for explicit instruction on informal classroom QL assessment in teacher education courses.

SCAFFOLDING GENERATIVE FEEDBACK WITH TECHNOLOGY IN ONLINE PROFESSIONAL DEVELOPMENT

Anthony Matranga
Drexel University
avm43@drexel.edu

Jason Silverman
Drexel University
js657@drexel.edu

This study examined 21 practicing teachers' participation in an online community-based professional development course. This study integrated a web-based assessment environment into the online course. The tool was designed to scaffold a virtual boundary encounter with the Math Forum. Teachers' interactions mediated by the tool and the discussion board (DB) was examined. Results indicate that the web-based tool scaffolded participants' development of feedback in qualitatively different ways than participants developed feedback in the DB. In the DB participants shared and compared ideas when providing feedback and scaffolded by the web-based tool participants challenged colleagues to refine their mathematical explanations.

Keywords: Teacher Education-Inservice/Professional Development, Technology

Introduction

Research and policy demand ambitious goals for mathematics instruction, which include calls for problem-based learning, peer-to-peer argumentation and formative assessment practices (NCTM, 2000). Professional development (PD) is crucial for achieving these goals and supporting teachers' instructional change. Community-based PD, in particular, provides context for the collective development of mathematical and pedagogical content knowledge, opportunities for teachers to reimagine their instructional practice, and has shown to support teachers' instructional change (Vescio, Ross, & Adams, 2008). There are shortcomings to school-based communities; for example, it is often difficult for teachers to fit community into their daily schedule and local school districts' norms for instruction typically do not align with those called for by research and policy. Online communities can address these shortcomings as teachers are not constrained to collaborate while at work and norms that emerge in alternative contexts are transferable into teachers' instruction (Vescio et al., 2008). There is a lack of research on teachers' participation in online communities. To fill this gap, the following research question was posed: How does a web-based assessment environment impact teachers' feedback practices in online community-based PD?

This study is framed by the conceptual framework communities of practice (Wenger, 1998) and conceptualizes mathematics teacher PD as participation in boundary encounters, which is an interaction between communities of practicing teachers and teacher educators (Sztajn, Wilson, Edgington, & Myers, 2014). Sztajn et al. (2014) regard this as a boundary encounter because teachers and teacher educators engage qualitatively different practices, particularly when engaging with students' ideas. This study extends the idea of mathematics teacher PD as a boundary encounter and conceptualizes of a *virtual boundary encounter,* which is a boundary encounter mediated by a web-based assessment environment designed to scaffold activities that are consistent with the practices of the Math Forum — a leading group for mathematics education in the United States (Shumar, 2009) — and enhance the process of developing feedback. The tool supports user's focus on the details of written mathematics work and grounding analysis within these details. In particular, the web-based environment includes design features that scaffold highlighting or "quoting" the details of colleagues' written mathematics work and then developing comments that are linked to these highlighted details. After participants engage these activities they share their highlights and corresponding comments with colleagues in the form of feedback. In this way, the assessment environment mediates participants' engagement in collective mathematical activity. These activities are also consistent with the Math Forum's evidence-based feedback practices. Thus, the tool is designed to act as a proxy for participation in PD with the Math Forum.

Methods

This study investigates 21 practicing teachers' participation in an online community-based PD course. The content-based course engages teachers in reasoning covariationally (e.g. see (Carlson, Jacobs, Coe, Larsen, & Hsu, 2002)) about quantitative scenarios. The assessment environment was integrated into this course to mediate participants' interactions around their mathematics work. Participants also communicated about mathematics in a non-scaffolded environment, the course discussion board (DB). The analysis in this study examined teachers' interactions in these two environments. A grounded theory approach was applied through open and axial coding procedures and the iterative analysis of themes (Glaser & Strauss, 1999).

Findings

The analysis of participants' interactions on the course DB and EE found that teachers provided feedback to colleagues in qualitatively different ways according to the mediating environment. Mediated by the web-based tool, participants frequently *challenged* one another to refine their mathematical explanations. Mediated by the DB, participants *shared and compared* their thinking when providing feedback. The following analysis will briefly examine an example of feedback developed in each environment and then will discuss the significance of these results.

The examples are in the context of the class's examination of quantitative relationships. Our ongoing work indicates that the class was participating in an emerging social norm for mathematical activity in which we refer to as *explaining why,* that is it was becoming normative amongst the class to provide reasons for why functions graphs look a particular way (Matranga, 2017). The first example is a discussion on the DB, where a participant, Hank, developed an initial post where he argued that the graph that resulted from tracking the covariation between two quantities could not be categorized as a parabola. In doing so, Hank referenced the "geometric" definition of a parabola in order to explain why the function graph could not be regarded as a parabola. In response to this initial post, Ava and Cindy develop posts that primarily share and compare their thinking. Consider the two posts:

> Ava to Hank: I have never heard the geometric definition of a parabola... or maybe I have and its been a long time... anyway, thanks for sharing as it made me think about parabolas and gave me a deeper understanding!
>
> Cindy to Hank: Hank, I thought the way you explained and reasoned your answers was very clear and precise. Also in my response, I said I wasn't sure if it was correct to say that the rate of change was constant as the car moved. You did an excellent job explaining why this is. And what an interesting way to think about the graph!

In this example, Ava appears to have compared her thinking to Hank's when she noted that she never heard of the particular definition of a parabola Hank referenced. In this sense, Ava commented on the comparison of the extent of their mathematical knowledge. Cindy's post was similar as she shared information when she seemed to evaluate Hank's idea ("your explanation was clear and precise") as well as when she appeared to praise Hank's explanation ("You did an excellent job explaining"). Cindy also compared the correctness of her thinking with Hank's when she said, "in my response I wasn't sure if this was correct…" Taken together, while Hank initiated a thread that introduced and argument for why a parabola was insufficient for making sense of the quantitative scenario, Ava and Cindy *shared and compared* information as they praised Hank's explanation, made evaluative comments, compared the correctness of their responses, and compared the extent of their mathematical knowledge.

The next example illustrates the way in which participants developed feedback to their colleagues mediated by the web-based assessment environment. The example is an occasion where a participant does not explain why a function graph looks a particular way. The feedback is interpreted as an occasion of challenge as Paul pushes Nina to explain why. The feedback has a particular structure that is a result of the scaffolding of the web-based tool. In particular, the structure includes a particular detail of Nina's work and a comment that is connected to that particular detail. Consider the interaction where Nina attempted to explain why the sine function has a particular look:

Paul's selection from Nina's work: You wrote: This graph appears as it does because of the Unit Circle. Essentially as the values of sin(x) make their way around the circle, they start again at zero.

Paul's comment to Nina: ...and I wonder... if you could elaborate on this concept more. Why do the values start again at zero? Why does the graph have hills and valleys?

In the above example, Paul highlighted a particular aspect of Nina's work that does not explain why the graph of y=sin(x) has a particular look. While Nina noted, "the graph appears as it does *because*..." her reason lacks detail as well as specificity. In Paul's comment to Nina, he pushed Nina to explain why: "Why do the values start again at zero?" "Why does the graph have hills and valleys?" The first 'why question' asked Nina for more detail regarding something she explicitly said in her solution. The second 'why question' explicitly pushed Nina to explain why the graph has particular visual features ("hills and valleys"). Thus, it appears that Paul was challenging Nina to refine her mathematical explanation.

The above examples illustrate the difference in feedback according to the environment in which it was generated. Mediated by the DB, participants *shared and compared* information where their feedback did not contribute to the mathematics being discussed. Scaffolded by the web-based tool, participants developed feedback that challenged colleagues and was generative in regard to pushing colleagues to expand and refine their mathematical explanations. This finding indicates that the web-based assessment environment likely contributed to participants' engagement in more generative feedback practices. In particular, the web-based tool scaffolded the structure of participants' feedback, that is the way in which the tool scaffolded highlighting aspects of colleagues' work and providing comments linked to that highlighted detail. This structure was illustrated in the example above as the feedback essentially included a "quote" (e.g. Paul's selection) and a comment linked to that quote (e.g. Paul's comment). Thus, it appears that scaffolding the examination of colleagues' work by highlighting details and making comments on those details contributed to participants beginning to challenge their colleagues to refine their mathematical explanations.

Discussion

The above analysis showed that the web-based tool likely contributed to teachers' development of more generative feedback. Research indicates that in online asynchronous discussions, teachers overwhelmingly share and compare their ideas Yücel & Usluel, 2016; Zhang et al., 2017). Gunawardena, Lowe, and Anderson (1997) developed a framework for examining the social construction of knowledge in online discussions and argued that questioning and challenging is a more generative form of interaction than sharing and comparing information. This suggests that the web-based tool scaffolded participants' development of more generative feedback practices that broke down typical norms for teachers' interactions in online discussions. Teachers' engagement in more generative feedback has implications for the emergence of generative and productive online communities of teachers as well as the potential for such feedback practices to transfer into teachers' instruction.

Conclusion

This study conceptualized mathematics teacher PD as a virtual boundary encounter. At the core of the notion of a virtual boundary encounter is the design of technology that can scaffold activity consistent with a community's practices. The results of this study show promise for the potential of this conceptualization of mathematics teacher PD as participants used the tool for its designed use (e.g. they highlighted aspects of colleagues' work and made comments on these highlighted details) and this activity contributed to their development of more generative feedback. In this sense, it was teachers engaged in practice mediated by technology that impacted their feedback. This indicates the potential scalability of this design for PD as technology begins to expand the outreach of teacher educators through scaffolding participation in community's of teacher educator's practice. Future research is needed to further investigate the role of the web-based assessment environment in teachers' development of feedback.

SECONDARY MATHEMATICS/ SCIENCE TEACHERS' CHALLENGES IN DESIGNING COGNITIVELY DEMANDING TASKS

Angelica Monarrez
University of Texas at El Paso
amonarrez5@miners.utep.edu

Mourat Tchoshanov
University of Texas at El Paso
mouratt@utep.edu

In this study, we examined the design of mathematical tasks at different levels of cognitive demand. There are four levels of cognitive demand by Stein et al., (2000) memorization, procedures without connections, procedures with connections, and doing mathematics. 55 secondary mathematics and science teachers were asked to design tasks at each level of cognitive demand and 13 were interviewed. We found that teachers had issues designing tasks at the higher levels. We also found the challenges of designing such tasks: teacher related challenges, students' related challenges, and selecting/modifying vs. designing tasks.

Keywords: Mathematical Knowledge for Teaching, Teacher Education-Inservice/Professional Development, Teacher knowledge

Objectives

Smith and Stein (1998) have argued that a selecting and creating good tasks are important to keep students engaged in the task and develop their problem-solving abilities. In this study, we examined the design of mathematical tasks at different levels of cognitive demand. We were interested in the teachers' creation of their own mathematical tasks to analyze their understanding of cognitively demanding tasks (CDT). This study addresses the following research questions: (a) How do secondary math and science teachers design tasks at different levels of cognitive demand?; (b) What are the main challenges secondary math and science teachers experience while designing tasks at different levels of cognitive demand?

Theoretical Framework

We used the construct of cognitive demand by Stein, Smith, Henningsen, and Silver (2000) to frame this study. Stein et al. (2000) have defined cognitive demand regarding mathematical tasks as "the kind and level of thinking required of students to successfully engage with and solve the task" (p. 11). There are four levels of cognitive demand by Stein et al., (2000) memorization, procedures without connections, procedures with connections, and doing mathematics. In this framework, the first two are considered a low-level and the last two are considered high-level of cognitive demands. Level 1 (memorization) is about reproducing formulas, rules, or facts without a procedure. For example, remembering a formula or a definition. Level 2 tasks (procedures without connection) are algorithmic such as substituting values in a formula. There are no connections to other concepts and does not require an explanation. Level 3 tasks (procedures with connections) require students to have a deeper understanding of the procedures to solve the task. Finally, the last and highest level of cognitive demand is level 4 (doing mathematics). This level is non-algorithmic and requires students to go beyond a procedure by exploring the concepts.

Modes of inquiry

Participants

This study was conducted as part of a larger project that took place during three years (2013-2015). It was a series of professional development workshops from the state-funded Teacher Quality grant. The workshops took place in a university located on the U.S.-Mexico border. The secondary school mathematics and science teachers met for three hours every other week as part of a professional development workshop. N=55 teachers from all the main districts in the region participated in the study.

Data Sources

First, teachers discussed in teams the meaning of cognitive demand, then they learned about the four levels of cognitive demand and had a group discussion about the topic. After that, teachers were asked to fill out a survey titled the cognitive demand survey. One part of the survey was aimed to measure whether teachers could design tasks at different levels of cognitive demand on topics relevant to secondary school mathematics and science curriculum. Individual interviews with a purposefully selected sub-sample of 13 teacher-participants were conducted. As part of the activities of the teacher quality grant, teachers had to develop a lesson to be presented to their peers. This activity was observed to assess the level of cognitive demand presented during their classroom. Similarly, as in the lesson during the workshop, teachers were observed during one class session to examine the level of the task presented in practice.

We conducted one semi-structured interview with each participant. We selected the participants for interviews based on the following criteria: a) teacher(s) who know different levels of cognitive demand but cannot implement CDT neither in the workshop nor in the classroom setting; b) teacher(s) who know the levels and can apply CDT in the workshop but not in the classroom setting; and c) teacher(s) who know the levels and can apply CDT in both the workshop and classroom settings. The interviews lasted in average approximately 35 minutes.

Data Analysis

The part of the cognitive demand survey about designing tasks at different levels was analyzed and graded by the researchers based on the following criteria: a score of 1 was assigned if the task was not designed at the desirable level or a teacher didn't provide any task, a score of 2 - if the designed task was partially correct, and a score of 3 - if the task was designed at the required level. Teachers were not provided with the total score on the survey in order to not impact their interview responses. The semi-structured interviews were coded to look for instances in which the teachers talked about the design of mathematical tasks. Emergent themes were extracted using linguistic analysis and meaning coding techniques (Kvale & Brinkmann, 2009) and placed into the following categories: teacher related challenges, students' related challenges, and selecting/ modifying vs. designing. Several meetings were held between the two researchers in order to reach consensus on all the codes from the interviews. All the names that appear in this study have been changed to pseudonyms.

Results

Table 1 shows the percentages of teachers rated on the tasks they designed at each level. As we can see from the table, the majority of the teachers were able to design tasks at level 1 and 2 but had issues with designing tasks at levels 3 and 4 with less than a quarter being able to design tasks at the high levels. In the case of the level, 3 task more tasks were rated as a 2 (47.3%) while for level 4 more tasks were rated as a 1 (51%).

In the designing survey, participants were given a topic, and then they had to design their tasks at each of the levels. Also, they were also required to provide a solution to the task they developed as well as an explanation of why they think that task is at that level. 83.6% of participants designed a task at level 1. Most of their tasks were about remembering a formula. Participants wrote as an explanation, "because it can be recalled without meaning or understanding" or "student doesn't need to apply any solution." Those who did not design a level 1 task created a level 2 task because it was more procedural than memorization. The majority of participants (94.5%) were able to design a task at level 2. One participant designed a task with a proportion and one missing value and then wrote:

"must find x using cross multiplication, then division, very procedural no connection." The few participants that did not design a level 2 task designed a task that was unfinished or left that part blank.

Less than a quarter of the participants (23.6%) correctly created a task at level 3. One participant created the following task "what is the maximum area of a rectangle if the perimeter is 20" and explained that it was a level 3 task because "it requires to use prior knowledge of area and perimeter." The following task was rated a level 2 task when the participant intended to write a level 3 task. "Find the amount needed to double or triple a recipe." Less than third of the participants (27.2%) were able to design a task at level 4 correctly. There were a few participants that created a level 2 or level 3 tasks instead of a level 4 task since the raters found them as more procedural. One participant that successfully designed a level 4 task on the topic of "Area of a triangle" created the following task "derive the formula for area of a triangle" and said, "they are doing mathematics because there must be deep understanding of concepts."

In the interviews, teachers stated that there are some challenges when designing tasks that are cognitively demanding. Through interview analysis, we identified the following emerging themes that addressed difficulties expressed by teachers: teacher related challenges, student related challenges, and selecting/modifying vs. designing tasks. The first emerging theme from the interviews was teacher related challenges because some teachers mentioned having issues understanding the higher levels of cognitive demand. Derek had challenges at designing a task at level 4 in the survey. When we talked to him during the interview, he confirmed this by saying

> Derek: the first three are probably really confident just the last one maybe not so much. I remember I was like yeah I can do the first three easy and ten the fourth one I took some more time to think about it.

Level 4 was challenging for him and took some time to create a task at that level. Another teacher expressed confusion between the levels because

> Monica: They're sort of, I think they are sort of confusing, like it could be a grey area with them it's not just ok this is level three, and this is level four, I think they can kind of, could overlap, so that's why I think that's where the confusion is.

Another emergent theme was addressing teachers' concern that the students are not ready to solve cognitively demanding tasks. Teachers feel that if they design a task that is at very high-level students will not be able to understand the task and therefore to solve it. Level 4 tasks have rigor and require students to discover mathematics and science concepts. Some teachers feel insecure engaging students in level 4 tasks claiming that students need guidance in working with this kind of tasks. For example, Anna said, said: "if students struggle with the concept a little bit as a teacher I feel like I want to give them all the tools they need and all the guidance instead of just kind of letting them work solving." Another teacher mentioned the level and language of the students and how she doesn't believe that they will be ready for a task that is too cognitively demanding,

> Isabel: Because my kids, if I bring an activity that is at a very high level… if you show a very difficult problem to a kid that is performing at a third-grade level and that English is not their primary language they probably won't do anything.

During the interviews and the workshops, the majority of the teachers expressed that they would rather select tasks that they want to implement in the classroom and then modify them instead of designing it. Cesar said in an interview, Cesar: I'm not that creative so coming up with my own stuff like I said most of the lesson that I have I borrowed from other teachers and modified, I am good at modifying things but actually creating my own, unique, individual lessons and problems, not as good at that.

Teachers said that they either take the tasks from the internet or other teachers and then they modify them to fit their classroom.

Table 1: Distribution of Teacher Responses on the Task Design Survey

Levels	L-1	L-2	L-3
Not correct	7.3%	3.6%	29.1%
Partially correct	9.1%	1.9%	47.3%
Correct	83.6%	94.5%	23.6%

Scholarly Significance

The significance of the study is twofold: from the scholarly lens, it attempts to address the issue of task design through the construct of teacher challenges, and from a practical perspective, it leads to understanding the issue of equal learning opportunities through cognitively demanding teacher preparation and professional development. More specifically, we engaged teachers in learning the four levels of cognitive demand and then designing their mathematical tasks at each level. Designing mathematical tasks is not an easy assignment for teachers. Most teachers had issues designing tasks at the higher levels of cognitive demand. Many created tasks that were at a procedural level instead of level 3 or 4. It is important to examine teacher's understanding of cognitive demand so we can better understand what kind of tasks they consider as cognitively demanding. Some teachers might think that a task requires more cognitive demand than what it requires. We have seen that there are different challenges for teachers to design mathematical tasks thus investigating these challenges further can help researchers understand the implementation of cognitively demanding tasks in mathematics and science classroom.

SUPPORTS FOUND BENEFICIAL AND CHALLENGES FACED BY ADJUNCT INSTRUCTORS WHEN IMPLEMENTING A RESEARCH BASED CURRICULUM

Zareen G. Rahman	Eileen Murray	Amir Golnabi
Montclair State University	Montclair State University	Montclair State University
Rahmanz1@montclair.edu	murrayei@montclair.edu	golnabia@montclair.edu

This report shares the initial results from research of a model designed to support Precalculus adjunct instructors. The model is based on the organization and coordination of Precalculus along with sustained professional development in the form of a professional learning community. The initial results for instructional practices and job satisfaction show that instructors found access to a course-coordinator and participation in a PLC beneficial.

Keywords: Post-Secondary Mathematics, Teacher Education-Inservice/Professional Development

Objectives

Research suggests that students' persistence in pursuing STEM degrees is influenced by their experiences in their first year mathematics courses (Hutcheson, Pampaka, & Williams 2011; Pampaka, Williams, Hutcheson, Davis, & Wake, 2012). In this regard, the quality of pedagogy can make a big difference in the retention of STEM students beyond beginning mathematics. Moreover, there is a growing trend that higher education institutions are increasingly employing part-time, non-tenure track faculty, such as adjunct instructors (Mason, 2009; Curtis, 2014). Between 2001 and 2011, the number of part-time faculty employed in degree-granting institutions increased by 35% (Snyder & Dillow, 2015). This trend points to a need to better understanding how institutional policies and practices, including the availability of professional development (PD), can improve part-time instructors' experiences (Kezar & Sam, 2013).

While there is a growing body of research aimed at providing PD for graduate teaching assistants (DeLong & Winter, 2001), much needs to be done with respect to the growing population of adjunct instructors (Austin & Sorcinelli, 2013). The current study focuses on the adjunct instructor population because of our own institution's increased reliance on this group, especially in our introductory mathematics courses. We are currently developing and refining a model to help adjunct instructors implement best practices for learning and instruction through professional development and course coordination. This model incorporates instructor supports backed by research and provides course coordination of Precalculus. Our course coordination includes a course coordinator, Precalculus tutors, a common pacing guide, syllabus, assessments and rubrics for all instructors. In addition, we provide a summer workshop for new Precalculus adjunct faculty and tutors, during which participants receive a comprehensive training on the adapted curriculum. This workshop is part of a larger PD effort that continues throughout the semester through online weekly meetings led by a full-time faculty member or graduate student. These meetings form the foundation of a professional learning community (PLC) focused on providing content and instructional support. Adjunct faculty highly regard such supports as they help improve teaching and integrate adjuncts into their institutions (Lyons, 2007; Bowers, 2013).

In this brief research report, we present some of the preliminary findings of our study where we investigate how the adjunct instructors view challenges and supports for this course.

Background

Our study is guided by research on policies and practices for supporting adjunct instructors. All faculty members are important to an institution and must be supported to fulfill their academic responsibilities (Gappa, Austin, & Trice, 2007). Training and development programs for part-time faculty are important because proper training and support can ensure that instructors improve their practice (Leslie & Gappa, 2002). Part-time instructors should feel involved and appreciated within the institutional community. The schedules of part-time instructors often do not allow them to interact with regular staff because of specific class schedules, classrooms in different buildings, and lack of proper office space within the department. In addition, a faculty member who is on campus to teach just one or two courses may have different professional growth interests than a full-time, tenure-track faculty member (Gappa et al., 2007).

To respond to the diverse needs of faculty members, many institutions have developed innovative approaches to PD. For example, some universities and colleges, in recognition of the time constraints, are providing online and in-person PD opportunities such as series of workshop sessions, one day retreats, and online programs (University of Central Florida); late-afternoon and early evening sessions including a light meal, a stipend and a certificate of completion (University of Louisville); or an orientation with mentoring and online PD (Ivy Tech Community College (ITCC)) (Lyons, 2007).

There is no single model that can fit the needs of all the institutions therefore institutions need to develop specific programs that cater to their own needs (Austin & Sorcinelli, 2013). New approaches to adjunct PD need to be established to flourish within organizations (Austin & Sorcinelli, 2013). One way of providing support and development to the faculty is a focus on collaboration both inside and outside the institution (Austin & Sorcinelli, 2013). Collaboration in the form of Professional Learning Communities (PLCs) has been proven to be a beneficial model for K-12 teachers, as teaching has been shown to be more effective, and student achievement improves, when teachers develop strong PLCs in their schools (Fulton & Britton, 2011). In an overview of the research on PLCs in higher education, Roth (2014) found that engagement from faculty in these communities also led to more effective teaching and improved student learning. In fact, all faculty members, regardless of their appointment type, can benefit from participating in PLCs (Gappa et al., 2007).

Methods

This brief research report presents the findings using a subset of data from a larger study. Our initiative aims to measure the impact of course coordination and support on adjunct mathematics instructors' knowledge, instructional practices, and job satisfaction. The transcription data from the interviews is being analyzing using thematic analysis. Through this analysis, we seek to discover emerging themes focused on changes in their class room practices, beliefs about teaching and learning mathematics, expectations of students, and persistent challenges of their role as adjunct instructors.

The study is taking place at a Ph.D. granting public institution in the northeastern United States. The current participants are 8 adjunct instructors implementing a research-based Precalculus curriculum. The instructors were interviewed in person at the beginning and end of the semester, and all the participating adjunct instructors had previously taught one or two Precalculus classes. The interview data has been initially analyzed and coded for emerging themes. This data will support results from our larger data sources including classroom observations, content assessment and belief survey to provide us with additional evidence of the impact of the course coordination and adjunct support. Our specific research questions for this report are as follows:

1. What challenges do adjunct instructors face when implementing a research-based Precalculus curriculum?
2. What supports do the adjunct instructors find more beneficial when implementing a researched-based curriculum?

Results

Based on our initial analysis, various themes emerged about the ways in which our adjuncts' instructional practices changed due to the challenges they faced as well as the supports they found beneficial. We hypothesize that these supports may lead to increased job satisfaction.

The reported challenges mostly focused on factors necessary to implement the curriculum well and the supports adjunct instructors would need in order to overcome these challenges. The instructors identified what specific supports were more beneficial to them, and reported back to us on how those supports and resources could be improved. In addition, the instructors' initial experiences with the curriculum allowed them to develop a plan of what changes they would need to make to their own instruction, pacing schedule, and other course planning.

Challenges

The first challenge stemmed from instructors' prior experience teaching Precalculus as either an adjunct instructor or high school teacher. Most of the adjunct faculty had several years of experience teaching Precalculus at the college level, with the exception of one instructor who was teaching the course for the first time. Some instructors were concerned about the fast pacing that covered the broad range of content in the new curriculum. They were afraid that as a result, their students may not be well-prepared to take the first Calculus course the following semester. The main reason behind such concern was the fact that the content they had covered when they had taught this course previously focused primarily on procedural techniques rather than conceptual understanding of the topics.

In addition, some instructors were not comfortable planning lessons and implementing the curriculum due to its novelty. Based on their past experiences, they had built a repertoire of techniques in terms of planning and delivering their lessons in class, and therefore had felt more confident in providing examples to the students because of this familiarity with the content. Many instructors were also concerned about bringing students onboard with the new curriculum, which focuses on conceptual learning and understanding. Based on their responses, it was clear that adjunct instructors had already started experiencing challenges in involving students in working through specific investigation modules throughout the course. This experience proved to be a source of dissatisfaction for the teachers both in the classroom and while planning for their lessons. They also found it challenging to communicate with students about the reasons the new curriculum required greater class participation.

Finally, structural issues like classroom size, set-up, traditional furniture and lecture style halls proved to be a challenge to implementing a new research-oriented Precalculus curriculum focusing on discourse.

Supports

Our second research question specifically talked about the supports that our adjunct instructors found beneficial when implementing the curriculum. While not surprising, we found it interesting that none of our adjunct instructors had ever received any form of mentoring as an adjunct instructor. While they may have received mentoring as a student teacher or during their first year teaching at the K-12 level, they had never been involved in any form of mentorship or professional development at the college level. They appreciated the online PLC meetings and having access to a course coordinator. The PLC meetings gave them a platform to learn about the ways in which the students should be guided through the investigations as well as a place to share their concerns and ask their questions. Similarly, having access to a course coordinator allowed them to share their concerns and get some direction. They found the common exams and the pacing guide that were designed by the course coordinator most beneficial. The exams and the pacing guide, as well as having a course coordinator as a go-to person opened up time for other activities like designing projects for students, developing online videos etc.

Our adjunct instructors also collaborated with each other in smaller informal groups and continued to engage in these collaborations along with the online PLC. The nature of these informal meetings was impacted by the curriculum as well as the discussions during the formal PLC meetings. The informal PLC conversations focused on content and pedagogy instead of logistical issues. This focus was a result of the logistical concerns being taken care of by the course coordinator.

Conclusions

The results presented here are part of a larger research effort to measure the impact of course coordination and support on adjunct mathematics instructors' knowledge, instructional practices, and job satisfaction. Our findings from the analysis of the initial interview data with the instructors focus on their instructional practices and job satisfaction. Moving forward we plan to extend our analysis to delve deeper into the ways in which supports, like weekly online meetings and access to a course coordinator, impacts our instructors. We are also interested in investigating how instructors' content knowledge might be impacted by these efforts. Our hope is that these findings will make a significant contribution towards the scant literature on supporting mathematics adjunct instructors.

This study reports on learning through Chinese lesson study (LS) by three elementary school teachers in the US. Three cycles of LS were facilitated by knowledgeable others to make sense of comparison subtraction through problem solving. Data consisted of lesson plans, videotaped research lessons, post-lesson debriefings, and reflection reports. The lesson improved regarding: using number talks to activate relevant knowledge; smooth transfer from acting out to using manipulatives to symbolizing the comparison model; and student outcomes. Teachers voiced they grew professionally and gained knowledge about content, pedagogy and student learning.

Keywords: Number Concepts and Operation, Learning Trajectories, Problem Solving

Introduction

Implementing common core mathematics standards in classrooms has been a nationwide effort since 2010 (CCSSI, 2010). *Principles to Actions* (NCTM, 2014) describes eight practices for research-based, effective teaching. However, it is still a daunting task for many teachers to teach in this way. Lesson study (LS) can be effective in helping them implement CSSM (Lewis & Takahashi, 2013) and improve their learning and students' learning outcomes (Huang & Shimizu, 2016). A team of mathematics teacher educators and mathematics specialists has developed and implemented a hybrid model of professional development (PD) for K-6 teachers consisting of an extensive summer institute, demonstration lessons and coaching or LS. Twelve of 48 participants in a PD project voluntarily participated in LS. Four LS groups completed the cycle of LS: designing a lesson, teaching/observing the lesson, debriefing, re-teaching the lesson, and re-debriefing and reflection. This paper reports on one of the LS groups which focused on comparison subtraction at grade 1 to address the research questions: (1) How did the research lesson improve through the LS process? (2) What did teachers perceive of and learn from LS?

Literature and Theoretical Framework

Chinese Lesson Study

Lesson Study, a practice-focused, collaborative, student-focused PD model, has been recognized as powerful for improving teaching and promoting student learning (Huang & Shimizu, 2016; Lewis, 2016). Similar to Japanese LS structurally (Lewis, 2016), Chinese LS emphasizes repeated teaching of the research lesson and knowledgeable others' input (Huang & Han, 2015). In the context of Chinese LS, Han and Paine (2010) found that improving teaching of mathematics as deliberate practice gave teachers an opportunity to refine their core instructional practice. Thus, Chinese LS can provide a way to improve instruction and professional expertise.

Teaching Mathematics Based on Learning Trajectory and Variation Pedagogy

Two theoretical frameworks guided the design of and reflection about lessons throughout the LS: learning trajectory (Clements & Sarama, 2004) and variation pedagogy (Gu, Huang, & Gu, 2017).

Learning trajectories (LT) have been proposed as a foundation for classroom instruction (Clements & Sarama, 2004; Simon, 1995). A hypothetical LT is a pathway on which students might proceed as they advance learning toward the intended goals, which describes children's thinking and learning in a specific mathematical domain and a conjectured route through a set of instructional tasks (Clements & Sarama, 2004). Variation pedagogy (VP) arises from the Chinese mathematical teaching tradition, and focuses on using deliberate and systematic variation in mathematics tasks to help students develop new concepts and problem solving abilities (Gu et al., 2017). The key idea is to emphasize the importance of constructing patterns of variation and invariance to create necessary conditions for mathematics learning.

Teaching and Learning of Subtraction with Whole Numbers

According to CCSSM 1.OA. A.1 (CCSSI, 2010), first grade students should learn to use addition and subtraction within 20 to solve word problems involving situations of adding to, taking from, putting together, taking apart and comparing by using objects, drawings, and equations. Three models for interpreting subtraction are: taking away, missing addend, and comparison (Sowder, Sowder, & Nickerson, 2014; Van de Walle, Karp, & Bay-Williams, 2016). The first two are based on the part-part-whole model which can be presented visually using a part-part-whole mat (Van de Walle et al., 2016). The comparison model involves the difference between two distinct sets or quantities, and can be represented visually by counters or cubes. However, "it is not immediately clear to students how to associate either the addition or subtraction operation with a comparison situation" (Van de Walle et al., 2016, p. 177). The dominating part-part-whole model may negatively impact students' understanding of the comparison model of subtraction. Researchers (Van de Walle et al., 2016) have suggested that when discussing the difference between bars, asking "how many more" may help students to generate the subtraction equation. Research further suggests that using physical actions to match concrete manipulatives in a one-to-one fashion leads to visualized objects being matched in the same manner, and finally to the development of number sentences using mathematical symbols (Zhou & Lin, 2001). The studies reviewed suggest that teaching the comparison model of subtraction should follow a hypothetical LT with five levels: (1) physically acting out comparison subtraction (how many more or how many fewer) within a daily context; (2) using manipulatives (counters or cubes) to model comparison subtraction concretely; (3) drawing diagrams to represent the model visually; (4) creating mathematical equations; and (5) varying problems regarding different unknowns (i.e., difference, larger or small quantities).

Method

Lesson Study Group

The LS took place in a school system in a mid-size city in a southeastern state in the USA. An expert team of three mathematics educators, two from the mathematics department and one from the college of education at a large public university in the city, and one mathematics specialist from the school system oversaw all LS activities. This included facilitating lesson planning and post-lesson debriefing meetings and commenting on lesson plans. The LS group included three first grade teachers from three schools, similar in terms of social-economic status and academic achievement. Table 1 contains information on the teachers.

Table 1: Background Information of the Participating Teachers in the Lesson Study

Name	Gender	Highest Degree	Teaching experience	Licensure
Ms. Luna	F	Master of Arts – Reading Education	6-10	K-6
Ms. Schultz	F	Bachelor of Science – Early Childhood Education	0-5	K-3
Mr. Murphy	M	Master of Education	>20	K-4

Data Collection and Analysis

The LS included one lesson planning meeting, three research lessons on the same topic, and three post-lesson debriefings. After completion of the LS process, teachers submitted a reflection essay guided by several questions. The three lesson plans, videotaped research lessons (including student work) and debriefing meetings, and reflection essays constitute the data set for this study.

Based on the framework of LT and VP, the three research lessons (videotaped) were analyzed with a focus on whether the LT was reflected and how the tasks were aligned with VP. The effect of each lesson was evaluated based on classroom observation and examination of exit tickets. Debriefing meetings were analyzed to reveal factors leading to changes in the lessons. Reflection essays were analyzed using NVivo to ascertain teachers' perceptions of the LS process and what they learned. Results are presented in alignment with research questions.

Results

The Major Changes across the Research Lessons and Key Causal Factors

Each of the three teachers taught the research lesson once. The goal was to develop students' understanding of comparison subtraction through solving word problems. Immediately after each lesson, there was a debriefing session on strengths and weakness of the lesson and suggestions for changes. Table 2 has major changes from initial to final lesson and associated casual factors.

Table 2: Major Changes between the Initial Lesson and the Final Lesson

Phases	Initial lesson	Final lesson	Changes
Number talk (Activating relevant knowledge, leading to new topic)	11+7=18; 7+?=11 Focus: Part-part-whole and missing addend subtraction	5+2=7; 7-2=5; 5-3=2 Focus: How many more and subtraction equation	Activating relevant knowledge closely related to new topic
Acting out comparison (match up boy and girl)	Matchup physically (9 and 14)	Matchup physically (9 and 11). Modeling with linking cubes. Drawing diagrams to match up. Setting equations.	Transferring from physical to visual to symbolic representations
Modeling and symbolizing (using linking cubes, diagrams and equations)	Task 1: Word problem without a picture (13-8=5). Task 2: Word problem without a picture (7-3=4). Less appropriate tools.	Task 1: Word problem with a picture (7-4=3). Task 2: Word problem without picture (13-8=5). Using linking cubes, diagrams, and equation.	Progression from simple to complex. Used multiple represent tations. Removed part-part-whole mat.
Challenging task	Task 3: If A is more than B and A+B=15, find A and B.	N/A	Removed
Exit Ticket	N/A	Task: Word problem without picture. Request: use diagram number line, equation.	Added
Learning outcomes	15% mastered comparing 13 with 8	63% mastered comparing 15 with 7	

Participant Teachers' Perception of the Lesson Study and Their Perceived Learning

Each teacher expressed enthusiasm for the LS process and product as illustrated by Ms. Schultz, "I was proud of our work on the compare lessons and enjoyed learning and participating in watching these lessons change, evolve, and enhance the learning of the children involved in this project." The teachers perceived their teaching skills and knowledge of content, pedagogy, and student thinking increased. Mr. Murphy reflected, "over the course of the LS we were able to make the necessary changes and see our students grow their mathematical thinking of word problems." They have already and will continue to implement what they learned from the LS in their classrooms. Ms. Schultz said, "I feel far more capable in my abilities to design a lesson trajectory that would better serve my students' learning. I now find myself to be more intentional in observing and reflecting upon my students' thinking to more thoughtfully write and revise my lesson plans so that I may better support the success of their learning." They also indicated the opportunity for discourse on mathematical practices was beneficial to their professional growth.

Discussion and Conclusion

This study demonstrated how the Chinese LS approach inspired by LT and VP can help teachers improve a lesson that promotes students' conceptual understanding of comparison subtraction. Meanwhile, the teachers not only deepened their understanding of the concept of comparison subtraction, but also increased specific pedagogical skills such as selection of appropriate tools, sequencing of tasks, transfer from concrete to abstract, and analysis of student thinking, which has impacted their daily teaching. Each teacher acknowledged both the process (enactment and reflection) and product (final lesson) of the LS as being beneficial. This study suggests that part-part-whole should not be used for exploring comparison subtraction (Van de Walle et al., 2016). It also suggests that beginning with the physical action of matching sets in a one-to-one fashion, then moving to using linking cubes for matching, and finally using diagrams for matching can help students develop equations for comparison subtraction problems (Zhou & Lin, 2001). Since the highest level of variation problem regarding different unknowns was eliminated from the lesson after the first teaching, exploration regarding the scaffolding needed for students to successfully investigate this challenging but mathematically rich task is needed.

TEACHERS' DEVELOPING QUESTIONING TO SUPPORT LINGUISTICALLY DIVERSE STUDENTS IN JUNIOR HIGH MATHEMATICS CLASSROOMS

Sarah A. Roberts
University of California, Santa Barbara
sroberts@education.ucsb.edu

Alexis Spina
University of California, Santa Barbara
adspina@education.ucsb.edu

This study examines three junior high school teachers' questioning practices of English learners (ELs). We build on prior research demonstrating the utility of questioning for developing mathematical discourse and apply it to the novel endeavor of having teachers use questioning purposefully as a means to engage ELs in mathematics discourse. Using qualitative methods, this pilot study examines three teachers' questioning practices prior to participating in professional development, how the teachers' practices differed for ELs versus non-ELs, and how the teachers explored expanding their questioning practices during professional development as they prepared to teach a cognitively demanding mathematics lesson.

Keywords: Teacher Education-Inservice/Professional, Equity and Diversity, Middle School Education

Objectives

This study's objective is to examine three junior high mathematics teachers' questioning practices of English learners (ELs). This paper builds on prior research that demonstrates the utility of questioning for developing mathematical discourse and applies it to the novel endeavor of having teachers use questioning purposefully as a means to engage ELs in mathematics discourse, providing potential pathways for ELs to access and engage with mathematics content and language in meaningful ways. In this pilot study, we examine the following research questions: What does questioning look like in teachers' classrooms? How do the teachers' questioning practices differ for ELs versus non-ELs? How do teachers explore expanding questioning in professional development (PD) as they prepare to teach a cognitively demanding mathematics lesson?

Perspectives

We ground our work using four key principles for supporting ELs in mathematics classrooms: providing cognitively demanding mathematics tasks, building on and understanding students' resources, providing language rich opportunities, and understanding students' language demands (Roberts, Bianchini, Lee, Hough, & Carpenter, 2017). We see these as important for working with teachers and for teachers working with their ELs.

With these four key principles, this study focuses on questioning that develops, attends to, and elicits higher-order thinking. Such questioning has myriad functions. Teachers can use their questioning to access student thinking and to gain important knowledge about possible trouble spots or misconceptions their students have with regards to particular content (NCTM, 2014). Ideally, questioning allows teachers to support students to listen carefully and to develop a fruitful exchange of ideas with rich and purposeful mathematics discussions (Imm & Stylianou, 2012). We focus on using high cognitive demand questions to create an environment of inquiry for ELs.

Such questioning requires teachers to move beyond close-ended questioning, where teachers use questions for information gathering only or getting to a desired procedure or conclusion, which allows for little veering from a limited desired path (NCTM, 2014). Instead, this study seeks to press ELs to "communicate their thoughts clearly, and … to reflect on their thoughts and those of their classmates" (NCTM, 2014, p. 37) through teacher questioning.

Methods

This study took place in California at a junior high school with an enrollment of almost 450 students, with approximately 45% of these students classified as ELs, 34% as FEP, and 18% redesignated as FEP. The majority of ELs (>85%) at the school were Spanish-speakers. The teacher participants were three White teachers with 2.5-5 years of teaching experience and included a bilingual Spanish speaker and a bilingual Vietnamese speaker. The teachers reported that 20-60% of their classes were designated as ELs.

The teachers participated in initial hour-long interview that focused on the their pre-participation questioning practices. The research team also videotaped a single lesson of each teacher to capture how they questioned students, in particular ELs, prior to participating in PD. Finally, the research team video- and audio-recorded a two-hour professional development meeting focused on teacher questioning, and collecting written work and reflections.

During the PD, we used a cognitively demanding mathematics task, “Orange Fizz Experiment” (Georgia Department of Education, 2016), as a focal point for organizing teachers’ questioning of ELs in their mathematics classrooms. Following discussions of the four core principles for supporting ELs in mathematics (Roberts et al., 2017) and some examples of questioning from the literature, we provided teachers with an opportunity to solve this mathematics task. Because teachers previously rarely used such tasks and in depth questioning, we provided teachers with time not only to solve the task but also to develop questions to use with the task as they planned their lesson around the task.

We analyzed the teachers’ use of questioning across data sources using open coding (Strauss & Corbin, 1990). In order to identify consistencies and inconsistencies across the research questions, we generated themes within and across each question.

Results and Discussion

RQ#1: What does this questioning look like in teachers’ classrooms?

The first theme that we noted when we looked within each teacher’s classroom and across the teachers’ classrooms was that the teachers tended to use fairly close-ended questioning with their students. This is likely linked to the type of mathematical work that they usually used with their students. In their interviews and in the professional development, the teachers talked about the fact that they used mostly direct instruction with their students and they rarely used tasks. For example, Teacher 1 explained, “I use a mixture of drill and kill….and [I have students] look for a number answer.” Teacher 1 asked such questions as, “What are some quantities? What else are you seeing? Do we know how many some is?” Teacher 2 described using acronyms to help students remember particular mathematical processes, sharing, “I don’t, like, just to tell them. [I ask them,] What is the acronym?...How can we use this?” Teacher 2 focused on students memorizing particular processes, and her questioning attended to reminding students of these procedures. Teacher 3 also focused his questioning on procedural mathematics, telling us, “I will often ask what the next steps are. What do we need to be careful of?.... I ask a lot of times is this positive or negative.” These close-ended questioning strategies in many ways mirror what Cazden (2001) refers to as an *Initiate-Respond-Evaluate (IRE)* sequence, with a teacher providing a question such as, “Is this quantity negative?” A student would respond, “yes” or “no.” And then a teacher would then evaluate the correctness of that response.

Our classroom observations helped to triangulate the teachers’ self-reporting of these IRE sequences. While the teachers did not lecture the whole time, we had seen them do so in previous visits to the school. Teachers 1 and 2, on the day of our observations, used the same activity, a “speed-dating” activity in which students worked in pairs to solve one- and two-step equations.

When the teachers asked questions, the students had to describe the steps they took for solving the equations. Teacher 3 did a different activity in which students had to complete a worksheet where they had to identify how to write an equation. He asked such questions as, "How do we use these numbers to write an equation?" "Do we see $39 in the equation?" "How many friends did he take to the movies?" The teachers were focused on questions that generally elicited one-word answers and demanded lower-level cognitive demand. Teachers were using questioning that was close-ended, and we linked this questioning with the mathematics tasks the teachers were using, which required less in depth questioning.

RQ#2: How Do Teachers' Questioning Practices Differ for ELs Versus non-ELs?

Overall, the three participating teachers commented that their questioning practices were generally the same with their ELs and their non-ELs. Teacher 1 explained, "Yeah. It's not much different." However, there were some instructional practices that the teachers shared that they used when they were describing their questioning work with ELs. Teacher 2 shared in both her interview and the PD that she used sentence starters and often provided them for all students. Teacher 3 described, "I also code-switch and use some words in Spanish," explaining that he gave some mathematics vocabulary in Spanish and English and then used connecting words in Spanish to support students in understanding the new mathematics vocabulary in English. All three teachers used general support strategies for working with ELs and did not generally alter their questioning strategies when working with ELs versus non-ELs.

RQ#3: How Do Teachers Explore Expanding Questioning in Professional Development (PD) as They Prepare to Teach a Mathematics Lesson?

Our answers to the first two research questions helped us to recognize that we needed to provide some foundational experiences for the teachers in their first PD. We decided that providing cognitively demanding learning experiences for ELs would ground the work for our questioning work with the teachers. Without a good task, we found that the teachers had little to ground their questioning. We also knew from prior research that ELs often have less access to cognitively demanding work for myriad reasons. We had a cognitively demanding task serve as a *crossroad* for the teachers and the questioning work we could do in the professional development as they prepared for their future questioning. The teachers solved a task together that came from optional district curricular materials, the "Orange Fizz Experiment" (Georgia Department of Education, 2016). They planned a lesson and created supporting questions to enact during their upcoming unit on ratio and proportion. This problem has students use ratios to figure out which soda formula has the best tasting flavor, comparing three different formulas of orange concentrate and carbonated water.

The teachers all noted that this problem was different than the type of problems they usually used in their day-to-day instruction, because it was not a standard lecture-practice type of lesson. All three teachers noted that the Orange Fizz Experiment problem afforded them the opportunity to ask different types of questions than they might have asked typically. Teacher 3 shared, "I'm going to try to ask higher-level questions of my students." Teacher 2 also explained:

> I plan to work on my questioning in this lesson by creating more open-ended questions that require more depth of knowledge than procedural questions (i.e. asking the students to discuss what we were comparing vs. saying 'we are comparing part to whole, so what's the 'part' and what's the 'whole'?').

Teacher 1 had the biggest change in her planned questioning, because she anticipated having her students explain more of their thinking. Her questions included: "Which formula has the most 'orange' taste? How do you know?" However, she also included procedural questions like, "What rules do we know we can use to work through ratio tables?"

We pushed teachers to consider their questioning specific to ELs. Teacher 3 explained that questioning, “can support ELs by having them use more language that's specific.” Teacher 2 went into more depth and drew on her students’ prior knowledge: “Questioning can support ELs by giving them opportunities to voice their existing knowledge and enabling them to recognize that they have valuable prior knowledge that can be applied to the problem at hand.” Finally, Teacher 1 found questioning with ELs to be an instructional tool that created space for students to share their thinking: “Questioning can support ELs because it starts with the student's thinking. It provides space for students to reflect and connect knowledge through their past or others. Questioning also has students reflect and justify their thinking.” Even though the teachers acknowledged ELs in our prompts, we found that we need to engage them more thoroughly in thinking about how they can use questioning to engage ELs in mathematical discourse.

The teachers noted that they were looking forward to more opportunities to learn about and to develop their fluency with questioning. For example, Teacher 3 explained, “Today I learned what higher level questions are. I've been struggling with understanding what questioning…meant in a very practical way, and today helped me with that.” Teacher 2 was particularly interested in working toward specifically “preserv[ing] mathematical rigor while meeting the needs of our EL students” using questioning. Going forward, the professional development we provide is going to have to meet both teacher and student needs.

Conclusions

Cognitively demanding tasks provided a crossroads in this project on teacher questioning with ELs. Tasks provided an inroad for our work with teachers in helping them to understand and appreciate how to develop questioning practices that support ELs’ discourse practices. We were able to see marked differences in the types of questions teachers were asking and their approaches to questioning through the use of a different type of task. We believe that this work on questioning lays the foundation for future work on developing rich discourse opportunities for ELs in mathematics and creating and studying PD for teachers in executing such practices.

THE INFLUENCE OF DAILY REFLECTION ON A MIDDLE SCHOOL TEACHER'S PRACTICE

Diana L. Moss

This report describes a framework used as a communication tool to reflect and adapt instruction to support student learning. Specifically, this framework was used as a bridge for collaboration between the classroom teacher and the researcher to reflect on daily lessons. The goal of this preliminary project was to adapt teaching and tasks to support seventh-grade students' learning of algebraic expressions and equations. The framework was used to document and summarize what occurred during the lesson on a daily basis and to identify learning goals for the subsequent lessons. The reflection process was helpful for the teacher to trace where students had been in their learning and to make decisions about how to foster learning in the following lessons. The framework served useful and made it easier for the teacher to adjust her instructional practices to support student learning in the classroom.

Keywords: Instructional Activities and Practices, Teacher Education-In-service/Professional Development, Middle School Education

Students' learning is influenced by how teachers design and implement lessons and assess student learning to make instructional decisions. A learning trajectories approach to teaching involves thinking about the goals and tasks, anticipating what students might do, and adjusting instruction and future tasks based on what students do and understand (Clements & Sarama, 2009). Research (Constantino & De Lorenzo, 2001; Danielson & McGreal, 2000; Glickman, 2002; Lambert, 2003) confirms the benefit of reflective practice in order to provide professional growth for teachers. Our goal was to understand how daily reflections on teaching algebra influenced the instructional practices of a middle school teacher. In doing so, we developed a reflection framework that documented what happened on a daily basis during the math lessons and what the teacher wanted to occur with respect to anticipated student learning in subsequent lessons. The framework served as an intersection point between the researcher and teacher to influence classroom teaching through a reflective process.

Theoretical Framework

The theoretical framework for this study was based on Danielson's (2009) four modes of educator thinking (Figure 1).

Mode of Educator Thinking	**Thinking based on:**
Formulaic:	prepackaged knowledge from external source
Situational:	decisions made on information gathered during a specific time in a specific context
Deliberate:	seeking more information than the immediate context provides
Dialectical:	deliberate thinking to gain understanding of a situation and generate solutions

Figure 1. A summary of the modes of educator thinking (adapted from Danielson, 2009).

An educator that thinks formulaically is grounded in general policies and rules that are part of the school culture and centers on standardized instructional decisions regarding curriculum. Situational thinking involves dealing with in-the-moment occurrences during teaching such as student dispositions. In deliberate thinking, an educator seeks to understand why or why not a method of instruction is successful. If the educator engages in finding a solution to the scenario during the deliberate thinking stage, then he/she is thinking dialectically.

The framework created and tested in this study was purposely designed for teacher reflection that was both deliberate and dialectical. Dialectical reflection in this case involved a logical discussion between the teacher and researcher; sharing ideas and opinions. One definition of dialectical thinking is to be concerned with or acting through opposing forces. The Reflection Framework sought to identify and understand the opposing forces within the classroom context during lessons over time. The daily reflection questions were developed to lead the educator through the trajectory of formulaic to dialectic reflection (see Figure 2). The framework began with mathematical meaning or the objective of the lesson. The teacher was asked to think about misconceptions generated and what may have caused this within the context of the lesson. Incorporating student comments from the lesson elicited deliberations regarding what it might be like to be a learner in the context. Finally, focusing on next steps provided a dialectical space to generate solutions.

Mathematical Meaning that you wanted to happen	Errors/Misconceptions that occurred for the students	What situation or activity led to this misconception?	Student comments/reflections	What did you change and why? What are you going to do for the next lesson?

Figure 2. The Reflection Framework that was used daily by the teacher.

Context and Methods

The teacher selected for this research was chosen because she had recently graduated with her doctorate in mathematics education, had 22 years of elementary teaching experience, and was in her first year of teaching seventh grade mathematics. The teacher taught at a public middle school in the western United States with an enrollment of 600 students, most from lower-to-middle-class families, and the majority of students were Latino/a or native. The teacher taught three seventh-grade mathematics classes with about 35 students in each class, ranging from 12 to 13 years old. The researcher in this study holds a doctorate in mathematics education, is a former middle school mathematics teacher, and met the teacher during her doctoral studies.

This research project evolved from a discussion between the researcher and the teacher regarding the teacher’s transition from elementary to middle school. The teacher identified that she was struggling with taking time to reflect on her teaching, the students’ understanding, and how to adjust her lessons based on student learning. After this discussion, the researcher and teacher created the Reflection Framework (Figure 2) on a shared Google Doc. Using the framework, the teacher reflected on teaching an algebra unit to her seventh-grade classes everyday for two weeks. Once the teacher wrote her reflection for each part of the framework, the researcher made comments and suggestions about how to adjust the lessons and address student misconceptions. At the end of the two weeks, the researcher and teacher individually answered the following questions prompted by their observations of using the framework:

1. Is the framework useful in general and why?
2. Why is this framework suitable for middle grades?
3. Did the framework help the teacher to shift her instructional practices? If so, in what ways?

To explore how the teacher reflected on her thinking using the Reflection Framework and how she adjusted her teaching based on these reflections, we read and examined the teacher's reflections, the researcher's comments and suggestions, and the answers to the questions for constructs, themes, and patterns. We then coded the themes using a constant comparative method (Strauss, 1987). Following the analysis, we were able to recognize three main themes regarding the benefits of the Reflection Framework.

Results

A lens for whole class learning of content

The process of reflecting on lessons everyday using the Reflection Framework allowed the teacher to focus on the mathematics content that the students' were learning. The teacher commented:

> In 7th grade, I teach roughly 120 students math each day. As a new teacher to this grade, it has been difficult to get a sense of what each student needs. This framework allowed me to analyze the lesson overall for the 7th graders. In accounting for their misconceptions and their understandings, I was able to address the learning of the group as a whole. This is very different from the elementary model where you focus on 30 students all day long and are quickly able to see the whole child as a learner in many different ways.

The teacher also revealed that feedback from a colleague gave her a new and different perspective on why the students might not understand the mathematics. For example, Figure 3 shows the teacher's reflection on students' misconceptions and suggestions and comments from the researcher.

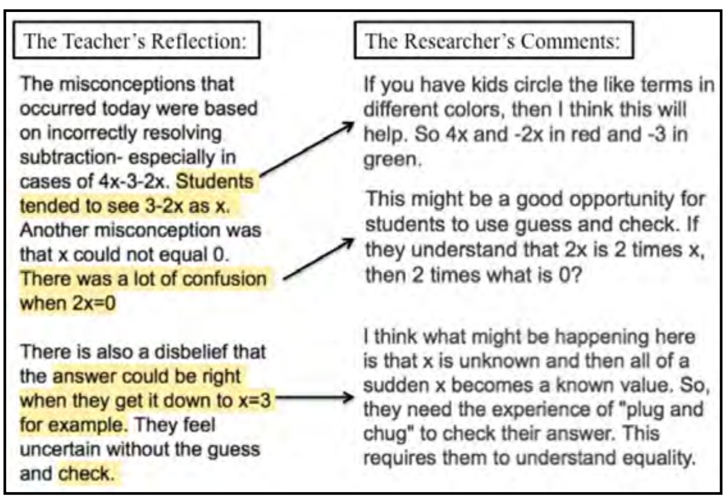

Figure 3. This is an example of the teacher's reflections on student learning and comments made by the researcher to offer suggestions on how the teacher could address these misconceptions.

Shifts in Instruction

The practice of reflecting using the framework made the teacher aware of what she needed to re-emphasize during the next class session. She wrote:

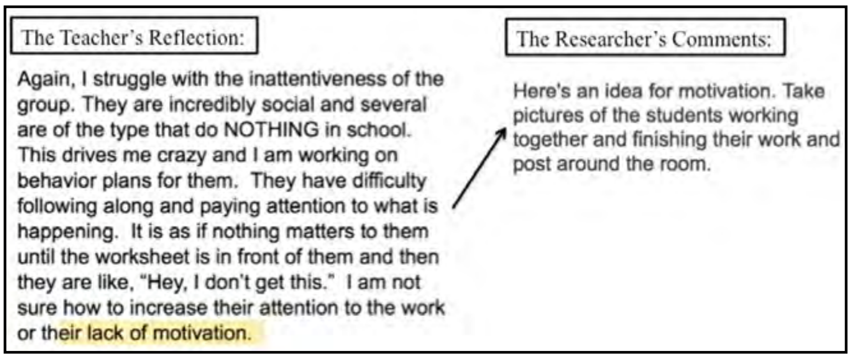
> In third period the algebra manipulatives were the most difficult for me to use. The students have poor self control and my initial perception was that this work was too easy. As I reflected on this each day, I realized that for most of this group, they did NOT understand what was happening.

> This shifted my approach as a teacher. Instead of expecting one assignment finished in one day, I allowed several days for completion continually providing those that were done with extensions.

By allowing extensions, several of the students took time to ask questions to help them make sense of the mathematics, rather than giving up. The teacher realized that she had to allow more time to scaffold her students' understanding.

Focus on Student Dispositions

As the teacher initially reflected using the framework, she focused on student dispositions in the class because she noted that their behaviors were inhibiting the whole class' learning of the mathematics (Figure 4).



The Teacher's Reflection:

Again, I struggle with the inattentiveness of the group. They are incredibly social and several are of the type that do NOTHING in school. This drives me crazy and I am working on behavior plans for them. They have difficulty following along and paying attention to what is happening. It is as if nothing matters to them until the worksheet is in front of them and then they are like, "Hey, I don't get this." I am not sure how to increase their attention to the work or their lack of motivation.

The Researcher's Comments:

Here's an idea for motivation. Take pictures of the students working together and finishing their work and post around the room.

Figure 4. This is an example of the teacher's frustrations with student dispositions and a suggestion made by the researcher on how to motivate the students.

The teacher recognized student dispositions and changed the lesson to make it less boring or more challenging to help her students focus. By taking student dispositions into account over two weeks, the teacher could see as a whole what had happened during the unit in terms of student learning and motivation.

Discussion

In our research, the Reflection Framework was used as a tool for keeping track of student learning and being able to identify the relationship between student learning and instruction to make more targeted teaching decisions. For the teacher and researcher, the framework served as the intersection for making sense of what happened in the classroom during a lesson and how to reflect on the teaching and learning that occurred. The framework should be explored further with inexperienced and experienced teachers to investigate if it supports them to make decisions when practicing a learning trajectories approach to teaching (Clements & Sarama, 2009) and changes their instructional practices to target students' learning needs.

TRACING TEACHER RESEARCHERS' TALK ABOUT AND USE OF POSITIONING

Beth Herbel-Eisenmann
Michigan State University
bhe@msu.edu

David Wagner
University of New Brunswick
dwagner@unb.ca

In this paper, we examine what teacher-researchers talk about and do as they engage with the idea of positioning in the context of study group discussions and cycles of action research. Using open coding, we analyze study group discussions and other artifacts across a five-year time span and examine how their talk and action changes over time. Broadly, we found that the teacher researchers were, at first surprised and unsure about how to positively influence positioning in their classrooms, then moved to a focus on the positioning of mathematics. As they adopted new curriculum materials, goals, and classroom norms, their talk and action shifted to focus on students' perspectives, voice, and issues of bias in their interactions with students. Such a longitudinal study can provide insights into how ideas like positioning might be used by teachers to work toward more equitable practices in mathematics classrooms.

Keywords: Classroom Discourse, Teacher Education-Inservice/Professional Development

We take it as central that the theoretical constructs we use matter most when we use them with teachers to see what is helpful to improving their practice toward their own ends of supporting student learning. In this way, we align ourselves with the views of crossroads as being an "intersection point" and see our collaborations with teachers as a "place of community" within which we (as mathematics education researchers and teacher educators) must learn. Here we examine the discussions and action research of a group of mathematics teachers the first author has collaborated with for five years to understand how the teacher researchers both talk about and use the idea of "positioning." Positioning refers to the "ways in which people use action and speech to arrange social structures" (Wagner & Herbel-Eisenmann, 2009, p. 2). In mathematics classrooms, words and actions carry implicit and explicit messages about who students are as learners, what they are capable of, and what it means to know/do mathematics. It has been shown that when particular positionings are repeated over and over, they can impact students' identity (Anderson, 2009) and disposition (Gresalfi, 2009) development. The results influence students' perceptions of themselves and others and are important to pay attention to, particularly in collaborative work with teachers. Thus, our goal is to answer the following question: When mathematics teachers talk about positioning across a five-year collaboration involving action research, what do they focus on and how do they report using it to improve their practice and student learning?

Positioning and Its Operationalization for Professional Development

Positioning theory is the "study of local moral orders" based on ongoing shifting patterns of "mutual and contestable rights and obligations of speaking and acting" (Harré & van Langenhove, 1999, p. 1). Important to issues of equity is that positioning theory does not assume that everyone in an interaction has equal access to rights and duties to perform any action (Harré, 2012). Although the theory focuses on local interactions (rather than the transcendental), it also shows the centrality of storylines and the communication acts that are employed in any interaction. Storylines are the ongoing repertoires that are already shared culturally or that can be invented as participants interact. We have described communication acts as the socially determined meaning taken from a communication action, which can be words, gestures, and physical positions and stances (Herbel-Eisenmann, et al., 2015). All three of these constructs--positionings, storylines, and communication acts-- mutually shape and constrain each other during an interaction. This theory has been increasingly used in the past decade of mathematics education research, with most of the articles appearing since 2009 (Herbel-Eisenmann, Meaney, Bishop Pierson, & Heyd-Metzuyanim, 2017). Very little of this work, however, actually involves collaborations with mathematics teachers to see what from the theory might be interesting and useful enough for them to change their practices. Our previous work that investigated theoretical constructs within the context of collaborations with teachers has illuminated how teachers make sense of the ideas and find them useful in their work but also has allowed us to reconceptualize the constructs in ways useful to practice (see Herbel-Eisenmann & Wagner, 2010; Wagner & Herbel-Eisenmann, 2014).

In the context of the collaborative work, we have used the *Mathematics Discourse in Secondary Classrooms* (Herbel-Eisenmann, et al., 2017) professional development (PD) materials to introduce the idea of positioning (and other constructs, which we do not focus on here) as a theoretical lens that can be used to interpret particular teacher discourse moves. In these PD materials, there are a series of "touchstone" readings that are used to formally introduce key concepts and tools of classroom discourse, one of which focuses on positioning. This touchstone document includes a focus on the positioning of people and the positioning of mathematics, which we describe very briefly here. In the positioning of people, teachers' attention is drawn to: (a) interactions between/among students and issues of status (Cohen, 1994), smartness (Featherstone, et al., 2011), and voice are highlighted and (b) interactions between the teacher and students, within which aspects of authority, agency, control, and competence are articulated. The positioning of mathematics highlights how the various activities, tasks, and words we use in relationship to the doing of mathematics shapes what students come to think it means to know/do mathematics. (We recognize that the positioning of mathematics is really about calling into question the storyline of typical school mathematics and not really about positioning. We decided to identify this as a type of positioning so that we did not have to bring in the additional idea of storyline.) Prior to reading the touchstone document, the teachers talked about ideas related to positioning by reflecting on videos, transcripts, and other practice-based artifacts. After they read the touchstone, the idea of positioning becomes a conceptual lens for considering how a range of specific discourse moves might be influencing students' opportunities to learn mathematics.

Context and Methods

The teacher research collaboration currently involves eight mathematics teachers who are working in a culturally, linguistically, and racially diverse school district and the first author of this paper, who works at a university near the district. The main school in which the majority of the teachers teach has about 800 students, across grades 6-8. Six of the eight teachers have been involved in the work for 4-5 years; two just joined the group when they were hired last year to teach 6th grade. Although the teachers have all taught at the middle school at some point in time, currently most of the teachers teach grades 6-8 mathematics and algebra, one teaches high school geometry, and one teaches multiple sections of 4th grade mathematics.

Our work is grounded in critical, sociocultural, and sociolinguistic perspectives, and as such, we see learning as related to how one participates in the discourse practices of a community. Our primary data source includes audio recordings of discussions from the study group meetings, which took place twice a month across the 5 years of the collaboration (approximately 16 sessions each year, one 4-hour meeting during the school day and another 1.5 hour meeting after school). We also examined the artifacts and information the teachers provided about their action research projects throughout the various cycles over the past four years. This included, for example, powerpoint presentations the teacher researchers did at a mathematics education conference, emails and journals they wrote about their action research projects, and a book chapter they co-authored with the first author of this paper that focused on how they use positioning in their teaching and action research.

We began by creating timelines of the work using agendas and field notes from the study group meetings. This information helped us reduce the amount of data by identifying where positioning-related discussions may have taken place. After narrowing the project discussion times, we used open coding (Esterberg, 2002) to code the nature of the focus of the discussions (e.g., whether they focused more on issues of authority or student status) as well as the various types of action the teachers reported taking related to positioning. We started with more recent meetings and worked backwards to see how the ideas appeared in previous years.

Preliminary Findings

Because we were still in the stage of open coding when this report was due, we share here broader scale findings about the changes in foci over time. We describe what they focused on about positioning but also some of the actions they described taking to focus on influencing student positioning. When we do our presentation, we will have more specific and finer grain sized findings to report. Generally, the year 1 discussions of positioning indicate that the teachers had not considered positioning in the ways described in the touchstone documents. They reported being aware of issues of social status related to things like popularity, but that they had not thought as much about this in relationship to *mathematics* learning. Their talk centered on their uncertainty about actions to take to counter positionings that they thought were not supporting student learning.

As they moved into their first cycles of action research in year 2, the talk about positioning focused on the positioning of mathematics. The teachers grounded these discussions about what kinds of tasks and activities they offered to students as well as what they expected students to do (e.g., how they would engage but also expectations for producing high quality explanations and justifications). Their action focused primarily on designing and finding high cognitive demand tasks to use with students. Toward the end of year 2, the talk about the positioning of mathematics shifted toward a slightly different kind of action: they identified the kinds of norms they could put in place, articulated a common set of goals they would work on, and planned for piloting new curriculum materials that would offer richer learning experiences for students (see Busby, et al. (2017) for more information). In year 3, all teachers used the same set of norms and goals and the teachers in grades 6 and 7 started to use the new curriculum materials. The shift in year 3, then, seemed to be away from the positioning of mathematics and more about issues of teacher authority (and the struggles associated with giving up control) and student agency (how they could get students to become more active participants).

By year 4 (2016-17), all of the teacher-researchers began to think about distributing authority more and focused on trying to get students to talk most of the time during whole group discussion. They continued to struggle, however, with the giving up of control and with some of the ways students seemed uncomfortable with being more active learners. Students' being uncomfortable with participating in more active ways, in fact, seemed to be especially acute in the 6^{th} grade where students had come from much more traditionally structured mathematics classes in the elementary schools. Three of the teacher-researchers began to develop instruments they could use to gather information from students about their experience, which included Likert scale items about how students felt about various learning activities and with the mathematics. The items also included information about students' developing agency for their mathematical thinking. Two teacher-researchers also began to give weekly reflections that required students to write about something they had learned from other students in the class discussions, which helped the teacher-researchers understand status in their classrooms. Although year 5 is still underway, the teacher-researchers continue to create structures to support students to have more space and voice in the classroom. One teacher-researcher has students in front of the room and co-facilitating parts of some of the activities. Three others have decided to focus centrally on how bias might be impacting their expectations of various groups of students along gender and racial lines. Thus, some of the shifts in attention to positioning in immediate classroom interactions have raised the prominence of student perspectives as well as how broader systems of privilege and oppression might be impacting the ways teacher-researchers interact with and support student learning.

Acknowledgments

The research reported in this article was supported with funding from the National Science Foundation ([NSF], Award #0918117). Any opinions, findings, and conclusions or recommendations expressed here are those of the authors and do not necessarily reflect the views of the NSF. We thank the teacher-researchers for engaging in this work with us.

WORKING TOGETHER: USING CONSULTATIONS TO IMPROVE MATHEMATICS TEACHING FOR STUDENTS WITH SPECIAL EDUCATION NEEDS

Samuel L. Eskelson
University of Northern Iowa
samuel.eskelson@uni.edu

Sarah van Ingen
University of South Florida
vaningen@usf.edu

In this study, we investigate the impact of mathematics elementary school teachers' and special education specialists' participation in professional development regarding how to conduct mathematics-specific consultations to improve mathematics learning opportunities for students with special education needs (SEN). We found that engaging in this professional development increased the participants' confidence in their abilities to (a) engage in future mathematics-specific consultations, (b) engage in consultations in other content areas, and (c) differentiate mathematics instruction for students with SEN.

Keywords: Elementary School Education, Instructional Activities and Practices, Teacher Education-Inservice/Professional Development

Study Purpose and Research Questions

Concern for equitable learning opportunities for students with special education needs (SEN) has resulted in strong commitments for inclusive education from organizations worldwide (e.g., Australian Disability Discrimination Act, 1992; Individuals with Disability Education Act (IDEA), 2004; UNESCO, 2009). Explicating its vision of mathematics teaching and learning, the National Council of Teachers of Mathematics lists *Access and Equity* as the first essential element of excellence and states, "An excellent mathematics program requires that all students have access to a high-quality mathematics curriculum, effective teaching and learning, high expectations, and the support and resources need to maximize their learning potential." (2014, p. 59). Unfortunately, access to equitable mathematical learning opportunities is not available to many students with SEN. This lack of access, in turn, impacts their mathematical learning and performance as evidenced in their low performance scores compared to their peers without SEN on national representative assessments (e.g., NCES, 2013).

The need to provide access and equitable learning opportunities for students with SEN requires general education teachers to meet the learning needs of these students. However, it is unrealistic to expect teachers, who must become experts in content areas, to also know how to meet all the widely varying needs of students with one or more special education need. In order to help teachers better manage the demands of meeting needs of each of their students, we conducted a pilot study involving six elementary teachers of mathematics, two special education specialists, and an instructional coach at Hawthorn Elementary School (all names of participants and schools are pseudonyms). The teachers, specialists, and coach were asked to engage in mathematics-specific consultations (described below). The purpose of our study was to investigate the following research question: How does participation in professional development on mathematics-specific consultations impact elementary school teachers' and specialists' perceptions of their ability to meet the mathematics learning needs of students with SEN?

Theoretical Framework

Collaborations between mathematics teachers and special education specialists are one attempt to assist teachers in meeting the mathematics needs of students with SEN. These collaborations can be powerful as they bring together the specialized mathematical knowledge for teaching of the mathematics teacher with the expert knowledge of teaching students with SEN of the special education specialist (van Ingen, Eskelson, & Allsopp, 2016). Consultations between general education teachers and special education specialists are one form of teacher collaboration that can be used to support teachers in providing learning opportunities for students with SEN. Teacher consultations can take varying forms and can follow different models (e.g., Richards, Hunley, Weaver, & Landers, 2003; Truscott et al., 2012; Wesley & Buysse, 2004). While these models differ, they do share some common elements. Previously, we created a synthesized model of the common consultation elements (van Ingen, Eskelson, & Allsopp, 2016); this served as the consultation model for this study. This model consists of: (a) initiate rapport building, (b) negotiate consultation relationship, (c) identify the problem, (d) develop recommendations, (e) finalize recommendations and solidify plan, (f) implement the plan, (g) evaluate the plan, (h) learn from results, (i) check back, and (j) re-engage.

Methods

The participants choose to participate in this study in conjunction with their voluntary participation in professional development which we provided at the school. Our professional development team, composed of two mathematics teacher educators and one special education teacher educator, met with the teachers, special education specialists, and mathematics coach to provide professional development regarding how to conduct mathematics-specific consultations about the learning needs of students who struggle with mathematics. The professional development consisted of an introductory session, two weeks of implementation (practice) with authentic consultations, a second session, and then additional weeks of implementation.

During the first session, we introduced the concept of mathematics-specific consultations and modeled how inservice elementary teachers of mathematics and their special education counterparts might engage in consultations. We provided the participants with templates that prompted them to ask the types of questions and/or provide the types of responses that would allow for maximum sharing of their respective specialized knowledge bases. The participants were given time to work in pairs or trios to plan when and how they would engage in the consultations. During this first session, participants also completed a questionnaire in which they identified their confidence level in their own ability to engage in consultations related to mathematics instruction and consultations related to reading instruction. We asked about their experiences and perceptions related to reading consultations as multiple teachers had experience with these previously and we wanted to use these as a comparison to the mathematics consultations. The participants also described any prior experiences they had engaging in consultations (regardless of content area), as well as what they felt were key aspects of successful mathematics consultations. At the end of the first session, participants were asked to engage in authentic consultations during the following two weeks.

During the second professional development session, we asked the participants to talk about their experiences engaging in the mathematics consultations. We also discussed next steps they could take to continue to work together to meet the needs of the students with SEN they had identified and who were the focus of their consultations. During this session, the participants completed a second questionnaire similar to the first asking about their confidence in their abilities to engage in consultations related to reading and mathematics instruction. It also asked them to explain the extent to which this experience did or did not develop their thinking/skills related to teaching mathematics to students with special learning needs and consulting with a special education specialist or elementary teacher of mathematics. They were again asked to identify the key aspects of engaging in a consultation.

Data Analysis

Participants completed questionnaires related to their confidence in their abilities to engage in consultations using a Likert scale with responses of 1 = Strongly Disagree to 5 = Strongly Agree. Although there were not sufficient participants to run statistical analyses on these data, we did compare the means of the data from the first and second questionnaires to identify possible patterns. The remaining questions were open-ended. We looked for similarities and themes across participants and between the two surveys in these responses.

Results

As seen in Figure 1, the participants strongly agreed on both the pre- and post-professional development questionnaires that consultations between mathematics teachers and special education specialists play an important role in meeting the mathematics needs of students with SEN. Their confidence in their ability to engage in mathematics-specific consultations and in differentiating instruction to meet the mathematics needs of students with SEN increased after participating in the professional development. Interestingly, although the professional development focused solely on mathematics-specific consultations, participants' confidence in their ability to engage in consultations related to reading instruction also increased.

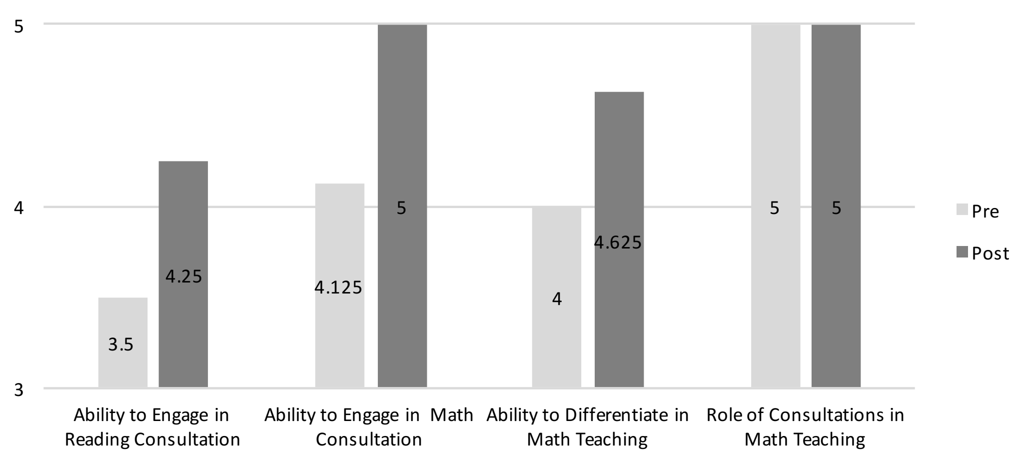

Figure 1. Mean scores of pre- and post-professional development self-reported data on perception of ability to meet the needs of students with SEN.

During the second professional development session, the participants reported on the impact of their participation in the mathematics consultations. They spoke positively about the experience and identified several ways in which they would use the same consultation process in the future and how the process helped them to meet the mathematics needs of students with SEN in their classes (see Table 1).

Table 1. Teachers Self-Report on the Impact of Participation in Mathematics Consultations

Effects on Ability to Engage in Productive Mathematics Consultations	Effects on Ability to Meet Math Learning Needs of Student with SEN
• A better understanding of questions to ask • A clear plan of how to prepare for and engage in consultation • Awareness of resources available • Awareness of the need to consider how a	• Greater understanding of how to support the mathematical practices when working with students with SEN • Thinking across grade levels and math content areas

student's overall learning issues may affect math learning in particular • Gained a deeper understanding of the specific needs of a student and how to set attainable goals	• Time to think about the specific needs of a student with SEN • An opportunity to create a specific action plan

Discussion and Significance

Meeting the mathematical learning needs of students with SEN can be extremely difficult for teachers of mathematics, yet they are under increasing pressure to do so. This study serves as a first step in exploring the impact of helping mathematics teachers to engage in mathematics-specific consultations with special education specialists. We found that that engaging in professional development that provides teachers and specialists guidance on how to participate in such consultations as well as the opportunity to do so was beneficial for both the mathematics teachers and special education specialists. As the teachers' and specialists' confidence in their own abilities to engage in these consultations and in providing differentiated instruction increase, we suggest that they will be more likely to have such discussions with one another and to focus on the mathematics needs of all their students, including those with SEN.

A JOURNEY IN TEACHING MATH FOR SOCIAL JUSTICE WITH YOUNG CHILDREN

Jennifer Ward
University of South Florida
Ward.Jennifer.K@gmail.com

As a developing early childhood mathematics teacher educator, the area of Teaching Math for Social Justice (TMfSJ) was relatively new to me. Given the diverse nature of children and families at our school and within the community, TMfSJ offered a space for children to become immersed in learning centered around both mathematics and social justice goals (Gutstein, 2006). With this goal, I engaged in an autoethnography which explored the question of: *What are the experiences of an early childhood educator working towards teaching mathematics for social justice?*

Drawing from critical praxis and sociopolitical norms for mathematics (Gutiérrez, 2013), I used an autoethnographic approach (Ellis, 2004) to challenge the idea that young children may not engage in this work. To do so, I taught four and five-year-old during a summer enrichment experience. As the school engages in Project Approach as a method of inquiry, lessons built off of topics the children were currently exploring, or demonstrated interest in the classroom through observation of informal conversations during elongated play. These included topics such as: access to public play spaces in our community, child hunger, and financial inequities. Data collected in a reflective journal, videotaped lesson implementation and children's work samples were examined to construct a narrative account of my experience. During narrative construction entries and videos were closely reexamined as notes were taken to weave into my narrative) and provide points for departure as I question my experience In this way, the narrative constructed represents a truthful and authentic account of the experience TMfSJ accounting for elements of story and attention to criteria for quality.

Based upon my experience, I offer points to consider when engaging in this work. During my lessons, issues of power and control emerged. These centered around management considerations, as I was focused initially on the children "behaving" and using tools appropriately, and questioning who had control over the lessons and thinking within the lesson. Having a focus on myself as the person constructing the lessons and sharing the knowledge, I fell into using deficit discourse to discuss the children and teachers at the school. While this occurrence was humbling, it led to my reexamination of the Funds of Knowledge children were bringing to the lesson as I reframed focus to highlight what children *could do*.

Furthermore, within the experience I began to reexamine my own beliefs about what young children were capable of mathematically. Children were successful in not only discussing social justice issues, but demonstrating connections between the social justice issues and mathematics topics often taught at upper elementary levels. These begins to challenge pre-existing ideas that mathematical learning at the early childhood level be solely organized by developmental age progression.

COLLABORATING WITH TEACHERS: A DESIGN EXPERIMENT TO DEVELOP AMBITIOUS MATHEMATICS INSTRUCTION

Dawn M. Woods
Southern Methodist University
dwoods@smu.edu

Keywords: Teacher Education/In-Service Professional Development, Classroom Discourse

Research (e.g., Fennema et al., 1993, Smith et al., 2001) has found that teachers who can observe student performance and respond by adjusting both content and methods empower diverse learners to succeed in doing mathematics. However, learning these kinds of ambitious instructional practices are challenging endeavors, but are manageable when collaboratively worked on with common materials (Lampert et al., 2011). Therefore, in this study, five third grade teachers and their students participated in a 20-week design experiment focusing on how to implement number talk instructional activities within their classrooms. The purpose of this design experiment was to implement a theory about how the pedagogies of enactment and investigation (e.g., McDonald et al., 2013) provide rich learning opportunities that would move teachers into roles where they prepared students to talk about mathematical ideas. To this end, this study aims to answer the following research question: how does the cycle of enactment and investigation support in-service teachers in learning about number talk instructional activities?

In order to answer the research question, video recordings of the teacher workgroup and enactments of number talks within teachers' classrooms were collected and analyzed. Transcripts of the teacher workgroups were coded for both the pedagogies of enactment and investigation and then for episodes of pedagogical reasoning (Horn, 2010) to gain understanding about how the teacher workgroup provided opportunities for teachers to make sense of both mathematics instruction and student learning. Additionally, classroom number talks were coded for levels of math talk learning communities (Hufferd-Ackels et al., 2004) in order to provide insight into how professional learning enables teachers to foster discourse within their classrooms.

Findings suggest that the pedagogies of enactment and investigation provide teachers with opportunities to interact with colleagues facilitating rich learning about how to promote mathematical talk with students. Moreover, analysis of classroom enactments suggest that the teachers' role in number talks shift from being the source of mathematical ideas to a role of facilitator, providing increasing opportunities for students to talk meaningfully about mathematics.

Teaching is an affective practice, demonstrated by teachers' interactions with students, relationships with parents, and the shared communities of practice established with other educators (Hargreaves, 1998). This atmosphere affects teachers' feelings of confidence, which we define as "part of an individual teacher's ways of learning through experiencing, doing, being, and belonging" (Graven, 2004, p. 179). The crossroads between the affective and cognitive aspects of teaching are an under-explored and therefore invisible phenomenon that requires further research. Our study makes visible teachers' emotions of confidence and insecurity and explores: what are mathematics teachers' lived-experiences of confidence and insecurity in classroom teaching?

To explore the affective component of the mathematics teaching profession, we conducted phenomenological interviews (Moustakas, 1984) with seven practicing mathematics teachers, ranging from elementary through secondary level. This phenomenological study allowed for an in-depth exploration of the feelings of confidence or insecurity teachers encountered during mathematics instruction. Our interview sessions utilized Van Manen's (2015) approach, where we focused on teachers' innermost feelings and viewpoints regarding specific phenomenon.

Our teachers expressed feelings of confidence through a range of experiences: (i) student characteristics and interactions (e.g., knowledge of student backgrounds, students' abilities to help one another), (ii) knowledge and experience gained through teaching (e.g., curriculum familiarity, ability to engage students), and (iii) fostering mathematical connections with the real world and previous and future schoolwork. These teachers expressed feelings of insecurity along similar content lines including: (i) student characteristics and interactions (e.g., working with high-ability or poorly motivated students), (ii) interactions with authority (e.g., administration, policy), and (iii) negotiations of knowledge (e.g., teaching new subjects, lack of autonomy).

This study contributes to the body of research on teacher emotion in mathematics education, as well as implications for teacher professional development. It suggests an intersection point—a place where teachers' confidence and insecurity collide with their knowledge, experience, and authority—demonstrating the value of studying the affective realm of teachers' practice.

Addressing problems of practice and implementation at scale is an issue that continues to challenge mathematics education researchers and practitioners (Cobb & Jackson, 2011). As part of a statewide research-practice partnership, we are currently using a design-based implementation research (Fishman et al., 2013) approach to organize the collaborative design of a multifaceted intervention for new state mathematics standards and the promotion of more equitable classroom learning opportunities for students and teachers. These efforts include common spaces and tools for teachers, leaders, and parents including: a closed webspace for teacher engagement, face to face professional development sessions, leader support tools, and parent outreach materials. The focus of this presentation in on the closed webspace for teachers seeking to promote the use of research on teaching and learning as teachers implement new state mathematics standards.

A review of the literature identified a number of characteristics of effective online learning environments that we drew upon to build our design principles for the webspace. Most importantly, opportunities for collaboration play a central role in both building community and the overall utility of online environments (Duncan-Howell, 2009). Therefore, a key design principle for the development of a common virtual space for teachers was the opportunity for teachers to collaborate with their colleagues around the new mathematics standards, their implications for mathematics teaching, and research on teaching and learning. In doing so, we conjecture that this space will foster collaboration and provide teachers with an asynchronous setting for learning and reflection at their own pace and tailored to their own needs (Clay, Silverman, & Fisher, 2012).

In this presentation, we will present aspects of our iterative design for creating a virtual space for teacher learning. We will describe our design conjectures for learning within this space and how they changed through findings from teachers' participation and feedback throughout the design process. We will outline aspects of the space and how we seek to create opportunities for teacher learning related to research on teaching and student learning. Finally, we will present preliminary results of research on teacher learning within the virtual space.

The National Council of Teachers of Mathematics' (NCTM) *Principles to Actions: Ensuring Mathematical Success for All* [(*PtA*, NCTM, 2014)] acknowledges the critical role of mathematics coaches in enhancing teacher capacity and positively influencing teacher beliefs. While *PtA* calls on mathematics coaches to "take action," coaches need guidance to meet the challenges of enacting the eight research-based teaching practices in their unique school contexts. To lower potential barriers to implementation, we designed a Decision-Making Protocol for Mathematics Coaching (DMPMC) which recognizes ranges of coaching contexts, focuses on mathematics content, and empowers school communities to surmount obstacles as identified in *PtA*.

The DMPMC provides a reflective four-phase cycle of coaching actions to support classroom teachers in building more opportunities for student reasoning and sense-making. Guiding questions allow coaches to purposefully bridge content considerations, research-based teaching practices and high leverage coaching practices (Gibbons & Cobb, 2012). After evaluating their contexts and defining a content focus, coaches establish goals, select appropriate coaching and teaching practices, and engage in collaborative debriefs of classroom enactments to inform further actions.

In semi-structured interviews with two novice coaches and one veteran coach, we explored initial reactions and subsequent descriptions of enacting the DMPMC with selected teachers. Emergent themes were the potential of the DMPMC to formally structure interactions with teachers and to informally support in-the-moment decision making. The guiding questions of the protocol elicited the purposeful selection of coaching practices aligned with teaching practices prior to engaging in coaching situations. For one coach, the four DMPMC phases also became working knowledge that she drew upon during informal conversations with teachers.

While all participants situated their contexts within the DMPMC, the novice coaches frequently sought affirmation of their actions from the researchers. Participants shared the advancement of their coaching practice through consistent interplay between coaching and teaching practices, which enabled a simultaneous focus on relationship building and making instructional shifts. Future research includes focus groups for coaches to share their perspectives and experiences with the DMPMC. We seek to further our contextual understanding of how this protocol can build coaching effectiveness through structured consideration of content, practices, and relationship building in tandem.

GRAPHING RULES OR CONVENTIONS? TEACHERS UNDERSTANDINGS

Teo Paoletti	Jason Silverman	Ceire Monahan
Montclair State University	Drexel University	Montclair State University
paolettit@montclair.edu	js657@drexel.edu	monahanc4@montclair.edu

Researchers have found that students and teachers often maintain insufficient meanings for function and their graphs (e.g., Montiel, Vidakovic, & Kabael, 2008; Moore, Silverman, Paoletti, & LaForest, 2014; Oehrtman, Carlson, & Thompson, 2008). Several of these researchers have noted that students maintain function meanings that are restricted to particular representations (e.g., the Cartesian coordinate system with the independent quantity represented by x on the horizontal axis). For example, Montiel et al. (2008) identified students applying the vertical line test, a common procedure in U.S. curricula, to determine if a graph represented in the polar coordinate system represented a function. As a second example, Moore et al. (2014) described pre-service teachers' responses to tasks in which hypothetical students provided mathematically correct work that did not follow conventions common to school mathematics (e.g., graphing the function $y = 3x$ with x on the vertical axis and y on the horizontal axis). Many of the pre-service teachers did not recognize that the hypothetical student's solution was correct, or identified that although the hypothetical student accurately represented the relationship defined by $y = 3x$, the student's solution was mathematically incorrect because he or she did not maintain conventions.

Extending Moore et al.'s (2014) work with pre-service teachers, we provided in-service teachers tasks similar to those by Moore and colleagues in pre and post course online surveys. The participants were enrolled in a fully online graduate mathematics course designed specifically for in-service teachers. The participants were geographically distributed across the U.S. and all had one to five years teaching experience. We coded their responses using a semi-open coding scheme, with the students' activities described by Moore et al. (2014) serving as the basis for an initial coding scheme. We adapted this initial scheme to capture the teachers' responses. We did this through an iterative process of analyzing teachers' responses, discussing commonalities across the responses, and adapting or creating new codes to satisfactorily capture the responses. In this poster, we present our coding of teachers' responses and compare our results with those reported by Moore and colleagues. Additionally, we compare differences in teachers' responses before and after a course designed to support their reasoning about relationships between quantities. Finally, we highlight differences between our results and those of Moore and colleagues that may stem from the methodological difference of collecting data from online surveys versus in-person interviews.

Professional development (PD) programs aim to change teachers' current practices and positively impact student outcomes. In this poster, we present a preliminary model investigating the effect of teachers' participation in sustained PD on student achievement.

Background and Data

This poster reports on a study looking at the efficacy of a 3-year PD program for 3rd-5th grade teachers in a mid-sized, urban school district. The PD (Foreman, 2010) is focused on a set of core mathematical habits for students and teachers that promote high-level reasoning and productive discourse (e.g. Stein, Engle, Smith, & Hughes, 2008) in mathematics classrooms. Student achievement was measured by mathematics scores on standardized assessments at the end of each grade. Over four years, 239 teachers spanning 34 schools participated in the study for a total of 10,076 students and 14,750 student assessment scores. Each school was either part of a sustained year long PD (Studio), or part of the summer sessions only (BP-only).

Model

To investigate the relationship between student achievement and teachers' participation in the PD, we developed a hierarchical linear model (HLM) with three levels to address students, teachers, and schools. Since over the years, students are not nested within teachers, we used a cross-classified random effects model with levels: (1) time series data of student scores (normalized), (2) row-factor: students; column-factor: teachers, and (3) schools as clusters.

Results and Discussion

Our preliminary HLM model suggests that our PD program had a positive impact on student outcomes as measured by end of the year standardized assessments. We found that by the end of the second year of being in a studio school, students scored .08 standard deviations higher ($p = 0.019$) than their counterparts. This result is reflecting a positive impact of a multi-year participation to the PD. This impact is robust remaining significant and positive when other variables such as free and reduced lunch at school and student level, student ethnicity, teachers' MQI scores, and hours of participation in the PD are added to the model.

MATHEMATICAL MODELING A CROSSROAD PROVIDING ACCESS FOR ELLS TO HIGHER LEVEL MATHEMATICS

Rejoice Mudzimiri
University of Washington Bothell
rejoicem@uw.edu

Robin Angotti
University of Washington Bothell
riderr@uw.edu

Keywords: Modeling, Mathematical Knowledge for Teaching, Equity and Diversity

Mathematical modeling is especially well poised to be successful in closing the opportunity gap for ELL students since it offers the opportunity to tackle "big, messy, realistic problems, helps students connect mathematics to life and empowers them to use their mathematics to solve relevant problems" (GAIMME Report, 2016, p. 23). High concentrations of ELL students, when immersed in classrooms where they are engaged in small group work involving authentic problem solving, showed significant gains on mathematics achievement, not only in computation, but also problem solving and language acquisition, two important components of mathematical modeling. However, many teachers have no formal preparation in teaching mathematical modeling.

The Study

The research featured in this poster is from a small, funded professional development project for teachers in rural western United States in which science and mathematics teachers were engaged in utilizing and creating mathematical modeling problems and enacting them in all classes through highly interactive classroom environments. It consisted of a two-part summer institute augmented with three additional workshops throughout the year. The emphasis of this professional development was, in part, on fostering language and content development of ELLs through mathematical modeling and also cultural responsive pedagogy as means of closing the opportunity gap for ELLs.

This study sought to address two research questions: (1) *How does mathematics and science teachers' conception of teaching mathematical modeling in ways that foster content learning and language development for ELLs emerge; and (2) what challenges do mathematics and science teachers face, as they experience year-long professional development focused on mathematical modeling.* This study used a mixed-methods design with focus group interviews, classroom observations, surveys, and lesson plans. Data collection is currently ongoing but preliminary data suggests that although students seem to benefit from well-designed mathematical modeling tasks, teachers' beliefs about pedagogical practices are very hard to change. Also, teaching mathematical modeling in ways that foster language development for ELLs can be challenging to implement due to time constraints since teachers are on a prescribed curriculum that they have to follow. This is significant because as we connect research to practice consideration should be made in terms of revising the curriculum to allow opportunities for teachers to implement pedagogical practices such as mathematical modeling, that help their diverse students access higher level mathematics.

EXPERIENCED AND NOVICE GRADUATE STUDENTS NAVIGATING MATHEMATICS INSTRUCTION TOGETHER

Kimberly Cervello Rogers
Bowling Green State University
kcroger@bgsu.edu

Sean P. Yee
University of South Carolina
yee@mail.sc.edu

Mathematics graduate student instructors (GSIs) teach hundreds of thousands of undergraduate mathematics students each semester, yet typically lack guidance and support to teach undergraduate students effectively (Rogers & Steele, 2016; Speer & Murphy, 2009). GSIs' initial teaching experiences represent a crossroad between how they teach in the short term in graduate school and in the long term as potential future faculty members (Lortie, 1975). To address this concern, we developed and implemented a peer-mentoring program at two universities in the US whereby experienced GSIs mentor first- and second-year GSIs (novices).

After a semester of being trained in ways to effectively serve as a peer-mentor, nine experienced GSIs mentored three or four novices on teaching similar content. Mentors facilitated bi-weekly small group meetings with novices as part of an NSF-funded peer-mentorship grant (IUSE #1544342 & 1544346). During these discursive meetings, mentors provided context-specific support, resources, and guidance to novices using practices that augment productive discourse (Smith & Stein, 2011). Within small groups, novices determined specific teaching and learning topics they wanted to discuss. Topics also included concerns mentors and novices raised later in the semester, or adapted from ideas other small groups discussed. We examined: *What topics from small-group peer-mentoring meetings did novices value?*

To answer our research question, we applied a social constructivist lens within each small group to identify how the small group topics were valued. Participants included 30 novices and nine mentors from two universities. At the end of one mentoring semester, novices rated how (a) valuable they found each topic discussed during their small group meetings and (b) interested they would have been in discussing topics from other small groups. Discussion topics were objective (e.g., Grading Practice and Determining Assessment Questions) and subjective (e.g., Work-Life Balance and Qualities of a Good Teacher). We first qualitatively coded data as either within a group or from other groups. We then quantitatively analyzed each novice's ratings of their own small-group meetings. From this analysis we identified topics that novice GSIs value and topics that their peer-mentors may struggle to facilitate well. Topics valued by novices that were facilitated well by mentors included (a) Managing Time During Class, (b) Presenting Mock Lessons, and (c) Incorporating Formative Assessments. Topics valued by novices that were not facilitated well by mentors included (a) Writing a "Good" Exam, (b) Dealing with Overbearing Students, and (c) Incentivizing Group Work. Moreover, these results offer insight and synergy between educating GSIs and improving undergraduate mathematics teacher pedagogy.

OPPORTUNITIES FOR ACTIVE LEARNING IN A MOOC DESIGNED FOR EFFECTIVE TEACHERS PROFESSIONAL DEVELOPMENT

Fernanda Bonafini
The Pennsylvania State University
fcb5100@psu.edu

Keywords: Teacher Education-Inservice/Professional Development, Technology

Over the last 17 years researchers have been investigating the features of effective professional development (PD) that affect teacher's knowledge and skills, and lead them to changes in classroom practice (e.g., Garet et al., 2001). Based on results from face-to-face PD, Garet and colleagues (2001) proposed six characteristics of high-quality and effective PD, in which opportunities for active learning is highlighted as a core feature of effective PD. *Active learning* denotes the extent to which PD affords opportunities for teachers to become engaged in meaningful discussion, collaborative work, planning, and reflection regarding their practice (Garet et al., 2001; Borko, 2010). Massive Open Online Courses (MOOCs) have generated notable disruption in higher education, and MOOCs as venues for teachers' PD are a relatively new field of study. There is a need to thoroughly understand which opportunities for active learning are present in MOOCs designed for effective teachers PD.

Context, Data and Methods

The context of this study is a MOOC offered by a large American university that has been designed for statistics teachers. This study aims to build answers to the research question: *What are the opportunities for active learning depicted in MOOCs designed for effective professional development of statistics teachers?* Qualitative research methods of content analysis were used to identify and describe *opportunities for active learning* as enacted in a MOOC designed for PD in statistics teaching. Data comprised 2370 forum posts distributed across 546 discussion threads.

Results and Implications

Results showed that by engaging in forums, teachers had opportunities to (a) interact with each other regarding the MOOC content, (b) share their experiences regarding statistics content and their practice of teaching, and (c) reflect on their practice. For example, teachers experienced the process of evaluating different statistics tasks according to a framework for statistical investigations, and subsequently engaged in discussion forums, sharing their perspective about how those tasks would promote productive statistical habits of mind and how these tasks could foster students' learning. The process of analyzing, reflecting, and suggesting improvements in the tasks produced meaningful opportunities for participants' active learning as stated in the literature. Implications from this study show the relevance of the connections and the network established by teachers in MOOCs. It indicates that future MOOCs for teachers' PD should be designed to nurture participants' connections and to help them in establishing virtual communities for shared practices.

INTEGRATING FACE-TO-FACE PROFESSIONAL DEVELOPMENT AND A MOOC-ED TO DEVELOP TEACHERS' STATISTICAL KNOWLEDGE FOR TEACHING

Ryan Seth Jones
Middle Tennessee State University

Jennifer Lovett
Middle Tennessee State University

Angela Google
Middle Tennessee State University

Keywords: Data Analysis and Statistics, Teacher Education-Inservice/Professional Development, Design Experiments

In our poster we will report on our effort to support middle grades teachers to develop the content knowledge, pedagogy, and self-efficacy necessary to support students to learn about statistical inquiry through authentic data investigations. There is a growing consensus that "every high school graduate should be able to use sound statistical reasoning to intelligently cope with the requirements of citizenship, employment, and family and to be prepared for a healthy, happy, and productive life" (Franklin et al., 2007, p. 1). This acknowledgement is represented in various content standards for mathematics at the K-12 level (CCSSM, 2010; NCTM, 2000). However, many practicing teachers have not experienced sufficient preparation to facilitate students' development of statistical literacy, and research has shown that most teachers do not have a deep understanding of the foundational concepts related to statistical inference (Franklin et al., 2015).

Thus, we have designed an innovative approach to supporting teachers through the integration of 1) a summer institute, 2) professional learning communities (PLCs), and 3) a Massive Open Online Course for Educators (MOOC-Ed). During the summer institute, teachers will meet together for a week-long professional development. The summer institute will focus on developing deep understandings of statistical concepts and exploring the ways students might engage with these ideas. We will use tasks from the research-based Data Modeling curriculum during the institute (Lehrer, Kim, & Schauble, 2007) to expose teachers to the need for statistical inference by exploring questions in the midst of widespread variability in data and explore different sources of variability and will discuss the conceptual principles of scale, interval, grouping, and order in visual displays of data. The MOOC-Ed, Teaching Statistics Through Data Investigations (Friday.institute/tsdi), was designed by Hollylynne Lee to develop teachers' knowledge of teaching statistics through the statistical investigative cycle (Franklin et al., 2007).

Our poster will report on the design framework for integrating Data Modeling resources and the MOOC-Ed to support sustained teacher support and to build collaborative communities. The poster will also report on early data about how new concepts and teaching practices travel across these different settings.

In this poster, we share details of a statewide Design-Based Implementation Research project's efforts supporting teachers' implementation of new state secondary mathematics standards. This includes design of project spaces and tools and preliminary results related to teacher interactions and learning.

Keywords: Teacher Education-Inservice/Professional Development, Design Experiments, Standards

Mathematics education researchers have built a strong body of research that continues to move the fields of both research and teaching forward; however, a divide continues to exist between research and practice and issues of implementation at scale (Cobb & Jackson, 2011). Responding to this challenge, researchers and funding agencies are encouraging research-practice partnerships where researchers and practitioners work together to iteratively design and research problems of practice (Penuel & Farrell, in press).

As part of a statewide research-practice partnership between a state education agency, district leaders, teachers, and mathematics education researchers at several institutions, our work draws upon Design-Based Implementation Research (DBIR) (Fishman et al., 2013) as an approach to facilitate the collaborative design of an intervention related to new state mathematics content standards and efforts to promote more equitable classroom learning opportunities for students. These efforts include common spaces and tools for teachers, leaders, and parents including: a closed webspace for teacher engagement, face to face professional development sessions, leader support tools, and parent outreach materials.

In this poster presentation, we will present DBIR as an approach to this work and share the ways in which we draw upon both communities of practice and boundaries to conceptualizing teacher learning (Wenger, 1998). We will describe the design process for both boundary encounters and boundary objects for which communities of high school mathematics teachers, teacher leaders, and parents/community members can collaborate and engage around research on teaching and student learning of mathematics. Finally, we will present preliminary findings on research related to interactions and learning within the spaces.

ONLINE FACULTY COLLABORATION TO SUPPORT INSTRUCTIONAL CHANGE

Nicholas Fortune
North Carolina State University
ncfortun@ncsu.edu

Karen Allen Keene
North Carolina State University
kakeene@ncsu.edu

Keywords: Post-Secondary Education, Mathematical Knowledge for Teaching

Research has shown that mathematicians may struggle implementing a new curriculum without support (Speer & Wagner, 2009; Wagner, Speer, & Rossa, 2007). Further, research has shown how summer workshops and online forums aid mathematicians in sustaining instructional change (Hayward, Kogan, & Laursen, 2015). However, new technology exists in which faculty collaboration can take place (e.g., online video calls). Research is underway that explores diverse ways to engage mathematicians and support them in reaching their goal for instructional change. This work is part of an ongoing project to support mathematicians' instructional change. This study focuses on one participant, Dr. J., and seeks to find links between his experiences in the online faculty collaboration and his instructional practice. The poster will address the following research question: How does one mathematician's instructional practice develop while participating in a faculty collaboration for inquiry-oriented differential equations?

Methods

Data for this case study (Yin, 2013) comes from observations of the faculty collaboration online meetings, Dr. J's classroom observations, and audio recordings of three interviews with Dr. J. Analysis of the classroom instruction uses the inquiry oriented instructional framework (Kuster, Johnson, Andrews-Larson, & Keene, n.d.). Analysis of the transcripts of the faculty collaboration uses a priori coding to explore Dr. J.'s changes in participation. Lastly, analysis of interview transcripts will be open in nature and serve as triangulation of data.

Preliminary Results

Analysis is ongoing but preliminary results seem to indicate that Dr. J.'s implementation of the IODE materials was influenced by his participation in the OWG. Although the interviews indicate that his desire to make changes in his instruction began prior to participation in the online working group, he uses the language and ideas of the inquiry-oriented instructional components presented in the project as a way to focus his teaching, offer feedback to other participants, and otherwise participate in the discussions. Further work will describe the connections and offer ideas to other facilitators of faculty online instructional support groups.

SECONDARY TEACHERS' PROFESSIONAL NOTICING OF STUDENTS' PROPORTIONAL REASONING

Raymond LaRochelle
San Diego State University
Rlarochelle89@gmail.com

Susan Nickerson
San Diego State University

Lisa Lamb
San Diego State University

Keywords: Teacher Education-Inservice/Professional Development

Professional noticing of children's mathematical thinking is a sense-making activity specific to the profession of teaching (Jacobs, Lamb, and Philipp, 2010). It distinguishes itself from other noticing conceptualizations in two ways: by including teachers' in-the-moment decision-making, and by focusing on children's mathematical thinking. Additionally, it is an essential part of instruction that builds on and responds to students' ideas. Herein we consider the professional noticing of students' mathematical thinking of 18 practicing secondary mathematics teachers in the domain of proportional reasoning (Lobato & Ellis, 2010).

Participants were a part of a larger professional development[1] aimed at supporting secondary mathematics and science teachers to improve in their practice and become leaders of their teaching communities. At the time of data collection, 13 participants had received 2.5 years of sustained professional development around students' mathematical thinking, and 5 had just begun. Each participant considered three samples of student work about proportional reasoning, and responded to the three professional noticing prompts (Jacobs et al., 2010): (1) Describe in detail what each student did. (Attending); (2) What did you learn about the students' mathematical understandings? (Interpreting); and (3) Pretend you are the teacher of these students. What problem might you pose next, and why? (Deciding how to respond).

The authors then coded participants' responses according to the amount of evidence demonstrated of considering the students' mathematical thinking: robust, limited, or a lack of evidence (Jacobs et al., 2010). Percentages of scores can be seen in Table 1. In sum, we find more evidence that improvement in professional noticing of students' mathematical thinking requires sustained professional development around students' mathematical thinking

Table 1: Percentages of Initial and Advancing Participants' Codes Per Component-Skill

	Attending		Interpreting		Deciding how to Respond	
	Initial	Advancing	Initial	Advancing	Initial	Advancing
Robust	40%	38%	0%	31%	0%	31%
Limited	40%	62%	80%	69%	20%	31%
Lack	20%	0%	20%	0%	80%	38%

RE-STORYING THE RITUAL OF CRITICAL INCIDENTS TO EMBRACE VULNERABILITY AND EMOTIONS AS EPISTEMOLOGY

Andrea McCloskey
Penn State University
amccloskey@psu.edu

Signe Kastberg
Purdue University
skastberg@purdue.edu

Shelly Harkness
University of Cincinnati
harkneml@ucmail.uc.edu

Keywords: Teacher Education, Research Methods

Critical incidents (Goodell, 2006) in mathematics teacher education have historically focused on teaching as a practice of problem solving. This poster describes findings from a collaborative self-study on the impact of this “problems of practice” perspective on ourselves as knowers in mathematics teacher education. Instead of continuing to ritually make use of critical incidents to explore such “problems of practice,” we sought to explore whether critical incidents could function in more positive and sustaining ways.

Early, reflective analyses of our conversational transcripts revealed that our initial sharing of critical incidents provoked largely negative activating and deactivating emotions. Our discussions of the critical incidents as “problems of practice” and how to solve these problems left us feeling mostly defeated. Previous mathematics education scholarship (Confrey, 1995; Forgasz & Clemans, 2014) has discussed the marginalization of emotion as a separate and inferior form of sense-making than cognitive perspectives of knowledge. We sought to challenge this historic tendency in our field and looked for ways to discuss practice that provoked positive activating emotions. We began crafting and discussing critical incidents that were at the crossroads of cognition and positive activating emotion.

Thematic analysis of 6 narratives of critical incidents and transcripts of 11 of our 30- 90 minute conversations over 5 months evoked by the incidents, resulted in several findings. For example, an analysis of one of the transcripts revealed that expressions of vulnerability that were brought to the group (such as: “If I can be really vulnerable…” and, “someone else positions us in such a way that we’re blindsided into being vulnerable”) suggest that vulnerability may be an important characteristic for mathematics teacher education development that allows the sharing of critical incidents to become productive. Interpretation of additional transcripts indicates that this discussion of vulnerability and our own willingness to open ourselves to be vulnerable with each other contributed to a re-storying of our work and ourselves in more positive ways (Brown, 2006). Further analysis of transcripts revealed ways in which the emotional terrain constructed during the experience of articulating critical incidents and re-storying served an epistemic role. Emotions allowed us to make sense of the incidents in new ways. We assert that a critical friends group and the sharing of positive incidents has the potential to provoke and sustain explorations of mathematics teacher educator practice without concomitant negative and deactivating emotions that had been provoked by explorations through a “problems of practice” lens.

THE CROSSROADS OF STAKEHOLDERS' VIEWS OF CCSSM IMPLEMENTATION

Daniel L. Clark
Western Kentucky University
daniel.clark@wku.edu

Keywords: Policy Matters, Standards (broadly defined), Teacher Education-Inservice/Professional Development, Elementary School Education

The current effort to implement the *Common Core State Standards for Mathematics* (*CCSSM*) is the latest in a series of mathematics standards implementation efforts in the United States over the last half century. When implemented, previous standards efforts have either failed or been less successful than anticipated for a variety of reasons. Two oft-cited reasons are a lack of a shared understanding about what the standards are and how to incorporate them effectively at various levels of an existing education system, and perceived and/or real flaws in the standards themselves.

With this past in mind, as well as requests for studies of this type from the mathematics education research community (Heck, Weiss, & Pasley, 2011), this study sought to document whether and to what extent these problems exist within Michigan's education system as the state implements the *CCSSM*. More specifically, this study sought answers to two research questions: To what degree is there alignment between Michigan Department of Education (SDE) officials', regional professional development providers', and elementary teachers' views of the goals of *CCSSM* implementation? Also, do those outside MDE charged with the implementation feel adequately supported in effecting their part of the transition to the *CCSSM*?

MDE officials, regional professional development providers, and elementary teachers were surveyed and interviewed as part of this mixed methods study in order to gather their thoughts on what they believe the goals of the *CCSSM* to be, what they believe their roles in the implementation effort are, and how they are supported in that effort. Responses were analyzed for commonalities and differences in the perceptions of individuals at the varying levels of the state's education system.

While elementary teachers were confident in their abilities to implement the *CCSSM* effectively, they still desired more professional resources related to the CCSSM and were generally unfamiliar with several resources others in Michigan's education system were promoting. Furthermore, as the *CCSSM* became a political issue that was widely discussed outside the education community, each of the three stakeholder groups that participated in this study were affected by and dealt with that development in different ways. These responses can be compared and contrasted with the findings of McDonnell and Weatherford (2016) as well as Polikoff, Hardaway, Marsh, and Plank (2016).

Purdue University
janewton@purdue.edu

Borko (2004) outlined four elements of a professional development (PD) experience (i.e., the PD program, teachers, facilitators, and context), and suggested three phases of research to investigate the interactions between these elements: (1) focusing on an individual PD experience at a single site, (2) expanding the study to a single PD experience enacted by more than one facilitator at more than one site, and (3) comparing multiple PDs at multiple sites. Garet et al.'s (2001) survey of teachers highlighted desirable core characteristics of PD experiences (i.e., focus on content knowledge, opportunities for active learning, coherence with other learning activities) and structural features (i.e., form of activity, collective participation of teachers from the same school, grade, or subject; duration of the activity).

In this poster, we report on a three-year phase 2 PD experience across four universities involving 60 middle school and secondary mathematics teachers. The project aims to enrich teachers' knowledge and skills for teaching algebra. Here, we investigate the ways in which PD for middle school and secondary mathematics teachers may be evaluated in order to give a holistic view of the PD experience. Eight objectives (e.g., collaborate to locate and develop algebra activities, engage students in solving rich algebra tasks) were set at the beginning of the program with six planned instruments to measure progress towards achieving those objectives. The following data sources were used to measure the progress of the project: a knowledge for teaching algebra assessment, lesson plans, PD and critical friend reflection forms, action research projects, and students' state standardized test scores.

Most compelling of our preliminary results has been the benefits of multiple data sources to provide a broad picture of teachers' development. Giving a pre- and post-test in knowledge for teaching algebra provides one lens for evaluating the PD, while the lesson plans and reflection forms give insight to how the teachers implemented PD foci (e.g., mathematics teaching practices) and illustrate teachers' creativity. Critical friend reflection forms show growth in teachers' ability to provide feedback to peers in ways that support algebraic thinking, and PD survey data indicate that teachers find value in the PD work itself and the ability to collaborate with their colleagues. Action research projects are individualized or collaborative and allow us to gain insights into the teachers' needs and how they perceive their progress. Collectively, these items give us a holistic view of the PD experience.

A STUDY OF PRE-SERVICE TEACHERS USE OF REPRESENTATIONS IN THEIR PROPORTIONAL REASONING

Kim Johnson
West Chester University
Kjohnson2@wcupa.edu

Proportional reasoning is important to the field of mathematics education because it lies at the crossroads of additive reasoning in the elementary school and multiplicative reasoning needed for more advanced mathematics. This research reports on the representations used by pre-service teachers (PSTs) as they responded to tasks involving proportional reasoning. The findings highlight three common difficulties that were prevalent among participants' responses. An analysis of the representations used by participants revealed that the representations that PSTs created in their effort to solve the problems often enabled them to overcome these difficulties. Prior research is used to hypothesize explanations of the extent to which different forms of representations were useful and productive for the participants. Implications include ways that use of these multiple representations could aid in the teaching of proportional reasoning.

Keywords: Mathematical Knowledge for Teaching, Rational Numbers, Modeling

Proportional reasoning is important to the field of mathematics education because it lies at the crossroads of transitioning from additive reasoning in the elementary school to multiplicative reasoning necessary for proportional reasoning and more advanced mathematics. Lesh, Post, and Behr (1988) describe the importance of proportional reasoning, saying that it is "widely recognized as a capability which ushers in a significant conceptual shift from concrete operational levels of thought to formal operational levels of thought" (p. 101). This shift in understanding can lead to advanced mathematical thinking and is paramount in achieving success in higher level mathematics courses.

Pre-service teachers (PSTs) enter college with prior assumptions about mathematics and mathematical concepts. Often PSTs have many deep-rooted misconceptions about the multiplicative relationships involved in proportional reasoning and struggle with solving tasks that involve these concepts (Simon & Blume, 1994; Smith, Silver, Leinhardt, & Hillen, 2003; Sowder, Armstrong, Lamon, Simon, Sowder & Thompson, 1998). The question becomes: What mathematical knowledge do PSTs have in relation to proportional reasoning? Understanding this knowledge is important in helping them develop the specialized content knowledge necessary for teaching. And how do PSTs use representations to deepen their understanding of proportional relationships? This report focuses on particular tasks that were used to elicit proportional reasoning of PSTs, the misconceptions that surfaced and how PSTs used representations in their problem solving to overcome these obstacles. These findings can help improve mathematics teacher education, as we can gain a better understanding of how PSTs think about proportional reasoning.

Conceptual Framework

While the definition of representation in mathematics education vary, most researchers differentiate between external and internal representations where external representations are embodiments of ideas or concepts such as charts, tables, graphs, diagrams, etc., and internal representations are cognitive models that a person has (e.g., Janvier, Girardon, & Morand, 1993). In this study, representations are external mathematical embodiments of ideas and concepts that provide the same information in a drawing, picture, table or graph.

According to Dufour-lanvier et al. (1987) the role of representations in mathematics education has several characteristics: (1) Representations are an inherent part of mathematics, (2) Representations provide a concrete example of a concept, (3) Representations are used locally to mitigate certain difficulties and (4) representations are intended to make mathematics more interesting. It is this third role that this report will illustrate in terms of PSTs proportional reasoning. In particular this study focuses on the use of representations to overcome difficulties and misconceptions.

The use of multiple representations is advocated by many mathematics educators and supported by the National Council of Teachers of Mathematics (NCTM) Standards (NCTM, 2000). It is suggested that multiple representations provide an environment for students to abstract and understand major mathematical concepts. Constructivist theory also suggests that we need to understand students' thinking processes in order to facilitate their learning in more empowering ways (Steffe, 1991). Therefore, it is necessary for mathematics teacher educators to understand how PSTs use representations, not only to understand their thinking, but to develop a repertoire of useful representations for teaching and discussing proportional reasoning. The results of this report will provide mathematics teacher educators with multiple representations that are productive in the teaching and learning of ratio and proportion.

Methodology

Twenty-five elementary and secondary math education PSTs were selected for this study at the beginning of their first mathematics methods courses at a large research university. A nine-problem questionnaire was developed and used to ascertain each PST's current level of understanding about proportional reasoning. (See Johnson, 2013 for more details on questionnaire). The responses were coded and participants were divided into four groups based on the analysis of their responses. Group 1 was distinguished by having a high level of proportional reasoning while Groups 2 and 3 showed moderate levels of proportional reasoning and group 4 gave evidence of little to no proportional reasoning. Eleven individualized interview schedules were created in order to challenge the PST understandings and misconceptions about proportional reasoning that surfaced from the questionnaires; the interviews were implemented, videotaped, transcribed and annotated. Individual interview data was coded and analyzed to create descriptions of the nature of the participants' understanding of proportional reasoning. A group of trained graduate students also coded the data and these codes were then discussed and revised to provide a higher degree of validity and reliability (Johnson, 2013). Another pass through the analysis showed patterns that emerged within each of the four groups in terms of their use of representations and it was noted that there were stark differences between those students in Group 1 and the students in the other groups. This report discusses and illustrates how PSTs in Group 1 utilized representations in solving these proportional problems during the interview and why these representations were important for them in overcoming certain challenges. Additionally, I will contrast these representations with those created by participants who were less successful in reasoning proportionally about these problems.

How Did Pre-Service Teachers Use Representations When Given Tasks Focused on Proportional Reasoning?

For this study tasks were designed to address distinct aspects of PSTs' difficulties with proportional reasoning that surfaced from the questionnaire. Three of these misunderstandings were: (1) The epistemological obstacle of linearity (Brousseau, 1997), (2) confusion between ratio and fraction (Karplus, Pulos, & Stage, 1983), and (3) inability to reason quantitatively (Thompson, 1994). Below, I illustrate how these particular tasks were designed to challenge PSTs' prior assumptions and how PSTs used representations to reason proportionally.

Galindo, E., & Newton, J., (Eds.). (2017). *Proceedings of the 39th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* Indianapolis, IN: Hoosier Association of Mathematics Teacher Educators.

Difficulty #1: Epistemological Obstacle of Linearity.

Modestou and Gagatsis (2007) studied students' improper proportional reasoning as an epistemological obstacle of linearity. An epistemological obstacle is NOT one in which there is a lack of knowledge, but one in which a piece of knowledge is appropriate only within particular contexts. The epistemological obstacle often generates false responses outside that context (Brousseau, 1997). These responses are recurrent, universal, and resistant to a variety of forms of support aimed at overcoming the problem (De Bock, Verschaffel, Janssens, Van Dooren, & Claes, 2003). For example, problems involving proportionality are often characterized as an epistemological obstacle in linearity. Missing value problems often include the basic structure of four quantities (*a*, *b*, *c* and *d*) of which, in many cases, three are known and one is unknown. Additionally, many proportional problems involve the context of speed. The Bike problem is this type of scenario; it involves students riding their bikes to school at the same speed. It provides PSTs with three numbers and asks them to find the fourth (see Figure 1).

Ben and John both ride their bikes to school at the same rate. Ben leaves his house first and meets John after riding 10 blocks at which time John has only rode 7 blocks. If John's trip to school is 14 blocks, how many blocks does Ben ride his bike to school? (Adapted from Cramer, Post and Currier [1993, p. 159])

Figure 1. Bike problem designed to elicit the obstacle of linearity.

Despite the structure of a missing value problem and context of speed, this problem does not involve a proportional relationship between the quantities. Research has found that this structure and context evoke a strong tendency of students to use direct proportions even if it does not fit the problem (DeBock, et al., 2002; Van Dooren, De Bock, Hessels, Janssens, & Verschaffel, 2005). 64% of the PSTs answered the bike problem incorrectly which demonstrates that students are drawn to the illusion of linearity in this problem and desire to solve it by setting up a proportion and cross multiplying even though there is not a proportional relationship. Verschaffel, Greer and DeCorte (2000) claim it takes a radical conceptual shift to move from the uncritical application of this simple neat mathematical formula to the modeling perspective that takes into account the reality of the situation being described. It is not surprising that the 36% of the PSTs interviewed who correctly used additive reasoning to solve this problem all created a diagram as part of their reasoning. The diagrams all illustrated the context of the problem (see figure 2).

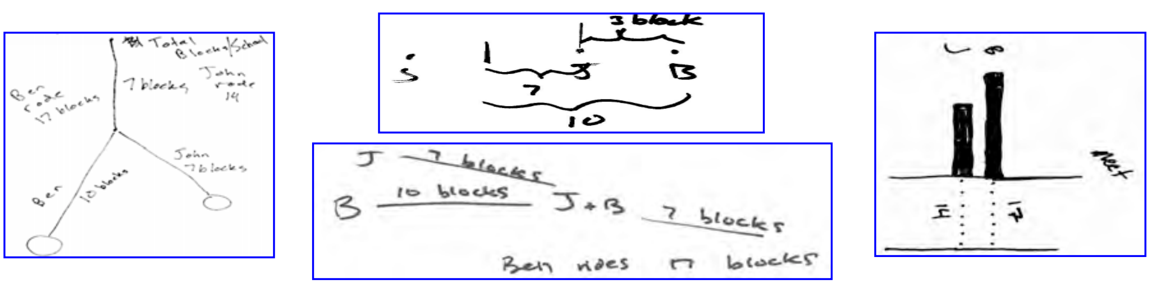

Figure 2. Representations created by PST to solve the Bike problem and overcome the obstacle of linearity.

It was the use of the diagram that helped them to situate and solve the problem as well as overcome the obstacle of linearity. Their representations modeled the additive reasoning necessary to solve the task despite its context and structure that led most PSTs to overextend the concept of proportions. These PSTs used the representation to illustrate that the two boys ride at the same speed

Galindo, E., & Newton, J., (Eds.). (2017). *Proceedings of the 39th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* Indianapolis, IN: Hoosier Association of Mathematics Teacher Educators.

then meet and travel together meaning that Ben rides his bike 3 more blocks than John. It is through modeling the context of the problem that meaning is achieved.

Difficulty #2: Confusion between Ratio and Fraction.

A link between fractions and ratio is often not made explicit in mathematics textbooks or classrooms. The difficulties surface if ratio and fraction are understood as equivalent mathematical terms when they are fundamentally different. Even though there are similarities in representations of ratio and fraction (i.e., fraction 2/3; ratio 2/3), the interpretations of those representations differ in important ways. In the case of ratio both the numerator and the denominator can represent parts (i.e., 2 parts to 3 parts); this is not the case with fractions. The Dog/Cat problem (see figure 3) was meant to elicit this type of difficulty in reasoning by PSTs. The correct interpretation of the situation is a part-to-part relationship. The numbers were chosen so that regardless of whether the participant interprets the ratio as a part-whole relationship or a part-part relationship, the solution will be an integer.

When animal lover Mr. Henry died he left 240 thousand dollars to be divided amongst two animal shelters using a 2:3 ratio between the amounts that Cat Best Home and Dog Lover Home gets. How much money should each shelter get? (Adapted from Peled [2007, p. 21])

Figure 3. Dog/Cat problem to elicit understanding of part to part ratios.

This problem was given on the initial questionnaire and a third of the PSTs interpreted 2:3 as 2/3rds and arrived at an incorrect solution of $80,000 to the Cat home and $160,000 to the Dog home. When interviewed these students who were asked to explain their reasoning and some were able to recognize that 2:3 is a part to part relationship, not a part whole relationship. In order to explain this relationship, these PSTs utilized representations to find the solution, either in a table or a model. For example, Eve started by doing an easier problem of 100 thousand dollars and created a pie chart to show the distribution of money. She then used a similar pie chart to determine the distribution for the 240 thousand dollars in the problem (see figure 4).

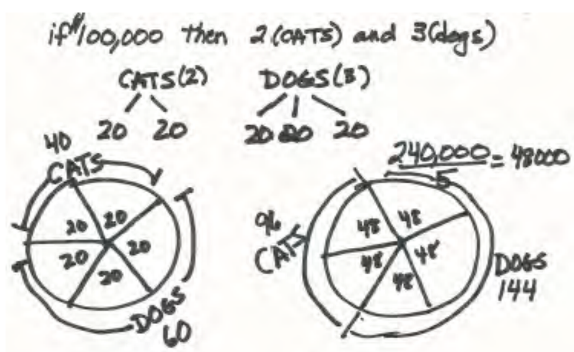

Figure 4. Eve's representation of her solution to the Dog/Cat problem.

Her representations illustrate a deep understanding of the part-to-part relationship presented in this problem. However, many of the PSTs who did answer this problem correctly on the questionnaire were unable to explain the procedure they used to find the solution. When asked how they solved the problem they would re-iterate the steps in the procedure (i.e. you add the two numbers given in the ratio, then you create two fractions 2/5 and 3/5 and multiply by them by the 240) but when asked to explain why it makes sense, replied, "I don't know, this is what I was taught to do when solving this type of problem, I don't know what it means or why it works." In order for these students to develop the specialized content knowledge needed for teaching proportional reasoning a discussion of illustrations such as Eve's would be beneficial. The pie chart can provide an understanding of what part-to-part relationships represent and why their procedure finds the solution. The slices of the pie show the number of pieces in the whole created by adding the two parts together and provide a visual representation as to why 2/5 times 240 (i.e. it is 2/5ths of the whole) results in the amount of money the Dog home receives.

Difficulty #3: Inability to Reason Quantitatively

PSTs in this study struggled with proportional reasoning situations that involved the distinction between quantitative reasoning and computation. Quantitative reasoning is making sense of relationships among measureable attributes of objects in a situation (Thompson, 1994) while computation is the result of an arithmetic operation to evaluate quantities. In general, reasoning about quantitative situations involves conceiving of circumstances in terms of quantities by constructing networks of quantitative relationships. For example, PSTs often set up proportions but do not understand what the ratios represent in the context of the situation.

The Lemon/Lime task was used to challenge the PSTs' misconception about quantitative reasoning and computation (see figure 5). In this task, participants were asked to compare two different lemon/lime mixtures (3 lemon:2 lime and 4 lemon:3 lime) to determine which was more lemony, **without doing ANY calculations** but by representing the mixtures with green and yellow unifix cubes. The request to not use calculations posed a high degree of difficulty for most of the PSTs interviewed, because it forced them to reason quantitatively and conceptually rather than computationally.

Jen and Alice are making lemonade. Jen mixes 3 cups of lemon juice with 2 cups of lime juice. Alice mixes 4 cups of lemon juice with 3 cups of lime juice. Whose mixture is more lemonier? Justify your solution without using calculations. You may rearrange the cubes in such a way that they demonstrate which one's more lemony tasting or that they are the same. (Heinz [2000, p. 70])

Figure 5. Lemon/Lime Problem.

60% of the PSTs interviewed used an additive relationship when they reasoned without calculations, claiming that there was "one more cup of lemon in each mixture so the mixtures were the same." However, when allowed to utilize calculations, these same PSTs created a multiplicative relationship (i.e. 3/2 = 1.5 and 4/3 = 1.333) by dividing the quantities in order to compare the decimal representations of the mixtures. Their calculation of the relationship caused them to reevaluate the original statement that the mixtures were the same and state that the 3 lemon:2 lime mixture had more lemon taste than the 4 lemon:3 lime mixture. But why did the PSTs not recognize the multiplicative relationship when reasoning quantitatively (without calculations)? What is surprising is how the PSTs used the cubes when they initially reasoned about the situation. The 40% of the PSTs who utilized multiplicative reasoning ALL created models where the green and yellow cubes were separated (see figure 6), while the 60% who reasoned additively all created models with the green and yellow cubes attached (see figure 7).

Separating the lemon from the lime allowed the PSTs to recognize the multiplicative relationship between the two quantities and not focus on the fact that there is one-cup difference between the two mixtures. In contrast, those representations created by the PSTs where the lemon and lime remained attached seemed to force the PSTs' focus on the fact that there was one more cup in each mixture. The reason may be because the attached cubes resemble lines that would have length. Kaput and West (1994) found that there was a strong tendency to adopt additive reasoning when problems involved linear measurements. So by, separating the cubes by color the PSTs were able to attend to both quantities multiplicatively because their prior assumptions about length would not have been brought forward as strongly by the representation. Knowing this distinction we can create powerful discussions about the quantitative reasoning necessary for solving proportional problems.

Figure 7. Examples of PSTs representatoin of the Lemon/Lime problem that utilized additive reasoning.

Conclusion

In all of the cases presented in this report, PSTs used representations to clarify and explain their proportional reasoning. Whether they used tables, drawings, pie charts, or unifix cubes, the models that represented the context and particular situation of the tasks led to reasoning that had deep meaning. Lo (2004) suggests that providing pre-service teachers with mathematical tasks that are rich in context and encouraging them to develop drawings and representations that convey the meaning of their solution methods to other students deepens their mathematical reasoning. The use of representations when teaching proportional reasoning can provide opportunities to distinguish between proportional and non-proportional situations, explain part to part relationships involved in ratios, and support students' multiplicative reasoning necessary for the development of deep proportional reasoning. Lobato and Ellis (2010) discuss the use of representations in many of their proposed essential understandings of ratio and proportion; however, the role of representation in developing and modeling reasoning is not given the priority it warrants.

This study suggests that greater importance should be given to representations that students produce while solving proportional problems and that the use of multiple representations while

Galindo, E., & Newton, J., (Eds.). (2017). *Proceedings of the 39th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* Indianapolis, IN: Hoosier Association of Mathematics Teacher Educators.

teaching about ratio will lead to deeper understanding of the concept of proportion. Representations allow individuals to attend to important aspects of their reasoning, including the two quantities involved in the ratios, the context of the problem, and the multiplicative relationship needed in proportional reasoning. Yetkiner and Capraro's (2009) research summary for National Middle School Association stated that until teachers can develop specialized content knowledge in multiplicative and proportional reasoning, they would struggle to provide students with multiple representations that can address the different learning styles found in their classroom. As mathematics teacher educators we should begin to address the difficulties PSTs have with proportional reasoning by providing multiple representations in our own classrooms and discussing their benefits. This report illustrates several representations of proportional reasoning that proved to be useful.

The interpretive cross-case study focused on the examination of connections between teacher and student topic-specific knowledge of lower secondary mathematics. Two teachers were selected for the study using non-probability purposive sampling technique. Teachers completed the Teacher Content Knowledge Survey before teaching a topic on division of fractions. The survey consisted of multiple-choice items measuring teachers' knowledge of facts and procedures, knowledge of concepts and connections, and knowledge of models and generalizations. Teachers were also interviewed on the topic of fraction division using questions addressing their content and pedagogical content knowledge. After teaching the topic on division of fractions, two groups of 6th grade students of the participating teachers were tested using similar items measuring students' topic-specific knowledge at the level of procedures, concepts, and generalizations. The cross-case examination using meaning coding and linguistic analysis revealed topic-specific connections between teacher and student knowledge of fraction division. Results of the study suggest that student knowledge could be reflective of teacher knowledge in the context of topic-specific teaching and learning of mathematics at the lower secondary school.

Keywords: Teacher Knowledge, Rational Numbers, Mathematical Knowledge for Teaching

Purpose of the Study

In the last several decades, research on teacher knowledge initiated by work of Shulman (1986) has focused on teacher knowledge as a major predictor of student learning and achievement. Since then the field benefited from numerous studies that substantially advanced the conceptualization of teacher knowledge. Scholars (e.g., Chapman, 2013; Izsak, Jacobson, & de Araujo, 2012) examined different facets of teacher knowledge without explicitly emphasizing its connection to student learning. Studies also stressed the importance of the kind of knowledge a teacher possesses because it impacts his/her teaching (Steinberg, Haymore, and Marks, 1985). Another line of research (e.g., Hill, Rowan, & Ball, 2005; Baumert et al, 2010; Author, 2011) specifically targeted the effects of different types of teachers' knowledge on student achievement.

Recently, scholars have advanced the field by examining teacher knowledge in variety of domains including number sense (Ball, 1990), algebra (McCrory et al., 2012); geometry and measurement (Nason, Chalmers, & Yeh, 2012), and statistics (Groth & Bergner, 2006). However, the field lacks research that provides an in-depth analysis of the various facets of teacher knowledge and its connection to student knowledge at *a topic-specific level*. To know what kind of teacher knowledge impacts student learning in the topic-focused context is an important issue worth of studying. Considering the importance of topic-specific knowledge, this study was guided by the following *research questions*: (1) Does what a teacher knows matter in regard to her students' topic-specific knowledge and performance? (2) What is the nature of topic-specific connections between teacher and student knowledge?

Conceptual Frame: Topic-Specific Content Knowledge

Division of fractions is one of the topics in lower secondary school mathematics curriculum for grade 6th in Russia (Ministry of Education and Science of Russian Federation, 2004) where the study was conducted. Scholars (Ball, 1990; Ma, 1999) found that the teachers have limited topic-specific content knowledge and they lack conceptual understanding of the topic. One of the main reasons is that the topic of division of fractions is traditionally taught by using the "flip and multiply" or "cross-multiply" procedure (e.g., invert-and-multiply algorithm) without helping learners to understand why it works (Siebert, 2002).

Although some teachers consider the traditional algorithm as one of the efficient procedures to divide fractions, they lack understanding of its connection to the inverse nature of division and multiplication (Flores, 2002; Lamon, 1999). Moreover, profound understanding of division of fractions requires connections to other topics such as measurement and sharing/ partitioning interpretations of division (Ball, 1990; Flores, 2002). Other important meanings of fraction division are "finding a whole given a part", "missing factor problem" interpretation of fraction division (Flores, 2002), and "the common-denominator algorithm" (Sharp and Adams, 2002).

In order to develop students' knowledge and comprehension of fraction division teachers themselves need to understand underlying meanings of the algorithms and procedures (Ball, 1990) to make their mathematical knowledge connected and conceptual (Ma, 1999). To be connected topic-specific teacher knowledge should address different *cognitive types*: knowledge of facts and procedures, knowledge of concepts and connections, and knowledge of models and generalizations (Author, 2011).

Analyzing cognitive types of teacher knowledge and its connection to student knowledge within a topic-specific context will contribute to the field of mathematics education and provide tools to enhance teacher education and professional development in order to improve student learning.

Methodology

The interpretive cross-case study (Merriam, 1998) focused on the topic-specific connections between teacher and student knowledge of lower secondary mathematics. Two teachers were selected for the study. Teachers completed the Teacher Content Knowledge Survey (TCKS) before teaching a topic on division of fractions. The TCKS consisted of 33 items measuring teachers' knowledge of facts and procedures, knowledge of concepts and connections, and knowledge of models and generalizations. Teachers were also interviewed on the topic of fraction division using questions addressing their content and pedagogical content knowledge. After teaching the topic on fraction division, students of the participating teachers were tested using similar items measuring students' knowledge of procedures, concepts, and generalizations. The cross-case examination was performed using meaning coding and linguistic analysis techniques (Kvale & Brinkmann, 2009) to report connections between teacher and student knowledge of fraction division.

Participants

The study participants were selected using non-probability purposive sampling technique based on the following set of criteria: 1) selected teachers should represent upper and lower quartiles of the total scores on the TCKS; 2) selected teachers should have similar teaching experience; 3) selected teachers should have similar teaching assignments; 4) selected teachers should teach at similar school settings.

The TCKS was administered to the initial sample of lower secondary (grades 5-9) mathematics teachers (N=90) in Russia (Author, 2015) and then the sample was subdivided by quartiles using teachers' overall TCKS scores. The maximum teacher score on the TCKS was 27 (out of 33) and the minimum score was 13. With regard to the first criteria, the overall sample of teachers was reduced to 43 teachers: 17 of which represented the upper quartile with the range of total TCKS scores 24-27 and 26 teachers represented the lower quartile with the range of total TCKS scores 13-18. After applying the remaining set of criteria 2)-4) we identified two teachers who met the requirements of the purposive sampling (names of the teachers are changed to keep the data anonymous) - Irina (with a total score of 25 on the TCKS) and Marina (with a total score of 17 on the TCKS). Both selected subjects are experienced lower secondary mathematics teachers and both of them are females of the same ethnic origin. Irina has 33 years of teaching experience and Marina - 21 years of teaching experience. Participants have similar teaching assignments - 5-8 grade mathematics with content addressing the following main objectives: Arithmetic, Algebra and Functions, Probability and Statistics, and Geometry. They both teach at urban public schools with similar student population concerning its' ethnic distribution and SES level.

We purposefully selected two contrasting cases with regard to teachers' mean scores on different cognitive types of content knowledge to closely examine the impact of teacher topic-specific knowledge on student performance while solving a set of problems related to division of fractions. The cluster sample of N=55 6th grade students of participating teachers (29 students in Irina's group and 26 students – in Marina's group) was used for collecting student level data after they studied a topic on division of fractions. The topic was a part of the chapter on operations with rational numbers placed in the 6th grade mathematics curriculum at the beginning of the fall quarter (Ministry of Education and Science of Russian Federation, 2004). Additionally, both Irina and Marina were teaching mathematics to the participating cohorts of students for the second consecutive year starting at 5th grade. Therefore, one may say that they established a certain teaching and learning "history" with these students.

Data Sources

The study used the following data sources: 1) TCKS to collect data on cognitive types of teacher knowledge; 2) structured teacher interviews on the topic of division of fractions; and 3) student data on solving three tasks related to the topic of division of fractions.

TCKS is the instrument that was designed to assess teacher content knowledge based on the cognitive types identified above. The survey consisted of multiple choice-items addressing main topics of lower secondary mathematics: Arithmetic, Algebra and Functions, Probability and Statistics, Geometry and Measurement. Specification table along with item analysis was performed to ensure content and construct validity of the TCKS along with its' reliability measured by the Cronbach alpha coefficient at *.839* (Author, 2011).

Teachers were interviewed using two sets of questions related to the topic of fraction division. First set of questions was aimed at tapping into teachers' pedagogical content knowledge whereas the second set was focused on different cognitive types of teacher content knowledge.

Students' written work on solving three tasks related to similar questions on division of fractions was collected and analyzed to examine connections to teacher knowledge. We purposefully used similar questions for teachers and students in order to trace linguistic, procedural, and conceptual traits in their reasoning as well as to analyze non-parametric quantitative trends in student topic-specific knowledge.

Data Analysis

For the qualitative phase of analysis, the teacher interviews were audio recorded and transcribed. Student written work was collected after the completion of the unit on division of fractions. In order to respond to the research questions we conducted meaning coding and linguistic analysis (Kvale & Brinkmann, 2009) of teacher narratives as a primary method of analysis. The data-driven meaning coding technique was used for the purpose of "breaking down, examining, comparing, conceptualizing and categorizing data" (Strauss & Corbin, 1990, p. 61). The linguistic analysis technique addressed "the characteristic uses of language, … the use of grammar and linguistic forms" (Kvale & Brinkmann, 2009, p. 219) by participating teachers and students within the topic-specific domain of lower secondary mathematics. The meaning coding and linguistic analysis was performed and cross-checked by two of the co-authors of this paper.

Considering ranked nature of the quantitative data collected in the study, we employed non-parametric technique (Chi-square test of goodness of fit) to detect group differences using frequency data in student responses.

Results

In this section, we will present major findings of the study starting with teacher responses on pedagogical content knowledge questions. Then we will report data on questions and tasks focused on teacher content knowledge and student knowledge of fraction division. Finally, we will present results of the quantitative analysis of students' performance on selected tasks.

In the qualitative phase of the study, we conducted structured interviews with two of the study participants – Irina and Marina. Irina's mean scores on the TCKS items are as following: score on items measuring knowledge of facts and procedures – 80%, items measuring knowledge of concepts and connections – 46%, and items measuring knowledge of models and generalizations - 30%. Irina's total TCKS score is 51%. Marina's mean scores on the TCKS are as following: knowledge of facts and procedures – 90%, knowledge of concepts and connections – 69%, knowledge of models and generalizations – 70%, and total score – 75%.

The qualitative phase of the study included two stages: (1) teacher interview and (2) student problem solving. The teacher interview consisted of the following two sets of questions: a) the subset of questions 1)-2) tapping into teachers' pedagogical content knowledge and aiming at teachers' understanding of learning objectives for the topic of fraction division; and b) the subset of questions 3)-6) focusing on teachers' possession of cognitive types of content knowledge. The first subset included the following questions: 1) When you teach fraction division, what are important procedures and concepts your students should learn? 2) What is the meaning(s) of division of fractions?

The second subset consisted of the following questions: 3) What is the fraction division rule? 4) Divide two given fractions 1 3/4 and 1/2. 5) Construct a word problem for the fraction division from the previous question. 6) Is the following statement $\frac{a}{b} \div \frac{c}{d} = \frac{ac}{bd}$ *(a, b, c,* and *d* are positive integers) ever true?

Responses were audio recorded and teachers were provided with a scratch paper. We used open coding followed by axial coding technique (Strauss & Corbin, 1998) applied to the transcribed narratives to analyze meaning expressed and language used in teachers' responses. Below we present teachers' narratives to the first two pedagogical content knowledge questions.

Teachers' Responses to Pedagogical Content Knowledge Questions

Participants' responses to the question 1 is transcribed below. Based on Irina's response to the first question, it is evident that she capitalizes on her procedural knowledge with little or no attention to concept development. There is a slight indication of applying the rule in "standard situations" (lines 8-9 of Irina's interview excerpt for the question 1) with no further clarification on the nature of this application. Whereas Marina extends the application of the fraction division rule to the "non-routine problem solving situations" (lines 6-7 of Marina's interview excerpt for the question 1). Also, we thought that Irina's reference to "factorization of polynomials" in teaching fraction division was not further elaborated by her and, therefore, was confusing.

IRINA

Before introducing the fraction division, I would like my students to recall the topic on factoring a polynomial, recall the rule of fraction multiplication, and recall reciprocals. After the lesson on fraction division I expect my students to know fraction multiplication and division rules, acquire skills to use these rules *in standard situations* [emphasis added], as well as apply factorization of polynomials.

MARINA

When I teach fraction division, first of all, I expect students to learn fraction division rule as it applies to the case of common fractions. Then, I expect them to know how to apply the rule to mixed fractions. Further, students need to understand how to use the fraction division *in routine and non-routine problem solving situations* [emphasis added]. Pedagogy wise, I always support students' motivation through engaging students in small group work and classroom discussion.

Responding to the question 2, Irina used the part-to-whole interpretation of fraction division whereas Marina offered two different but somehow related interpretations of the meaning for division of fractions.

IRINA

Well… there are two main problems in school arithmetic: finding a part of a whole and finding a whole knowing its' part. Said that, the meaning of *fraction division is finding a whole knowing its' part* [emphasis added].

MARINA

From my perspective… There are at least two meanings for division of fractions. First meaning is based on the interpretation of *division as operation opposite to multiplication* [emphasis added]. In other words… to divide a fraction A by a fraction B means to find a fraction C such as A=B x C. For example, 5/6 divided by 1/6 means that there is a fraction C such as 5/6 = 1/6 x C. Or 5/6 ÷ 1/6 =5. On the other hand, *division is kind of "sorting"* [emphasis added]. For instance,1/2 = 1/4 + 1/4 = 1/4 x 2 meaning that 1/4 goes 2 times into 1/2 whereas 1/2 goes 1/2 times into 1/4. Hope it makes sense… [smiles]

Teachers' Responses to Content Knowledge Questions

Irina's response to the question 3 further confirmed that she has well-established procedural knowledge of the fraction division rule.

IRINA: The rule of fraction division is reduced to the rule of fraction multiplication. Therefore, you need to multiply the *first fraction* [emphasis added] by the reciprocal of *the second one* [emphasis added].

INT: What do you mean by reduced to fraction multiplication?

IRINA: As students say, *cross multiply* [emphasis added] fractions.

Marina's response to the question 3 is depicted below. Surprisingly, Marina used a similar conclusion connecting fraction division to multiplication as Irina did in her response to the same question.

MARINA: In order to divide fractions, you need to multiply *dividend* [emphasis added] by the reciprocal of the *divider* [emphasis added]. For example, $\frac{15}{4} \div \frac{3}{10} = \frac{15}{4} \times \frac{10}{3} = \frac{25}{2}$ (writes on a scratch paper). Generally speaking, fraction division "boils down" to multiplication.

Galindo, E., & Newton, J., (Eds.). (2017). *Proceedings of the 39th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* Indianapolis, IN: Hoosier Association of Mathematics Teacher Educators.

Irina's response to the question 4 consisted of the solution only (she wrote it on a scratch paper) without any commentary: $1\frac{3}{4} \div \frac{1}{2} = \frac{7}{4} \times \frac{2}{1} = \frac{7}{2} = 3.5$.

Unlike Irina, Marina supported her response to the question 4 with step-by-step comments.

MARINA: First, we convert given mixed fraction 1 3/4 to common one 7/4. Notice, here the numerator is larger than denominator. Then, we replace division by multiplication *reversing the divider* [emphasis added]. Hence, $1\frac{3}{4} \div \frac{1}{2} = \frac{7}{4} \times \frac{2}{1} = \frac{7}{2}$ (writes on a scratch paper).

With regard to the question 5, it took a while for Irina to think about the problem. Then Irina clarified whether she can write down the word problem she came up with on a scratch paper.

IRINA: May I write down the problem on the paper?
INT: Yes, of course.
IRINA (writes on a scratch paper): Area of a rectangle is equal to 1 3/4 cm^2, its length is equal to 1/2 cm. Find width of the rectangle.

Irina was consistent in applying the part-to-whole interpretation in her response, more specifically – using "the missing factor problem" as a meaning for division of fractions (Flores, 2002).

After some thinking, Marina offered the following word problem in her response to the question 5.

MARINA: Here is my word problem: an automated machine packs butter in 1/2 kg bricks. How many bricks one can make out of 1 3/4 kg of butter?
May I draw a picture!?
INT: Sure.
MARINA: (draws a picture on a scratch paper)

We noticed that Marina herself offered drawing a picture to illustrate her word problem.

In Irina's answer to the question 6, she basically repeated her response to the question 2.

IRINA: The given statement is not correct. In order to divide fractions you need to multiply the *first one* [emphasis added] by a reciprocal of the *second one* [emphasis added].

Question 6 was the most challenging to Marina. Nonetheless, she confessed that she liked it.

MARINA: I like this question. It makes me think.
INT: Good.
MARINA: Alright, notice that in order to solve this problem *ac/bd* should be equal to *ad/bc*. Right?
INT: So…
MARINA: Therefore, $c/d = d/c$. This is possible only if $c = d$.

Students' Responses to Fraction Division Questions

At the stage of student problem solving, we asked groups of 6th grade students of participating teachers (Irina's group had n=29 students and Marina's group n=26) to solve a subset of questions corresponding to different cognitive types of content knowledge similar to those presented to teachers: 1) Divide two given fractions. 2) Construct a word problem for fraction division from the previous question. 3) Is the following statement $\frac{a}{b} \div \frac{c}{d} = \frac{ac}{bd}$ *(a, b, c,* and *d* are positive integers) ever true?

Questions were presented to students after they completed a chapter on the basic operations with fractions. Student wrote down their responses on a paper and student work was collected for further analysis. The number of correct students' responses on questions 1-3 along with the chi-square statistic comparing student performance between groups on each question is presented in the table 1 below.

Table 1. Chi-Square Analysis' Results of Student Responses on the Fraction Division Questions

	Question 1	Question 2	Question 3
Irina's Group (n=29)	28	12	1
Marina's Group (n=26)	25	15	10
Chi-square and *p*-value (df=1)	χ^2=.41 *p*=.522	χ^2=.88 *p*=.348	χ^2=8.43 *p*=.0037

As we mentioned before, questions selected for the student problem solving session reflected different cognitive types of content knowledge on the topic of division of fractions.

Discussion: Does What a Teacher Knows Matter?

The most important finding of the study was the evidence collected and analyzed in support of the first research question: what a teacher knows matters in regard to his/her students' topic-specific knowledge. As we expected based on similar teachers' scores on cognitive type 1 items (measuring knowledge of facts and procedures), there was no difference observed between student performances in two groups on the procedural question 1. There was some difference, not significant though, observed on the question 2 measuring knowledge of concepts and connections (in favor of students in Marina's group). The most evident difference between student performance in two groups was observed on the question 3 (measuring knowledge of models and generalizations) was statistically significant (χ^2*=8.43, p=.0037).* We were surprised by the partially-correct student's response from Irina's group considering the fact that Irina herself was not able to correctly solve the question. Overall students' responses were reflective of their teachers' knowledge: student performance in Marina's group was stronger than in Irina's group, particularly in solving questions 2 and 3 with difference in responses to question 3 being statistically significant.

The data collected and analyzed to respond to the second research question - What is the nature of topic-specific connections between teacher and student knowledge? – revealed that teacher's mastery of cognitive types of content knowledge is associated with the students' topic-specific knowledge. Thus, findings of this study contribute to the body of research claiming that teacher content knowledge is critical for student learning (Hill, Rowan, & Ball, 2005; Baumert et al., 2010). Teacher interviews and students' problem solving helped us to closely look at the nature of the relationship between teacher knowledge and student performance.

We are cognizant that the study had its limitations such as teacher sample size, multiple-choice format of the teacher content knowledge survey, to name a few. Following on the discussion about complexities of assessing teacher knowledge (Schoenfeld, 2007), we are aware of the limitations of the multiple-choice format in test construction and assessment of teacher knowledge (p. 201). Therefore, we included the qualitative phase of the study to zoom further into teacher knowledge and understanding. We are also cognizant that classroom observations could be another source of data in this study. However, to explicitly address the research questions we purposefully focused the study on the link "teacher knowledge-student performance" in the topic-specific context. Considering these limitations, we are sensitive enough to not overgeneralize the results obtained in the study. The major findings of this study open an opportunity to discuss the importance of different cognitive types of the topic-specific teacher knowledge and its potential impact on student knowledge and learning.

Presentamos los resultados del análisis de los conocimientos puestos en acción por una maestra de matemáticas de secundaria en su práctica en el aula. Éstos toman forma y se despliegan como estrategias didácticas específicas para gestionar su clase cuando incorpora Computer Algebra Systems. A partir de observaciones no participantes de clases cotidianas y entrevistas, encontramos que los conocimientos de esta maestra (matemáticos, didácticos y tecnológicos) son movilizados en varios momentos y a través de diversas estrategias didácticas. Ello depende de una amplia diversidad de factores entre los que destacan el objetivo de la planeación, el momento específico de la clase, las participaciones de los estudiantes y el uso de la herramienta tecnológica. En esta complejidad la maestra aplica sus estrategias didácticas de manera flexible y logra controlar e incluso modificar la gestión de su clase.

Palabras Clave: Conocimiento Matemático para la Enseñanza, Álgebra y Pensamiento Algebraico, Educación Secundaria, Technology

Introducción

Para acercarse al conocimiento profesional del profesor de matemáticas y sus prácticas han surgido diferentes marcos de análisis, metodologías y propósitos que aún siguen en refinamiento y en discusión al interior de la propia comunidad (Ball, Thames y Phelps, 2008; Ponte y Chapman, 2006; Gaeber y Tirosh, 2008). Ponte y Chapman (2006) sugieren tomar en cuenta la estrecha relación de este tipo de conocimiento y la práctica, las condiciones de trabajo y los objetivos explícitos e implícitos de dicha labor. Por su parte, Davis (2014) señala que el conocimiento necesario para un profesor de matemáticas es una red compleja en la que interactúan "una mezcla de varias asociaciones/instanciaciones de conceptos matemáticos y una conciencia de procesos complejos en los cuales se producen las matemáticas" (p. 155). De hecho, el conocimiento del profesor es "enactuado (puesto en acción/*To be enacted*) e implícito" (p. 155).

La investigación sobre el uso de Tecnologías Digitales (TD) para la enseñanza de las matemáticas es amplia. Se ha encontrado que la incorporación de Computer Algebra Systems (CAS) a los salones de clases generan cambios en las prácticas matemáticas (Pierce y Stacey, 2004) y que el profesor es central para proveer condiciones que ayuden a los estudiantes a su comprensión matemática, con uso de estas herramientas (McFarlane, Williams y Bonnett, 2000).

Elegimos el tema de la enseñanza del álgebra con CAS debido a que una de las ventajas de esta herramienta es que puede usarse para proveer de significado a las transformaciones y expresiones algebraicas. Numerosas investigaciones han mostrado evidencia sólida de que la tecnología puede ser un elemento activo en la construcción de significados de los conocimientos algebraicos. (Puig & Rojano, 2004; Hitt y Kieran, 2009; Kieran y Drijvers, 2006; o bien por Solares y Kieran, 2013.) Nuestro estudio se ubica en esta línea, centrándose en el estudio de los conocimientos y las prácticas docentes en clases cotidianas de álgebra con CAS. Buscamos profundizar en la comprensión de cómo los profesores movilizan estos conocimientos (matemáticos, didácticos y tecnológicos) y les dan sentido en términos de sus prácticas (Ponte y Chapman, 2006). Específicamente buscamos responder: ¿Cómo los conocimientos didácticos y matemáticos se ponen en acción durante una clase en la que se usa CAS? y ¿cómo estos conocimientos se manifiestan por medio de las estrategias didácticas?

Perspectiva Teórica: Conocimiento Especializado del Profesor de Matemáticas

Nos interesa identificar los conocimientos puestos en acción por un profesor cuando enseña álgebra con el uso de CAS a partir del análisis de sus estrategias didácticas. Para considerar la especificidad de este conocimiento respecto a la enseñanza del álgebra escolar y para efectos de análisis partimos del modelo del *conocimiento especializado del profesor de matemáticas* (MTSK por sus siglas en inglés) (Carrillo, Climent, Contreras, & Muñoz-Catalán, 2013).

Este modelo se refiere al conocimiento específico (en su conjunto) del profesor de matemáticas el cual se compone de dos dominios: Conocimiento Matemático (MK) y Conocimiento Didáctico del Contenido (PCK). El primer dominio está compuesto de tres subdominios: Conocimiento de los Temas, de la Estructura de la Matemática y de la Práctica Matemática. El segundo, el Conocimiento Didáctico del Contenido, está compuesto por: Conocimiento de la Enseñanza de las Matemáticas, de las Características del Aprendizaje de las Matemáticas y de los Estándares de Aprendizaje de las Matemáticas.

Por las características de nuestro objeto de investigación, nos centramos en el segundo dominio (PCK). A continuación, describimos brevemente en qué consiste cada uno de los tres subdominios que lo componen. El *conocimiento de la enseñanza de las matemáticas* (KMT) está vinculado con estrategias y teorías de enseñanza, materiales y recursos vinculados con el contenido a enseñar; el *conocimiento de las características del aprendizaje de las matemáticas* (KFLM) incluye asuntos sobre cómo se aprenden ciertos conceptos, intuiciones, errores y formas como los alumnos interactúan con cierto contenido matemático y, finalmente, el *conocimiento de los estándares de aprendizaje de las matemáticas* (KMLS) se refiere a lo qué es esperable (en términos del propio currículo) en un nivel escolar determinado incluyendo también las indicaciones y formas de aprender dicho contenido desde un "referente estandarizado" (p. 598).

Lo anterior da cuenta de la complejidad en la que está inmersa la tarea de enseñanza de un profesor al momento de impartir su clase. Sin embargo, no todos los conocimientos se adquieren en instancias institucionales, muchos de ellos se construyen en la práctica de aula, en el intercambio con otros colegas y en el propio contexto donde se realiza la tarea de enseñar. Desde nuestra perspectiva los conocimientos de los profesores para la enseñanza de las matemáticas se ponen en acción y toman forma específica como estrategias didácticas que ellos modifican al momento de gestionar su clase.

Metodología
