PME-NA History and Goals

PME came into existence at the Third International Congress on Mathematical Education (ICME-3) in Karlsrühe, Germany in 1976. It is affiliated with the International Commission for Mathematical Instruction. PME-NA is the North American Chapter of the International Group of Psychology of Mathematics Education. The first PME-NA conference was held in Evanston, Illinois in 1979.

The major goals of the International Group and the North American Chapter are:

- To promote international contacts and the exchange of scientific information in the psychology of mathematics education;
- To promote and stimulate interdisciplinary research in the aforesaid area, with the cooperation of psychologists, mathematicians, and mathematics teachers;
- To further a deeper and better understanding of the psychological aspects of teaching and learning mathematics and the implications thereof.

PME-NA Membership

Membership is open to people involved in active research consistent with PME-NA's aims or professionally interested in the results of such research. Membership is open on an annual basis and depends on payment of dues for the current year. Membership fees for PME-NA (but not PME International) are included in the conference fee each year. If you are unable to attend the conference but want to join or renew your membership, go to the PME-NA website. For information about membership in PME, go to igpme.org and click on "Membership" at the left of the screen.

Preface

These Proceedings are a written record of the research presented at the 34th Annual Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education (PME-NA 2012) held in Kalamazoo, Michigan, November 1–4, 2012.

The theme of the conference, *Navigating Transitions Along Continuums*, focuses on an important set of opportunities for research to be useful in improving mathematics teaching and learning. Plenary speakers consider transitions across four continuum groupings: (1) student learning of mathematics (Jere Confrey); (2) professional learning, ranging from preservice mathematics teachers through teacher leaders (Deborah Ball and Suzanne Wilson); (3) school mathematics articulation, from topic to topic within grade levels as well as across grade bands (Amanda Jansen, Janie Schielack, Cathy Seeley, and Jack Smith); and (4) innovation to support mathematics learning, from the smallest of scale to the largest (Jo Boaler).

The Proceedings include papers from 2 plenary talks, 69 research reports, 124 brief research reports, 111 posters, and 10 working groups. The plenary and working group papers are the first and last chapters, respectively. Papers from the research reports, brief research reports, and posters are organized into chapters by topics. Each paper is indexed by authors and keywords. Underlined author indicates presenting author.

We would like to thank Hope Smith for her dedication to the technical details of putting together a high-quality document and James Kratky for his skill in making it easy to navigate. We are pleased to present these Proceedings as an important resource for the mathematics education community.

ARTICULATING A LEARNING SCIENCES FOUNDATION FOR LEARNING TRAJECTORIES IN THE CCSS-M

Jere Confrey[1]
North Carolina State University
Jere_Confrey@ncsu.edu

The paper describes the history of how learning trajectories (LTs) were associated with the Common Core State Standards for Mathematics (CCSS-M) and discusses the degree to which the two correspond faithfully. It reports on a website, www.turnonccmath.com, which organizes the K–8 standards into 18 LTs describing the development of big ideas over time, informed by empirical studies of learners. The paper illustrates how descriptors for each LT identify: (1) conceptual principles, (2) strategies representations, and misconceptions, (3) meaningful distinctions and multiple models, (4) coherent structure, and (5) bridging standards. The design principles for the website are illustrated describing how the CCSS-M are related to a learning trajectory on division and multiplication.

Keywords: Standards, Cognition, Teacher Knowledge, Learning Trajectories

The Common Core State Standards for Mathematics (CCSSO, 2010) have been represented as "fewer, clearer, and higher," reflecting the view that revised standards should be: (1) focused, (2) rigorous and applicable, and (3) coherent. They offer "a more coherent progression of learning" described as "… clearly articulat[ing] how knowledge builds from year to year. Each standard extends previous learning while avoiding repetition and large leaps in instruction" (Hunt Institute, 2012, p. 8). Despite this intent, the progressions themselves are not immediately accessible to readers, so other documents are needed to articulate and display these relationships in different formats. Our research group has done this as a set of posters (www.wirelessgeneration.com/posters) and as a website (www.turnonccmath.com). After reviewing the history of how learning trajectories became foundational in the writing of the CCSS-M, I describe the elements of a learning trajectory analysis of the CCSS-M as a means to support implementation of standards and conduct of related professional development. The advantages of researchers working together, to create resources on learning trajectories built on empirical study are discussed, along with a warning of the likely costs of failing to do so.

History of Learning Progressions in the CCSS-M

In the summer of 2009, a meeting was held at the Friday Institute for Educational Innovation in North Carolina where researchers on learning trajectories hosted the writers of the Common Core State Standards (CCSS) and other leaders from the Council of Chief State School Officers (CCSSO).[2] The proposed standards were to be based on scientific evidence. While the College- and Career-Ready Standards (U.S. Department of Education, 2010) could be sufficiently justified with evidence of international benchmarking and studies of the needs and expectations of colleges and entry-level careers, the grade-level standards required a basis in the research on student learning. A number of learning sciences and mathematics education researchers gave presentations (including M. Battista, D. Clements, J. Confrey, G. Kader, and R. Lehrer) on learning trajectories (also called "learning progressions"). After the conference, many of the attendees were invited to participate on the CCSS-M writing teams. The use of these teams during the Standards development was perceived by many as more sporadic than systematic—and the teams were only one voice among many (including state departments, mathematics faculty, and teachers) in influencing the development of the Standards. However, their ideas contributed significantly to the final document. In sum, the CCSS-M incorporated a foundation in learning trajectories that can propel the country forward now, and be strengthened over time. In the period since the publication of the CCSS-M, at least three groups have engaged in efforts to delineate the trajectories in more detail (Confrey et al., 2011; Hess & Kearns, 2010; McCallum, 2011).

www.turnonccmath.com

Once the CCSS-M was validated and widely adopted, and in response to the need expressed in the field for urgent assistance, the DELTA research group at North Carolina State University (NCSU) decided to connect the Standards more directly with associated research on learning trajectories. Many state leaders had reported that teachers perceived little change from their old or current state standards to the new CCSS-M, and expected that "crosswalks" would provide a sufficient basis to support the transition to the CCSS-M and the related curriculum and assessment. In this scenario, teachers would only change the way they teach new topics at the grain size of the individual grade levels and otherwise continue teaching by making small adjustments to their lesson plans. A close reading of the CCSS-M document, my understanding of the CCSS-M from experience on the National Validation Committee, and our group's close comparison of the CCSS-M to previous state standards, however, told a different story. There are major changes in when and where mathematical topics are emphasized, namely the intensity of content treatment at earlier grades and major shifts in several topics that will radically change teacher preparation and professional development. The "higher" and "fewer" aspects of the CCSS-M mean, also, that there is much less room for repetition of content at each grade.

We found learning trajectories useful in supporting implementation, because they focus attention on gradual and systematic student learning over time, a form of "genetic epistemology" (Piaget, 1970). The idea behind explicitly mapping learning trajectories onto the CCSS-M is to help teachers and students build consistently stronger understandings of big ideas by revising and modifying prior views in light of new conditions and challenges. Rather than emphasize a standard-by-standard view of implementation of new or revised content, learning trajectories support "vertical teaming" by teachers. This allows an exciting chance for teachers to discuss and plan their instruction based on how student learning progresses. An added strength of a learning trajectories approach is that it emphasizes why each teacher, at each grade level along the way, has a critical role to play in each student's mathematical development.

Our effort to build a website that synthesizes the relevant research and to lay out a manageable number of learning trajectories for the CCSS-M began as a result of a meeting of the *Measurement Mini-Center*.[3] Many of the group's participants had conducted pioneering work on learning trajectories, and each has his or her preferences about how to characterize, emphasize or order underlying proficiencies and concepts. Concerned that the interpretation of the CCSS-M should be better and more publicly informed by "learning sciences research," my research team drafted a synthetic trajectory built around the CCSS-M, drawing from these scholars' work, and brought it to the meeting for discussion. The Mini-Center's response to the effort was positive and constructively critical—the group reviewed the proposed trajectory, offered valuable suggestions and distinctions, and labored until an acceptable synthesis was negotiated. This specific trajectory as finalized is represented on the turnonccmath.com site (Confrey et al., 2011) and is described in more detail in a 2012 PME-NA paper (Lee, Nguyen, & Confrey, 2012).

Buoyed by this experience and stimulated by requests from the field, our NCSU team decided to undertake a full learning trajectories analysis of the K–8 Standards. Using a hexagon map of the CCSS-M (designed by Jere Confrey and ©Wireless Generation) to display the Standards and learning trajectories visually, I dissected the CCSS-M into 18 learning trajectories. Over a concentrated period of six months, the research team undertook writing, revising, and interlinking *descriptors*, which are text-based descriptions of standards in terms of students' movement from more naïve to more sophisticated ideas for each of the trajectories. Our working assumptions were that the web-based environment would: (1) provide the opportunity for continuous incremental improvements in the descriptors that would serve the needs of the field for rapid access to the associated learning trajectories for the Standards, and (2) permit us to gradually strengthen the site based on feedback and review. In the next sections, the hexagon map is introduced along with an explanation of the framework used to analyze the trajectories and unpack them into descriptors.

Turnonccmath: by Grade

The website http://www.turnonccmath.com displays a "hexagon map" of the CCSS-M. In designing this map, decisions to use a predictable and consistent method to assign standards to hexagons were largely pragmatic. Standards in the CCSS-M are of many different grain-sizes, which added considerable challenge to the effort in mapping them to hexagons. Standards were assigned to individual hexagons using the following scheme: (1) If a Standard has no subparts, the hexagon represents the entire standard. However, multipart Standards were too dense to be summarized in a single hexagon. Therefore, (2) for any Standard with subparts (e.g., a, b, c, etc.), each subpart was assigned its own hexagon. The map can be displayed in three views: by grade levels, by LT with the LTs labeled, and by LTs without labels. The topics within the standards generally proceed from less complex (lower left) to more complex (upper right).

The hexagons for the different grade levels occur in bands that are more or less orthogonal to the progression of the topics. In the grade level display, the lower left ends of any relevant learning trajectory contain the earliest grade-level standards, beginning (if applicable) with kindergarten standards, followed by first through eighth grade Standards built on top and to the right, and coded such that a hexagon's background color represents its grade level. The text color in each hexagon represents the content strand; for example in K–8, blue text corresponds to Number and Operations; red text corresponds to Measurement and Data, and black text corresponds to Geometry. In terms of the relative positions of different main content strands and learning trajectories, I chose to put Number and Operation-related standards on the bottom with Measurement-related standards on top of those, diagonally, and then Geometry-related standards above measurement. At the very top is a peninsula where the very thin learning trajectory for Elementary Data (Statistics) and Modeling is placed. This trajectory comprises K–5 standards in the Measurement and Data cluster that address how to build and interpret data representations. Having opposed the writers' decision to reduce the treatment of statistical reasoning in the CCSS-M at the elementary level, I left space to expand these standards in future revisions.

From the grade-level display, one can discern certain patterns. For instance, one can see that third grade is almost entirely comprised of standards on number and measurement, with only one standard in geometry. In contrast, one can see that in sixth grade, there are three distinct clusters of topics: (1) statistics, (2) ratio and proportion, and (3) equations and expressions.

The Relationship Between the Learning Trajectories and the CCSS-M

The purpose of a learning trajectory is to describe and synthesize what is known about how students reason over time. The term *Learning Trajectory* (LT) has varied meanings in mathematics education. Simon (1995) first defined the term hypothetical learning trajectory (HLT) to be "The learning goals, the learning activities, and the thinking and learning in which students might engage" (p. 133). We define it as, "a researcher-conjectured, empirically-supported description of the ordered network of constructs a student encounters through instruction (i.e., activities, tasks, tools, and forms of interaction), in order to move from informal ideas, through successive refinements of representation, articulation, and reflection, towards increasingly complex concepts over time" (Confrey, 2008; Confrey, Maloney, Nguyen, Mojica, & Myers, 2009, p. 2-346). We view a learning trajectory as a path through a conceptual corridor in which there are predictable obstacles and landmarks and thus a student's particular path is an issue of expected probabilities and likelihoods: LTs permit one to specify at an appropriate and actionable level of detail what ideas students need to know during the development and evolution of a given concept over time.

Learning trajectories provide a way to create coherence within the CCSS-M by drawing attention to how knowledge develops over time. If teachers try to implement the CCSS-M standard-by-standard, they will be unlikely to leverage the underlying structure of the standards and support gradual transformations in student reasoning. When we have worked with teachers in unpacking our learning trajectories, they have commented on the value of creating a "story" which illustrates how the ideas are likely to evolve in the minds of students when they are provided appropriate curriculum tasks, instruction, and opportunities for discourse. Therefore, our goal is to provide this type of support to teachers by providing them efficient and coordinated access to related research. In the end, the success of the CCSS-M rests on its potential to support alignment, including curriculum, assessment (formative *and* summative), and professional development, at a level not previously possible. But to achieve the deep and lasting change envisioned by the Common Core State Standards Initiative and the mathematics education community, the knowledge of learning trajectories must be made clear, accessible, compact, and well-integrated within the CCSS-M.

The relationship between the learning trajectories and the Standards is complex. To a degree, the CCSS-M were built on the foundation of learning trajectories. But it would not be accurate to say that there is an isomorphic relationship between the CCSS-M and the learning trajectories. In fact, acknowledging this, the Standards' writers call the progressions in the standards, "standards progressions" (Common Core Writing Team, 2011). The reasons include:

1. Different researchers have differing views of learning trajectories, even within strands;
2. Not all topic areas have been studied as learning trajectories; and
3. The writers took suggestions from mathematicians who conflated learning trajectories with logical progressions created by "thought experiments," independent of empirical verification.

This outcome is to be expected in a document resulting from negotiations and differences of opinion among disciplinary scholars, researchers and practitioners; moreover, it creates the possibility now to systematically test, compare, and refine those trajectories in light of students' work. Also, in order to construct "fewer" and "clearer" standards, the learning trajectories in the CCSS-M are of necessity *abridged*; that is, they do not and could not contain a full treatment of all the big ideas contained in the research literature. To address this in our analysis, we added "bridging standards" as needed. These statements are similar in structure to the CCSS-M standards, but represent topics that would be required in a more fully articulated (i.e., unabridged) learning trajectory. Because of the dual nature of standards as both assessment targets and targets of understanding, bridging standards can permit one to describe standards that need to be addressed in preparation for a later standard but which will not be assessed directly at that specific time. Finally, even after debate and review, there are a few standards that were poorly constructed, inconsistent, or unadvisable, based on mathematics education or learning sciences literature; a bridging standard may be added to improve the coherence of the trajectory overall.

Standards, by themselves, can serve as a skeleton for learning trajectories, but they need to be interpreted and made unabridged to serve this purpose. Moreover, the interpretation must make explicit the connections to the research base and provide a more complete articulation of how the ideas in a trajectory evolve in light of students' documented behaviors, emergent relations and properties, and generalizations (Confrey, Maloney, Wilson, & Nguyen, 2010). To this end, and so that there would not be too many LTs to manage, we decided to create a mapping such that every standard would belong to exactly one LT, each targeting a key "big idea" or set of related big ideas. The CCSS-M document itself does not suggest an instructional sequence or rigid ordering of the Standards beyond specifying grade level, as the authors have stated: "These Standards do not dictate curriculum or teaching methods" (CCSSO, 2010, p. 3). Therefore, we reorganized standards within a trajectory if this would show the student learning development more clearly (while keeping the grade level position of standards and topics). Thus, sequencing within grade was malleable; we adjusted it to fit the learning trajectories structure (hence the numbering of the standards can be "out of order" within a grade). We also assisted readers in seeing the internal structure of and the relations among the learning trajectories by (a) creating sections to reveal underlying development, (b) providing structural overviews, and (c) cross-referencing and referencing forward and backward within a LT.

Turnonccmath: by Learning Trajectories

The hexagon map of the CCSS-M, with learning trajectories labeled, is shown at www.turnonccmath.com (Figure 1). The two-dimensional structure of the map lends itself to parallel structures among some learning trajectories, in some cases, to represent close relationships between various big ideas. One of these is the fundamental role played by (1) *counting*, (2) *equipartitioning*, (3) *addition and subtraction*, and (4) *place value and decimals* in developing an early sense of number and operations. These four learning trajectories are situated at the lower left portion of the map. *Counting* is directly tied into *addition and subtraction* and develops in tandem with *place value and decimals*. *Equipartitioning* leads directly to supporting the development of (5) *division and multiplication*, and subsequent rational number reasoning, with contributions from *addition and subtraction*. (6) *Fractions* are most closely related to equipartitioning and division and multiplication, with (7) *ratio and proportion and percents* being most closely tied to division and multiplication and fractions in topic and grade-level development within the CCSS-M. (8) *Rational and irrational numbers* link to *ratio and proportion and percents.*

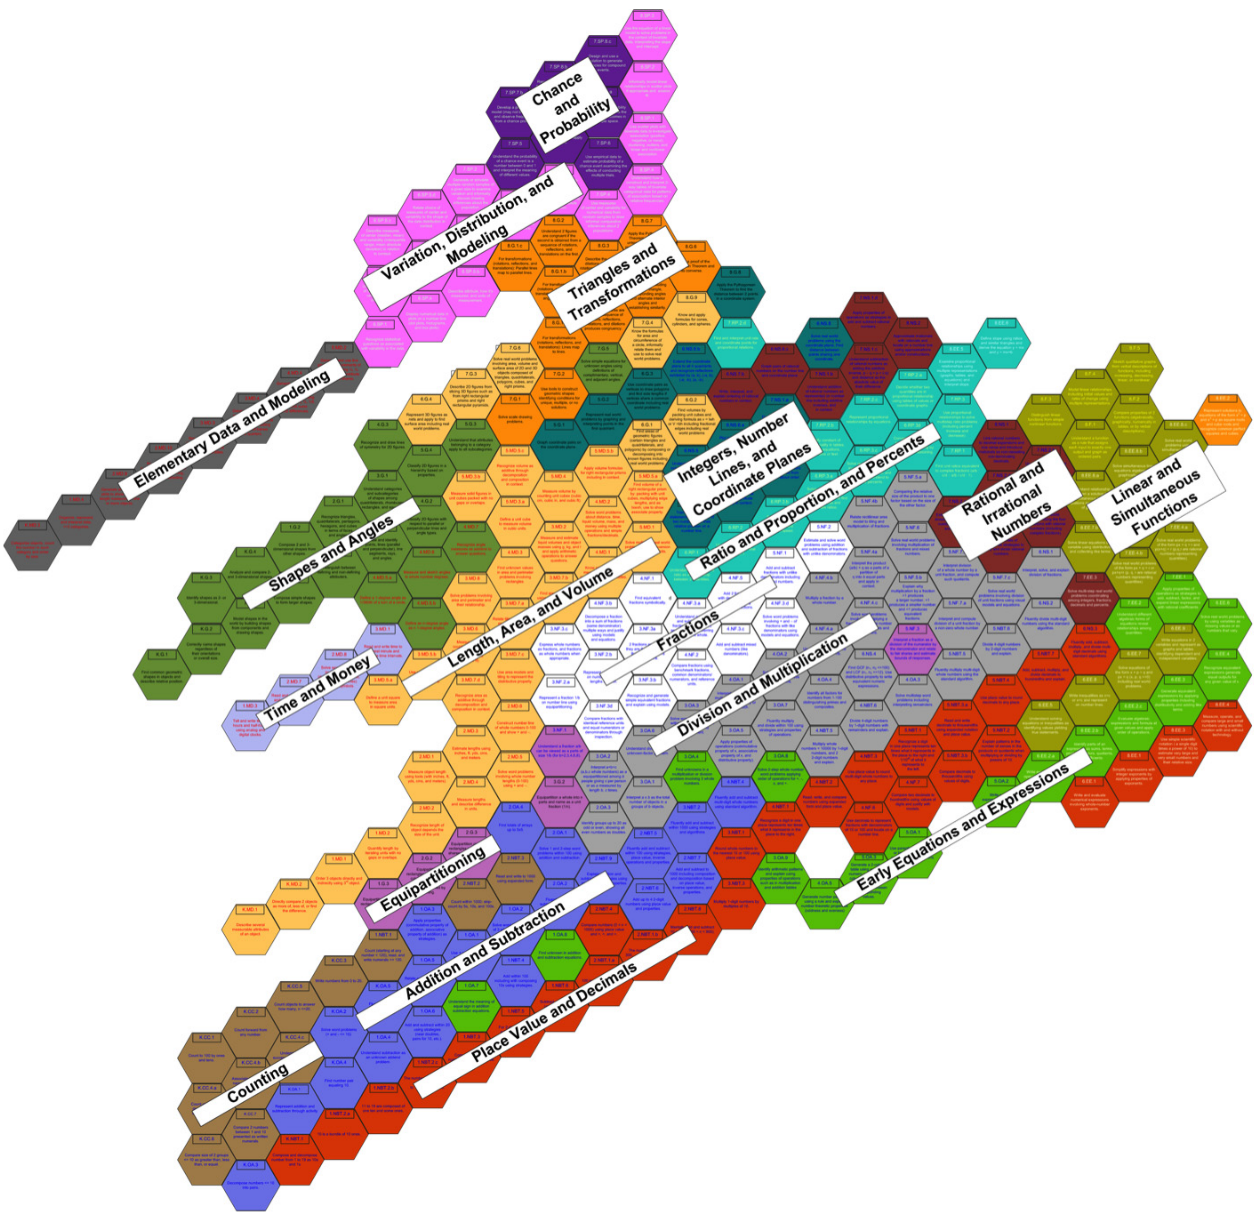

Figure 1. Hexagon Map of K–8 Common Core State Standards for Mathematics with individual learning trajectories color-coded and labeled

The learning trajectory for (9) *length, area and volume* is situated next to equipartitioning in recognition of their close relationship in early reasoning about shapes and measurement, and because they cover a considerable amount of conceptual development in spatial, measurement, and geometrical reasoning. This forms a large anchor LT. (10) *Time and money*, a small early-grades set of topics, is tucked into the left side of the map. The measurement cluster has close links to (11) *shapes and angles*, which carries into (12) *triangles and transformation* as students progress into the middle grades. *Integers, number lines and coordinate planes* (13), a mostly 6th-grade set of topics, are placed close by to support further development of other middle-grades trajectories linking geometry and number systems. The cluster of learning trajectories that comprise data, statistics, and probability—(14) *elementary data and modeling,* (15) *variation, distribution and modeling,* and (16) *chance and probability*—are located along the top of the map, as they were most closely related to each other. The limitations of the two-dimensional space on which the map was constructed prevented us from linking them more closely to measurement and ratio reasoning.

Further upwards and to the right are the more complex topics of (17) *early equations and expressions,* which are built on the four operations and which link to (18) *linear and simultaneous functions* to create a foundation for algebra in the 9–12 Standards.

A Framework for Unpacking Learning Trajectories

When one hovers the cursor over a hexagon on the hexagon map of www.turnonccmath.com, the full Standard is presented verbatim in a box in the bottom left corner. If one clicks on a hexagon or learning trajectory, a new window with the descriptors for the selected learning trajectory appears. The descriptors are organized as follows: A "Structural Overview" is presented at the beginning of each LT, identifying the sections of the LT and showing its development across the relevant grades. Sections are then used to create a sub-organization of the learning trajectory. In addition, a framework of five elements was created to systematize the unpacking of the each trajectory:

1. *Conceptual principles*: These are a list of underlying cognitive principles, identified by researchers, which support the overall development of the ideas.
2. *Strategies, representations, and misconceptions:* When students encounter new tasks that are presented as a cognitive challenge, they invent strategies and representations as they solve them, demonstrating their ways of thinking and, often, revealing related misconceptions that need to be addressed instructionally. Because misconceptions typically have a kernel of "right thinking" (Confrey, 1990), these thoughts must be elicited and then refined into alternative conceptions or valid intermediate steps on paths to more sophisticated thinking.
3. *Meaningful distinctions and multiple models:* All educators recognize the value of prior knowledge and the importance of identifying clear targets for learning. A major challenge, however, lies in identifying and evaluating intermediate states of proficiency and understanding their role in moving students forward in their thinking. To describe these intermediate states, teacher and researchers must recognize or invent meaningful distinctions; vocabulary terms for these tend to exhibit properties that are both cognitive and mathematical, such as partitive vs. quotative division, which later simply collapse to "division." We refer to these as "meaningful distinctions." In addition, for "big ideas"—also described as a learning trajectory's "domain goal of understanding"—there are often multiple earlier models that correspond to the different schemes that govern recognition of situations in the real world. These big ideas are typically captured as a "generalization" that, while "encapsulating" their meanings in the minds of experts, hides or loses the details of the distinctions and models, so students should be afforded sufficient opportunity to explore the distinctions and models *before* they move to the generalization, in order to understand its many referents and applications.
4. *Coherent structure:* In a learning trajectory, a pattern often emerges in how a topic is developed; commonly, that pattern is repeated as the students expand it at later grades and apply it to increasingly complex cases, representations, tools, choices of numeric values, or spatial

dimensions. For example, students' understanding of area is expanded as the lengths of the sides take on fractional values. Understanding such structure, and considering which parts of it remain invariant and which change under these expansions, is a characteristic of mathematical reasoning.

5. *Bridging standards*: Moving from "abridged" learning trajectories represented in the CCSS-M to more fully-articulated, "unabridged" standards requires the addition of "bridging standards" that might not have represented major intellectual targets within the CCSS-M but which may nonetheless be necessary to support a successful progression of learning for students. Based on our structural analysis, we sometimes found gaps or inconsistencies in the Standards. In these cases we also added bridging standards. The bridging standards are identified by their use of a capital letter (A, B, C, …) at the end of the standard number, and the use of brown font. Each bridging standard includes an explanation for its addition to the descriptors document.

A question can be raised about the relationship of the eight mathematical practices to our learning trajectories analysis of the CCSS-M. We do not address the practices directly in the analysis, although the practices are critical elements of the curricular instantiations of the CCSS-M. First of all, we emphasize that a learning trajectories analysis is not a curricular analysis, although one can conduct analysis of curricula using the learning trajectory construct (Nguyen & Confrey, in press) by considering the learning trajectory as a boundary object (Confrey & Maloney, in press; Star & Griesemer, 1989). Furthermore, as students progress along a learning trajectory, they will employ the various mathematical practices, such as applying repeated reasoning, and using precision, articulating arguments, or building or critiquing new modeling.

An Example: The Division and Multiplication LT

Data on large-scale assessment show weakness in U.S. student knowledge and understanding of division and multiplication (NAEP, 2009). Furthermore, division and multiplication are topics around which there is considerable research. Fischbein et al. (1985) introduced the idea of primitive schemes for division and multiplication, claiming two for division (partitive and quotative) and only one for multiplication. Partitive division was linked to schemes based on dealing (usually to obtain the size of a share or group) while quotative division, later commonly referred to as "measurement division" (Simon, 1993), was linked to repeated subtraction or addition, in an iterative manner.

Elaborating further on how children learn multiplication, many researchers (Kamii, 1985; Steffe & Cobb, 1998) describe a process of accumulating equal-sized groups by describing how children learn to coordinate the process of differentiating the roles of numbering the groups and naming the group size. In doing so, they derive multiplicative structures from additive ones. They describe a gradual process of skip counting, double counting, and eventual description as a product, *ab*, comprised of a number of groups, *a*, of a particular size *b*. Because multiplication then is comprised of two elements, group size and number of groups, these researchers tend to follow Fischbein et al. (1985), in recognizing the two types of division, one focused on finding the size of the group (partitive) and the other the number of groups (quotative).

Other researchers categorize word problem types in multiplication or division (e.g., equal groups, rates, comparison, Cartesian products, scaling, etc. undertaken by scholars such as Nesher (1980, 1988, 1992), and Carpenter, Fennema, and Romberg (1993). These scholars have a tendency to associate multiplication with a certain set of problems and each type of division with other sets of problems. For example, equal groups problems are associated with multiplication, fair sharing problems are associated with partitive division, and measurement problems (e.g., How many 3 inch ribbons are there in a ribbon that is 36 inches long?) with quotative division. It is preferable, in our opinion, to distinguish among the questions asked (e.g., the size of a group or fair share and the number of groups or the number of shares) and to associate these questions, and not problem categorizations, with the processes students use to solve a problem. One advantage is that this leaves open the possibility of students using other approaches (e.g., co-splitting (Corley, Confrey, & Nguyen, 2012), or the use of arrays or area models models (Battista, Clements, Arnoff, Battista, & Borrow, 1998; Outhred & Mitchelmore, 2000). Researchers who rely on categorization schemes (CGI, others) tend to focus on these as applications of operations rather than to go further to use them to define the underlying cognitive schemes (Carpenter & Fennema, 1992).

A contrasting trend in research was introduced by Vergnaud in his work on multiplicative conceptual fields (MCF) (Vergnaud, 1983, 1988), when he articulated the relations among ratio and proportion and multiplication and division. The MCF, he argued, consisted "of all situations that can be analyzed as simple or multiple proportion problems and for which one usually needs to multiply or divide" (Vergnaud, 1988, p. 141). He connected the many parts of the MCF to a four part relationship (visually, a two-by-two arrangement) among quantities in which movement horizontally was described as a functional, demonstrating a direct variation relationship between two quantities (i.e., $f(x) = ax$) and vertical movement was referred to as an "*isomorphism of measures.*"

In a related vein, in 1988, I articulated my splitting conjecture (Confrey, 1988), arguing that multiplication and division could be linked to ratio and proportion as derived from an early application of an operation I labeled *splitting,* and subsequently also labeled *equipartitioning*. In a three-year teaching experiment of children in 3rd–5th grade, I demonstrated the advantages to student learning of co-defining multiplication, division, and ratio (Confrey & Scarano, 1995) and showed the effects of teaching fractions as expressing a particular subset of ratio relations.

Data suggest that, contrary to most textbook sequencing, equipartitioning and partitive division are understood at an early age (Bell, Fischbein, & Greer, 1984; Confrey et al., 2009; Confrey & Scarano, 1995). Moreover, approaching division and multiplication through early experience with ratio has been supported by research on protoratio (Noelting, 1980a; Noelting, 1980b; Resnick & Singer, 1993), on splitting (Confrey, 1988; Confrey & Scarano, 1995), and on distribution (Streefland, 1984, 1991).

Schwartz (1988) distinguished between referent-transforming and referent-preserving operations, suggesting that additive structures are referent-preserving (preserves the referent unit, e g., 4 apples plus 3 apples equals 7 apples) while multiplicative ones are referent-transforming (does not preserve the referent unit, e.g., 20 coins shared among (divided) 5 people results in 4 coins per person). He also introduced the distinction between extensive quantities (magnitude) and intensive quantities (indirectly measured as composed from other quantities). However, I argue that multiplication can also be referent-preserving when only the particular unit changes (e.g., in the case of measurement conversion, the use of groups, or scaling).

This second set of approaches deemphasize the role of addition and subtraction in the construction of division and multiplication. Instead I view division and multiplication as related operations describing the same situations in reverse. The two operations are interlocked in a four-part relationship that can be described by ratio relations. For example, in the "division problem" 20 coins shared among 5 people results in 4 coins per person, the ratio relationship is 20 coins : 5 people :: 4 coins : 1 person. Multiplication can be used to describe the movement from 4 coins to 20 coins and 1 person to 5 people and division can be used to describe the reverse movement. Because they rely on ratios, this treatment of division and multiplication is necessarily related to the use of two distinct quantities: the case of referent-preserving division and multiplication is cast as the reduced case where groups, unit-changes, or a scalar are introduced. These approaches also tend to support the extension of the operations to non-whole numbers, and more intuitively anticipate the operator construct of rational numbers (Behr, Harel, Post, & Lesh, 1994), which I locate in this trajectory.

Both generalized approaches recognize the use of division and multiplication in area measurement and find ways to incorporate it. In the first approach through counting and additive structures, arrays can be viewed as a transitional tool. If the groups are lined up in columns and placed side by side, then the resulting array can be viewed as representing both the number of groups (rows) and the size of the groups (columns). Proceeding from the discrete case to the continuous case can still support a definition of the multiplication operation in terms of the number of groups and their sizes. The integrated approach also uses area problems but does so through the application of scaling operations from the single unit on the lengths of the sides of a rectangle, and subsequently on the area of the resulting rectangular figure.

In deciding how to approach the learning trajectory, I sought ways to:

1) combine the strengths of both models, while emphasizing importance of multiplicative structures;
2) build from what the children already knew from the related learning trajectories of equipartitioning, length, area and volume, and addition and subtraction;
3) ensure the approaches were sensitive to the variety of situations connected to division and multiplication; and
4) anticipate how sufficient the models would be as the numeric values in the problems changed from whole numbers to non-whole rational numbers.

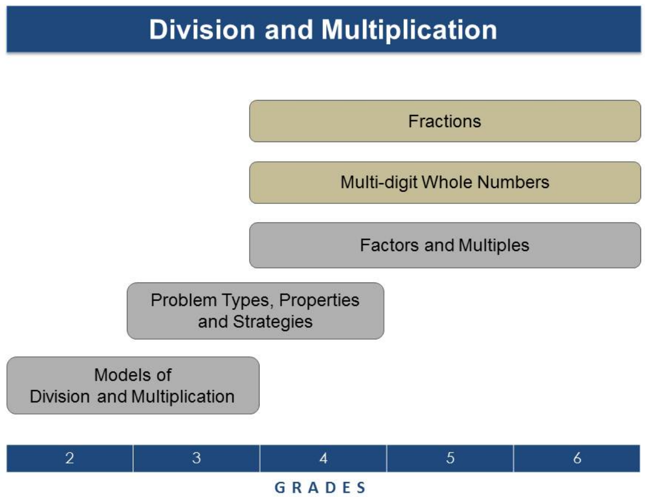

Figure 2. Structural Overview diagram for Division and Multiplication learning trajectory

Framework for Learning Trajectories, Applied to the Division and Multiplication LT

The Structural Overview of the learning trajectory is shown above (Figure 2) whereby one can see that the LT stretches from second through sixth grade. Students develop three models and then apply them to a variety of problem types. As they become fluent in the number facts, they learn about factors and multiples and then extend their knowledge to more complex cases. In the following sections, a window into the structure of the division and multiplication learning trajectory (DMLT) is provided using the five-element framework described previously.

The Target of the Learning Trajectory for Division and Multiplication

Learning trajectories always incorporate assumptions about what students have experienced and know, and what the target of that learning should be at the upper end of the trajectory. The primary target of the DMLT is for students to understand the relationships captured in the equation: $ac/bd \div a/b = c/d$. As explained below, these relationships can be understood either as they reside in a ratio box or in relation to two-dimensional area relations (which can later be extended to higher dimensions).

Ratio boxes relate two quantities such that the relationship is preserved across multiplicative changes to both quantities. All but elementary uses of the ratio box for fair sharing explicitly show the preservation of the ratio across multiplicative changes by using two pairs of "arrows," one which shows the multiplicative or divisional operation that relates the two sets of numbers vertically and showing the other relationship horizontally (Confrey, 1995). Noelting refers to these as, respectively, "between" and "within ratio relations (Noelting, 1980a, 1980b). Characteristic of a ratio box is that the pairs of opposite arrows are identical.

The DMLT can be summarized as an evolving sequence of types of ratio boxes and area models. Those ratio boxes start with a "fair sharing box," and proceed to a division/multiplication box (D/M box) to complete the DMLT. In the ratio and proportion and percents LT, the boxes evolve into a fully developed ratio box. Figure 3, below, illustrates the fully developed ratio box. Given any three values students find a fourth unknown value of the proportion, and describe the relationships represented by the operator arrows, either as shown here as multiplication, or its inverse, division (not shown).

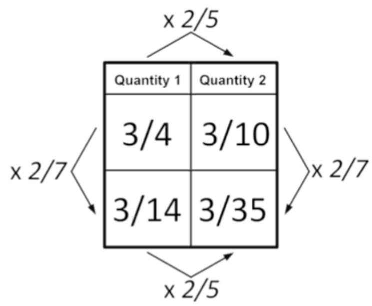

Figure 3: A ratio box solution, with multiplication shown

The DMLT begins from a "reduced ratio box" known as a fair-sharing box in the equipartitioning LT (EQLT). Second-graders can fill in the column headers and the two rows when sharing, for example when fair-sharing 12 coins among 3 people, they fill in 12 and 3 in the top row, and 4 and 1 in the bottom row (Figure 4a). Also based on the EQLT, they express the sizes of upper row numbers relative to lower row numbers as "*b times as many*." At this young age and lacking any formal introduction to multiplication or division, children are not expected to use the arrow notation. For the EQLT, the final target goal can be expressed in a ratio box (Figure 4b) corresponding to Standard 5.NF.3 ("Interpret a fraction as division of the numerator by the denominator ($a/b = a \div b$). Solve word problems involving division of whole numbers leading to answers in the form of fractions or mixed numbers, e.g., by using visual fraction models or equations to represent the problem").

Number of coins	Number of persons
12	3
4	1

Figure 4a: Fair share box for equipartitioning a collection of 12 coins

Number of coins	Number of persons
a	b
a/b	1

Figure 4b: Generalized fair share box for equipartitioning collections

Building from the fair sharing box, the first target for the DMLT is a slightly more sophisticated reduced ratio box called a "division/multiplication box" (D/M box). The D/M box (Figure 5a) also has a 1 in the lower right corner because in the four-part relations for MCF, for division and multiplication, one cell is equal to 1. For example, in the problem "at a tire shop, six cars are getting their 4 tires changed. How many tires are needed?," the final D/M box would have two columns—one for the number of tires and one for the number of cars—and show 24 tires associated with six cars and 4 tires with *one* car. The number facts, $6 \times 4 = 24$, $24 \div 6 = 4$, and $24 \div 4 = 6$, do not show the *one*. At first, the use of the D/M box can be constrained to whole numbers only. The D/M box differs in two respects from the fair-sharing box. Firstly, it is not restricted to fair-share situations, and secondly, as students learn to work with division and multiplication operations symbolically, they add arrows to define the relationships (operators) explicitly. The associated area model, can also initially use whole numbers (Figure 5b).[4]

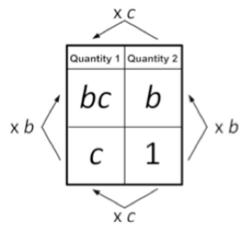

Figure 5a: D/M box adapted for whole-number multiplication

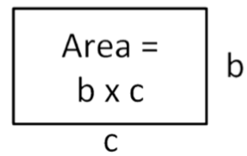

Figure 5b: Whole-number multiplication model for the area of a rectangle

In order to understand the D/M box and the rectangle area model, students describe and work with all three related equations of $a \times b = ab$, $ab \div$ b = a and $ab \div$ a = b. These intermediate goals are presented here in symbolic form for brevity, for the benefit of experts; students, however, are expected to understand where they come from, explain and represent them, relate them to prior and related knowledge with justifications, and apply them to solve a rich variety of problems. In addition to correctly producing their answers, students are expected to be able to move about flexibly and fluently in multiplicative space using factors, including primes and multiples, and recognize, discover, and use the relevant properties and practices.

The final target for the DMLT is a D/M box showing division, multiplication, and a rectangular area model (Figures 6a, b, c) where the non-one values in the cells can be any rational numbers. The DMLT can be understood now as poised between (a) equipartitioning, and (b) ratio and percent. As will also be shown, it draws on elements of other LTs on the length, area and volume, addition and subtraction, and place value and decimals.

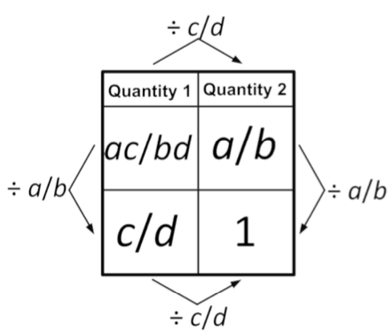

Figure 6a. D/M box (division)

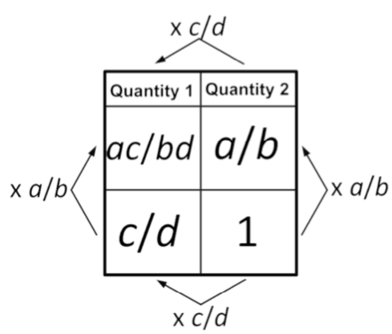

Figure 6b. D/M box (multiplication)

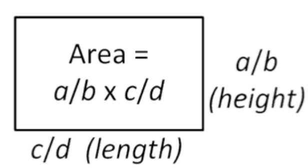

Figure 6c. Area model

Also, later in the length, area, and volume LT, the product can include more than two dimensions (essential for the associative property), so that one can explain volume as $v = l \times w \times h$, or as v = area $\times\, h$, and one can increase dimensionality as required for modeling multiplication in higher dimensions that lack obvious spatial analogues. This set of related learning trajectories: equipartitioning, division and multiplication, ratio and proportion and percents, and length, area and volume, together with similarity (within the triangles and transformations LT), comprise the majority of the content that resides in the multiplicative structures.

It is important to understand as fully as possible the target or domain goal understanding for a learning trajectory, because while it often cannot be directly taught, it must be reached as the product of a careful series of transformations based on empirical study of student learning. By delineating it carefully, one can distinguish intermediate states that are productive from ones which will limit students' chances of obtaining a full and nuanced perspective.

Distinctions and Models

A synthesis of the literature yields three fundamental *models* for the joint operations of division/multiplication, each of which generate both division and multiplication contexts. These are (a) referent-transforming, (b) referent-preserving, and (c) referent-composing models. These three models are necessary to sufficiently link division and multiplication to its related trajectories, from equipartitioning and addition/subtraction to ratio and proportions and percent, fractions, chance and probability, and length, area, and volume, and to support mathematical modeling. The three models are described below:

a) *Referent-Transforming.* Division/multiplication in these models involves changes in the attributes or referents connected with the quantities, or action on a quantity of one attribute or referent by a quantity of another attribute or referent. For instance, in fair sharing, coins are shared among people to produce coins per person (Figure 7). Rate problems also fit in this category. In relation to the D/M Box, the student sees $6 \times 3 = 18$ as shifting from 6 people to 18 coins by means of a multiplication by 3 coins per person, which transforms the referent using an intensive quantity as an operator. There are two associated division problems for fair sharing $18 \div 6 = 3$ and $18 \div 3 = 6$, each of which is referent-transforming. Students are likely to solve the first one partitively and the second quotatively.

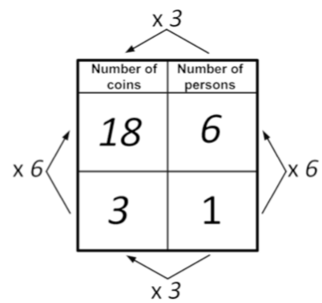

Figure 7. D/M box used to model referent-transforming multiplication

b) *Referent-Preserving*. Division/multiplication in these models involves a multiplicative comparison of two amounts of a single quantity. This can be accomplished using a new unit, a composite unit such as a group or a scale, or by using one amount to measure another while the referent or attribute is maintained. For example, if one is told that the distance from New York to Kansas City is six times the distance from New York to Baltimore (approximately 200 miles), the D/M box would look like Figure 8a:

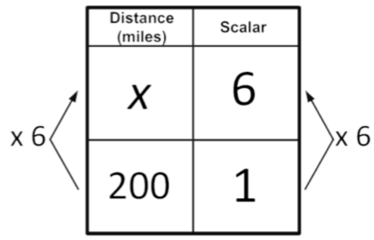

Figure 8a: Referent-preserving multiplication problem modeled with a D/M box

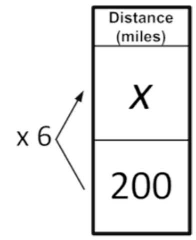

Figure 8b: The same D/M box with arrow indicating the scalar

The scale in the right-hand column is, by most accounts, unit-less, but the right column is used to establish the vertical arrow, or the "within" or referent-preserving relation, "multiply by 6." Thus to solve this problem, one maps miles to miles, multiplying by the dimensionless scalar 6, to get 1200 miles. Because the left-hand column with the scalar multiplication is sufficient to solve the problem, a two-by-one display of this relationship is sufficient as shown in Figure 8b. Likewise we suggest that problems involving groups and measurement conversions can and probably should be treated as referent-preserving because only the unit and not the referent changes.

We note that because the D/M box always has a 1 in one cell, collapsing it to a 2×1 box or a 1×2 box is always possible because the operator arrows will "carry" the information from the non-one cell as illustrated in figure 8b. These collapsed views permit one to assert a single model for division/multiplication; a drawback of this curtailment, if done too early, conceals some of the richness of the relational reasoning.

c) *Referent-Composing.* Division/multiplication in these problems involves the creation of a new referent or attribute not previously associated with the other quantities. For example, the division/multiplication associated with area produces square inches from side lengths in inches. In Cartesian products, a number of shirts and a number of pants produce a number of outfits, and so on. Volume as a product of three length measures or as a product of length and area, and higher dimensions also fit in this category. Arrays can form a transitional representation linking referent-preserving and referent-creating, such that the product can be computed by multiplication of the number of dots in each of the two sides, but the product remains a number of dots so no new referent is composed. The row and column structure, while geometrically extending in two dimensions (length and width) still produces a product that is a total number of dots.

These three models of division and multiplication can be summarized as shown in Table 1 along with examples of problem contexts associated with each model.

Table 1. Three Models of Division/Multiplication, Along with Common Contexts for Each

Model 1: Referent-Transforming	Model 2: Referent-Preserving	Model 3: Referent-Composing
Fair Sharing	Unit Conversion	Arrays
Rate	Scaling	Area
Equal-sized Groups		Cartesian Product

Note the placement of the equal-sized groups context, in which one reasons with the number of groups, the size of the group; the resulting product is placed in both models 1 and 2. A problem such as "a bookshelf has four shelves with six books on each, how many books are there?" can be viewed as referent-transforming (number of books per shelf × number of shelves = number of books) or as referent-preserving (4 groups of 6 books).

As a result of this analysis, the team recognized that the transition to division and multiplication needed to be broadened and strengthened. We analyzed the experiences of children that would support these varied models, especially in the earlier trajectories of equipartitioning and addition/subtraction. The expectation for the DMLT was that students would encounter the models as simple whole-number cases until they built up their repertoire, became fluent and flexible in their knowledge of the associated facts, and explored the properties. As the numbers became larger, the algorithms would be developed. Though not fully developed in this paper, students' introduction to non-whole quantities in the LT division and multiplication involves reconceptualizing meanings based on their understanding of relational naming (describing 12 shared among 4 as 1/4 of the collection) and reassembly from EQLT. Over time, students generalize across the various number types, models and applications as division/multiplication more abstractly. However, by avoiding overgeneralizing and simplifying to one single model, students should remain flexible in selecting appropriate models for division and multiplication in modeling activities.

Bridging Standards

From EQLT, children enter third grade with experience in fair sharing, relational naming, and composition of splits, all of which can support their movement to division/multiplication. Composition of splits refers to children splitting a split (such as a rectangle into two parts vertically and three parts horizontally) and learning to predict six (2 × 3) instead of five (2 + 3) resulting parts. The addition and subtraction LT also links to DMLT through a standard on the array structure and repeated addition. The length, area, and volume LT also contributes to students' conceptions of division and multiplication, and the relevant commutative and distributive properties with such activities as finding a common unit for area measurement and composing and decomposing rectangular areas. Nonetheless, a set of bridging standards were needed—first, to make the necessary connections to these earlier learning trajectories, and secondly, to interpret the meaning of the standards in light of our targets and distinctions.

There are four Standards in CCSS-M that specifically carry the weight of introducing division and multiplication:

- 3.OA.1: "Interpret products of whole numbers";
- 3.OA.2: "Interpret whole-number quotients of whole numbers";
- 3.OA.3: "Use multiplication and division within 100 to solve word problems in situations involving equal groups, arrays, and measurement quantities, e.g., by using drawings and equations with a symbol for the unknown number to represent the problem"; and
- 3.OA.6: "Understand division as an unknown-factor problem."

(Note: 3.OA.4 is placed in elementary algebra because it involves solving for an unknown in any position in $a \times b = c$; 3.OA.5 (concerned with properties) and 3.OA.7 (concerned with fluency) are placed in the next section of the DMLT.)

While these four standards are sufficient to support the distinctions offered above, they are awkward to interpret standard by standard: three of them are required to introduce and link multiplication and division (3.OA.1, 2,and 6), and the examples mentioned along with the first two in the CCSS-M document seem to imply that a problem type is linked to an operation (groups to multiplication and fair sharing to division). Furthermore, 3.OA.3 seems to imply that the problem situations are used to apply the operations rather than that the operations are developed to model the situations. This bias seems to be pervasive in the K–8 Standards.

However, what appears to be awkwardness in the Standards can be addressed because the examples therein are not intended to limit the cases but only to illustrate them. Therefore in our interpretations, we explain the three cases of multiplication (referent-transforming, referent-preserving and referent-composing), then treat division similarly, using Standard 3.OA.6 to link the operations. While the model remains referent-transforming, the observed processes for the division problems may appear as partitive or quotative.

Standard 3.OA.3 provides an opportunity to summarize the entire framework with descriptions of the overall D/M box for whole numbers and the area model. In preparation for Standard 3.OA.3, three bridging standards were required for the model for referent-composing D/M. The bridging standard 3.OA.F ("Students reason with arrays using multiplicative relationships") was added to provide students opportunities to work multiplicatively with arrays. This was necessary because the standard authors had restricted the approach to arrays in second grade to repeated addition (2.OA.4: "Use addition to find the total number of objects arranged in rectangular arrays with up to 5 rows and up to 5 columns; write an equation to express the total as a sum of equal addends"). This constraint ruled out other approaches such as by decomposing and composing arrays into other equivalent arrangements (for instance, rearranging a 6 × 4 array as a 12 × 2 or a 24 × 1), or using skip counting.

Building on a bridging standard from the EQLT (2.G.C: "Equipartition a rectangle using vertical and horizontal cuts and predict the resulting number of parts."), another bridging standard, 3.OA.D ("Students learn to code composition of splits as multiplication and can state the associated division problem"), supports students in coding compositions of splits as multiplication and division. From the length, area and volume LT, the standard 3.MD.7.b ("Multiply side lengths to find areas of rectangles with whole-number side lengths in the context of solving real world and mathematical problems, and represent whole-number products as rectangular areas in mathematical reasoning"), links to the emerging DMLT. To complete the idea of referent composition then for both area and for pairing of attributes to create Cartesian products, bridging standard 3.OA.B was added, stating "Relate multiplication and division problems to rectangular area (e.g., 3 inches × 4 inches = 12 square inches) and Cartesian products (e.g., 3 pants × 2 shirts = 6 possible outfits)."

With this set of three bridging standards carefully linked to the four CCSS-M Standards, third grade students who accomplish the related content should be able to apply all three models to situations to produce both division and multiplication problems and solve for unknowns in all of the three positions of the problem in standard 3.OA.3. Well-prepared with three models, students can be carefully introduced to the cases in which non-whole numbers are involved, topics that are discussed more fully on the website. As argued previously, this approach is also powerful because it builds explicitly from prior learning trajectories and anticipates later ones.

Strategies, Representations, and Misconceptions

The previous section on distinctions and models supports students in creating a rich variety of representations for multiplication and division (groups, tree diagrams, measures, scaled drawings, and Cartesian products shown as two dimensional cross products). A second important area of development involves how children learn their "multiplication and division facts." Confrey and Scarano (1995) had demonstrated that children are not given adequate support to "move in multiplicative space." Most teachers assume that multiplication should be introduced separately from division and that learning number facts should proceed in the same order as addition facts, from small to large numbers. Instead, the LT research shows how many forms of interrelationships among and between multiplication facts can be fostered by teaching children rich strategies that build on early understanding of numbers. For example, instead of teaching multiplication facts in the order of the counting numbers (i.e., ×1, ×2, ×3, etc.), Confrey showed that a sequence of double (×2), double-double (×4), double-double-double (×8), then multiplying by 10 and then by 5 (×10 ÷2), then tripling (×3), multiplying by 6, (triple-double, or ×3 ×2), and by 9 (triple-triple), and then, finally, by 7, is more readily understood by students, and makes more sense to them. (The related division facts are practiced simultaneously with multiplication facts in this sequence.) Instead of viewing multiplication facts as simply a list of things to be memorized, students begin to get a foundation of the multiplicative relationships among numbers—what I have previously called "moving around in multiplicative space" (Confrey, 1995).

Two misconceptions are addressed in the DMLT. An early standard in the LT regards the idea of "evenness" (as contrasted with "oddness"), and the descriptors carefully articulate two approaches, (1) fair sharing by two, and (2) pairing up. In addition, the descriptors warn that students use the term "even" to describe when a collection can be fairly or evenly shared, for example, in the sentence, "It came out even." The descriptors discuss how the term "even" therefore can be used simultaneously by students in two conflicting ways, (1) to describe when a factor divides evenly—then the result is even (so that six shared among two is three which is "even" or fair), and (2) to describe that when a number is "even," i.e., is divisible by two. The two meanings must be distinguished by students, so they avoid or resolve a "misconception." This is a prime example in which we wrote into the descriptors an important distinction that we believe many teachers would not readily recognize and discuss with their students.

The second, more widely recognized, misconception is "multiplication makes bigger and division makes smaller" (MMBDMS) (Greer, 1992). The CCSS-M address this misconception directly in 5.NF.5.b ("Explaining why multiplying a given number by a fraction greater than 1 results in a product greater than the given number (recognizing multiplication by whole numbers greater than 1 as a familiar case); explaining why multiplying a given number by a fraction less than 1 results in a product smaller than the given number; and relating the principle of fraction equivalence $a/b = (n \times a)/(n \times b)$ to the effect of multiplying a/b by 1").

In the DMLT, the misconception is addressed in relation to each of the three models. In the unit transforming model, the descriptors illustrate that any two numbers can be related in an equation, such as rate × time = distance, so that 30 mph can be multiplied by a half hour to produce 15 (i.e., fewer) miles. Students also learn to interpret division of two quantities, in the form a/b and c/d, as a ratio of fractions or ratios ($3/4 \div 1/2 = 3/2$). This example demonstrates that division can result in a larger quantity than the quantity one begins with. In referent-preserving situations, division by n is shown to be equivalent to multiplication by $1/n$, with students learning to predict the effects of multiplication by a/b as a composition of multiplication and division, just as was done originally in Dienes's work on operators (e.g., stretchers and shrinkers) (Dienes, 1967). Finally, for contexts using the area model, students learn that area measured in square units can be of a smaller magnitude than the magnitudes of either of the sides.

Conceptual Principles

The development of conceptual principles in the DMLT can revolve first around the ideas of factors and multiples. Overreliance on multiplication as exclusively derived from repeated addition leaves students insensitive to the distinctions between additive and multiplicative reasoning. As noted above most students are not given enough experience moving in multiplicative space. In the descriptors, we also offer the view that students should be challenged to find multiple ways using only multiplication and division to move among numbers, such as between 15 and 24 (dividing by 5 and multiplying by 8). I called these types of problems "daisy chains" in earlier work (Confrey & Scarano, 1995). This encourages students to work with common factors. In addition, it helps students to develop knowledge of the principles of multiplication by 1 (identity), multiplication by zero, the commutative property of multiplication, the associative property of multiplication, and, later, multiplicative inverses. It can also lead to students recognizing rational number multiplication and division. In the DMLT, we also treat distributivity very carefully and explicitly, as it is the means by which the additive structures are linked to the multiplicative structures.

Coherent Structure

The coherence of the DMLT's structure can now be summarized. The LT builds from the prior LTs of (a) equipartitioning; (b) length, area, and volume; and (c) addition and subtraction to establish the three models applied to whole numbers. The interrelationships among the ideas of factors and the patterns in the multiplicative table are used to support the evolution of the properties and draw connections to multiplicative vs. additive comparison. Then at the upper end of the LT, two types of extensions occur: the application of the problems to multidigit algorithms using the distributive property, and the inclusion of fractions and ratios as operators. These extensions are carefully constructed in the context of the three underlying models. The extensions to fractional operators are also connected to the learning trajectory on length, area and volume where the MMBDMS misconception can be most readily remediated.

Overall the LT is designed to set up the movement to ratio reasoning through connections to the two Standards on tables of values, 4.MD.1 on conversions and 5.OA.3 on tables of values. Finally, students are prepared for the culmination of equipartitioning in the fifth grade standard (5.NF.3: "Interpret a fraction as division of the numerator by the denominator ($a/b = a \div b$). Solve word problems involving division of whole numbers leading to answers in the form of fractions or mixed numbers, e.g., by using visual fraction models or equations to represent the problem"). The target goal of the LT is reached in a set of Standards that include 6.NS.1 ("Interpret and compute quotients of fractions, and solve word problems involving division of fractions by fractions, e.g., by using visual fraction models and equations to represent the problem"), and 7.RP.1 ("Compute unit rates associated with ratios of fractions, including ratios of lengths, areas and other quantities measured in like or different units").

With this example of how an LT is related to the standards, one can see that the process of linking an LT to standards requires careful and synthetic applications of empirical research literature. The overall framework for multiplication and division is thin in the early grades and tends to overemphasize a relationship to additive structures, resulting in an underdeveloped framework for multiplicative structures. We have attempted to articulate a stronger framework for a stronger multiplicative structures approach by adding a few key bridging standards within the learning trajectory which link to equipartitioning and help to explain how multiple models of division and multiplication can be supported in classroom instruction. The authors of the CCSS-M left room for such interpretations by avoiding the mistake of *defining* multiplication as repeated addition (which had been included in early drafts of the CCSS-M). The learning trajectory also makes the case for both strong distinction among the strategies, and strong relationships among the models, strategies, and associated properties.

Implications for Researchers and Professional Developers

The www.turnonccmath.com website was visited more than 7000 times between its release in April 2012 and late May 2012. The primary visitors have been state and district personnel and teachers looking for a means to make sense of and make instructional interpretations from the CCSS-M. Some found the website on their own while others have found it as a result of presentations and mailings. We are currently in the process of improving the site in several ways. We are adding in the relevant references to research that we were unable to do in the first round due to the pressures of time and the focus on creating coherence and consistency in the descriptors; as one can imagine, this has been hard work. We are also preparing to undertake an expert review process, similar to the process we conducted for vetting the LT on length, area and volume with the researchers from the Measurement Mini-Center.

We are also committed to working with districts and states using the LTs and their descriptors as a basis for professional development. These efforts include both pre-service and in-service teachers. We have worked with Colorado, West Virginia, North Carolina, and Washington, and have received requests from other states. In this work, it becomes clear that the foundation of knowledge in the unpacking is not on its own sufficient to support professional development; the examples in this paper make it clear that the written descriptors by themselves can serve as an important part of efforts to help teachers understand the mathematical knowledge embedded in the trajectories and to translate them into robust learning trajectory-based classroom practice.

There are numerous opportunities for college and university faculty and state and district mathematics coordinators to use these materials to support professional development. We have engaged in creating digital presentations to show, in a more visual and story-based way, how the LTs are linked to the standards. One could imagine building webinars and course materials to provide hands-on experiences for teachers with these ideas as well, assuming sufficient available resources. Some of the teams developing the original LTs have already created related professional development materials that can be used in creating a nationwide application of this work.

Perhaps even more relevant to the PME-NA audience is the potential professional value of the website to the research community. To some degree, the influence of learning trajectories/progressions on the CCSS-M was mitigated by ambiguity, dispute, or lack of synthesis by the research community. While this is not surprising in a field as young as ours, its maturation depends on our willingness to undertake synthesis, and suggests it would be wise to engage in more of this kind of activity. While researchers may wish to "do their own thing" or await some other body to interpret and synthesize the development of the Standards, it would improve our professional reputation as a field if we were to take up this challenge ourselves.

It is often reported that in medicine, prior to the famous Flexner report (Flexner, 1910), physicians received education in general basic science and then apprenticed to a working physician until they were ready to establish their own practice. If that mentor was a strong and knowledgeable role model, the apprentice was likely to emerge as a well-qualified and very competent physician as well. If not, another "quack" might be added to the rolls. After the Flexner report, the medical field stepped up to create a practitioner-informed practice-oriented knowledge base for "clinical training" of physicians and to standardize medical education. In some ways, we are in a similar predicament in mathematics education research. Someone studying in a strong program, or apprenticing with a strong faculty member, tends to move into teacher education well prepared. Study in a less rigorous program and navigating the literature without any guidance leaves one tasked with "inventing" a deep understanding of the literature: the job is highly inefficient, at best, and likely to leave a student poorly prepared to take up highly informed work or to make insightful contributions. Synthesis work is challenging, sometimes grueling, and yet remarkably satisfying. The www.turnonccmath.com website is meant to serve as one contribution to increasing the accessibility, completeness, and consistency of the interpretation of the significant portion of the research base in mathematics education on student learning.

Our research group has been the beneficiary of one of the REESE synthesis grants to bring together a literature on rational number reasoning that consists of some 600 articles. This experience has led us to this synthesis of the LTs work with the CCSS-M. It may be the case that the idea of LTs will fade, just as so many movements in mathematics education do (e.g., metacognition, problem solving, differentiated instruction, active mathematics teaching, and individualized instruction; the list is, sadly, quite long). Many valuable lessons resided in those movements, and for the field to become robust for guiding the conduct of practice, it must create a means for its empirical work to accrue progressively and be refined over time. Such a means would help reduce the frequency with which we see the same studies conducted (e.g., students mistaking the visual path of a function's representation for the behavior of the function has been studied too many times to count), and help to define a cutting edge field where scholars can aim to make progress. All of these suggestions fulfill the vision of the conference organizers for this PME-NA annual meeting to discuss transitions. The bulk of this paper addressed how to create supports for teachers as they transition to the CCSS-M, but the discussions herein also address transitions for professional developers and researchers in the everyday conduct and sharing of our practices.

Endnotes

[1] The author was a member of the National Validation Committee for the Common Core State Standards.

[2] This meeting was jointly hosted by the DELTA research group (directors Confrey and Maloney) and the Consortium for Policy Research in Education (co-sponsors F. Mosher, P. Daro, and T. Corcoran).

[3] The Mini-Center comprises faculty and senior researchers (J. Smith, organizer, J. Confrey, J. Barrett, R. Lehrer, M. Battista, D. Clements, B. Dougherty, D. Heck) and associated postdoctoral researchers and graduate students.

[4] One can also use the D/M box (Figure 5a) to apply to area, if one starts with a unit square and views b as stretching b into a strip of b units, for example, as a strip along the top of Figure 5b. Then if c represents a c × 1 strip vertically along the left edge, then stretching it by b produces bc; and the ratios are preserved. This model seems too abstract and so we prefer to introduce the area model separately.

Acknowledgments

This work was supported by grants from the National Science Foundation (DRL-0758151, DRL-0733272), Qualcomm, and the Oak Foundation. The entire writing team for the website (Kenny Nguyen, KoSze Lee, Andrew Corley, Nicole Panorkou, and Alan Maloney) reviewed this paper and offered valuable contributions.

Students experience a variety of challenges as they move from one level in school to the next. In this session, we consider and discuss two central questions related to students' progressions through their mathematical experience, particularly at transitions roughly characterized as elementary to middle school, middle school to high school, and high school to post-secondary: What are the key dimensions/aspects of such transitions? What kinds of system-level responses address students' issues with transitions, particularly when they are problematic? We discuss research and practice related to students' challenges and the nature of system-level responses to various aspects of these school mathematics transitions, including mathematical content, curriculum, students' dispositions, classroom teaching practices, and school structures. Characteristics of selected strategies and programs are discussed and questions for further research are presented.

If students' motivation to learn mathematics, attitude toward mathematics, and interest in mathematics tends to decline as students progress through levels of education (Middleton & Spanias, 1999), then it is worthwhile to look more closely at how students experience school mathematics over time. Additionally, concerns have been expressed about the shortage of qualified workers for careers in mathematics, science, engineering, and technology (National Science Board [NSB], 2006) and the mathematical demands of informed civic engagement. Although we recognize that there are many fulfilling professional paths outside of STEM fields, it is important to consider how the accumulation of students' school mathematics experiences over time could inform their career choices and their relationships with the discipline of mathematics. If students choose not to engage further in mathematics beyond their required school experience, ideally they would make this choice because they prefer another option, not because their school experiences have taught them that mathematics is an intellectual and practical activity to avoid.

This paper addresses school mathematics articulation in terms of students' experiences as they move through school – from kindergarten through college. The study of students' progressions through levels of education provides insights about what we know and don't know about being a mathematics learner at various points in time in students' lives. We summarize research findings from some select studies to describe some transition issues as students move from (a) elementary school to middle school, (b) middle school to high school, and (c) high school to post-secondary experiences. To provide some conceptual clarity for the study of students' progressions through levels of education, we ask, "What are some of the aspects and dimensions of students' transition experiences as they move through their schooling?" To address this question, we will discuss various conceptualizations of students' transition experiences across school settings, such as: factors in school mathematics settings that can change over time, student-level factors that could indicate variations in their "transition" experiences, and conceptual lenses for viewing these factors (person-environment fit, what counts as a "mathematical transition," boundary-crossing, and rite of passage). We follow this discussion with the question, "What kinds of system-level responses address transition issues?" In response, we describe a few promising system-level responses to describe possible efforts to support students as they progress through mathematics programs over time. Finally, at the end of the paper, we explore promising possibilities for future research on students' transitions.

Van Zoest, L. R., Lo, J.-J., & Kratky, J. L. (Eds.). (2012). *Proceedings of the 34th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* Kalamazoo, MI: Western Michigan University.

Focus on Students' Experiences as They Move through School Settings

One of our premises in this paper is that students' experiences as learners of mathematics as they progress through school are important to understand and support. In addition to learning mathematics content, students are *becoming* mathematics learners as they move through school settings:

> As they [students] are compelled to sit in a mathematics classroom for a significant period of their school life, they come to learn how to participate in that context – they learn when to respond, when to resist, how to appear busy but avoid work. They learn how to cope with the embarrassment, the joy, the cajoling. They learn how the actions in the classroom have meaning and how some of the actions of teachers, texts and students take on substantially different meanings for themselves and others. They learn how to *be* a mathematics student. They develop a sense of who they are as learners within this context, a context which may be very different from other subjects within the school context and beyond the school context. (Boaler, William, & Zevenbergen, 2000, p. 3)

In this manner, we foreground the study of students' identities, as some have argued that "…learning and a sense of identity are inseparable: They are the same phenomenon." (Lave & Wenger, 1991, p. 115). Although our perspective does not equate learning and identity development, we highly value identity development as a significant outcome of students' school mathematics experiences, in addition to learning academic content. As students move through school settings, students develop their beliefs and practices as learners of mathematics and develop affiliations (or not) with the subject matter. Understanding students' experiences as a process of identity development is a way of conceptualizing learning. According to Wenger (1998), learning occurs through participating in communities of practice. Participating involves not only thinking and acting, but also developing increasingly central membership within communities. From this perspective, learning "changes who we are by changing our ability to participate, to belong, to negotiate meaning" (Wenger, 1998, p. 226).

What students learn—the ways students come to participate, come to view themselves, and come to view mathematics—is situated within opportunities to participate, and opportunities to participate are likely to vary as students move across school settings. School settings can be considered to be "facilitating contexts" (Grootenboer & Zevenbergen, 2008, p. 245) in which students have opportunities to develop relationships with mathematics. We recognize that opportunities to participate in school experiences may change as students move from one classroom to another. However, in this paper we focus on changes that can occur between grade bands—moving from elementary school to middle school, middle school to high school, and high school to other post-secondary experiences. An assumption in work on students' school transitions is that there are often more differences in mathematics teaching and learning between school buildings than within them and that these differences have implications for students' experiences.

We acknowledge that structures of school settings vary within the United States and also can differ between the U.S. school system and those of other North American nations. For instance, within the U.S. structure of elementary and middle schools, there are various configurations. Students may attend schools that include kindergarten through eighth grade on the same campus. Another structure involves schools constructed by grades K–5 on one campus and grades 6–8 on another campus. Still other configurations include grades K–6 on one campus and grades 7–9 on another (with high school starting at grade 10 rather than grade 9). For the purposes of this paper, we consider "elementary school" to encompass kindergarten through fifth grade, "middle school" to address grades six through eight, and "high school" to include grades nine through twelve. These demarcations follow the grade bands described in the *Principles and Standards for School Mathematics* (NCTM, 2000).

There may be an embedded assumption in work on school articulation and transitions across school settings that students remain in a particular school setting or school district for an extended period of time. We recognize that students may be mobile even during a particular school year. According to recent data (US GAO, 2010), 11.5 percent of K–8 schools have high rates of student mobility, such that more than 10 percent of students left by the end of the school year. These schools also had higher percentages of students who were low-income, English language learners, and received special education. However, we believe that the conceptual lenses and the transition issues affecting students discussed in this paper could be applied to some degree to students moving into new schools or new classrooms at other points in time.

Experiencing transitions involves navigating change, such as changes in approaches to mathematics teaching and curriculum between school buildings. In our effort to understand school mathematics articulation (or lack of it) over time, we do not believe that it is entirely possible or necessarily desirable to eliminate the changes that students experience. A perfect alignment of experiences over time is not possible or even ideal. Rather, we hope to consider the kinds of changes students might experience, whether students are aware of these changes and how they might respond, how to support students in navigating changes between school settings over time, and whether the changes that students encounter are purposefully created or occurring haphazardly.

The four authors of this paper collaborated because of our different experiences with scholarship around students' school mathematics transitions. Amanda and Jack worked together, with a number of other scholars, on the Mathematical Transitions Project [MTP]. Funded by the National Science Foundation (Jack Smith, Principal Investigator), our work in MTP investigated students' experiences as they moved from middle school to high school and high school to college when the mathematics curriculum materials shifted from either reform to traditional or traditional to reform (cf., Smith & Star, 2007; Star & Smith, 2006; Star, Smith, & Jansen, 2008; Jansen, Herbel-Eisenmann, & Smith, in press, 2012). Cathy and Janie were involved with writing a series of articles for *Teaching Children Mathematics* (Schielack & Seeley, 2010), *Mathematics Teaching in the Middle School* (Brown & Seeley, 2010), and *Mathematics Teacher* (Hull & Seeley, 2010) about students' experiences as they move from one level of education to another. This paper is an opportunity to synthesize and share what we've learned and to encourage mathematics educators to do more to consider how to understand and support developing students in the context of moving across school settings.

Conceptualizing Students' School Mathematics Transitions

Research on students' school mathematics transitions can be conducted from a range of perspectives. There can be a focus upon (1) the *internal* experiences of students, (2) the success (or not) of particular students in "moving along" as judged by *external* standards (grades, course-taking, etc.), (3) the success (or not) of institutions in supporting *aggregate* student success over time, (4) the effects of curriculum or teaching practice as they *correlate* to students' experience (internal) and/or success (external). To explore some of these foci, we share a representation that highlights some of the main factors in school mathematics settings that could either change or remain consistent over time and student-level dimensions that could indicate variations in their "transition" experiences (Figure 1).

We wanted this figure to display four temporal stages in time or grade bands (elementary years, middle school years, high school years, and post-secondary years of college and/or career). Also, we wanted to highlight a few factors in the school settings as well as student-level dimensions (both internal and external). The central column (large arrow) lists important student-level dimensions, such as learning, achievement, dispositions, patterns of working, and identity/direction. These dimensions could be relevant for students at any point in time. The ovals represent factors in school settings that may influence students' at any point in time and that could influence or shape any of the student-level dimensions. Figure 1 highlights some of the complexities of students' transitions across school mathematics programs, as changes along any of these factors in school settings or changes in any of the student-level dimensions could be significant to students in their experiences with school mathematics.

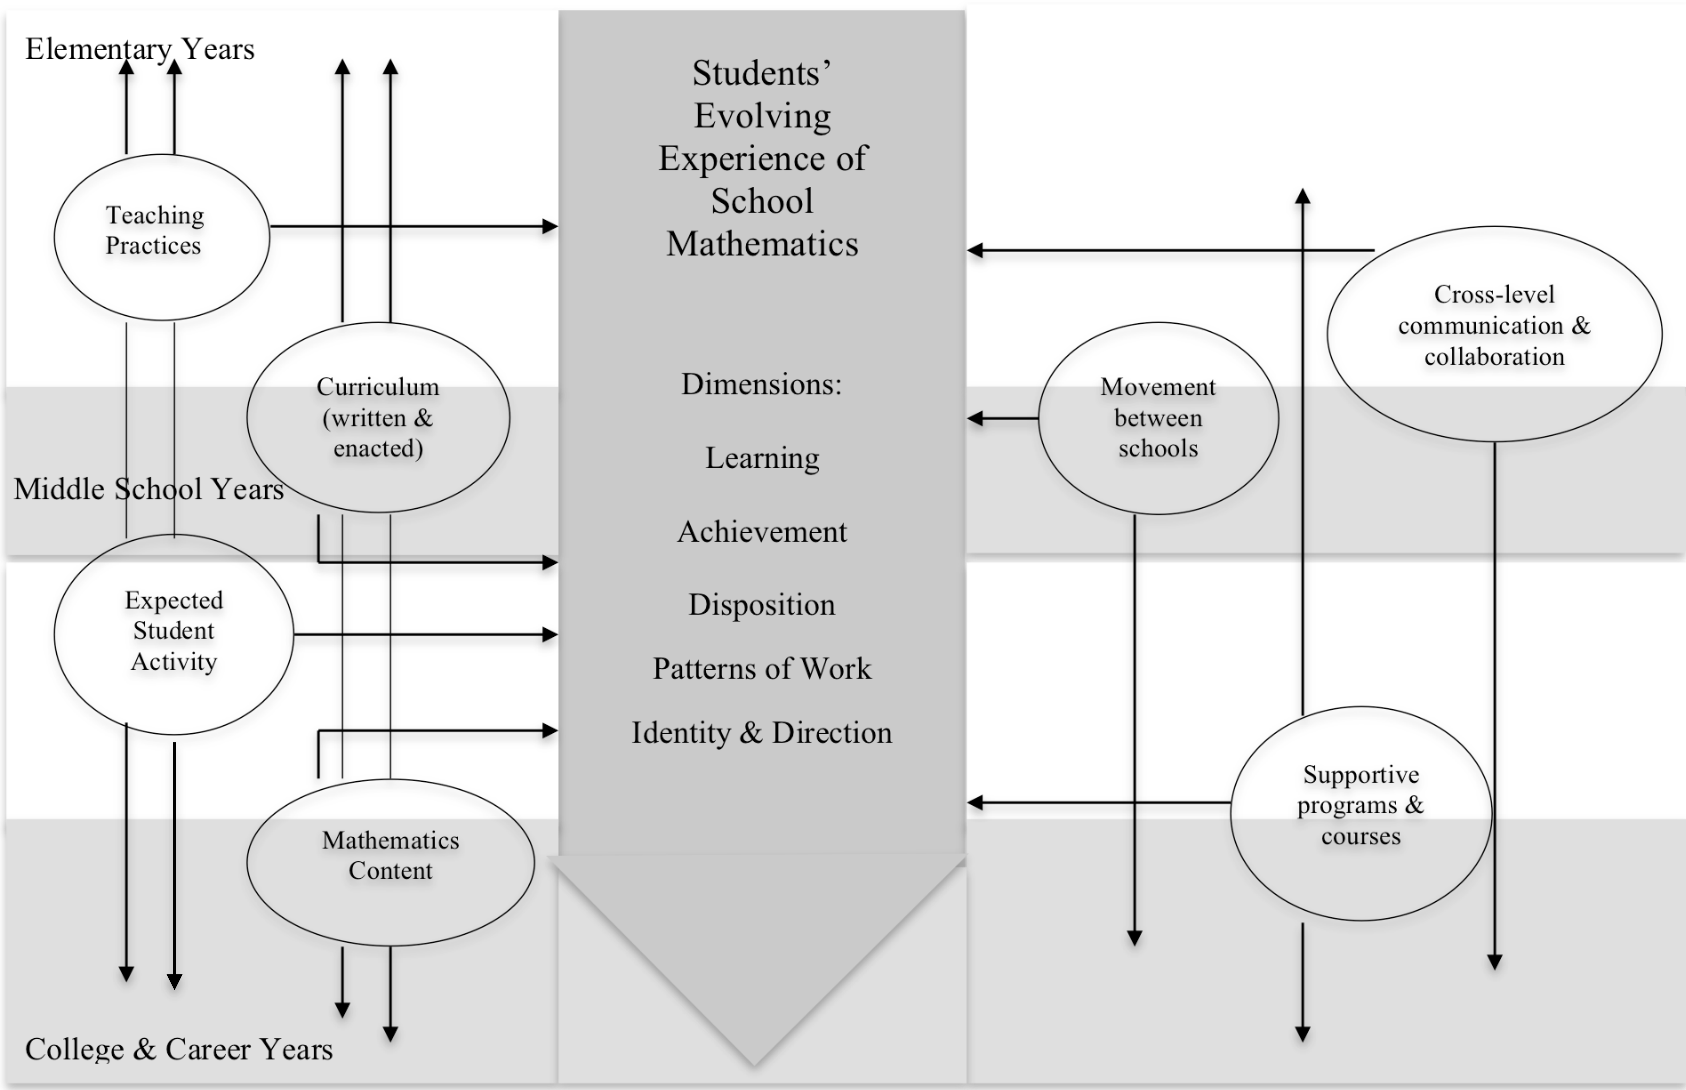

Figure 1: Visualizing students' transitions and the factors that shape them

Aspects and Dimensions of Issues in Students' Transitions

We wrestled with the order through which to present students' experiences over time. In the spirit of backwards design (Wiggins & McTighe, 2005), we considered starting our discussion of transition issues with post-secondary experiences (college and careers) and working back to earlier stages of schooling. This approach would have affording reflecting upon where students could land and working backward to support their successful journeys. Alternatively, we could begin with elementary school and move forward, because this timeline aligns with how students experience the accumulation of school mathematics experiences. After much discussion, we chose the latter option, as (for one reason) it is such a familiar frame for the issues that we consider.

Below, we share findings from a few select research studies. These studies provide insight on some conceptual lenses that have been used to understand the nature of students' transition experiences as they move across school settings: stage- or person-environment fit, boundary-crossing, and rite of passage. We present each of these conceptual lenses as we discuss the grade band of students or level of transition that the researchers studied. However, we do not mean to suggest that the conceptual lens should be used only with this grade band. Rather, we believe that these conceptual lenses could provide insight at any transition period, so lenses used previously to understand the transition from elementary school to middle school could also be useful for studying other transitions, such as the transition from high school to college (or to other post-secondary experiences). Other conceptual lenses that are useful for understanding students' experiences will be presented later in the paper.

The projects we discuss also highlight transition issues that students might experience as they move through school over time. We selected these studies because they highlighted ways to see interactions between dimensions of students' school mathematics transitions and system level responses, as many other studies report outcomes rather than offering explanations about why students might experience these outcomes.

Elementary School to Middle School

Schielack and Seeley (2010) previously summarized some of the issues that students often experience when moving from elementary into the middle grades mathematics. They described a student-level dimension: decreases in achievement in mathematics over time. Prior research suggests that, in general, students experience significant declines in academic achievement as they move from elementary school to middle school (Alspaugh 1998). They also highlighted factors in school settings, such as surface and substantive differences in curriculum materials, the variance in instructional approaches between settings, changes expectations for students' work, and increased difficulty in content. Some of the surface level features in the curriculum materials include change in color schemes, word density, font size, frequency of word problems or computational items in exercise sets. More substantively, the curriculum materials generally differ with respect to the types of representations used. For instance, elementary school mathematics textbook representations may be large and spacious (e.g., use of area models to represent fractions), and middle school mathematics textbook representations often using more symbolic and compact representations (e.g., linear models or number lines to represent fractions). Instructional approaches often vary in the degree to which teachers enact direct instruction and position students as receivers of knowledge or whether teachers encourage open exploration in which teachers act as facilitators. Schielack and Seeley (2010) acknowledge that these differences in curriculum or instruction could be reversed at the different grade levels. Changes in expectations for students' work in middle school include increases in the amount of independent work, including homework.

One conceptual lens that researchers have used to view students' experiences as they move from elementary school to middle school is the *stage-environment fit* perspective, which focuses on the degree to which students' developmental needs are met by the structures and practices of schooling. Foundational research on adolescent development (outside of mathematics education) has conceptualized students' experiences in the context of educational change in terms of fit between students' developmental needs and the school environment. This line of research addresses changes in adolescents' motivation over time as they move between school buildings. Declines in student motivation have been explained as a lack of a stage-environment fit (or a mismatch) (Eccles et al., 1993, following Erikson [1968]). "[R]esearch has found that academic declines in interest and self-concept are a function of the mismatch between the school environment and the adolescent" (Zarrett & Eccles, 2006, p. 17). A stage-environment fit is the quality of the match between the developmental needs of adolescents and the nature of the learning and social opportunities afforded to them. From this perspective, declines in students' motivation are not conceived as student deficits but as results of misalignment between students' needs at their stage of development and the learning and social opportunities afforded to them in their school experiences. Alternatively, students' motivation could remain strong or improve if there exists a fit between the student's needs and his or her experience in school.

Studies of the transition from elementary school to middle school reveal some examples of stage-environment mismatches (e.g., Eccles et al., 1993; Roeser, Eccles, & Sameroff, 2000; Wigfield, Eccles, & Roderiguez, 1998). The move toward ability grouping in the transition to middle school emphasizes social comparison at a time of heightened self-focus for adolescents. If teacher control increases and students' choices decrease in middle school, this conflicts with adolescents' increasing needs for autonomy. If teachers become more distant in their interactions with students in middle school, this may conflict with an adolescents' need to foster stronger relationships with adults outside the home.

Transition studies often provide insight at more of a top level, such as why students would continue to engage or not in school generally. However, there are some noteworthy exceptions. Roeser, Eccles, and Sameroff (2000) found that when middle school students perceived their school's curriculum to be meaningful, relevant to their lives, and supportive of their autonomy, they also expressed higher academic competence and higher academic value. Additionally, Midgley, Feldlaufer, and Eccles (1989) found that, during their transition into middle school, students who perceived lower degrees of support from their new mathematics teachers also reported lower intrinsic values for mathematics. More troubling, these findings were stronger for lower achieving students.

Looking back at our representation in Figure 1, these studies highlight particular factors in school settings and student-level dimensions. A move toward ability grouping indicates an example of change in the structure of the mathematics program that students experience. A more distant teacher-student relationship, reduced teacher support, and an increase in teacher control represent changes in instructional practices. An example of curricular factors was the degree to which the curriculum was perceived to be meaningful and relevant. These studies varied in terms of whether the factors in the school setting were perceived by students (self-reported) or observed by researchers. Student-level dimensions described were their reflections upon their identities (heightened attention to self, need for relationships with adults outside of the home) and disposition (need for autonomy, sense of competence, high value for academics).

Middle School to High School

As students move from middle school to high school, some of the factors in school settings and student-level dimensions occur again for students, and additional factors and student-level dimensions are incorporated for others. Brown and Seeley (2010) describe a range of factors in school settings and student-level dimensions that often change as students move from middle school into high school. Regarding school factors, they identified potentially insufficient alignment of mathematics instruction and curriculum materials across grade bands, specific issues with mathematics content in high school (e.g., mandatory Algebra I), and problems that could occur if high school teachers construct students as being "unmotivated" rather than trying to understand what they can do to motivate students. They also describe student-level dimensions, particularly decreases in achievement that seem to occur if students experience lack of alignment in curricular or instructional approaches (differences in the degree to which the mathematics programs are problem-centered and evoke sense-making or focus on teacher-directed procedural instruction). As we review some of the prior research on students' transitions into high school mathematics programs, we describe three conceptual lenses: person-environment fit, defining the nature of a mathematical transition, and boundary crossing.

Person-Environment fit. The person-environment fit conceptual lens is a variation on stage-environment fit. Studies of stage-environment fit have been conducted in the context of the transition from middle school to high school (e.g., Barber & Olsen, 2004; Isakson & Jarvis, 1999), not only in the context of the transition from middle school to elementary school. A transition into high school typically involves similar changes as those that occur during a transition from elementary to middle school (e.g., decreased autonomy in the classroom, decreased support from teachers). A transition into high school may be less disruptive than a transition to middle school, since the first transition tends to have more impact (Barber & Olsen, 2004). However, for students who attended a school structured in grades K-8 prior to high school, the transition into high school may be their first move between buildings. Students' transitions into high school have been associated with declines in their academic performance (Barber & Olsen, 2004; Isakson & Jarvis, 1999; Rice, 2001). For high school students, one important developmental challenge of middle adolescence is to become more self-reliant and self-governing (Kimmel & Weiner, 1995; Powell, Ferrar, & Cohen, 1985). In contrast to early adolescents, middle adolescents face increased future-related pressures as they begin to prepare for their lives beyond K–12 education. This perspective draws attention to student-level dimensions, such as achievement and identity (becoming more self-reliant) as well as direction (future-related pressures).

A fit or a mismatch with one's environment may not necessarily be developmental, so we believe that *person-environment fit* (Hunt, 1975) can be a more appropriate term for understanding students' experiences than stage-environment fit. Stage-environment fit addresses the fit between the school setting and a student's developmental needs, but there may be other aspects of the person that can fit or not with the environment. For example, a fit or mismatch may be due to the alignment (or lack thereof) between students' individual epistemological beliefs about the nature of knowing and the approach to mathematics instruction in their classrooms, and these beliefs may not be tied to students' development. Epistemological beliefs have been shown to vary by gender (Gilligan, 1982) and by curricular contexts (Star & Hoffmann, 2005). Boaler (1997) explained high school females' experiences in different mathematics programs in terms of the fit or mismatch between their academic contexts and women's ways of knowing. She drew on the work of Gilligan (1982), who described differences between "separate" and "connected" knowing. Separate thinkers prefer to work with subjects that are characterized by logic, rigor, absolute truth and rationality; and connected thinkers prefer to use intuition, creativity, personal processes and experience. The young women in Boaler's study expressed a preference for learning mathematics through a more open, problem-solving approach that supported their autonomous sense making in mathematics, or an approach more aligned with connected knowing, and they expressed dislike for a more closed, teacher-led approach that was more aligned with separate knowing. Epistemological beliefs represent a student-level dimension (disposition). School-level factors described in this work include teaching practices, enacted curriculum, and expected student activity.

Looking across conceptual lenses that address "fit" (or mismatch) with environment, a common approach is to characterize the degree of overlap between students' perceived needs and preferences and what the environment affords. Both students and school settings change over time. An implicit assumption with this research is that two settings should adjusted to become more aligned (and aligned in ways that also support developing learners). The alternative perspective is that change and challenge is essential to healthy development so the focus should be on how students adjust to those changes and challenges But what frames are available to examine adjustment to changing mathematical contexts for learning? Two perspectives, the concept of a mathematical transition and the lens of boundary crossing, provide alternative ways to view moving into new school settings other than fit with environment.

What counts as a "mathematical transition"? Something to consider in research on educational change is whether changes are noticed by students and how students respond when noticing particular changes. The Mathematical Transitions Project [MTP] team (cf., Smith & Star, 2007; Star, Smith, & Jansen, 2008; Jansen, Herbel-Eisenmann, & Smith, in press, 2012) did assume that changes that adults observed in curriculum and instruction when students moved from one building to another would necessarily be important for students. Our starting point in characterizing what counts as a mathematical transition was to understand the transition experience from students' perspectives (either when moving into a mathematics program that was reform-oriented from a more traditional program or when moving into a mathematics program that was more traditional from a reform-oriented program). The term, "reform-oriented," in this discussion simply signals the possibility of significant changes in curricular content and instructional practice.

We proposed that students experienced a *mathematical transition* if data indicated a significant change along two or more (out of four) dimensions. These dimensions were chosen to capture students' cognitive, affective, and behavioral experiences and included: (a) whether a student reported a significant number of *differences* between their middle school and high school programs, (b) self-reported changes in a student's *disposition* toward mathematics, (c) significant changes in mathematics *achievement*, and (d) self-reported changes in a student's *approach to learning* mathematics. We defined a "transition type" as any combination of significant changes in two or more of these dimensions. (For more on concepts and methods in MTP, see Smith and Star [2007].) Note that factors in school settings were captured from students' perceptions, with respect to the differences that students self-reported. Student-level dimensions that we investigated included their achievement (in terms of course grades over time and overall GPAs), dispositions (self-efficacy, attitude toward mathematics, reports of career goals), and patterns of work (approach to learning). We collected our data over two and a half years at two high school sites and two universities and followed approximately 25 students at each site.

Two of the MTP sites captured students' experiences as they moved from middle school to high school, and results indicated that two-thirds of our focal participants did not experience significant changes in achievement and less than 20% of our high school students changed their learning approaches (Smith & Star, 2007). (When high school students' achievement did change, in approximately three-fourths of these cases, achievement fell.) However, we do not mean to suggest that such lack of change when moving into high school is representative or typical, as we only worked with about 25 students at each high school. Rather, these data suggest that students could have a mathematical transition when moving into high school that does not primarily focus upon changes in achievement or learning approach as the most relevant student-level dimensions.

When students experienced "mathematical transitions" at the two MTP high school sites, they noticed significant differences between their middle school and high school mathematics programs and changed their dispositions toward mathematics. Patterns in students' disposition changes at each site appeared to vary with respect to curricular shifts (Smith & Star, 2007). When the dispositions towards mathematics of students who moved into a high school with a reform-oriented mathematics program (in which the teachers used Core Plus Mathematics Project [CPMP] [Hirsch, Coxford, Fey, & Schoen, 2005]) changed, they became more positive. In contrast to their prior experiences in a more traditional middle school, these high school students reported liking CPMP's focus away from repeated practice on very similar problems, increase in story problems, more group work, and a focus on understanding and sense making. Students who moved into a more traditional high school mathematics program from a reform-oriented middle school mathematics program (in which the teachers used the Connected Mathematics Project [CMP] [Lappan, Fey, Friel, Fitzgerald, & Phillips, 1995]) experienced a range of disposition changes. Among the students whose dispositions changed, there was a mix of both more positive and more negative dispositions toward mathematics in high school, with slightly more students developing slightly more negative dispositions. Students whose dispositions changed reacted to similar factors in school settings (e.g., more distant teacher-student relationships in high school, more challenging mathematics content in high school, more word problems in reform mathematics programs), but some students preferred the middle school and others preferred the high school mathematics program.

Learning during boundary crossing. Rather than assuming that school settings could potentially become more aligned or assuming that change in mathematics programs over time is inherently problematic, the conceptual lens of learning during boundary crossing could be used for understanding how students experience educational change. "Boundary crossing" refers to a person's interactions and transactions across different settings (Akkerman & Bakker, 2011). Jansen, Herbel-Eisenmann, and Smith (in press, 2012) drew upon the concept of boundary crossing to examine two cases of MTP students' transitions into the high school site in which students moved from a middle school that used CMP into a high school with a more traditional mathematics program. Following Akkerman and Bakker (2011), a "boundary" was seen as "a sociocultural difference leading to a discontinuity in action or interaction"

(p. 134). A discontinuity could involve changes along any of the factors in school settings, as presented in Figure 1. Such changes could lead to students' experiences of adjusting their roles in each setting. Following Jackson (2011), "setting" was a distinct physical space, and we considered that different physicals spaces (i.e., school buildings) could typically "enclose" different school practices. Rather than viewing boundary crossing experiences as barriers to learning, they can be perceived as potential resources for learning.

Jansen, Herbel-Eisenmann, and Smith (in press, 2012) presented cases of two students that exemplified two learning processes that could occur during boundary crossing in the process of transitioning out of a reform mathematics program into high school. Drawing on Akkerman and Bakker's (2011) characterizations of learning mechanisms during boundary crossing, our cases illustrated two processes of making sense of practices in multiple contexts: identification and reflection.

> Where identification represents a focus on a renewed sense of practices and a reconstruction of current identity or identities, reflection results in an expanded set of perspectives and thus a new construction of identity that informs future practice. (Akkerman & Bakker, 2011, p. 146)

These conceptualizations highlight that learning during boundary crossing can involve reifying one's current identity (identification) or constructing a new identity through expanding one's perspectives about practices in both settings (reflection). In this work, we present analytic tools for identifying students' boundary crossing experiences and describe the nature of learning that appeared to occur during those experiences.

The case of Bethany (identification) illustrated a student who had a strong preference for her CMP experience in middle school and fought to retain the aspects of that experience that she preferred, even when her high school experience did not provide clear opportunities to do so. For instance, she valued that her middle school mathematics teachers explicitly encouraged her to develop and share her own solution methods, expressed frustration that her high school mathematics teachers were "teaching one way… I've never done the same way as the teacher," and experienced conflicts with her mathematics teachers when they took off points for solutions that were correct yet did not align with their taught procedure or when they would not listen to her ideas for how to solve the problem. Through making sense of her boundary-crossing experience, she appeared to solidify her identity as a learner and doer of mathematics.

Ethan's case (reflection) demonstrated a student who, through his continual use of metaphors, expanded his perspective about school mathematics through experiencing two different mathematics programs. One of these metaphors included running water over an ice cube tray. He observed that the middle school mathematics teachers filled the ice cube trays slowly and carefully while the high school mathematics teachers ran the water quickly over the trays, which represented the degree to which teachers monitored student understanding in each setting. He reported liking his high school mathematics program slightly more than his middle school mathematics program, because he appreciated what he perceived to be an increase in autonomy and challenge. Learning occurred for Ethan through reflection because he constructed new understandings of the differences between the two settings and developed a new sense of identity (that he called "ambidextrous") such that he believed that he could be successful in either type of setting.

High School to Post-Secondary School (College and/or Careers)

We recognize that ideally all students should have a diversity of learning and work options beyond high school; not every student should be expected to attend a four-year university. This diversity of potential post-secondary experiences adds additional challenges to studying the transition out of high school. Even college-bound students who have been historically successful in mathematics may not be successful in college mathematics (Smith & Star, 2007). It is important to understand the range of factors at play in students' experience with the transition to post-secondary experiences. Hull and Seeley (2010) note some factors in students' experiences that appear to be lacking: adults might have lower expectations for students' post-secondary goals than students have for themselves and students are often lacking information about post-secondary experiences, including what colleges require for entrance or placement in particular mathematics courses.

Although we acknowledge the range of post-secondary experiences, the prior research that we describe below primarily focuses upon students' transition from high school to college mathematics programs. We describe two conceptual lenses, including the MTP conception of a mathematical transition and the concept of "rite of passage." Additionally, we describe other transition issues that students might experience when moving into college or a work career.

What counts as a "mathematical transition"? There were two university sites in the MTP project; one included students who experienced CPMP or another reform-oriented curriculum in high school and entered a university with a more traditional calculus program and the other site included students who experienced a more traditional high school mathematics program and moved into a university with a reform-oriented calculus program.

At both university sites, the changes that students experienced appeared to be more similar than different, which suggests that their transitions had more to do with moving into college than shifts in their curriculum materials (Smith & Star, 2007). More than four-fifths of the students at both university sites experienced drops in their achievement. When students' dispositions toward mathematics changed at either university site, their dispositions became more negative. About half of the students at each university site changed their approaches to learning mathematics. Students who moved into the university that had a more traditional mathematics program than they had experienced in high school changed their intellectual participation by struggling to attend class when the dominant activity was lecture presentation in college. Students may have struggled to attend class due to being able to choose whether or not to attend class in college or because they had a preference for their high school mathematics courses that were not lecture-oriented. However, at both sites, the general pattern in their learning approach changes was to read mathematics textbooks more carefully and extensively in college, to complete more homework (even when voluntary), study more for tests, and to seek more help from institutional resources or peers (but not from teachers) in college. Most participating students at both sites reported significant differences between high school and college. Some of these differences were more about the move into college generally, such as the new and more difficult mathematics content that they observed, and other differences were more closely aligned with the shift in curricular programs, such as the increase or decrease in contextual story problems, the increase or decrease of fixed procedures available to solve the problems, and the increase or decrease of the expectations to explain solutions in writing or verbally. Although most students at both universities experienced change on our dimensions, these changes seemed to be more about moving into college generally than the shifts in curricular programs.

Rite of passage. Clark and Lovric (2008, 2009) addressed a need for a theoretical model to understand the high school to university transition in mathematics by adapting the concept of "rite of passage." This concept affords an understanding of both the nature of the transition experience and suggests possibilities for supporting students as they move into college. Below, we will describe how the rite of passage concept provides insights on the nature of the transition experience, and later in the paper we will revisit the concept to consider how to support students' transitions into college.

Rite of passage is a concept from anthropology that describes how people experience a crisis, according to Clark and Lovric (2008, 2009). In such a crisis, routines are interrupted, changed, and distorted (discontinuities in experience). In rites of passage, young people re-establish balance and bring back more regular routines. There are three phases associated with a rite of passage: separation (distancing one's self from a high school mathematics experience and beginning to anticipate the tertiary experience), liminal or transitional phase, and the incorporation phase. The process involves cognitive conflict and culture shock. This rite of passage is marked by a physical separation from family and former homes; combined with the large scale of university settings and programs, shock and stress may be inevitable. The success of moving through a rite of passage depends at least in part upon the assistance offered to the individual undergoing the experience.

Clark and Lovric (2008, 2009) relate the experience of moving from secondary mathematics programs into tertiary programs. They describe the discontinuities in terms of college faculty perceiving a lack of preparation in students' technical or procedural facility and analytic skills and deficiencies in students' fundamental notions about the nature of mathematics (particularly a lack of understanding about the role of proof in mathematics). Additionally, citing Tall (1991), they note that college students struggle with building the cognitive apparatus needed to handle advanced mathematics. A student who completes this rite of passage becomes able to think in more productive ways that are aligned with the new environment. From the perspective of rite of passage, the transition into college will likely involve significant discontinuities. Rather than trying to remove the discontinuities, the goal is to think about how to support students with successfully navigating the discontinuities. (Clark and Lovric's [2008, 2009] suggestions, as informed by the rite of passage concept, will be explored later in this paper.)

System-Level Responses to Support Students as They Progress Through School Experiences

Given the range of discontinuities students might experience in school-related factors as they move through grade bands over time (and associated or co-occurring responses at student-level dimensions), it would be useful to explore some recommendations for supporting students with their transitions through mathematics programs over time. We do so with a caveat: many of these system-level responses have not been thoroughly examined empirically. Some of the recommendations address minimizing the discontinuities between factors in school settings at the transitions between grade bands. Other recommendations take discontinuities between grade bands as a given and focus on how to help students navigate them. More research is needed to understand the conditions under which these system level responses are more and less effective for supporting students in their transitions across grade bands.

Regarding efforts to minimize discontinuities, a consistent recommendation has been for teachers to communicate across grade bands about mathematics teaching and learning (Brown & Seeley, 2010; Hull & Seeley, 2010; Schielack & Seeley, 2010). Teachers at the earlier temporal stages of transitions can develop awareness of what their students will experience in the future and prepare them. Teachers at the later temporal stages can learn more about what their future students will have experienced and what they might be capable of doing or understanding about mathematics. The specific recommendations about how to go about this sort of communication vary slightly. It has been suggested that elementary and middle school mathematics teachers can visit each other's classrooms and have comparative discussions about assignments and students' work (Schielack & Seeley, 2010). Middle school and high school teachers could engage in cross-site collaboration to improve alignment in instructional practices and collaboratively study mathematical goals and expectations (Brown & Seeley, 2010). College faculty and high school teachers could collaborate to develop a shared understanding about what students need to know, develop tasks that exemplify these expectations, and establish exemplars of student work that reflect the depth of knowledge that should be promoted (Hull & Seeley, 2010). To engage in such cross-site collaboration, teachers would need support (in terms of time, structure, and guidance) and shared motivation for working toward better alignment across grade bands. Where the latter may exist in some, perhaps many communities, the support resources typically do not.

Given potential challenges associated with reducing unproductive discontinuities, system-level supports designed to support students with navigating transitions seem more pragmatic and promising. Teachers could create a support network with other teachers, counselors, administrators, and parents to provide students with an early vision about what being "good in mathematics" could mean for students' futures (Schielack & Seeley, 2010). Middle school teachers could work to create classroom cultures that actively engage students such that they support students' cognitive, emotional, and social development (Brown & Seeley, 2010). These efforts could usefully promote the ideas that mathematical competence is malleable rather than fixed and that being good at mathematics involves effort rather than solving problems quickly, and provide every student with a sense of belonging in the mathematics classroom. High school teachers could promote high expectations for every student, build strong relationships with students to reinforce high expectations, and know about (and communicate with students about) what students need to do to prepare for college mathematics courses and mathematics placement exams (Hull & Seeley, 2010).

To prepare for success in tertiary education, high school students should receive clear messages about the importance of taking mathematics for all four years in high school and how effort matters for mathematics learning, support for learning to read mathematics textbooks for understanding, and encouragement to form study groups among peers.

Seeley and colleagues have made some specific content recommendations to support students with navigating transitions. For the middle grade bands, they advocate promoting proportional reasoning to support success in high school mathematics (Brown & Seeley, 2010). In high school, they advocate increasing mathematical expectations for students, but rather than advocating that every student take calculus, they recommend that some students take a fourth year mathematics course consisting of statistics, probability, data analysis, and modeling (Hull & Seeley, 2010). These "new" areas of mathematical content are promising focal areas given the nature and demand of many fields of work, before and after college.

Rite of passage and implications for supporting the college transition. Considering the rite of passage conceptual lens, Clark and Lovric (2008, 2009) made some specific recommendations to assist students as they navigate their transition into their college mathematics programs. Rather than change college mathematics courses to be more like high school courses, the rite of passage perspective suggests that it is more appropriate to focus upon making expectations more transparent to students. This would mean telling high school students more directly, accurately, and in detail about their future work in university or college mathematics classrooms.

Regarding mathematics placement tests, Clark and Lovric (2009) suggest that recognizing that a rite of passage involves the whole student, an effective mathematics placement test would incorporate more than mathematics content. Beyond testing mathematics background knowledge and skills, placement tests could capture the whole individual. This would include measuring students' attitudes toward learning mathematics, their motivation, and their preferences for learning and social engagement in the classrooms, and designing appropriate mathematical learning experiences according to the outcomes.

These authors note that a rite of passage takes time and should not (and cannot) be accelerated.

> Rather than trying to "ease the transition" or "make it smoother," it [a successful transition program] needs to acknowledge that the transition [to college] will be painful, difficult, and—perhaps most importantly—that it will take time. Students undergoing transition need to know that all discomfort, pain, stress, even severe anxiety—in the end—will be proven worthwhile. Confusion and uncertainty are integral parts of everyone's learning process (Clark & Lovric, 2009, p. 764).

Realistic expectations for the length of time it will take for students is important, as short orientation sessions about how to be a more effective note-taker or how to manage time are not enough to help students (Clark & Lovric, 2008). We should not expect that short, one-shot workshops are enough to support students with a transition to college.

Additionally, a rite of passage suggests that individuals who engage in the process should take some responsibility for it (Clark & Lovric, 2008). To ease the process of students taking responsibility, groups of students can be brought together to support each other as they navigate the transitions together (Clark & Lovric, 2009). Students who have already successfully transitioned into college can serve as mentors to first-year students. It is not inappropriate, from this perspective, to expect first-year college students to accept at least some responsibility for taking initiative to negotiate the transition. Too much help may serve to disempower students.

Promising Possibilities for Future Research

Given the complexity of students' experiences in school over time, we are hesitant to prescribe specific questions for future research. However, we would like to suggest an issue to consider and a promising theme for researchers to pursue if they are interested in better understanding students' transitions in school mathematics. An issue to consider is which processes and outcomes to investigate when conducting research on students' transitions. Additionally, we believe that a promising path to pursue would be to further document the effects of interventions designed to support students with their school mathematics transitions over time.

We recommend that researchers build upon and extend this line of research through examining factors other than achievement and course-taking. Outcomes such as achievement and performance measures have dominated prior research (cf., Barber & Olsen, 2004; Hill & Parker, 2006; Isakson & Jarvis, 1999; Post, Medhanie, Harwell, Norman, Dupuis, Muchlinski, Andersen, & Monson, 2010; Rice, 2001). However, dispositional factors may be as potent for mathematics learning as any set of factors, particularly as a mediating variable between instruction and performance or understanding. Accounting for these mediating variables could enhance research on transitions by providing explanations or insights about why students' performance or achievement outcomes or course-taking patterns occur.

Future studies about transitions between school settings should be more closely situated in relation to shifts in curriculum or instructional practices of specific subject matter. Relating studies of transition in relation to specific subject matter can provide insights for how the teaching of particular content can support or constrain the degree to which students will continue to engage or not with that content.

There is a need to continue to report the effects of promising interventions that support productive outcomes. Certainly this paper did not exhaustively explore all of the research that has been conducted on productive interventions, but there is a need for more research that uncovers conditions that lead to students experiencing school mathematics transitions in productive ways. We recognize the challenge in this sort of work. There is a severe difficulty of relating change in any variable to the effect of one factor represented in the intervention.

Conclusions

In this paper, we examined questions about aspects and dimensions of students' transitioning through educational settings over time along with concerns for system-level responses to support students as they move through these transitions. We highlighted conceptual lenses to help understand students' experiences over time during transition points in school mathematics programs as well as issues that students may experience due to factors in school settings and student-level dimensions. We advocate for attention, through both research and practice, to students' socio-emotional well-being and developing identities as they navigate changes in their mathematics programs over time. Understanding the nature of changes that students experience at transition points across their school experiences can be helpful for those who are invested in supporting students' mathematics learning and development.

This paper describes a model for building cognition-and-instruction-based goal trajectories (GT) in the context of a study that examines the validity of curriculum-embedded assessments. The model consists of six design processes and two constraints. The GT is constructed from curriculum-specified learning goals as well as developmental progressions and learning trajectories derived from empirical research. The GT is designed to inform both the selection of assessment activities for data collection and the interpretation of empirical results. Two primary results of the design process are presented: (a) a goal trajectory for promoting algebraic understanding and (b) the relationships between the trajectory and features of the Common Core State Standards. Implications of the design model for building GTs that can be used to assess student reasoning are discussed.

Keywords: Assessment and Evaluation; Curriculum Analysis; Learning Trajectories

Introduction

Learning trajectories are constructs designed to approximate variability and change in student knowledge states over time. They are domain-specific and therefore relate to understanding and reasoning in a particular domain such as algebra, geometry, place value, and rational number (e.g., Clements & Battista, 2000; Clements, Wilson, & Sarama, 2004; Confrey & Maloney, 2010; Daro, Mosher, & Corcoran, 2011; Fuson, 1998; Griffin, 2009; Simon, 1995; Simon & Tzur, 2004). With optimal design, learning trajectories can be used to support formative assessment processes that include connecting observed student performances to domain-referenced (e.g., "student *x* is distance *y* from expected 'expert' performance levels") and individual-referenced (e.g., "student *x* is distance *y* from expected student *x* performance levels given what the teacher understands about the knowledge states of student *x*") ways of acting (Cowie & Bell, 1999). Thus, if a trajectory reveals a diagnostic range of student understanding that a teacher or student is likely to encounter it may provide a basis for instructional responses that promote learning.

Most learning trajectories are designed to directly inform learning and instruction. Indeed, the *goal trajectory* (GT) concept described here is based upon the well-established idea of the learning trajectory, but the GT serves a different purpose which is to make the otherwise implicit models of learning progressions in a math curriculum explicit, an express priority for researchers interested in tracing student knowledge states in the context of a math curriculum. The present paper describes a model for building a GT and explicates its utility for evaluating the variation and growth of mathematical understanding and reasoning in the contexts of particular curriculum-embedded assessments in K–6 math curricula. The research is situated in the context of a larger study designed to address some of the most pressing problems of classroom assessment practice, and is aimed at strengthening the linkages among assessment design, instruction, and student learning.

The current notion of the GT incorporates elements of the developmental progressions that partially compose typical learning trajectory constructs (e.g., Fuson, 1997; Griffin, 2009). Elsewhere, cognition-and-instruction-based design methods have been designed for "forward engineering" a mathematics curriculum (e.g., Clements & Battista, 2000). By contrast our GT serves a purpose of principled retrospective evaluation that is focused on the embedded assessments in an existing mathematic curriculum.

Thus, the current approach to formulating a goal trajectory will be most useful to researchers and practitioners that work in situations where an instructional sequence is present (i.e., in a "scope and sequence") but where a developmental progression—as defined by empirically and theoretically grounded models of learning—is implicit. The approach consists of six primary design processes: (a) Define the design product, (b) Specify the purpose of the product, (c) Identify the features of the design product, (d) Evaluate, (e) Update, and (f) Classify the features. To illustrate these design processes, we focus on the goals that comprise the algebraic reasoning strand of the standards-driven curriculum, *Everyday Mathematics* (EM; Bell et al., 2007).

Method: Six Design Processes and Model Constraints

Our curriculum-and-instruction-based model for building a goal trajectory has six design processes and two design constraints (see Figure 1). The processes are cognitive activities that are either expressed by an individual or distributed across several people and media.

a. Define Goal Trajectory as the Design Product

The first process, *Define the Design Target*, refers to activities in which the researcher or evaluator articulates what will be designed. In the present case we sought to design a GT that modeled variability and growth in knowledge states in and over time for fifth-graders learning how to reason algebraically in the context of a specific math curriculum. We wanted the GT to be a cognitive model with cognitive units at a level of specificity described by the curriculum. Additionally, we wanted the GT to have properties such that it could be used to estimate variability and growth through its different "levels."

b. Specify the Purpose of the Goal Trajectory

The second process, *Specify the Purpose*, refers to activities in which the researcher or evaluator specifies the aim of the design product. It addresses the question, "Why do we need or desire to design such a product (i.e., the GT)?" In the present case, the purpose of designing a GT that models variability and growth in student knowledge states in and across time was to help us (a) select curriculum-embedded activities, and (b) interpret student performance on the selected assessments. The GT is an important tool in our investigation of the cognitive, instructional, and inferential validity of curriculum-embedded assessments. Thus, in the current situation the purpose was pragmatic. However, in other cases the design product can have empirical, pragmatic, and/or theoretical considerations.

c. Identify the Features of the Goal Trajectory

The third process, *Identify the Features of the Goal Trajectory*, operationalizes the elements of the design product. In the present situation the features were cognitive units and properties of the GT. As mentioned earlier we were concerned with preserving the level of cognitive specificity described by the curriculum. In the context of *Everyday Mathematics* (EM), the cognitive units were tied to the learning goals such as *Use patterns to find basic facts* and *Use rules to complete function tables/machines*. The learning goals comprised the Patterns, Functions, and Algebra (PFA) learning strand in the Grade 5 EM curriculum. Another feature was the ordinal property of the GT. Our intent was to design a GT with ordinal levels that could approximate variation in student performance and growth in cognitive complexity over time.

d. Evaluate Process Outcomes

As shown in Figure 1, the fourth process in the model, *Evaluate*, serves at least two functions. One is to evaluate the agreement between the purpose of the design product (i.e., process b) and its features throughout progress in the design cycle. For example, given the purpose of the design (see section *b. Specify the Purpose*), selecting cognitive units at the larger grain sizes of learning strands (e.g., measurement, number, or geometry) or content threads (e.g., patterns and functions, algebraic notation and solving number sentences, or properties of the arithmetic operations) would not have given the GT the necessary power to model cognitive *variability* in or among students. At those levels the GT would only describe two knowledge states: haves and have-nots. Therefore, it was critical to evaluate each feature of the GT with this constraint in mind.

A second function of the *Evaluate* process is to assess the extent that the design features and the method for assigning them into meaningful levels of the GT is viable given the model's design constraints which are explained below. The dashed circular path indicates that (a) the outcomes of two related processes are cross-evaluated (e.g., outcomes of processes *c* and *f*) and (b) the decision to move forward with the design depends on the balance of that cross-evaluation; if the balance is positive (i.e., consistent with the scope of the model) then advance, if negative (i.e., inconsistent with the scope of the model) then the model needs to be updated (process *e*).

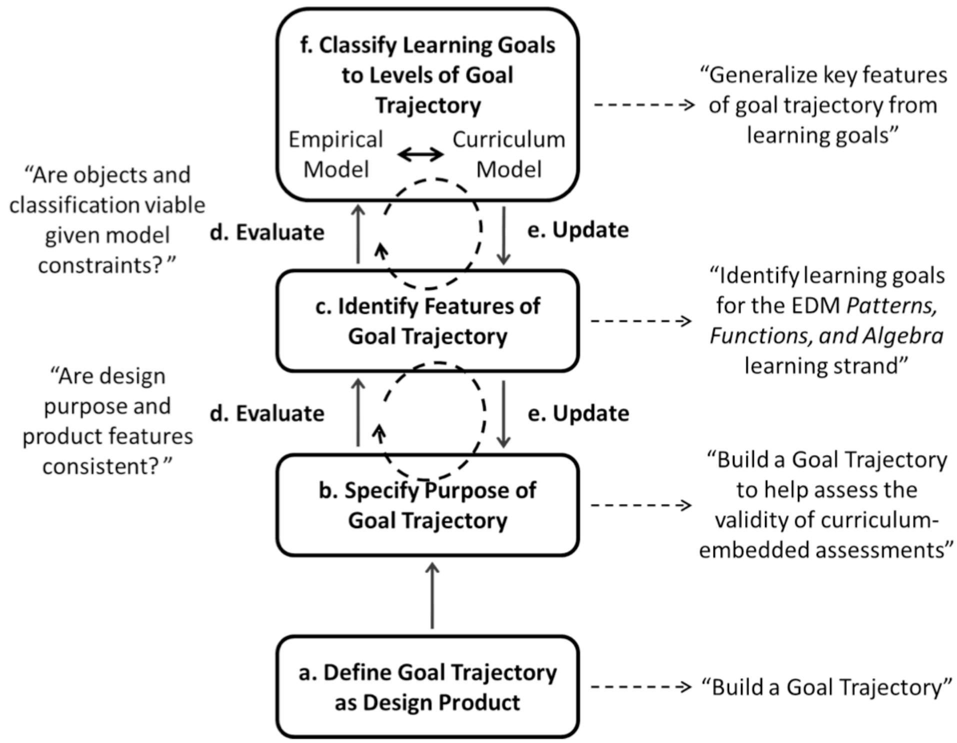

Figure 1. Model of goal trajectory design processes with examples

e. Update

The fifth process, *Update*, serves to make process outcomes consistent with the model or make the model consistent with process outcomes. If an evaluation of two process outcomes reveals an inconsistency (e.g., a learning goal defined as a feature of the GT does not "fit" into a level of the GT), then one or both of those outcomes will need to be updated. In this example a decision may be made to modify a trajectory level, a decision may be made to expand the trajectory by adding a level; or a decision may be made to modify the learning goal. If the two evaluated outcomes are related to processes *c* and *f*, then it may also be necessary to evaluate the outcome of process *b*. This particular chain of evaluations may support a decision to update the purpose of the design (e.g., the GT is useful for selecting embedded assessments but not for interpreting student performance). The cyclic iterations between *Evaluate* and *Update* processes can be one, few, or many in the actual design cycle. Indeed, the model is referred to as a design "cycle" because it is not linear in a strict sense. It is important that researchers or evaluators engaged in the design cycle keep careful records of the model's development from initial conception to final design. In our project we write reports that trace the nature of the design cycle as it unfolds.

Once the learning goals were identified in the curriculum and extracted, we met with the curriculum developers to evaluate (a) the extent that our search for PFA learning goals was exhaustive, (b) our understanding of the curriculum layout, and (c) the degree that the level of learning goal information we decided to use at that point in our design would enable us to build the desired GT. Indeed, our in-depth curriculum analysis revealed several layers of learning goal information. In its early stages, our GT referenced information from all of these layers. However, based on discussions with the curriculum developers we updated the model to include only a single source of learning goal information, the Grade-

Level Goals Chart. Our rationale for this decision was that the Grade-Level Goals Chart highlights the units in which the Grade 5 PFA learning goals are introduced. Using the Grade-Levels Goal chart as our point of reference we were able to “see” the concepts and skills that encompassed the Grade 5 curriculum over time. This satisfied a demand of our model (i.e., build a GT whose levels express ordinal relations) and we were ready to enact the sixth design process.

f. Classify Features into Levels of the Goal Trajectory

The sixth design process in our model for building a goal trajectory is *Classify*. To classify means to abstract a smaller set of cognitive constructs from the learning goals that approximated the major forms of reasoning in the trajectory. The Grade-Level Goals Chart yielded 38 PFA learning goals across the 12 units of the Grade 5 curriculum. The goals were organized into seven general levels of reasoning that were scheduled to be introduced in the PFA trajectory. In effect, the *Classify* process “collapses” all related learning goals across task demand (e.g., recall vs. recognition) and external representation format (e.g., base-10 blocks vs. arrays) resulting in a general set of learning goals and a manageable GT. Notice how Figure 1 indicates that the *Classify* process is constrained by two sources of information: (a) prior research in developmental psychology, cognitive psychology, and mathematics education on the development of and variability in algebraic reasoning (i.e., the “Empirical Model”), and (b) the instructional sequence of key concepts and skills as outlined by the curriculum (i.e., the “Curriculum Model”). As depicted in Figure 1, the resulting learning trajectory was subjected to an Evaluate-Update Cycle before final approval.

Learning Goal Trajectory for Understanding Patterns, Functions and Algebra

The result of the design processes in the current case is the Patterns, Functions, and Algebra (PFA) goal trajectory shown in Table 1. The design processes revealed that the general PFA goal trajectory for acquiring algebraic thinking was implicitly characterized by EM as growth from none or very little understanding of patterns, to identifying and using patterns, to formalizing patterns as a means for solving problems, to generalizing rules from patterns and sequences, to formalizing rules in notational, graphical, and tabular formats, to finally being able to reason with and about variables. The organization of the trajectory was consistent with a growing body of research in cognitive science and mathematics education which suggested that algebra acquisition could be defined by cognitive growth along a multi-path continuum of reasoning with patterns and sequences, generalizing rules from patterns and sequences, representing functions among rules, patterns, and sequences, and formalizing variables to think about functions (Carraher & Schliemann, 1992; Kaput & Blanton, 1999; Moss & McNabb, 2011; Smith & Thompson, 2007; Warren & Cooper, 2008).

Table 1: Goal Trajectory for Understanding Patterns, Functions and Algebra

	Level of Understanding	Examples
6	**Abstract Algebraic Functions** (Represent functions using words, algebraic notation, tables and graphs; represent patterns and rules using algebraic notations; translate from one representation to another; use representations to solve problems involving functions)	• Use a variable to represent unknown quantities to solve problems • Represent an algorithm as a general pattern with variables • Solve linear equations with one unknown and multiple operations using trial-and-error or equivalent equation strategies • Solve problems involving functions using representations; including translating from one representation to another
5	**Algebraic Functions** (Represent functions using words, symbols, tables and graphs; use those representations to solve problems)	• Represent functions using algebraic notations • Use representations of function(s) in tables and graphs to solve problems • Use patterns, tables and graphs to define relationships between volumes of 3D solids or between radius and area; • Represent rates with formulas, tables and graphs
4	**Function Rules** (Describe and/or write rules for functions involving the four basic arithmetic operations; use rules to solve problems)	• Identify and use patterns in graph coordinates to match graphs with situations • Use patterns to identify the relationship between numerators and denominators; use patterns to identify relationships between fractions and decimals • Generate rule for comparing, ordering fractions • Describe the patterns in an area model • Use rules to complete function tables/machines • Use words and symbols to extend patterns/ to describe the operations of Addition, Subtraction, Multiplication and/or Division and/or create/use rules to solve problems
3	**Numeric Pattern Rules** (Use words or symbols to create and/or describe rules for numeric patterns; use rules to extend patterns and solve problems)	• Use words and/or symbols and/or arithmetic notation and extend patterns to describe geometric rules • Use and describe patterns to find sums • Describe number patterns related to exponents and/or use them to solve problems
2	**Numeric Patterns** (Identify, use, expand, describe, or create numeric patterns)	• Complete number sequences • Use patterns to find basic facts • Describe and extend patterns among facts and their extension • Identify and/or use patterns in skip counting • Count in Equal Intervals
1	**No Understanding of Patterns**	• Not able to complete number sequences or count in equal intervals

Relationships Between the PFA Goal Trajectory and the Common Core State Standards

In addition to being consistent with empirical models of growth in algebraic reasoning, the trajectory also aligned with the mathematical content domains and practices outlined by the Common Core State Standards (CCSS) in several interesting ways. First, the Grade 5 EM trajectory for understanding patterns, functions, and algebra embodies two Grade 5 CCSS content domains: *Operations and Algebraic Thinking*

(OA) which focus on writing and interpreting numerical expressions and analyzing patterns and relationships and *Number and Operations in Base 10*. Second, the Grade 5 goal trajectory relates to these CCSS content domains across Grade 2, Grade 3, and Grade 4 but the mathematical foci (i.e., "clusters") vary among the grades. For example, whereas the CCSS Grade 5 OA domain has two relevant clusters that focus on (a) writing and interpreting numerical expressions, and (b) analyzing patterns and relationships, the CCSS Grade 3 OA domain has four clusters that emphasize (a) representing and solving multiplication and division problems, (b) understanding properties of multiplication and the relationship between multiplication and division, (c) multiplying and dividing using strategies (e.g., $8 \times 4 = 32$ therefore $32 \div 4 = 8$) and properties of operations, and (d) solving for unknown quantities that involve the four operations in addition to identifying and explaining arithmetic patterns. Aspects of the goal trajectory also map onto features of the Grade 6 CCSS content domain, *Expressions and Equations*, which includes clusters that focus on (a) applying and extending what is understood about arithmetic to algebraic expressions, (b) reasoning about and solving one-variable equations and inequalities, and (c) representing and analyzing the relationships between dependent and independent variables.

Besides aligning with the CCSS mathematical *content domains*, we also found the goal trajectory to be well-aligned with the CCSS mathematical *practices*; that is, the various habits of mind that mathematics instructors are expected foster in their students such as constructing viable arguments and reasoning with others, modeling with mathematics, using appropriate tools strategically, and attending to precision. There are various mathematical practices that map onto particular levels of the goal trajectory. For instance, take *Use a variable to represent unknown quantities to solve problems*, taken from the sixth level of understanding in the goal trajectory, *Abstract Algebraic Functions* (Table 1). The level of understanding relates to the CCSS mathematical practice that indicates variables are used to solve problems because they can help *make sense* of quantities and relationships. This mathematical practice implies that variables have greater utility than as simple tools for identifying or recalling answers. A second example of the alignment between the trajectory and the mathematical practices described by the CCSS can be found if one looks at *Complete number sentences* in the *Numeric Patterns* level of understanding in the goal trajectory. The latter is related to the CCSS mathematical practice that promotes the capacity to seek and use structure to describe and extend facts and patterns. The implication is that engaging students in practices that give them opportunities to identify the structure of number sequences should lead to efficient pattern identification strategies that can be applied across different task situations.

Discussion

A six-process model for building curriculum-and-instruction-based goal trajectories for cognitive research and instructional assessment was proposed. We instantiated the processes of the model in the context of our work with the Patterns, Functions, and Algebra learning strand in the Grade 5 *Everyday Mathematics* curriculum. The design processes yielded a unique representation of the goal information that was already represented—albeit, "hidden"—in the organization of the curriculum. Interestingly, the representation that we constructed as the PFA goal trajectory was quite different from the representation of that information as presented by the curriculum.

Re-Presentations of Curriculum-Embedded Goal Structures

Cognitive psychologists have reliably shown that different representations of equivalent information can vary in the way that they preserve information, and this in turn can yield differential affordances for accessing and utilizing the same information (e.g., Larkin & Simon, 1987; Palmer, 1978; Zhang & Norman, 1994). An evaluation of the model proposed in this paper indicates that the benefits of the constructed GT are the result of the aforementioned *representational effect* (Nickerson, 1988; Zhang, 1997). Indeed, the GT affords fresh and important insights into student understanding that expand upon what is available from the *Everyday Mathematics* curriculum materials, while also remaining faithful to the curriculum by basing the GT on the curricular learning goals and instructional materials. For one, the goal trajectory allows us to predict and account for a wider range of student performance on an activity than what is usually estimated by the curriculum, because the curriculum-based representation is typically limited to dichotomous evaluations of student performance such that student performance either reflects evidence of goal acquisition or it does not. A second benefit of the PFA goal trajectory is that it makes it possible to interpret student performance in terms of the cognitive constructs that are relevant to a particular domain in the contexts of the curriculum and scientific progress. Thus, the goal trajectory affords greater diagnostic information about student performance relative to the learning and acquisition of algebraic thinking.

Investigating Curriculum-CCSS Goal Alignment

Although the CCSS are based on notions of a learning trajectory or progression, their explicit description of one is limited to expectations of mathematical content domains and practices *across* not *within* grades. By comparing our constructed GT to the CCSS it became clear that for a teacher at a particular grade the CCSS was not intended to represent the expected understandings and reasoning patterns of students "well below or well above grade-level expectations," nor was it meant to account for variation contributed by English language learners or children with special needs. We propose that GTs help to illuminate—within the context of a particular mathematics curriculum—the potential for multiple levels of knowledge and reasoning that may be observed as students complete a given activity.

Mapping the CCSS Operations and Algebra content domain onto the GT of an elementary grades math curriculum revealed interesting relationships between each level of the goal trajectory and the CCSS. In particular, as the GT levels progressed, the number of shared relations between each level and the standards increased. Whereas the earlier levels of the trajectory shared a one-to-one relationship with the CCSS standards, the advanced levels of the trajectory shared a one-to-many relationship with the standards in which a single level of the GT was linked to multiple goals in the CCSS. Finally, in support of the CCSS's position about the breadth of mathematical practices, our analysis indicated that the CCSS mathematics practices were differentially instantiated at each GT level of understanding. The extent that these patterns will emerge with other GTs (e.g., Number and Numeration) and the empirical validity of the GT levels is currently being investigated.

Acknowledgments

The authors would like to thank Susan Wortman for helping with some of the earlier curriculum analyses. We are also grateful to Louis V. DiBello, James W. Pellegrino, Susan R. Goldman, and three anonymous reviewers for their thoughtful comments on an earlier draft. This research was supported in part by grants from IES (#R305A090111) and NSF (DRL-0732090). The opinions expressed in this paper are those of the authors and do not necessarily reflect the views of IES or NSF.

This paper explores how curriculum and classroom conceptual and procedural emphases affect the learning of algebra for students of color. Using data from a longitudinal study of the Connected Mathematics Program (CMP), we apply cross-sectional HLM to lend explanatory power to the longitudinal analysis afforded by Growth Curve Modeling that we have reported elsewhere. Overall, we find that the achievement gaps tend to decrease over the course of the middle grades. However, differences in open-ended problem solving and equation solving performance persist for African American students. Classroom conceptual and procedural emphases also appear to differentially influence the performance of Hispanic and African American students, depending on the aspect of algebra learning that is being measured.

Keywords: Curriculum Analysis; Equity and Diversity; Algebra and Algebraic Thinking

Classrooms in the United States are becoming increasingly ethnically diverse. However, disparities in the mathematics achievement of different ethnic groups remain a persistent challenge (Lubienski & Crockett, 2007). Since teaching and learning are cultural activities, students with different ethnic and cultural backgrounds may respond differently to the same curriculum. Given the development and implementation of curricula based on the *Standards* documents developed by the National Council of Teachers of Mathematics (NCTM, 1989, 2000), a key question about curriculum reform is: How does the use of a *Standards*-based curriculum like CMP impact the learning of students of color as compared to White students?

In our project, Longitudinal Investigation of the Effect of Curriculum on Algebra Learning (LieCal), we used a longitudinal design to examine the similarities and differences between a *Standards*-based curriculum called the Connected Mathematics Program (CMP), and more traditional curricula (non-CMP). We investigated not only the ways and circumstances under which the CMP and non-CMP curricula affected student achievement gains, but also the characteristics of these reform and traditional curricula that hindered or contributed to the gains. One aspect of the LieCal analysis was an examination of potentially differential effects of curriculum and procedural and conceptual emphases in the classroom on the achievement of students of color. In this paper, we present results from a cross-sectional analysis of student growth within each grade level. This analysis allows us to add depth to our previous analysis using Growth Curve Modeling by probing effects that are significant at individual grades but which were not uncovered in our longitudinal analysis.

Background

Algebra readiness has been characterized as the most important "gatekeeper" in school mathematics (Pelavin & Kane, 1990). In particular, success in algebra and geometry has been shown to help narrow the disparity between minority and non-minority participation in post-secondary opportunities (Loveless, 2008). Research shows that completion of an Algebra II course correlates significantly with success in college and with earnings from employment. The National Mathematics Advisory Panel (2008) found that students who complete Algebra II are more than twice as likely to graduate from college as students with less mathematical preparation. Furthermore, the African-American and Hispanic students who complete

Algebra II cut the gap between their college graduation rate and that of the general student population in half. However, success in high school algebra is dependent upon mathematics experiences in the middle grades. In fact, middle school is a critical turning point for students' development of algebraic thinking (College Board, 2000).

In a *Standards*-based curriculum like CMP, the focus is on conceptual understanding and problem solving rather than on procedural knowledge. Students are expected to learn algorithms and master basic skills as they engage in explorations of worthwhile problems. However, a persistent concern about Standards-based curricula is that the development of students' higher-order thinking skills comes at the expense of fluency in computational procedures and symbolic manipulation. In addition, it is not clear whether this potential trade-off might play out differently for students from different ethnic backgrounds. Some reports have suggested that Hispanic and African American students using the CMP curriculum may in fact show greater achievement gains than students from other backgrounds (Rivette, Grant, Ludema, & Rickard, 2003). Still, research is needed to assess whether and how the use of a Standards-based curriculum such as CMP can improve the mathematics achievement of all students while helping to close achievement gaps (Lubienski & Gutiérrez, 2008; Schoenfeld, 2002).

Since the effectiveness of a curriculum depends critically on how it is implemented by teachers in real classrooms, studies of the effectiveness of Standards-based curricula must examine how teachers use the curricula (Kilpatrick, 2003; NRC, 2004; Wilson & Floden, 2001). The data gathered must be analyzed in appropriate ways to control for variations in classroom instruction and the learning environment. In order to determine the effects of curriculum on learning, it is essential to examine the classroom experiences of the teachers and students who are using the different curricula. In this paper, we take features of classroom instruction into consideration when we examine the impact of curricula on students' learning of algebra. In particular, we examine the extent to which teachers emphasize concepts and procedures in the classroom. As was reported by Moyer, Cai, Nie, and Wang (2011), CMP teachers placed more emphasis on conceptual understanding whereas non-CMP teachers placed more emphasis on procedural knowledge.

Our previous longitudinal analyses of the LieCal data using Growth Curve Modeling showed that over the three middle school years, African American students experienced greater gain in symbol manipulation when they used a traditional curriculum. The use of either the CMP or a non-CMP curriculum improved the mathematics achievement of all students, including students of color. The use of CMP contributed to significantly higher problem-solving growth for all ethnic groups (Cai, Wang, Moyer, Wang, & Nie, 2011). In this paper, we take a cross-sectional approach and examine the achievement of students of color in each grade level while controlling for the conceptual and procedural emphases in classroom instruction.

Method

Sample

The LieCal project was conducted in 14 middle schools of an urban school district serving a diverse student population. When the project began, 27 of the 51 middle schools in the district had adopted the CMP curriculum, and the remaining 24 had adopted more traditional curricula. Seven schools were randomly selected from the 27 schools that had adopted the CMP curriculum. After the seven CMP schools were selected, seven non-CMP schools were chosen based on comparable demographics. In sixth grade, 695 CMP students in 25 classes and 589 non-CMP students in 22 classes participated in the study. We followed these 1,284 students as they progressed from grades 6 to 8. Approximately 85% of the participants were minority students: 64% African American, 16% Hispanic, 4% Asian, and 1% Native American. Male and female students were almost evenly distributed.

Assessing Students' Learning

Learning algebra involves honing procedural skills with computation and equation-solving, fostering a deep understanding of fundamental algebraic concepts and the connections between them, and developing the ability to use algebra to solve problems. Thus, to assess students' learning of algebra, it is important to consider their conceptual understanding, their symbol manipulation skills, and their ability to solve problems. We used state test scores in mathematics and reading as measures of prior achievement. We used LieCal-developed multiple-choice and open-ended assessment tests as dependent measures of procedural knowledge and conceptual understanding in algebra, respectively. The two LieCal-developed tests were administered four times, once as a baseline in the fall of 2005, and again each spring (2006, 2007, and 2008).

We used multiple-choice items to assess whether students had learned the basic knowledge required to perform competently in introductory algebra. Each version of the multiple-choice test was comprised of 32 questions that assessed five mathematics components (Mayer, 1987): translation, integration, planning, computation (or execution), and equation solving. For this paper, we report on the results from the translation, computation, and equation-solving components of the multiple-choice tasks. In addition, the open-ended tasks were designed to assess students' conceptual understanding and problem-solving skills. These tasks were adopted from various projects including Balanced Assessment, the QUASAR Project (Lane et al., 1995), and a cross-national study (Cai, 2000). Since only a small number of open-ended tasks can be administered in a testing period, and since grading students' responses to such items is labor-intensive, we distributed the non-baseline tasks over three forms (five items in each form) and used a matrix sampling design to administer them. Examples of the items and tasks used in the LieCal assessments can be found in Cai et al. (2011).

The multiple-choice items then were scored electronically, either right or wrong. The open-ended tasks were scored by middle school mathematics teachers, who were trained using previously developed holistic scoring rubrics. Two teachers scored each response. On average, perfect agreement between each pair of raters was nearly 80%, and agreement within one point difference out of 6 points (on average) was over 95% across tasks. Differences in scoring were arbitrated through discussion. The two-parameter Item Response Theory (IRT) model was used to scale student assessment data on both multiple-choice tasks and open-ended tasks (Hambleton, Swaminathan, & Rogers, 1991; Lord, 1980).

Conceptual and Procedural Emphases as Classroom-level Variables

Mathematical proficiency includes both conceptual and procedural aspects (NRC, 2001), and teachers can shape instruction in ways that emphasize either or both aspects. We used conceptual and procedural emphases as classroom variables when examining the impact of curriculum on students' learning. To do so, we estimated the levels of conceptual and procedural emphases in the CMP and non-CMP classrooms using data from 620 lesson observations of the LieCal teachers, which we conducted while the students were in grades 6, 7, and 8. Each class was observed four times, during two consecutive lessons in the fall and two in the spring. Further details about the observations are documented in Moyer et al. (2011). One component of the observation was a set of 21 items using a 5-point Likert scale to rate the nature of instruction for each lesson. Of the 21 items, four were designed to assess the extent to which a teacher's lesson had a conceptual emphasis. For example, observers rated a lesson's conceptual emphasis using the following item: "The teacher's questioning strategies were likely to enhance the development of student conceptual understanding/problem solving." Another four items were designed to determine the extent to which a teacher's lesson had a procedural emphasis. For example, observers rated a lesson's procedural emphasis using this item: "Students had opportunities to learn procedures (by teacher demonstration, class discussion, or some other means) before they practiced them." Factor analysis of the LieCal observation data confirmed that the four procedural-emphasis items loaded on a single factor, as did the four conceptual-emphasis items. Since students changed their classrooms and teachers as they moved from grade 6 to grade 7 and from grade 7 to grade 8, each student could have a different value each year for three years, but all students in the same classroom at each grade had the same value.

Quantitative Data Analysis

To examine student growth within each school year while controlling for multiple factors such as gender, ethnicity, and classroom conceptual and procedural emphases, we used hierarchical linear modeling (HLM). After unconditional models were fitted, two sets of conditional cross-sectional HLM analyses were conducted. The first set of models was composed of cross-sectional hierarchical linear models that included student-level variables and a curriculum variable. These models used four different student achievement measures: open-ended, translation, computation, and equation solving. Each HLM model used data from one of the four dependent achievement measures in one of three middle grades, together with an independent prior achievement measure, namely the results of the state mathematics testing in the fall of the corresponding year. So, each model examined a single type of learning within a specific grade level. Since we had four achievement measures at each of three grade levels, there were 12 cross-sectional models in this first group.

The next set of models built on the first group of models by adding two classroom-level variables: the conceptual emphasis of the classroom and the procedural emphasis of the classroom. These cross-sectional HLM models were of the following form:

Level-1 Model

$$Y_{ij} = p_{0j} + p_{1j}(\text{Prior Achievement}_{ijk} - \overline{X}_1) + p_{2j}(\text{Gender}_{ijk} - \overline{X}_2) + p_{3j}(\text{African American}_{ijk} - \overline{X}_3) + p_{4j}(\text{Hispanic}_{ijk} - \overline{X}_4) + p_{5j}(\text{Other Ethnicity}_{ijk} - \overline{X}_5) + r_{ijk}$$

Level-2 Model

$$p_{0j} = b_{00} + b_{01}\text{CMP} + b_{02}\text{Conceptual Emphasis}_j + b_{03}\text{Procedural Emphasis}_j + r_{0j}$$

Interactions between conceptual emphasis, procedural emphasis, and curricula were tested, but found to be not significant.

Results

We present the results of our analysis in two parts. First, we report on the cross-sectional HLM models that included student-level and curriculum variables. Then, we examine the impact of including the classroom-level conceptual and procedural emphasis variables in the models.

Student-Level and Curriculum Cross-sectional HLM Models

Table 1 shows the standardized results from an examination of the performance of African-American and Hispanic students relative to White students, when controlling for prior achievement, gender, and curriculum (but not conceptual and procedural classroom emphases).

Table 1: Effect of Ethnicity on Mathematics Achievement

	Grade 6		Grade 7		Grade 8	
	African American	Hispanic	African American	Hispanic	African American	Hispanic
Open-ended	-0.50***	-0.21*	-0.26**	-0.22*	-0.28***	-0.13*
Translation	-0.24**	--	--	--	--	--
Computation	-0.37***	-0.22*	--	--	--	--
Equation solving	-0.35**	-0.23*	-0.24**	-0.22*	--	--

* $p < .05$. ** $p < .01$. *** $p < .001$.

In the sixth grade, an achievement gap was seen between African American students and White students on all four student achievement measures, and between Hispanic students and White students on the open-ended, computation, and equation solving measures. The gaps on the open-ended and equation solving measures remained in the seventh grade for both groups. However, performance on the computation and translation measures had equalized across the groups. In the eighth grade, the only gap that remained was on the open-ended items. The overall trend was a gradual decline or elimination of the achievement gap among the ethnic groups.

To better understand if using the CMP curriculum would reduce achievement gaps, we conducted separate parallel analyses for CMP and non-CMP students. The results are shown in Table 2. In the analysis of the combined CMP and non-CMP student sample, achievement gaps for the translation and computation measures occurred only in the 6th grade: White students outperformed African American students on both measures, and White students outperformed Hispanic students on computation. However, in the analyses of the separate student samples, we found that although all three of these gaps appeared for the non-CMP students, the only achievement gap for the 6th grade CMP students was in computation. In grades 7 and 8, the performance parity on computation and translation items observed in the combined sample of students was mostly preserved in the separate analyses, except for the appearance of a gap between CMP 8th grade African American students and White students on computation items.

Mirroring the results from the combined sample, White students outperformed African American students on open-ended items across all three grades regardless of curriculum. For students using CMP, White students also outperformed Hispanic students on these items in Grades 7 and 8. For non-CMP Hispanic students, however, there were no parallel achievement gaps. For the equation solving items in the combined analysis, White students outperformed African-American and Hispanic students in grades 6 and 7, with no achievement gap in grade 8. These gaps were attributable to the CMP students; there were no achievement gaps found for equation solving items among the non-CMP students. For CMP students, White students outperformed African American students in all three grades, and White students outperformed Hispanic students in grades 7 and 8.

Table 2: Effect of Ethnicity on Mathematics Achievement for CMP / Non-CMP Students

	Grade 6		Grade 7		Grade 8	
	African American	Hispanic	African American	Hispanic	African American	Hispanic
Open-ended	-0.40** / -0.91***	-- / --	-0.27** / -0.23*	-0.31**/ --	-0.36** / -0.26**	-0.28**/ --
Translation	-- / -0.37*	-- / --	-- / --	-- / --	-- / --	-- / --
Computation	-0.43** / -0.27**	-- / -0.35**	-- / --	-- / --	-0.22* / --	-- / --
Equation solving	-0.35* / --	--/ --	-0.44** / --	-0.45**/ --	-0.23**/ --	-0.22*/ --

* $p < .05$. ** $p < .01$. *** $p < .001$.

Student-Level, Classroom-Level and Curriculum HLM Models

We built on the results of Table 1 with the addition of the conceptual emphasis and procedural emphasis classroom-level variables. Our goal in adding these variables to the analysis was to begin to probe the complexity that underlies conclusions we might otherwise draw from one-dimensional comparisons of students in different ethnic groups. With respect to the analysis of the combined CMP and non-CMP students, however, the addition of the classroom-level variables did not greatly perturb the results save for the disappearance of the gap in Hispanic students' performance on open-ended tasks in the 8th grade.

We again conducted parallel analyses for the CMP and non-CMP students, this time including the conceptual and procedural emphasis classroom-level variables. The results are presented in Table 3. For the CMP students, two achievement gaps were no longer statistically significant with the addition of the classroom variables: 8th grade African American students on computation items, and 8th grade Hispanic students on equation solving items. For non-CMP students, the performance gap of 6th grade African American students on translation and computation items ceased to be significant.

Table 3: Effect of Ethnicity on Mathematics Achievement for CMP/Non-CMP Students Controlling for Conceptual and Procedural Emphases

	Grade 6		Grade 7		Grade 8	
	African American	Hispanic	African American	Hispanic	African American	Hispanic
Open-ended	-0.40** / -0.90***	--/ -0.33*	-0.28** / -0.27*	-0.30**/ --	-0.36** / -0.23**	-0.29**/ --
Translation	-- / --	-- / --	-- / --	-- / --	-- / --	-- / --
Computation	-0.37** / --	-- / -0.33**	-- / --	-- / --	-- / --	-- / --
Equation solving	-0.35*/ --	-- / --	-0.45** / --	-0.44**/ --	-0.21** / --	-- / --

* $p < .05$. ** $p < .01$. *** $p < .001$.

For the combined student groups, the performance of Hispanic students in the 8th grade was not significantly different from 8th grade White students for all four achievement measures. Similarly, the performances of 8th grade African American and White students were not significantly different except on the open-ended items; there was no achievement gap between African American and White students in the 8th grade on translation, computation, and equation solving items. When analyzed as separate groups, the CMP and non-CMP students of color generally showed achievement gaps on open-ended items compared to White students using the same curriculum. Within the CMP student group, there were also achievement gaps for African American students on equation solving items.

Discussion

In examining how Standards-based curricula such as CMP affect the mathematics learning of students of color, it is important to use nuanced analyses to look beyond one-dimensional comparisons (Lubienski, 2008). The longitudinal growth curve analysis of the LieCal data provided mixed conclusions regarding the use of the CMP curriculum with students of color (Cai et al., 2011). Though, over the course of the middle grades, African American and Hispanic students had growth rates similar to students not in their ethnic groups on the open-ended, translation, and equation solving measures, African American students had a smaller growth rate on the computation measure. The cross-sectional HLM analysis in this paper provides detail not captured in the longitudinal analysis.

Overall, the results of the cross-sectional analysis show a trend of decreasing gaps in achievement. Whereas Hispanic and African American students score significantly lower than White students on most or all of the measures at the end of 6th grade, by the end of 8th grade, only the open-ended measure still reflects a gap. Moreover, when classroom conceptual and procedural emphasis is taken into account, the only difference that remains at the end of 8th grade is in African-American students' performance on the open-ended tasks. Despite the slower growth rate in African American students' performance on computation tasks that was identified in the longitudinal analysis, the effect seems to be largely limited to the 6th grade.

When the cross-sectional analysis is limited to the CMP students, the open-ended measure reflects a persistent gap between White students and students of color. Similarly, for African American students in the CMP group, equation solving remains an area of challenge throughout the middle grades. Even when classroom conceptual and procedural emphasis variables are included, these gaps remain. Indeed, these performance gaps in the CMP analysis do not decrease with grade level, as many of the other performance gaps do. Thus, despite the fact that the longitudinal analysis showed comparable growth curves for White students and students of color on the open-ended measure, the cross-sectional analysis suggests that there may be opportunities within the CMP curriculum for developing open-ended problem-solving skills that are being differentially accessed by students of different ethnic backgrounds.

It is interesting to note how the influence of classroom emphasis variables played out differently for different student groups. For example, the profile of Hispanic CMP students' equation solving performance was somewhat different from the African American students'. For Hispanics, the negative CMP effect was limited to the 7th grade. Classroom conceptual and procedural emphases, not curriculum, appear to account for Hispanic student performance differences in the 8th grade. Moreover, the reverse appears to be the case with respect to the translation and computation measures in the 6th grade. When controlling for classroom emphasis, there was no longer an achievement gap for African American students. This difference in the effects of classroom emphasis on Hispanic and African American students merits exploration.

In conclusion, the longitudinal and cross-sectional analyses continue to paint a mixed picture of the effects of the CMP curriculum for students of color. By grade 8, most performance differences on the measures in this study were no longer significant. Though African-American students' computation skills appeared to grow more slowly across grades 6 through 8, the effect of this difference seems to have been primarily limited to grade 6. However, the persistent gaps between African American students and White students on the open-ended and equation solving measures, even when classroom emphases are taken into account, invite further investigation.

UNPACKING THE COMMON CORE STATE STANDARDS FOR MATHEMATICS: THE CASE OF LENGTH, AREA AND VOLUME

KoSze Lee

Adoption of the Common Core State Standards present challenges to school districts, school administrators, and teachers. To assist in this endeavor, we present our work on unpacking the CCSS-M for the length, area, and volume Learning Trajectory (LT). The overarching theme of "genetic epistemology" and a five-characteristic framework guided our work of unpacking the Standards. As a result, we added "Bridging Standards" to mediate students' progression through the length, area, and volume LT to provide a coherent structure through this trajectory. The implications of our work were discussed.

Keywords: Standards; Learning Trajectories; Curriculum

Objective

The Common Core State Standards for Mathematics (CCSS-M) (CCSSI, 2010) are a major revamping of existing and past state standards. Adoption of the CCSS-M presents many challenges for school administrators and teachers. In particular, the learning trajectories that ostensibly undergird the Standards are not readily accessible to readers because they are *abridged* within the standards and do not contain a full treatment of the research base (Confrey, 2012). Hence, there are gaps between standards reducing their cohesiveness. Finally, the Standards authors state: "These Standards do not dictate curriculum or teaching methods" (CCSSI, 2010, p. 3) which is commendable, however, this implies that teachers need resources and support to understand the gradual evolution of the "big ideas" within the Standards.

Our research group has unpacked the grade K–8 standards for the CCSS-M (http://www.turnonccmath.com) (Confrey et al., 2011) by mapping each of the K–8 standards onto 17 LTs (Confrey, 2012). For each trajectory, we unpacked the Standards, or parts of a Standard if it had a few parts (e.g., 3.MD.7 had three parts: 3.MD.7.a, 3.MD.7.b, and 3.MD.7.c), into descriptors to include a careful discussion of the full learning trajectory. The descriptors include: (1) Conceptual principles; (2) Misconceptions, strategies, and representations; (3) Introduction of meaningful distinctions about mathematical concepts and multiple models of situations; (4) A coherent Structure of Development underlying the LT; and (5) Bridging Standards. Other groups who are unpacking the standards tend to elaborate on the mathematical content in each Standard (e.g., McCallum, Black, Umland, & Whitesides, 2010) or make comparisons between existing standards and the CCSS-M (e.g., North Carolina Department of Public Instruction, 2011). Though important, these approaches do not always give perspective on how students' mathematical ideas advanced under instruction. In this paper, we present our work on unpacking the K–5 CCSS-M Standards for the *length, area, and volume* LT. Drawing upon the literature, we created an initial draft to reveal a coherent structure for this LT.[1]

Literature Review

Learning Trajectories

The term *learning trajectories (LT)*, has different meanings among researchers in mathematics education. Simon (1995) first defined a *hypothetical learning trajectory* (HLT) to be, "The learning goals, the learning activities, and the thinking and learning in which students might engage" (p. 133). Our research group defines a learning trajectory to be,

> a researcher-conjectured, empirically-supported description of the ordered network of constructs a student encounters through instruction (i.e., activities, tasks, tools, and forms of interaction), in order

> to move from informal ideas, through successive refinements of representation, articulation, and reflection, towards increasingly complex concepts over time. (Confrey, Maloney, Nguyen, Mojica, & Myers, 2009)

We view LTs as expected probabilities of students' progresses in their development of mathematical knowledge in terms of sequence and likelihood. LTs permit one to specify at an appropriate and actionable level of detail what ideas students need to know during the development and evolution of a given concept over time. This definition allowed us to unpack and sequence of the CCSS-M Standards guided by the research literature on spatial measurement.

Learning Trajectories for Length, Area, and Volume

Synthesizing the literature in length and area measurement (Nguyen, 2010), we found three different viewpoints on measurement: (1) those who have built LTs for length and area using an external iterating unit (Barrett, Clements, Klanderman, Pennisi, & Polaki, 2006; Battista, 2007; Battista, Clements, Arnoff, Battista, & Borrow, 1998; Clements & Sarama, 2009; Outhred & Mitchelmore, 2000); (2) those who have investigated the use of common units as measure (Lehrer et al., 1998; Nguyen, 2010); and (3) those who have built an entire numeration system based on measurement (Dougherty & Venenciano, 2007). By approaching measurement as a "systematic process to compare two or more quantities" (Confrey, 2011), we expanded the meaning of measurement beyond association a number of units with a given quantity to include building number-unit relationships using units that are internal of and external to the object being measured. In our work, we treated students' learning of the concepts and skills of length, area and volume as progressions through a single LT instead of separate LT for the above reason.

Development of length trajectories. Sarama and Clements (2009) have proposed a LT for length measurement based on a mixed method analysis and synthesis from other studies (e.g., Hiebert, 1981; Lehrer, 2003; Piaget, Inhelder, & Szeminska, 1960; Stephan, Cobb, & Gravemeijer, 2003). Their LT identified five areas of how students build concept and skills through instructional experiences: (1) alignment of endpoints to compare lengths (Piaget et al., 1960); (2) comparing the lengths of two objects using a third object and transitive reasoning (Hiebert, 1981); (3) finding the lengths of an object by "tiling" or "iterating" smaller identical objects as length units and associating higher counts with longer objects (Hiebert, 1981; Lehrer, 2003; Stephan et al., 2003); (4) understanding that length measure requires equal-length units (Ellis, Siegler, & Van Voorhis, 2000); and (5) using rulers and length measures to investigate real-world phenomenon (Lehrer, 2003; Stephan et al., 2003).

The evolution of students' concepts and skills on length measurement is described in terms of students' developmental progressions and their action schemes (see Sarama & Clements, 2009, pp. 289–291 for details). Seven levels were identified in the LT: (1) Pre-length quantity recognizer; (2) Length quantity recognizer; (3) Length direct comparer; (4) Indirect length comparer; (5) End-to-end length measurer; (6) Length unit relater and repeater; and (7) Length measurer. Sarama & Clements' (2009) work and its supporting corpus of studies provided the research input needed to unpack the Length Standards (Sarama, Clements, Barrett, Van Dine, & McDonel, 2011).

Development of area trajectories. Researchers have documented that to have a deep understanding on area, students must first understand the idea of systematic coverage (no overlaps or gaps) by a square unit (Outhred & Mitchelmore, 2000). They learn to align the units into an array of rows and columns, relating rows and columns to the lengths of the sides, and finally to calculate area from the number of units of length and width (Battista et al., 1998). Other aspects of a more complete learning trajectory for area would include developing student understanding about measuring with a square unit versus with a ruler, linking to lattice point arrays, the impact of different sized units on the magnitude of the area, linking area and perimeter, and extending to triangles or circles. Finally, it would include student understanding of the calculation of fractional area with an anticipation that the product of two numbers produce an area that is smaller than an area of either one of the linear dimensions by 1 unit (e.g. ½ in. x $^3/_4$ in. = $^3/_8$ sq. in. is less than ½ in by 1 in. or $^3/_4$ in by 1 in.).

Nguyen (2010) documented that students could construct common units to compare areas when asked to compare two or more areas without the provision of an external unit. Through equipartitioning (Confrey et al., 2009) of the two areas into smaller areas, students created a same-sized area unit embedded in the original areas to be used as the basis of comparison. He also demonstrated that students eventually generalized that if two areas are equal, they must be measured by the same-sized unit the same number of times. As a result, his students were able to correctly predict the effects of changing the unit size on the measure of an area. Others have investigated a number of these ideas (Simon & Blume, 1994), but work remains to synthesize these findings into a unified description linked to student behaviors.

Development of volume trajectories. Battista and Clements (1996) showed five levels of student behaviors when working volume tasks. At Level A, students only begin to conceptualize a set of cubes that forms a rectangular array. At Level B, students have conceptualized the cubes, but do not utilize the inherent layer structure of a 3-dimensional cube. At Level C, cube faces are used, however, either all of the face cubes are counted or outside the cubes. At level D, students use the volume formula and count a row of face cubes to calculate volume. Lastly, level E is reserved for outliers. Students who were not yet at Level A were generally unable to find out how many cubes there were in a 3-dimensional box, since seeing a mental array picture is only the beginning step to Level A understanding. To such students, the L × W × H formula means very little. Those who applied the formula tended to ignore the three-factor product that results from volume measurement. Multiplication was also not the only operation relied on to calculate volume. Addition, skip counting, and repeated addition were also used.

Battista (1999) followed with a teaching experiment to see if fifth graders could enumerate cubes. All six students in the study were able to structure and enumerate 3D cube arrays. However, their use of layering did not immediately lead to its use in subsequent predictions. Battista (2007) currently claims seven levels of sophistication in students' uses of cubic arrays to construct volume, ranging from organization or location of units in arrays, to introducing composite units, emergent array structures, and spatial structuring and enumeration.

Curry and Outhred's (2005) work distinguishes "packing volume" with cubes and "filling volume" with liquid or sand. While investigating students' understanding of the relationship between length, area, and volume, they discovered that student scores on packing volume tasks were highly correlated with scores on length. In these tasks, students were asked to pack an area with a unit box. They performed much better on tasks involving filling volume with water or sand. The authors conjectured that a filling procedure and length iteration were related processes. This literature informed our consideration of the contents to be included in the descriptors.

Unpacking the Length, Area, and Volume Trajectory

An overarching theme of our work is to consider the "genetic epistemology" (Piaget, et al., 1960) of how instruction refines students' informal mathematical idea successively and develop more complex ideas, as informed by research from a cognitive and instructional standpoint. The adoption of the genetic epistemology approach motivated a five-characteristic framework for unpacking the mathematical content of the Standards into the descriptors. First, the descriptors provide an explicit breakdown of complex mathematical ideas into its *conceptual principles*. For example, the descriptor for standard 1.MD.2 spells out the principles of using a length unit to measure. Second, the descriptors address the *misconceptions, strategies, and representations* that students may encounter as their informal ideas evolve into complex mathematical ideas. For example, the descriptor for standard 2.MD.1 addresses the misconception in using a ruler, where students may misinterpret the number of tick marks spanned by an object as its length. Third, the descriptors identify *meaningful distinctions* about a mathematical concept. These distinctions lead to *multiple models* of problems and support students' generalizations. For example, the descriptor for standard 3.MD.5.b makes three distinctions about the idea of "an area of n square units" as: (1) iterating an area unit $n - 1$ times, (2) "n times as big" as an area unit, and (3) a sweep of a line segment over a distance. Fourth, the organization of the descriptors of a LT reflected a genetically *coherent structure* of development through which students develop "big ideas." For example, the descriptors of this LT are organized to highlight the genetic sequence in which students develop length, area, and volume by: (1) Defining the attribute, (2) Direct comparison, (3) Indirect comparison, (4) Measuring using a unit with no gaps or overlaps, and (5) Compensatory and Additive principles. Fifth, we introduce “Bridging Standards,” additional mathematical knowledge that mediates students’ progression from prior concepts in earlier Standards to more sophisticated and formal concepts in later standards. These Bridging Standards and their descriptors provide a complete genetic epistemological account of a LT. For example, qualitative comparison of area and volume were added as Bridging Standards, since this mathematical knowledge was instrumental to the coherent structure underlying students’ development of measurement, but was not included in the CCSS-M.

We approach the task of unpacking the CCSS-M by describing students’ development in terms of the characteristics mentioned above. Our unpacking proceeded in the following manner. First, we sequenced the relevant Standards in a way that generally reflects research findings about how students progressively learn the ideas. A set of sequenced Standards can be regarded as an *abridged* LT. Second, based on the abridged LT, we built an unabridged version where we incorporated research findings to bridge the instructional gaps between and within the standards of a LT. For length, area, and volume, we synthesized different research findings in the domain of spatial measurement into a unified description of how students’ mathematical knowledge evolved as they encounter activities, tasks, tools, and forms of interaction. Third, we added Bridging Standards when we felt the research suggested mediating ideas that were necessary to be learned before progressing to the next standard in the LT.

We drafted the text of the unpacked LTs in the format of a two-column table, in which the left column showed the standards and its codes as sequenced in the LT and the right column showed the descriptor of the standard. We used Confrey’s (2010) hexagons map to represent how the LTs develop over time and to depict how they are relate to each other visually. The length, area, and volume LT was organized into six sections: (1) Attributes, Measuring Length and Capacity by Direct Comparison; (2) Length measurement using units and tools; (3) Area and Perimeter; (4) Volume Measurement; (5) Conversion; and (6) Area and Volume of Geometrical Shapes and Solids. The move to subdivide the entire LT into sections does not signify some disconnect between the contents of the descriptors but rather permit us to focus on unpacking the more intertwined connections among some Standards. In fact, cross-references between the Standards were often made when drafting the descriptors.

Report of the Unpacking of Length, Area and Volume Standards

We wrote 50 descriptors in the length, area, and volume LT (36 from CCSS-M and 14 Bridging Standards). Below we present a summary of the mathematical knowledge that we have unpacked, according to the five-characteristic framework. The most updated edition of the descriptors can be accessed online (http://www.turnonccmath.com).

Conceptual Principles of Length, Area, and Volume

In the descriptors, we unpacked a list of conceptual principles to be mastered by students across length, area, and volume. They are: the Conservation Principle, the Compensatory Principle, the Principle of Unit Placement, the Principle of Unit Conversion, and the Additive Principle. The Conservation Principle states that the length (or area or volume) of an object remains unchanged under any rigid transformation. The Compensatory Principle states that there is an inverse relationship between the size of the unit (length, area, or volume) used for measurement and the measure (count of the units). The Principle of Unit Placement states that the units used to measure the length (or area or volume) of an objects must be placed without gaps or overlaps and along a path aligned with the object's length (or arrays in the case of area and volume). The Principle of Unit Conversion states that smaller units can be composed to form larger units and that larger units can be regrouped into smaller units. The Additive Principle states that the joining of two lengths (areas or volumes) are sums of the lengths (areas or volumes). From the LT perspective, these principles are foundational to students' development across length, area, and volume. This does not imply that they are taught directly, but rather that the students’ understanding of them evolves gradually through the course of activities and tasks.

Misconceptions, Strategies and Representations

We identified a number of misconceptions informed by NAEP results. These concerned students'' use of rulers and their understanding about area and perimeter. For example, when measuring the length of an object, many students do not check if the object aligns with the zero mark. They also tend to treat tick marks on the ruler as the length of the object instead of the interval between the tick marks. In area and perimeter, students tend to measure the perimeter of a rectangle using square tiles around the corner and believe that increasing the perimeter of a rectangle always increase its area.

We described length as being represented on a number line by equally spaced intervals from 0 as a useful representation of addition and subtraction. Addition of two numbers ($a + b$) could be thought of as combining a length of a units with another length of b units. Subtraction of two numbers, $a – b$ can be thought of as comparing the difference between two line segments or taking away b units from a line segment of a units. For strategies, we also highlighted various ways in which students can directly compare two lengths, two areas and two volumes. Because length, area, and volume have different spatial properties, the strategies of direct comparison varied. For example, straight lengths can always be directly compared, while some areas may overlap and need decomposition to compare. Likewise, the capacity of two containers can be directly compared if poured into cylinders with the same base, whereas volumes of solids will require a systematic means of decomposition.

Distinctions and Models

While the Standards did not introduce any distinctions between volume of a solid and the volume of a container, we use “capacity” to refer to the latter in the descriptors. We also make distinctions among concepts of area and volume which were not explicit in the Standards. For example, the area of a rectangle can be viewed as composed of smaller square units versus the sweeping of a length over a distance. Likewise, we distinguished between volume as the packing of space-filling units versus the sweeping of an rectangular area over a height.

We also distinguished the area formula of rectangles involving fractions from whole-number lengths and introduced four models of fractional multiplication of lengths based on equipartitioning of areas in the descriptors: (1) a whole number and a unit fraction; (2) two unit fractions; (3) two proper fractions but not unit fractions; and (4) one or two mixed numbers (or improper fractions). This is consistent with the sequence in the standards for fractions for multiplication, which is developed fully in the division and multiplication LT. Likewise, in the unpacking of the volume formula of a rectangular prism, we introduced different models of Volume = L × W × H related to the associative property. Coordinating across learning trajectories and providing multiple models supports future development in these topics.

Coherent Structure

As Smith and Gonulates (2011) reported, the Standard’s treatment of length measurement is the most complete in alignment with the research literature as students are expected to distinguish length as a measureable attribute (K.MD.1), directly compare two objects based on length (K.MD.2), order three objects based on length (1.MD.1), iterate a length unit to express the length of an object as a whole number of those length units (1.MD.2), use tools to measure the length of objects (2.MD.1), and measure the length of an object using different length units (2.MD.2).

However, for area measurement, the Standards writers presented an abridged version of this sequence where students immediately iterate a unit square to cover a rectilinear area and call this measure n unit squares (3.MD.5.a and 3.MD.5.b), then learn to measure area by counting unit squares (3.MD.6), and finally find the area of a rectangle by multiplying the length by the width (3.MD.7.a). They then include a standard for students to understand that areas are additive (3.MD.7.d), a Standard that was missing in the Length content. Similarly, for volume measurement, the sequence first started with students’ measurement, estimation of volume and one-step volume problems of involving any of the four operations (3.MD.2). Due to the abridged treatment, the structure underlying students' development in Area and Volume was incomplete.

To ameliorate these issues, we identified from the length, area, and volume contents a template of key ideas found in students' development of spatial measurements. We then applied this template across length, area, and volume Standards in our unpacking. As a result, a coherent structure of the LT descriptors emerged across length, area, and volume, which showed how students' concepts and skills of Length and Area and Volume become more sophisticated under instructions over time: (1) Describe and recognize the measureable attribute; (2) Direct comparison of two objects; (3) Indirect comparison of two objects; (4) Comparison of three or more objects; (5) Define what is meant by *n* units; (6) Express the attribute as a whole number of the units. (7) Measure the attribute twice using different units (compensatory principle); (8) Measure to determine how much bigger or smaller; and (9) Recognize the attribute as additive. Describing students' development of mathematical knowledge within such a coherent structure leveraged on the relevant research in providing teacher readers a sense of an overall developmental progression of students' knowledge as well as the interconnectedness between different Standards when unpacked.

Addition of "Bridging Standards"

As a result of our undertaking of "generic epistemology" account of students' learning, we introduced a total of 14 Bridging Standards unpacked with descriptors based on the coherent structure ands. Five were associated to the conceptual principles of length, including the missing additive principle; five were associated to the conceptual principles of area; three were associated to the volume concepts; and the last one connected the surface area with the volume of the cylinder. The last Bridging Standard was added based on a suggestion from a district curriculum coordinator who noted its absence. When read as parts of the trajectory, these descriptors filled in the knowledge gaps between some Standards and provided a coherent structure for students' development of length, area, and volume.

Discussion

The length, area, and volume Standards in the CCSS-M provide an example of why carefully unpacking the Standards is important. We detailed a trajectory of weaving the relevant Standards together in our unpacking in place of a piece-wise Standard-by-Standard elaboration. Next, we discuss the implication of our work for State Standards and Curricula.

Cross-walk between CCSS-M, State Standards and Curriculum

Comparing the CCSS-M and existing State Standards provides a quick and pragmatic way of evaluating the amount of re-alignment needed for curricular and assessment purposes. However, this approach is insufficient in itself to prepare teachers for implementation. For example, how should matched State Standards be re-ordered to maintain a coherent learning path? Do unmatched State Standards matter to students' learning? A minimalist approach might do more harm in this case. Unpacked using a LTs perspective, the descriptors provide educational practitioners access to a research basis in making educated decisions. For example, the coherent structure of moving from "Defining attributes" to "Comparison" in the length, area, and volume LT provide grounds for including addition of areas as a grade-level objective in the CCSS-M. Similarly, an LT analysis supports a means to conduct content analyses of proposed curricula and CCSS-M. The five characteristics of our unpacked descriptors provided teachers with curricular "landmarks" in anticipation of identifying and filling in instructional gaps in curricula.

Endnote

[1] We thank the participants of the 2011 Measurement Mini-Center Conference (Rich Lehrer, Doug Clements, Jeff Barrett, Jack Smith, Mike Battista and others) for reviewing an earlier draft of these descriptors. This process of peer-review enriched our work with the current views of the research community.

Acknowledgments

This work was supported by grants from the National Science Foundation, Qualcomm, and the Oak Foundation. In addition to the author, the writing team consisted of Kenny Nguyen, KoSze Lee, Drew Corley, Nicole Panorkou, and Alan Maloney. We also wish to acknowledge the role of Pedro Larios, Austin Programming Solutions in building the site and Shirley Varela in site design and editing.

ANALYSIS OF TWO-VARIABLE FUNCTION GRAPHING ACTIVITIES

Rafael Martínez-Planell
University of Puerto Rico at Mayagüez
rafael.martinez13@upr.edu

María Trigueros Gaisman
Instituto Tecnológico Autónomo de México
trigue@itam.mx

This is a study about the didactical organization of a research based group of activities designed using APOS theory to help university students make constructions, needed to understand and graph two-variable functions, but found to be lacking in previous studies. The model of the "moments of study" of the Anthropological Theory of Didactics is applied to analyze the activities in terms of their institutional viability.

Keywords: Advanced Mathematical Thinking; Geometry and Geometrical and Spatial Thinking

Introduction

Functions of two variables are of great importance in applied mathematics and engineering. However, despite their importance, there are few publications that take advantage of their particularities in order to study their teaching and learning. The first published article we found that explicitly treats functions of two variables is by Yerushalmy (1997). In it she insisted on the importance of the interplay between different representations to generalize key aspects of these functions and to identify changes in what seemed to be fixed properties of each type of function or representation. Kabael (2009) studied the effect that using the "function machine" might have on student understanding of functions of two variables, and concluded that it had a positive impact in their learning. In other work, Montiel, Wilhelmi, Vidakovic, and Elstak (2009) considered student understanding of the relationship between rectangular, cylindrical, and spherical coordinates in a multivariable calculus course. They found that the focus on conversion among representation registers and on individual processes of objectification, conceptualization and meaning contributes to a coherent view of mathematical knowledge. Martínez-Planell and Trigueros (2009) investigated formal aspects of students' understanding of functions of two variables and identified many specific difficulties students have in the transition from one variable to two-variable functions. Using APOS theory, they related these difficulties to specific coordinations that students need to construct among the set, one variable function, and R^3 schemata. In a study about geometric aspects of two variable functions, Trigueros and Martínez-Planell (2010) concluded that students' understanding can be related to the structure of their schema for R^3 and to their flexibility in the use of different representations. These authors gave evidence that the understanding of graphs of functions of two variables is not easy for students and in particular, that intersecting surfaces with planes, and predicting the result of this intersection, plays a fundamental role in understanding graphs of two variable functions and was particularly difficult for students. More concretely, students showed difficulty intersecting fundamental planes (that is, planes of the form $x = c$, $y = c$, or $z = c$ where c is a constant) with surfaces given in different representational formats. Hence they had difficulty with transversal sections, contour curves, and projections. Finally, Trigueros and Martínez-Planell (2011) used the moments of study of the Anthropological Theory of Didactics to analyze the didactical organization of a widely used calculus textbook (Stewart, 2006) and showed that its organization was neither effective in fostering the needed constructions nor viable from the praxeological point of view. This stressed the need to supplement traditional calculus textbooks with activities which cover those aspects found to be lacking in most textbooks. Our research questions in the present study are:

- Does a set of activities designed using a genetic decomposition of functions of two variables help students interiorize actions found to be necessary for a process conception of function of two variables?
- Is the didactical organization of the activity sets conducive to their functioning well at the institutional level?

Theoretical Framework

Since APOS is a well known theory we will only briefly discuss the notion of a genetic decomposition which is important to the content of this paper. For more information on APOS the reader may refer to the brief discussion in Trigueros and Martínez-Planell (2010), or more extensive treatments in Asiala et al (1996), and Dubinsky (1991, 1994).

In APOS Theory, the study of student understanding of a particular concept starts with a "genetic decomposition." This is a hypothesis advanced by the researcher and based on his/ her knowledge, experience, and any available previous data of the actions, processes, and objects that must be constructed in order to attain the desired conceptual understanding. A genetic decomposition is not unique, as different researchers might propose different decompositions. However, it is important that the decomposition be contrasted with data obtained from student interviews to ascertain the constructions actually being made by students. Typically, research data results in revisions of the genetic decomposition as researchers discover unforeseen constructions made by students, or constructions that are assumed to be readily made by students but which are not. The resulting revised genetic decomposition can be used in research and also in the design of activities that may be incorporated into the instructional cycle and that may help students make the desired constructions.

The initial genetic decomposition for function of two variables is given in Trigueros and Martínez-Planell (2010). In order to accommodate results of that study, the genetic decomposition was refined to include the following paragraph on the construction of the schema for R^3, which is important in the present study: The Cartesian plane, real numbers, and the intuitive notion of space schemata must be coordinated in order to construct the Cartesian space of dimension three, R^3, through the action of assigning real numbers to points in R^2, and the actions of representing the results of those actions as 3-tuples, in a table or as points in space. These actions are interiorized into processes that make it possible to consider different sets or subsets, in particular fundamental planes, in each representation register. These processes can be encapsulated into objects on which further treatment actions or processes can be performed. These treatment actions or processes include intersecting fundamental planes with other surfaces to form transversal sections, contour curves and projections, and processes of conversion of those sets and subsets among representations in a schema which evolves and that can be thematized as a schema for three-dimensional space, R^3.

A set of activities was prepared to help students make the constructions suggested by the revised genetic decomposition. We considered it important to analyze and discuss its organization and effectiveness. The *moments of study* of the Anthropological Theory of Didactics (ATD) was used as a tool for the epistemological analysis of the group of activities. In ATD the mathematical activity and the activity of studying mathematics are considered parts of human activity in social institutions (Chevallard, 1997; Bosch & Chevallard, 1999). This theory considers that any human activity can be explained in terms of a system of *praxeologies*, or sets of practices which in the case of mathematical activity constitute the structure of what are called *mathematical organizations* (MO). Mathematical organizations always arise as response to a question or a set of questions. In a specific institution, one or several techniques are introduced to solve a task or a set of tasks. Tasks and the associated techniques, together form what is called the *practical block* of a praxeology. The existence of a technique inside an institution is justified by a technology, where the term "technology" is used in the sense of a discourse or explanation (*logos*) of a technique (*technè*). The technology is justified by a theory. A theory can also be a source of production of new tasks and techniques. Technology and theory constitute the *technological-theoretical block* of a praxeology. Thus a praxeology is a four-tuple ($T/\tau/\theta/\Theta$) (tasks, techniques, technologies, theories), consisting of a practical block, (T/τ), the tasks and techniques, and a theoretical block, (θ/Θ), made up of the technological and theoretical discourse that explains and justifies the techniques used for the proposed tasks.

Within an educational institution a mathematical praxeology is constructed by a didactic process or a process of study of a MO. This process is described or organized by a model of six moments of study (Chevallard, 2007) which are: *first encounter* with the praxeology, *exploratory moment* to work with tasks so that techniques suitable for the tasks can emerge and be elaborated, *the technical work moment* to use and improve techniques, the *technological-theoretical moment* where the technological and theoretical discourse takes place, the *institutionalization moment* where the key elements of a praxeology are identified, leaving behind those that only serve a pedagogical purpose, and *evaluation moment* where student learning is assessed and the value of the praxeology is examined. It is important to clarify that the order of the moments is not fixed. It depends on the didactical organization in a given institution, but independently of the order it can be expected that there will be instances where the class will be involved in activities proper to each of the “moments”.

In a recent article, Trigueros, Bosch, and Gascón (2011) discussed the elements of APOS and ATD theories that may be used to expand the theoretical basis of each of these theories without violating their respective basic tenets. They observed that the model of the moments of study may be used in APOS theory to examine instruction based on activities designed in accordance to APOS.

Method

In view of the results obtained in Trigueros and Martínez-Planell (2010, 2011), four activity sets were designed to help students make those constructions found to be needed to understand functions of two variables. The activity sets dealt with (a) fundamental planes and surfaces, (b) cylinders, (c) graphs of functions, (d) contour maps and graphs of functions. All activity sets stress the use of sections in graphical analysis. For example, in a problem of the first activity set students are given the set $S=\{(x,y,z): z=x^2+(2+y)^3x+y^2\}$ and are asked to draw on a Cartesian plane its intersection with the plane $y=-2$; represent physically the intersection in space (using the manipulative in McGee, 2009); draw in three-dimensional space the resulting intersection curve making sure it is placed in its corresponding plane; and give three points in the intersection. This is to be done right after students are introduced to three-dimensional space, after they have constructed fundamental planes as processes, and before functions of two variables are defined. It aims to have students act on their process of fundamental plane thus helping the encapsulation of fundamental planes into objects. In another problem students are asked to represent physically in space the set $\{(x,y,z): z=xy^2, y=0\}$ and draw it in three-dimensional space. This is a variation of the algebraic representation of the previous example.

After designing the activity sets, they were analyzed in terms of the genetic decomposition and revised until the researchers agreed they covered those constructions predicted by the genetic decomposition. Then, the moments of study of the ATD were used to analyze their didactic organization in two different institutions. For example, the problems presented above are designed to be part of *the moment of the first encounter*, where students meet an important idea needed to construct their R^3 schema.

Activities were classroom tested and revised in two consecutive semesters. After class testing the activities, a set of interviews was undertaken to evaluate them. This produced new observations leading to further improvements on the activity sets. Fifteen students were chosen and interviewed after they had just finished an undergraduate multivariable calculus course. Of the 15 students, 9 had used the activity sets and 6 had not. Each of these two groups of students had equal number of above average, average, and below average students, as judged by their professors. Each interview lasted approximately 45 minutes. They were transcribed and analyzed independently by the two researchers. The conclusions were negotiated.

The interview questions relevant to this study are reproduced below:

1. Draw or represent in three-dimensional space the set of points in space that satisfy the equation $y=2$ and that are also in the graph of the function $f(x,y)=x^2+y^2$.
2. What can you say of the intersection of the plane $x=0$ with the graph of the function $f(x,y)=x\sin(y)$? Represent the intersection in three-dimensional space.
3. Students were to choose the graph of $f(x,y)=\sin(xy)$ among six given surfaces.

Results

APOS and Activity Sets

Results suggest that most students who used the activities had an interiorized process of intersecting planes with surfaces. Orlando, who used the activities, obtained a correct graph:

Orlando: I believe this is a cone … it would be… a circle, may I draw it?
Interviewer: Yes, of course
Orlando: … then this is a parabola on the zx plane that is 4 units up… [even though he says "zx" plane he draws and represents it physically correctly in the plane $y = 2$].

Note that even though initially he gave an incorrect answer, Orlando decided the issue by using sections, as practiced repeatedly in the activity sets, thus obtaining the correct graph. The most common student mistakes on the first question were: acting on the familiarity of "$x^2 + y^2$" conclude that the graph was a cylinder (without using sections) and then trying to obtain the intersection geometrically from that graph; and obtaining the correct formula $z = x^2 + 4$ but being convinced this is a parabola on the *xz* plane, not placing it correctly in space. Students not using the activities were more prone to commit these errors as they had less practice intersecting fundamental planes with surfaces and placing the resulting curve in space. Valerie, a student who did not use the activities, seems not to have interiorized the use of sections as a process:

Valerie: … $x^2 + y^2$ would be, a circle … this is harder than I thought … if I draw it … in the *xy* plane, it would be a circle in the *xy* plane, then, if $y = 2$ … it doesn't give the radius…

Question 2 revealed students' difficulties with free variables. Most students did not realize that after substituting $x = 0$ into $z = x\sin(y)$, the variable *y* can take any value, so that the desired intersection is the *y* axis. For example, Jackeline, who had used the activity sets in her class, was able to respond correctly; however it seems she avoids dealing with the free variable by using other sections to visualize the graph of the surface:

Jackeline: … would have the sine function, then as *x* increases the amplitude is going to increase … so this would be a line [under questioning she specifies it is the *y* axis]

On the other hand Victor, also troubled by the free variable, but who did not use the activity sets, does not evidence a process of using sections:

Víctor: $x = 0$, this is confusing … the entire function $x\sin(y)$ becomes 0 … therefore this would be a plane like this and a plane like this… the intersection consists of two planes

In Question 3, the pattern observed in previous questions continued with students who used the activity sets in class showing more of a tendency to use sections and thus performing better.

Activity Sets and the Moments of Study

According to ATD, a balance of the moments of study is needed for materials to help student learning in an institution. As mentioned before, activities that show the importance and usefulness of intersecting fundamental planes with surfaces can be considered as pertaining to the *moment of the first encounter*. The analysis of the activities showed that a large part of them are related to the *moment of task exploration*. This is no wonder, given that in APOS theory reflection on actions so that they may be interiorized into processes, and applying actions to processes so that they may be encapsulated into objects is of fundamental importance, The activity sets start by exploring a wide range of types of tasks aimed at giving students the opportunity to start building a schema for R^3 in which fundamental planes, intersections of fundamental planes with subsets of R^3, free variables, and quadratic surfaces, in different representational formats will be understood. Task exploration continues in the second activity set with cylinders, that is, surfaces in three-dimensional space described with only two variables. This gives the opportunity to have students reflect on how to plot the graph of $z = x^2$ in three dimensions by initially exploring a point by point representation. In our previous studies we had conjectured that the action of point by point representation may be interiorized into the process of drawing graphs by sections, and this construction was included in the refined genetic decomposition. The last set of interviews showed clearly that this construction is necessary and how a lack of interiorization can act as an obstacle for the coordination of important processes needed to learn the particularities of functions of two variables. The interiorization of actions such as graphing $\{(x, y, 0): y = |x|\}$, $\{(x, y, 1): y = |x|\}$, and $\{(x, y, 2): y = |x|\}$, help students reflect on what is happening as *z* takes on different values, and can be interiorized when they are asked to draw the graph of $y = |x|$ in three-dimensional space. Coordination of different processes and reflection on them leads students to develop a method for drawing cylinders in three dimensions. Later, in the third and fourth activity sets, tasks explicitly involving the use of those methods for functions of two variables gives students the opportunity to start by point by point construction actions and quickly move on to generalize the constructed processes for other functions like $f(x, y) = x^2 + y$. They are also asked to verify their graph by giving values to *z* and showing the resulting curves as part of the surface drawn previously, an activity which may be considered as part of the *moment of evaluation* as are problems in which students compare their graphs of surfaces to contour diagrams they draw. Other tasks that are explored include darkening the curves where specific fundamental planes intersect a given graph of a surface; matching a given set of formulas to a given set of graphs of surfaces with justifications given in terms of transversal sections, which can be considered as *technological- theoretical moment*. The fourth and final activity set reviews transformations in the context of graphing functions of two variables. The variety of activities in the *moment of task exploration* stresses the use and geometric significance of transversal sections making the *technical work moment* explicit. Many of the problems are broken down into parts to guide students in a step by step construction and reflection on the graphing process. This is in accordance with the didactical approach of APOS theory and is intended to complement traditional textbooks, which (Trigueros & Martinez-Planell, 2011) tend to overlook students' difficulties using transversal sections and contours to graph two-variable functions.

The *technical work moment* is present in the activities as the number and variety of problems enables an increasing number of students to construct a process of graphing functions of two variables with understanding. Activity sets allow students to build a schema for R^3 with the necessary coordinations to sustain ensuing graphing activities. Although traditional books present techniques for graphing functions of two variables, the number and variety of problems directly exploring the use of fundamental planes is limited.

As discussed in Chevallard (2007), the *technological-theoretical moment* is closely interrelated with each of the other moments of study. This is also the case in this topic. The technology of using traces or cross-sections to draw the graph of a two-variable function is introduced in the moment of first encounter and developed with multiple opportunities to do task explorations using the activity sets. Even though the activity sets do not include an explicit discussion of the theory, they include opportunities to discuss and justify the methods used by students; also throughout the activity sets it becomes clear that substituting a number for a variable in an equation with three variables corresponds to intersecting a fundamental plane with the graph of the equation. This being the "*technology*" (in the sense of explanatory discourse) used for graphing functions of two variables, the consistent use of this idea aids the construction of cross-sections, projections, and contours, otherwise found to be difficult for students. Many textbooks typically do not explicitly emphasize the role of fundamental planes in graphing activities and hence students seem to come out of these courses without a clear notion of this "*technology*."

The *moment of institutionalization* is present when the activity sets are formally included in the course syllabus, but more importantly when fundamental planes are explicitly used as an important justification technology throughout the course, for example, when explaining partial derivatives, tangent planes, differential, directional derivatives, iterated integration, and drawing solids whose volumes or mass is to be computed with a double or triple integral. The idea of analyzing a function of two variables by using knowledge of functions of one variable is pervasive in the course, so that opportunities abound during class discussion for building upon the knowledge of fundamental planes constructed early on in the course, and to institutionalize the processes and objects constructed. Ideas in the activity sets that serve only a pedagogical purpose are not institutionalized; for example, the action of plotting individual points in a graph of a function is quickly interiorized into a process of graphing by sections. The *moment of evaluation* is abundantly available as activity sets present an opportunity for students to auto-evaluate and discuss their work. It is also present if activities are collected and corrected to evaluate students, used in group activities, or used as the basis of test items, or when activity sets themselves are evaluated by studies, such as this one, comparing student performance.

Conclusion

Results suggest that the activity sets help students interiorize actions described in the genetic decomposition of function of two variables into processes, and encapsulate processes into objects and thus, when used effectively, have the potential to improve students' understanding of graphs of functions and their performance in graphing activities. This can only improve as activity sets are iteratively used and discussed in class, refined on the basis of classroom observations, and further studied in depth with successively improved interview instruments, as has been shown in this study. For example, this study uncovered the need to target activities early on that explore the use of free variables, the convenience of using surfaces with graphs that are unlikely to be memorized by students, and the need that some students have of doing a point by point sketch of a graph before they are able to effectively use sections. Some work remains to be done to complete the sets of activities to explore other aspects of the construction of the concept of functions of two variables, such as recognizing domain and range, and working with restricted domains, but so far, interview results show that they improve students' understanding.

The activity sets shows the presence of all the moments required in the study of the graph of these functions. In comparison with traditional texts and courses, the moment of first encounter is clearly present in the activity sets, while the moment of task exploration offers a wide range of activities and opportunities to interiorize actions into processes or to encapsulate processes into objects. The moment of work on the techniques presents the challenge of balancing the number of activities in each set that can realistically be used in class, or be assigned to students. The moment of institutionalization is present when the praxeology developed in the activities is built upon throughout the rest of the course. Finally, the moment of evaluation is present when evaluating student individual and group performance in the activities, including in similar test items, and most importantly, when evaluating the effectiveness of the activity sets per se.

APOS and semiotic representation theories are cognitive theories of learning and as such are limited in their capacity to describe and predict the effects on learning of social and institutional constraints. However, we have shown a situation where one of the models of the ATD can be useful in analyzing the design of activities that result from a cognitive analysis of a learning situation. Constructions and coordinations found to be missing in studies of students' construction of graphs of two-variable functions can be addressed with activities specifically designed to foster those constructions, in a pedagogical organization that takes the different moments of study into account.

Although Chinese students outperform U.S. students according to international mathematics studies, it is suggested U.S. students are equally or even more successful than Chinese students in sense-making and open-ended problems (Cai, 1995, 2000). We hypothesize different treatments on learning to solve problems in Chinese and U.S. curricula may contribute to the difference in performance. We explored what and how meaning, strategy, and procedure were introduced in curriculum. Two U.S. textbooks and one textbook from each of China and Taiwan were analyzed. The initial results show that the Chinese textbooks focus on efficient problem-solving strategies, and the opportunity for students to develop equation transformation skills. The U.S. textbooks place significant emphasis on understanding components of equations and the rationale of equation transformation by presenting procedural steps in a detailed way.

Keywords: Algebra and Algebraic Thinking; Curriculum Analysis; Problem Solving

Introduction

International mathematics studies in the past decade show Chinese students outperform U.S. students (TIMSS 2003, 2007) for both fourth and eighth grades. However, studies also show U.S. students are equally (Cai, 1995; Cai & Silver, 1995) or even more successful (Cai, 2000) than Chinese students in sense-making and open-ended problems such as story problems or problems that can not be solve by simply applying a formal or standard algorithm. We hypothesize textbooks' different treatments on problem solving contribute to the difference in performance because curriculum has been identified as one of the main factors that affect teachers' teaching and students' learning (McCrory, Francis, & Young, 2008). The purpose of the study is to explore different treatments, if there are, between textbooks for what textbooks say (e.g., concepts, strategies, procedure) and how textbooks say (e.g., statement, work example, question, group activity) about solving one-variable linear equations.

Theoretical Framework

Problem solving has been regarded as the heart of mathematics (Schoenfeld, 1992). Polya identified four parts of problem solving which are to understand the problem, make a plan, carry out the plan, and look back at the completed solution. To elaborate, problem-solving process includes subject matter knowledge (e.g., definitions, properties) for understanding a problem, heuristics or strategies to make a plan, the application of definitions or properties for implementing a plan, and the justification of solution procedure according to the plan and definitions or properties. To explore what textbooks can say about solving problems (of one-variable linear equations), based on Polya's idea described above, we identify three categories of knowledge, which are meaning, heuristic and strategy, and procedure. Meaning contains definitions, properties, or rules such as the definition of term or equation. Heuristic and strategy refer to problem-solving plan in general such as isolating the variable or combining like terms. Procedure refers to the application of definitions, properties, or strategies such as combining $2x$ and $3x$ when solving $2x + 3x = 10$ or dividing both sides of the equation $4x = 16$ by 4.

How can textbooks say about problem solving? Textbooks can convey knowledge in the following six forms: statement, work example, question, problem, demonstration, and group activity (Smith et al., 2008). To illustrate, problem-solving strategies could be conveyed in a statement, a question, a work example, or a group activity. Knowledge could also be conveyed in an open or explicit way (Alro & Skovsmore, 1998;

Christiansen, 1997; Silver, 1997; Voigt, 1994). For example, problem-solving steps could be presented in detail (explicit way) or with details skipped (open way).

Methods

This study asks the following question: How do U.S., Taiwan, and China textbooks treat the meaning, strategy, and procedure for solving one-variable linear equations? Particularly, what do the textbooks say about the meaning, strategy, and procedure, how are the meaning, strategy, and procedure presented quantitatively, and how are they introduced qualitatively? We selected one 7th grade mathematics textbook from each of China and Taiwan based on its large market share, and we selected two "Algebra I" textbooks from the U.S. that hold different philosophy of design (i.e., traditional and integrated) and have large market share. We analyzed chapters about solving one-variable linear equations. A coding scheme was constructed based on the framework including 24 meaning items, 17 strategy items, and 25 procedure items. The three authors were paired into two teams (the U.S. team and the Chinese team). The U.S. team achieved 88% inter-rater reliability from 10% coding materials. The Chinese team resolved all of the discrepancies instead. The following table (Table 1) illustrates our coding. The left part of the table is to-be-coded text, and the right part contains codes and descriptions.

Table 1: Coding Example

<table>
<tr><td colspan="2">Text to be coded</td><td>Code</td><td>Code Description</td></tr>
<tr><td colspan="2">The goal of solving an equation is to isolate the variable p.</td><td>S-S06</td><td rowspan="6"><u>The letter before hyphen</u>

W-S15</td></tr>
<tr><td>p = –126</td><td></td><td>W-P02
W-P04</td></tr>
</table>

Analysis and Results

The current results are based on 40% to-be-coded pages of the two U.S. textbooks (Teacher Edition) and 40% to-be-coded pages of the two Chinese textbooks (Student Edition). The distribution of meaning, strategy and procedure as well as the top meaning, strategy, and procedure items are compared between the U.S. and Chinese textbooks.

The distribution of meaning, strategy and procedure are similar between U.S. Integrated and Taiwan textbooks where strategy is about 25% and procedure is about 70% of all coded knowledge items (i.e., meaning, strategy, and procedure items). On the other hand, U.S. Traditional and China's textbooks have similar distribution of meaning (about 5%), strategy (about 50%), and procedure (about 45%, See Table 2).

Table 2: The Distribution of Meaning, Strategy, and Procedure

Percentage/ Frequency	U.S. Int.	U.S. Trad.	Taiwan	China
Meaning	1.8/6	5.4/9	5.5/10	5/7
Strategy	26.7/87	50.6/85	26.5/48	51.8/72
Procedure	71.5/233	44/74	68/123	43.2/60

The top three meaning items from each of the four textbooks show that the Chinese textbooks focus on the meaning of equations and meaning of solution of equations (M08 and M12 respectively). However, the U.S. textbooks focus on the meaning of components of equations (e.g., M06: Term, M07: Like Terms) and the meaning of operations on an equation (e.g., M09: Equivalent Equations, M14: Addition Property of Equations, M15: Multiplication Property of Equations, See Table 3).

Table 3: The Top Five Meaning Items

Meaning Item / Percentage	U.S. Int.	U.S. Trad.	Taiwan	China
1st	M06/33.3	M09/22.2	M08/20	M12/28.6
2nd	M07/33.3	M14/22.2	M12/20	M08/14.3
3rd	M11/16.7	M15/22.2	M15/20	M10/14.3

The top six strategies from each of the four textbooks show that the Chinese textbooks put much more emphasis on story problems than the U.S. textbooks. The Chinese textbooks have more than 57% but the U.S. textbooks have less than 48% strategies about solving story problems (S01, S02, and S03, see Table 3). If we take away items about solving story problems (the shaded cells in Table 3) from the top six strategies, the left three strategies show the U.S. textbooks have S07 (Undo/Inverse Operations) and S08 (Manipulative) that have not been seen in the Chinese textbooks, and the Chinese textbooks have S14 (Move Terms) and S17 (Eliminate Parentheses) that have not been seen in the U.S. textbooks (See Table 4).

Table 4: The Top Six Strategy Items

Strategy Item/ Percentage	U.S. Int.	U.S. Trad.	Taiwan	China
1st	S01/17.2	S02/21.2	**S01/35.4**	**S02/25**
2nd	S07/16.1	S08/17.6	**S02/18.8**	**S01/18.1**
3rd	S08/16.2	S03/15.3	**S03/14.6**	**S03/13.9**
4rd	S03/14.9	S09/12.9	S09/10.4	S10/12.5
5th	S02/12.6	S01/10.6	S10/8.33	S15/11.1
6th	S13/9.2	S07/5.88	S17/4.17	S14/6.94

The top four procedure items from each of the four textbooks show that the Chinese textbooks have significant skip in procedure (P22), but the U.S. textbooks tend to make procedure explicit (P03-P06: the application of addition and multiplication property of equations, see Table 5).

Table 5: The Top Five Procedure Items

Procedure Item/ Percentage	U.S. Int.	U.S. Trad.	Taiwan	China
1st	P03/27.9	P04/29.7	P03/24.4	P01/23.3
2nd	P04/18.9	P03/20.3	P04/20.3	P22/18.3
3rd	P05/12.9	P05/16.2	P22/13	P03/15
4rd	P06/8.58	P06/13.5	P21/9.76	P23/11.7

Discussion

According to the results, the Chinese textbooks apparently have different treatments on solving one-variable linear equations compared to the U.S. textbooks in the following three phases. First, the Chinese textbooks focus on the meaning of equations and solution of equations. However, the U.S. textbooks place emphasis on the components of an equation or the rationale of operations on an equation. Second, for the top six strategies, the Chinese textbooks have significant problem-solving strategies that focus on efficiency (e.g., Move, eliminate) and that have not been seen in the U.S. textbooks, and the U.S. textbooks have significant problem-solving strategies that focus on understanding (e.g., undo, manipulative) and that have not been seen in the Chinese textbooks. Third, the Chinese textbooks treat procedure in a quite open way (with procedural steps skipped), but the U.S. textbooks treat procedure in a quite thorough way (with procedural steps presented in detail). In brief, we find the Chinese textbooks focus on the task of solving equations by providing efficient problem-solving strategies, and the opportunity for students to figure out missing procedural steps in a solution procedure. The U.S. textbooks place significant emphasis on the understanding of components of an equation and rationale of operations on an equation. Problem-solving procedure is also presented in a detailed way to help student understand the reasoning in a solution procedure. Knowing whether written curricula place different emphasis on the meaning, strategy, and procedure of problem solving where students have demonstrated strength and weakness, as in this case for solving linear equations, can support revision and improvement of those materials, and efforts to improve the enacted curriculum as well.

DIMINISHING DEMANDS: SECONDARY TEACHERS' MODIFICATIONS TO TASKS FOR ENGLISH LANGUAGE LEARNERS

Zandra de Araujo
University of Missouri
dearaujoz@missouri.edu

English language learners (ELLs) are the fastest growing segment of U.S. students. Many teachers who have little or no training with regard to effective teaching strategies for ELL students now face the challenge of transitioning existing curriculum materials for use with ELL students. In this qualitative study, I examined three high school teachers' modifications to mathematical tasks for their ELL students and the resulting impact these modifications had on the tasks' cognitive demand. The primary data sources for this study include interviews, observations, classroom artifacts, and surveys. The findings suggest that teachers made modifications to both the tasks' content and the instructional formats used for the tasks. These modifications frequently resulted in lowered cognitive demand. Implications include suggestions for classroom practice and mathematics educators.

Keywords: Curriculum; Equity and Diversity; High School Education

Finding strategies to improve the educational outcomes of English language learners (ELLs) is imperative as they are the fastest growing segment of U.S. students (Wolf, Herman, & Dietel, 2010). Though the majority of teachers now have at least one ELL student in their classroom, only a third of teachers have received training to effectively teach ELL students (Ballantyne, Sanderman, & Levy, 2008). The mismatch between training and the realities of teaching has left many teachers to their own devices as they seek out or create curriculum materials for their ELL students. The purpose of this study is to examine modifications teachers make to mathematics tasks as they attempt to create a better alignment between their curriculum materials and their ELL students.

Perspectives

The demographics of U.S. students are rapidly changing. ELLs comprise approximately 11% of the students in U.S. public schools. This percentage represents a 51% increase in the decade since the 1997–1998 school year (National Center for English Language Acquisition, 2011). This rapid increase in the number of ELL students has resulted in many states that previously had small ELL populations experiencing large increases in ELLs. With these dramatic increases comes a new set of challenges to many school districts. Many teachers with no experience or training related to teaching ELL students now have several ELL students in their classroom. Additionally, recent results from standardized tests have revealed this quickly growing segment of students continues to reside on the lower end of the achievement gap in mathematics (Fry, 2008). These situations highlight the growing need to train teachers to teach effectively ELL students in both sheltered and mainstream classrooms. Of particular importance is the selection and use of appropriate curriculum materials for these students.

The selection of tasks is an important part of a teacher's practice and student learning. Kloosterman and Walcott's (2010) examination of NAEP results concluded there exists a "positive relationship between what is taught and what is learned" (p. 101). This implies the types of problems enacted impact the type of learning that occurs. Due to the important role tasks play in the mathematics classroom, I have focused my study on mathematical tasks. I have adopted Stein and Smith's (1998) definition of a mathematical task as a portion of the classroom centered on the development of a mathematical concept. Although several studies have examined teachers' use of mathematical tasks (e.g., Stein, Smith, Henningsen, & Silver, 2009), a review of the literature uncovered no studies specifically examining teachers' selection and use of tasks with secondary ELL students. In this study I examined three high school teachers' modifications to mathematical tasks. The following research questions related to this purpose:

1. How do teachers modify mathematics tasks for their ELL students?
2. In what ways do modifications teachers make to tasks impact the cognitive demand?

Methods

I employed a qualitative, multiple case study methodology. The participants—Ms. Thomas, Ms. Hunter, and Mr. Dubois—were secondary mathematics teachers who taught a ninth grade, mathematics class comprised entirely of ELLs, a so called sheltered mathematics course. I purposefully selected these teachers because of their role as sheltered mathematics teachers. Each of the teachers was in their sixth year of teaching.

This study is part of a larger study in which I examined teachers' selection and enactment of mathematics tasks for ELL students. The primary data sources for the present study are surveys, interviews, observations, and classroom artifacts. I observed each teacher's sheltered mathematics course daily for two weeks. Each observation was video recorded and partially transcribed. I conducted daily interviews with the teachers prior to observing their teaching and then conducted two extended interviews after the two weeks of observation, each of which I transcribed verbatim. The classroom artifacts included the tasks presented to the students.

I analyzed the data using the constant comparison method decoupled from grounded theory. This involved many rounds of inductive coding. I first analyzed each teacher individually and identified emerging themes using analytic memos. I then collapsed these themes into codes as I analyzed each of the different data sources for each teacher. I then performed a cross case analysis looking across the three teachers to identify those codes that were relevant to all the teachers. I consulted with my major professor in developing and verifying the codes. In the following section I discuss findings related to the teachers' task modifications.

Findings

Each of the teachers discussed the need to modify the content of tasks for their ELL students. I use the term content to refer to the features of the task including the written presentation, the mathematical values included in the task, and the task's visual presentation. Throughout my discussions with the teachers, each stated the need to modify the language of tasks for their ELL students. The teachers made statements such as "[I had to] cut out a lot of words" and "simplify" the tasks for ELLs. When asked if they modified tasks for all of their classes, the teachers stated that they did on occasion, but in general did not have as great a need for these modifications in their non-sheltered classes.

In addition to simplifying the language, the teachers discussed the need to simplify the mathematical content for their ELL students. Ms. Thomas discussed the need to lower the difficulty of tasks on several occasions during my time in her classroom. Though Ms. Hunter and Mr. Dubois did not explicitly state the need to simplify the content of tasks for their ELL students, they did describe modifications to tasks that simplified the mathematics. The simplification of content also extended to the teachers' presentations of mathematical content and their avoidance of mathematical proofs. Related to simplifying the mathematical content, the teachers discussed their desire to modify tasks so that they had only one solution or one solution path. Each of the teachers noted he or she thought presenting students with a multitude of ways to solve a particular problem created unnecessary confusion. Therefore, they preferred to set up tasks with a particular solution method in order to preempt possible student confusion.

Beyond discussion related to simplifying the mathematics and the presentation of the task, Ms. Thomas also stated that her task modifications for sheltered students often included visual representations. Ms. Hunter and Mr. Dubois did not directly discuss making modifications of this type with their sheltered students; however, during the interviews they did express approval of tasks that included visual representations.

In addition to modifications to the tasks' content, the teachers modified the instructional format they used for the tasks they selected for their sheltered course. I use the term instructional format to refer to the arrangement of students, time allowed for a task, and the resources with which the teachers provided students during the teachers' explanation of the task set up. The teachers often stated that the instructional formats they chose for their sheltered students served as a modification to their typical routine used with non-sheltered students.

Each of the teachers discussed the arrangement of students as a modification to the tasks they used, though the arrangements differed among the teachers. Ms. Thomas discussed her use of small groups within her sheltered course, a practice she avoided with her non-sheltered students. Similarly, Mr. Dubois often assigned problems and then encouraged students to work with and help one another. Ms. Hunter preferred direct instruction, often stating that her sheltered students did not value cooperative learning and got off task too easily.

The teachers often provided students with time limitations as they set up the tasks. For example, before a task that required students to rotate between stations, Ms. Thomas told students they would have five minutes at each station. The time constraints set up by the teachers seemed to try to focus student activity on mathematics and eliminate off task behavior.

In terms of resources provided during task set up, the teachers encouraged their students to draw on graphics, vocabulary aides, and manipulatives as they worked on tasks. Because the scope of this study did not include an in-depth examination of the teachers' non-sheltered courses, I cannot claim the teachers used these resources exclusively when setting up tasks for their ELLs. Although, in some instances, the teachers did explicitly state this was the case.

None of the task modifications resulted in an increase in cognitive demand. Of the modifications I have described, several did not result in a change in the cognitive demand. These modifications instead contributed to the maintenance of cognitive demand. These modifications included the use of visual representations, the time constraints, and the inclusion of resources.

The teachers included visual representations to supplement the written tasks in an attempt to connect the representations with other mathematical ideas in the task. The teachers did not explicitly connect the visual representations to the intended task outcomes; more typically, the representations were included to help students visualize concepts. The lack of intent to connect representations to the task or include reasoning about the representations as part of the outcome prevented the representations from increasing the demand. The time constraints the teachers placed on the tasks helped to prevent the tasks from devolving into non-mathematical activity. Though time in itself cannot raise the cognitive demand, Stein et al. (2009) cited time as a task feature that can aid in the maintenance of cognitive demand. The provision of resources during the task set up did not impact the cognitive demand prior to implementation. For the most part, the teachers suggested to students that they could use calculators, visual aids, textbooks, etc., but did not explicitly discuss how they should use them in conjunction with the task. Therefore, the inclusion of these resources did not work to raise or lower the cognitive demand.

The majority of tasks selected by the teachers were already low in cognitive demand. Therefore, modifications that lowered cognitive demand often resulted in memorization level or non-mathematical tasks. In general, the teachers thought text heavy problems obfuscated the mathematics for their ELL students. The teachers' decisions to simplify the language of tasks often resulted in lowered cognitive demand. On a number of occasions, the context described in a task would require students to interpret the situation and tie their numerical responses to the situation. The elimination of this connection lowered the cognitive demand, a phenomena of which the teachers were not aware.

The teachers' modifications to the mathematical content were the only modifications that had the intentional outcome of a lowered cognitive demand. The teachers' avoidance of proof in their sheltered courses led to lowered expectations in terms of students' justification of answers. In addition to avoiding proof, the teachers' reluctance to embrace multiple solution paths or tasks with multiple solutions lowered the cognitive demand. Stein et al. (2009) discussed the inclusion of multiple solutions and solution paths as a feature of high cognitive demand tasks. The teachers' decisions to avoid difficult mathematics so as not to confuse students resulted in the students experiencing mathematics through low cognitive demand tasks. The persistent use of low cognitive demand tasks is in opposition to the task literature that suggests a variety of tasks is important for student learning (Stein et al., 2009).

Discussion

Each of the teachers in this study cared about their students and modified tasks in ways they thought would improve their ELL students' learning outcomes. Providing teachers with more training on how to modify tasks for ELL students while maintaining cognitive demand is an important step towards improving the learning outcomes for ELLs. Teachers must approach the simplification of language in tasks with extreme care so as not to lessen the cognitive demand. Teachers should also avoid conflating language and mathematical abilities as they modify tasks. This may help to avoid modifications that unnecessarily simplify the mathematical content of tasks. Similarly, teachers should carefully consider the instructional format of lessons to support students without lowering the cognitive demand.

Knowing how to modify curriculum materials in ways that maintain the mathematical rigor is important for students to build mathematical understanding. This research may allow curriculum developers to understand the challenges teachers encounter when selecting curriculum materials for ELLs. This understanding can lead to improvement in curriculum materials that support teachers of ELLs. Finally, teacher educators can build on the findings of this research to develop strategies to better prepare teachers for this rapidly increasing population of students.

ANALYZING THE DIAGRAMMATIC REGISTER IN GEOMETRY TEXTBOOKS: TOWARD A SEMIOTIC ARCHITECTURE

Justin Dimmel
University of Michigan
jkdimmel@umich.edu

Patricio Herbst
University of Michigan
pgherbst@umich.edu

Geometry diagrams are multisemiotic texts that encode meaning across a range of communication systems. We propose a scheme for analyzing how geometric diagrams function as resources for mathematical communication in terms of four semiotic systems: type, position, prominence, and attributes. The semiotic architecture we propose draws on research in systemic functional linguistics (Halliday, 2004; O'Halloran, 2005); the architecture suggests a way of analyzing how geometry diagrams function as mathematical texts.

Keywords: Geometry; Classroom Discourse; Curriculum Analysis

Introduction

Mathematical communication employs various semiotic systems to make meaning, in particular language, symbols, and visuals (Lemke, 2003; O'Halloran, 2005). Duval (2006) uses *register* to refer to these semiotic systems. Building on that use of register, in their study of the types of translation tasks that students might be assigned in the geometry class, Weiss and Herbst (2008) argue that the diagrams of high school geometry comprise a distinct mathematical register—the *diagrammatic register*. The symbols of this register are "…pictures of (idealized) 'real' things…"—e.g., circles, points, parallel lines—together with the system of "markup signs"—e.g., congruence, perpendicularity, and parallelism markings—that encode the properties of those objects or permit references to those objects (Weiss & Herbst, 2008, p. 19).

The system of markup signs for geometric properties in diagrams and the norms that govern how diagrams represent specific geometric relations are products of the 20th century. The diagrams of Euclid and Descartes, as well as those in early 20th century plane geometry textbooks—particularly those from what Herbst (2002) called the Era of the Text and the Era of the Originals—were collections of strokes (for lines, line segments, and circles) and letters (for points). The diagrammatic register in these early textbooks of plane geometry lacked many of the features that one would expect from the diagrams in mainstream textbooks from the later 20th and 21st centuries. Figure 1 illustrates some of these differences.

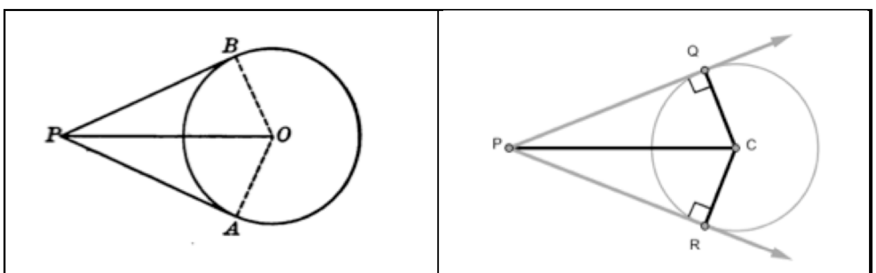

Diagram from Wentworth's *Plane Geometry* (1913, p. 107)	Replication of diagram from Merrill *Geometry* (1990, p. 366)

Figure 1: Comparison of two geometry diagrams

Figure 1 shows two different diagrams from two different textbooks (Wentworth, 1913, and Foster et al., 1990, respectively) that accompany the statement of the same theorem: that the external tangents drawn from a point to a circle entail segments ($\overline{PB}$, $\overline{PA}$ and $\overline{PQ}$, $\overline{PR}$, respectively) that are congruent. The diagrams in Figure 1 have commonalities. For example, each figure shows the segments one might use to prove the tangent segments theorem, and each figure labels the points one would expect to use in the proof

(P, B, O, A and P, Q, C, R). Yet the diagrams in Figure 1 are also clearly different: the later diagram marks <PQC and <PRC as right angles and uses different colors (the lighter lines are blue, the darker lines are red) for different strokes, while the earlier diagram uses different styles of lines ($\overline{BO}$, $\overline{BA}$ are dashed) and uniform choices for the thickness of strokes. The observable differences between these diagrams suggest that readers of diagrams need to be able to interpret and integrate different semiotic systems as they interact with diagrams. The semiotic architecture presented below aims to characterize these and other systems used in the visual display of geometric diagrams.

Semiotic Systems in Geometric Diagrams: Type, Position, Prominence, Attributes

We propose four semiotic systems to describe the range of variation in geometry diagrams. These systems are referred to as the *type*, *position*, *prominence*, and *attributes* systems. Our use of "system" concords with its use in functional grammar: systems contain the paradigmatic ordering of a language (a "what-could-go-instead-of-what relation," Halliday, 2004, p. 23). The systems we identify inventory the choices that are available when creating a geometry diagram. We identified these systems by analyzing the diagrams in 30 geometry textbooks published by mainstream publishers (including Merrill, Ginn and Company, McGraw-Hill, Glencoe, and World Book) that span the 20th century—from 1899 to 2004. The systems we elaborate below capture the possible variations in how geometry diagrams function as representations (note: visual representations of these systems are in a longer version of this paper, available at: http://hdl.handle.net/2027.42/91288)

The Type System

The Type system categorizes the different *parts* of a geometric diagram according to their visual qualities. In any diagram, there could be parts that represent geometric objects (e.g., dots, strokes, regions) and parts that represent geometric (and potentially other mathematical) properties of objects (e.g., hash marks, arrows, small arcs). The parts of a diagram can be differentiated analogously to the way that *free* and *bound* morphemes are differentiated in linguistics (Engelhardt, 2002, p. 24). The free parts are those that can appear on their own (e.g., dots, strokes), while the bound parts are those that can only appear with others (e.g., hash marks on strokes, arrows on strokes).

The divisions in the Type system are visual, not geometric. Keeping visual properties distinct from the geometric properties allows one to study how different geometric properties are represented as visual parts in diagrams. Thus, for example, lines, segments, and rays are all examples of {strokes: straight} and are visually of the same kind. The geometric differences between lines, segments, and rays are encoded through the use of different Attributes (see below).

The Position System

While the Type system provides a scheme for identifying the possible participants in any statements a diagram can make (e.g., points A, B, and C lie on line *l*), the Position system captures how those different participants relate to each other spatiographically—where parts are located relative to one another and how those parts are oriented relative to the frame of reference of the page (Laborde, 2004). Categories in the Position system include *distance* (visual space between parts), *orientation* (heading of the part relative to a set of reference axes), and *connection* (the links between parts, such as strokes that share a dot), with subcategories that depend on a chosen frame of reference (e.g., radial, rectangular).

The Prominence System

Prominence refers to the visual prominence of a part in the display (O'Halloran, 2005, p. 136). There are emphasis and difference subsystems. Emphasis communicates the visual emphasis of a part, through choices for weight (strokes), gauge (dots), transparency (regions), and style (letters and symbols). Difference communicates the visual difference of a part with respect to other like parts, through choices for color (all parts), pattern (regions), fill (dots), and style (stroke). The interaction of these different systems is evident in Figure 1, where circle C (right frame) is given less emphasis relative to strokes $\overline{PQ}$,

$\overline{PR}$ and $\overline{PC}$, by virtue of its lighter weight, yet linked to $\overline{PQ}$ and $\overline{PR}$ —while being set apart from $\overline{PC}$ — through choices in color.

The Attributes System

The principal system that communicates the geometric properties of a diagram is the Attributes system. Attributes can be *relational* or *existential*; like the word "attribute," "relational," and "existential" are chosen to draw an analogy to functional linguistics. In this case, it is the distinction between relational and existential processes (Halliday, 2004). Relational processes serve to "characterize and identify" (Halliday, 2004 p. 210), while existential processes are those "…by which phenomena of all kinds are simply recognized 'to be'" (Halliday, 2004 p. 171). Similarly, the relational attributes of parts are those diacritical markings, measures, and labels that serve to identify and classify relations that hold among specific parts. These markings are resources in the diagram that encode geometric properties. Thus, for the modal viewer, a marked right angle is *right*, regardless of what it might actually look like (and conversely: an unmarked angle that looks right might not be).

Complementing the relational attributes are the existential attributes. Like their linguistic cousins, existential attributes are so named because they actually stipulate the existence of a part in a diagram. Consider, for example, points D, E, C, B, and A in Figure 5, a diagram in Wells and Hart's *Plane Geometry* (1915). In this diagram, the presence of the letters 'D', 'E', 'C', 'B', and 'A' positioned at the ends of the straight strokes mark the existence of points on their ends.

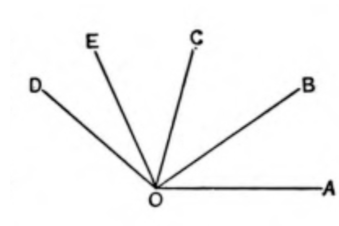

Figure 2: Diagram from Wells and Hart's *Plane Geometry* (1915, p. 19)

Arrows serve as existential attributes when they are applied to the ends of straight strokes, as the means of stipulating that a given straight stroke is a line (two arrows) or a ray (one arrow). The right frame of Figure 1 (see above) has examples of these attributes as they are applied to the stroke from P-R and the stroke from P-Q, thereby bringing into existence ray $\overrightarrow{PQ}$ and ray $\overrightarrow{PR}$ (as opposed to bringing into existence a segment or a line). Apart from the relational and existential attributes that apply to single parts, there are also attributes such as captions or arrows (transformational) that apply to the entire diagram or to several parts.

Summary

Geometry teachers have been concerned with how to teach students to communicate with geometric diagrams for more than 100 years (Baker, 1902). The evolution of the diagrammatic register in 20th century geometry textbooks speaks to this concern, and the semiotic architecture we have proposed in this report is one means through which this evolution can be analyzed. Studying the development of the diagrammatic register in 20th century textbooks will shine a light on how the multiple, ambiguous, and sometimes conflicting roles that diagrams play in student mathematical reasoning are semiotically managed. The work reported here is a step in this direction.

In this study, we investigated various aspects of the transition from state-specific mathematics standards to CCSSM, including a comparison of particular content strands of state standards compared to CCSSM and states' plans for implementation of CCSSM. With regard to content, findings indicated shifts in (1) grade levels at which fluency with mathematical topics is expected, (2) the amount of time spent learning topics, (3) focus on particular content, and (4) the way in which certain aspects of mathematics are addressed. Findings related to the implementation of CCSSM across states indicate variation in modifications made to CCSSM and the rate at which CCSSM is being implemented.

Keywords: Curriculum Analysis; Standards

Purpose

The 2010 publication of the *Common Core State Standards for Mathematics* (CCSSI, 2010) and its subsequent adoption will undoubtedly shift the focus and nature of mathematics education in the U.S. Because of the recent adoption and assessments in 2014–2015, state departments of education across the U.S. are transitioning in different ways and with varying levels of urgency. In this paper, we report findings for the following research questions: (1) To what extent have specific mathematics content in past state standards changed in their placement (grade level) and/or focus in the *CCSSM*? (2) What are the initial actions taken by states as they transition from existing state standards to *CCSSM*?

Perspective

Curriculum standards have dictated the content taught at particular grade levels, and due to the high stakes associated with the mandated assessments, the learning standards have strongly influenced what students have an opportunity to learn (Weiss, Pasley, Smith, Banilower, & Heck, 2003). Researchers have documented considerable variation across state mathematics standards, including the relative emphasis on particular topics, the grade level(s) at which specific content is addressed, and the types of expectations present in the standards (Reys, 2006; Smith, 2011).

CCSSM aims to move K–12 mathematics "toward greater focus and coherence" (CCSSI, 2010, p. 3) and outlines the mathematical expectations for K–12 students across the United States. It reflects the knowledge and skills needed to prepare students for success in both post-secondary education and their future careers (CCSSI, 2010). A survey in 35 common core adoption states, conducted by the Center for Educational Policy (CEP), found that the majority of state representatives believe *CCSSM* is more rigorous than previous mathematics state standards (Koeber & Stark-Renter, 2012). State representatives have begun taking steps to prepare districts for the implementation of *CCSSM* by developing timelines for implementations and crosswalks that compare state standards to *CCSSM*. The results from the CEP survey also indicate that most states do not expect to fully implement *CCSSM* until the 2014–15 school year (Koeber & Stark-Renter, 2012); however; states have begun to take initial steps toward the transition to implement this milestone in curriculum governance in the U.S. These include states (1) augmenting *CCSSM* to address district needs, and (2) developing a timeline and implementation plan for transitioning state standards to *CCSSM* (Reys et al., under review).

Modes of Inquiry

Data Sources and Analysis

The content standards analysis, conducted to answer the first research question, used two data sets: (1) learning expectations from state standards used in earlier state standards analyses (hereafter called "State Standards") (Reys, 2006; Smith, 2011) and (2) learning expectations from the *CCSSM* for the same content/strands as previous analyses. For the second research question, to capture the preliminary actions taken by state departments of education, all *CCSSM*-related documents available on each state department of education website were collected and summarized based on the actions state representatives were taking or planning to take relative to the implementation of *CCSSM*.

In State Standards (Reys, 2006; Smith, 2011), researchers used varying methods to capture themes across state standards as well as variation across states. For example, some teams analyzed the grade placement of particular topics to determine the number of grade levels that students spent learning a specific topic and at what grade level students were expected to demonstrate fluency. Other teams used an existing framework, such as the van Hiele levels of geometric thinking to analyze the descriptive geometry GLEs. Additionally, teams used different foci in examining the standards, ranging from examining specific mathematical topics within a content strand (e.g., fraction computation) to studying entire content strands (e.g., measurement). For all analyses, standards were tagged with state and grade level identifiers for analysis purposes. The same data collection and analyses process were employed in the comparative analysis of state standards and *CCSSM.*

Data analysis for states' initial actions with implementation of *CCSSM* consisted of two processes. First, the most recent state standards were searched to determine if additional standards or changes were made in comparison to *CCSSM*. All standards that were either modified or added to a state's curriculum document were collected for analysis. Second, state timeline documents were analyzed to study trends among state's *CCSSM* implementation schedules.

Findings

Comparison between State Standards and *CCSSM*

Analyses of K–8 state mathematics standards, conducted prior to the release of *CCSSM* under the auspices of the Center for the Study of Mathematics Curriculum (Reys, 2006; Smith, 2011), provided the lens through which changes in K–8 mathematics expectations as outlined in *CCSSM* are identified. Although our analyses revealed similarities between the mathematics described in State Standards and the *CCSSM*, the differences between the two were considerable and will likely be the focus of discussion as states transition to the *CCSSM*. These differences fall into four categories of shifts: (1) a shift in grade levels at which fluency is expected, (2) an expansion or contraction in the amount of time students will spend learning particular topics, (3) a change in overall focus on particular mathematical content at specific grade levels, and (4) a shift from including certain aspects of mathematics in individual standards to addressing them in more general terms in *Standards for Mathematical Practices*.

One key finding from State Standards (Reys, 2006; Smith, 2011) was that states vary considerably in the grade levels at which they expect fluency with particular topics. Therefore, it is inevitable that *CCSSM* will cause adjustments to learning expectations in order for many states to transition from the individual states' standards. Discrepancies in grade placement of standards are prominent when examining fraction computation and mastery of basic facts. For example, 40 of the 42 states examined in State Standards placed fluency with multiplying fractions at a later grade level than *CCSSM*. In contrast, mastery of basic facts is expected at an earlier grade level in *CCSSM* than was found in State Standards.

Differences also exist in the amount of time students will spend learning particular topics in State Standards and in *CCSSM*. For example, whole number computation for addition and subtraction is generally taught over a period of three years in State Standards; however, the development of this topic in *CCSSM* spans five years from the initial exposure of adding and subtracting whole numbers until fluency is expected. Conversely, while topics pertaining to probability were found across all grades K–8 in State

Standards, *CCSSM* confines coverage of probability to grade 7. Many probability topics found only in grade 7 of *CCSSM* are developed across multiple grade levels in State Standards, beginning in some states as early as grade 3. The overall focus on some mathematical topics in State Standards has also shifted in *CCSSM*. For example the emphasis on relationships between operations (e.g., multiplication as repeated addition) and mathematical properties (e.g., distributive property) increased three-fold in *CCSSM* compared to State Standards.

Finally, there was a shift from including certain aspects of mathematics in individual standards to addressing them in more general terms in the *Standards for Mathematical Practices (SMP)*, overarching statements that are included at the beginning of each grade level. For example, calculator and/or technology use was found in at least one standard at all grades K–8 in State Standards, with the overall number of standards increasing across grade levels. However, *CCSSM* does not mention technology and/or calculators within the individual standards until grades 7 and 8. Instead, *CCSSM* addresses the use of technology within the *SMP*, including the expectation that students are able to “use technological tools to explore and deepen their understanding of concepts” (CCSSI, 2010, p. 7). Likewise, reasoning for verification expectations (e.g., predicting, conjecturing, hypothesizing, justifying, drawing conclusions), common in State Standards are absent in *CCSSM*. However, reasoning abstractly and quantitatively, construct viable arguments and critique the reasoning of others and making sense of problems and persevering in solving them are addressed globally in *SMP* (CCSSI, 2010).

State Modifications of *CCSSM*

While the intention of *CCSSM* is common standards across the United States, states are granted permission to make some adjustments to *CCSSM* in order to better meet the needs of their local districts: “While states will not be considered to have adopted the common core if any individual standard is left out, states are allowed to augment the standards with an additional 15% of content that a state feels is imperative” (Achieve, 2010). As of February 2012, 35 of the 45 adoption states have not added any additional standards or changed the language of the standards (Reys et al., under review). Seven states (AL, AZ, CA, CO, IA, MA, NY) have added additional standards. California was the only state to move standards from one grade level to another grade level. Three states (AL, CA, and CO) have added or changed the wording of standards. Two states (MD and ND) have made changes to the format and/or annotated *CCSSM*. North Dakota added an “annotations” column with examples, definitions and comments in the state’s *CCSSM* document to help district administrators and teachers understand the standards and provide guidance in interpreting them (Reys et al., under review).

States’ Development of Transition Timeline

A number of states have developed implementation timelines, describing their plans and deadlines for transitioning from the current state standards and assessments to *CCSSM*. In order to transition to *CCSSM* most states developed “crosswalk documents.” These documents compare the current state standards to the *CCSSM*. The purpose of the crosswalk document is to assist teachers in understanding the shifts in learning expectations and more important, the necessary changes in instructional emphasis. In addition to the crosswalk documents, some states created “bridging documents” that address timelines for transitioning from current standards to *CCSSM*. The transition timelines address the timeframe for when teachers are expected to implement *CCSSM*. Some states also include plans for professional development.

Discussion

CCSSM is the latest educational reform measure in the U.S. designed to elevate student achievement in an understanding of mathematics. The transition from a system of state standards to the adoption and implementation of *CCSSM* will inevitably lead to several changes in K–8 mathematics. These changes have implications for multiple mathematics education stakeholders (e.g., curriculum developers, mathematics teachers). Although change is hard, the hope is that *CCSSM* will challenge the field to refocus our efforts on helping students be prepared for careers and college readiness. The shift of particular topics as well as the introduction of new content and the deletion of other topics will necessitate a transition period as teachers alter their instruction to accommodate *CCSSM*.

Although the transition to *CCSSM* may be seen as difficult, most states have already begun the implementation process. This fast action by states to create crosswalks and prepare professional development for their teachers provides some evidence that *CCSSM* is important and states are ready to make a difference in children's lives. However, with the quick implementation also brings obstacles (e.g., new curriculum, high school course sequencing). Providing teachers with curriculum that is aligned to the goals and standards in *CCSSM* may be the single obstacle that could cause this initiative to fail. Therefore, it is important to continue to monitor the situation especially as schools begin to transition to and implement *CCSSM* in more grade levels.

Jee Hyon Lee
Seoul Women's University
jh802@swu.ac.kr

This study examines student activities presented in written lessons on angle in four elementary mathematics curriculum programs, based on the assumption that student activities reveal the content students learn and the way students learn the content. In doing so, we analyzed the content span of the activities, relationships among activities, and the relationship between activities and other components of the lesson. The four programs share some commonalities and yet exhibited stark differences in the nature of student activities. This study suggests the significance of examining student activities in relation to individual and overall lessons in the written curriculum.

Keywords: Curriculum; Curriculum Analysis; Instructional Activities and Practice; Geometry and Geometrical and Spatial Thinking

This paper examines mathematical activities in four different elementary mathematics curriculum programs, especially those from lessons to teach angle. Activities not only provide the context in which students learn mathematics, but also embed the mathematics that students explore. Types of activities and their nature provoke certain kinds of thinking and learning, and shape students' learning experiences. In this study, we particularly focus on student activities used to develop the concept of angle in each program, in terms of their content span, the relationship among the activities, and their relationship to other components of the lesson, in order to infer what students are expected to do and learn. We examine student activities, not teacher activities, to account for the kinds of activities in which students are expected to engage in various curriculum programs. In this study, a curriculum program refers to written curriculum materials for day-to-day teaching, not one-day resources or supplemental materials. This may include, but is not limited to, a textbook, a student book, and teacher's guide.

Theoretical Perspectives

Student activities that are assigned in curriculum programs are crucial to understanding what students are expected to do and learn in the mathematics classroom (Li, 2000; Sternberg, 1996). Student activities can be understood as promoting authentic learning (D'Ambrosio, 1987; Smith & Stein, 1998; Stein, Grover, & Henningsen, 1996), as opposed to teacher demonstration and practice problems. Student activities genuinely drive and generate students' actions and performance that shape student learning (Bloom, 1956; Gronlund, 1978; Reed & Bergemann, 2001), by generating students' struggle or perturbation (Piaget, 1975) or motivating to fulfill goals of the activities (Leont'ev, 1981). Moreover, student activities can prompt students to think in diverse and sophisticated ways (Bloom, 1956; Gronlund, 1978; Reed & Bergemann, 2001). As such, examining student activities is crucial to infer what students are learning and thinking in the classroom. In particular, we examine student activities in a set of lessons on angle, in terms of the content span and the relationships among activities and the relationship between activities and other components of the lesson, in order to account for the nature of the activities, i.e., what students are expected to do and learn in each of the programs.

According to Leont'ev (1981), activities are processes. An activity requires a set of actions to accomplish the goal of the activity. Leont'ev emphasizes interrelatedness and situatedness of activities. Student activities can be considered in the same sense. A student activity is a process of learning while students perform a series of actions to reach the goal of the activity. A student activity is necessarily context-based. Whether it is concrete, real world, abstract, or imaginary, a student activity is bounded by the lesson and the previous activities and experiences. In this study, we analyze student activities as they are presented in the written curriculum materials. This constitutes the context of the study as well as the constraints of the study.

The span of the content in student activities tells the overall mathematical goals that each curriculum program envisions. Therefore, examining the content span helps one to imagine what students may be experiencing and learning in the classroom. It also helps one to see how mathematical content builds up as lessons move forward and how learning progresses. In fact, knowledge developed through prior activities serves as a resource to develop a new understanding in later activities (Kajander & Lovric, 2009). In this perspective, the correlation between prior and later activities or content is crucial. Moreover, the relationships between activities and other components of the lesson illuminate the role and significance of activities within the lesson, which helps explain the nature of student activities. These relationships influence students' trajectory of learning and thinking (Steffe, 2011). For example, an activity followed by teacher demonstration inevitably constrains students' thinking and action.

Methods

Four curriculum programs chosen for the study are *Investigations in Number, Space, and Data* (INV hereafter), Scott Foresman–Addison Wesley *Mathematics* (SFAW hereafter), *Math Trailblazers* (MTB hereafter), and the Korean elementary mathematics program, *Mathematics* (KMath hereafter). KMath is chosen because Korean students outperformed those in other countries in a number of international comparison studies (Mullis, Martin, Gonzalez, & Chrostowski, 2004; Schmidt, Blömeke, & Tatto, 2011), and yet we know little about what Korean students learn and what kind of curriculum programs they use. KMath is based on the National Curriculum of Korea revised in 2007 and is the only program available at the elementary level in the country. The three American programs represent a range of elementary mathematics programs, from reform-oriented and research-based to commercially developed. Reflecting reform needs in mathematics teaching and learning, INV and MTB were developed with funding from the National Science Foundation, and yet their approaches are slightly different: INV emphasizes student strategies and genuine investigation of mathematical ideas, whereas MTB integrates science and language arts with mathematics and covers advanced rigorous mathematics. SFAW is one of the programs commercially developed, and yet there is an attempt to incorporate research findings and reform recommendations in the program.

For the analysis, we collected curriculum materials/resources for both teachers and students that were needed for day-to-day teaching and learning, such as teacher guides and student books. These materials provided the details of the mathematical content and context for each lesson and student activities. First, we identified lessons exploring the concept of angle in each of the four programs. Next, we extracted student activities from each lesson, along with the mathematical content embedded in them. In determining what to consider as student activities, we relied on each program as they designated a certain portion of the lesson as activity. All four programs included at least one section for "activity" in each lesson.

The overall analysis focus was given to the features of the activities used to develop the concept of angle in each program. We created detailed descriptions of activities along with specific actions and content embedded. We also examined a general structure of the lessons in each program, in relation to the location and role of the activities in each lesson. In our subsequent analysis, we paid particular attention to what kind of actions students were expected to do in those activities, how each of these activities was connected to other components of the lesson, how they were related to each other, especially how later activities were built on previous activities, and how those activities were organized as a whole to develop the concept of angle. These helped characterize the nature of activities to teach the concept of angle as well as their scope and sequence. Finally, common features and differences in various aspects were compared among the four curriculum programs.

Results and Discussion

The four programs share some commonalities in terms of content covered, and yet they exhibited stark differences in the nature of student activities. In all four programs, right angles are introduced in grade 3 in the context of exploring polygons (e.g., triangles). While INV, MTB, and KMath have lessons on angle in grade 4, SFAW explores angle across grades 3, 4, and 5, one lesson in each grade. KMath devotes one entire chapter to the concept of angle (8 lessons) in grade 4, and all American programs address angle in the unit/chapter of geometry. Angles are further explored in polygons in grade 5 in INV, MTB, and KMath.

Student activities in the four programs address the concept of angle in quite distinct ways and promote different kinds of student actions and thinking. SFAW activities include minimal content; INV activities promotes students' thinking about the relationship among angles; MTB and KMath activities are the most diverse in terms of content embedded in them. The four curriculum programs, ranked from least to greatest in the extent to which student activities play a role in the lessons, are SFAW, KMath, MTB, and INV. It is even possible to teach a lesson without a student activitie in SFAW. KMath and MTB activities involve frequent teacher interventions toward lesson goals. In contrast, INV lessons are organized by student activities and discussions around them. Students explore mathematical ideas during activities and share what they found or did in the whole group discussion. INV lessons cannot be completed without activities, and the role of activities in a lesson is crucial.

MTB activities share some common aspects with KMath and INV. On the one hand, like KMath activities, some MTB activities are short and small-scale, involving teacher intervention along the way of exploration. On the other hand, as with INV activities, some MTB activities require extensive inquiry about the concept and mathematical relationships. In general, MTB activities progress along with discussions and teacher intervention when appropriate, whereas INV lessons designate certain time for discussion before or after activities, usually the beginning or the end of the lesson, in which students publicize and formalize what they found during activities.

KMath activities move from enactive to iconic, and to symbolic representations (Bruner, 1960) and from concrete to abstract fairly quickly. Concrete and enactive approaches are used at the beginning to introduce the ideas, and once reaching the abstract and symbolic level, concrete and enactive activities are rarely used. This is quite different from American programs analyzed. Moreover, KMath activities are highly structured and constrain students' learning experiences toward specific lesson goals. Following the steps, one by one, leads students to reach the desired outcomes in the activities. KMath activities also promote precision and accuracy very early on in the lessons, whereas activities in the American programs in general do not emphasize precision to that extent.

Commercially developed programs have a significant market share, which indicates their substantial influence on classroom practice. In the current reform era, these programs try to incorporate many reform efforts. For example, SFAW includes lessons on relationships among multiplication facts (e.g., $5 \times 9 = 5 \times 5 + 5 \times 4$) and uses games in some lessons. However, it is evident that activities in SFAW lessons on angle have a limited potential. This may be due to the topic chosen. Activities used in lessons on other topics may be different. This also suggests the importance of examining other topics as well, preferably involving a number of lessons and activities. Despite this possible explanation, the fact that there are only three angle lessons, one in each grade, and the fact that their activities have little connection among them indicate the need for improvement.

This study illustrates the significance of examining student activities in the curriculum. As activity theory posits, it is important to analyze a set of actions involved in each of these activities in order to investigate the characteristics of activities even further. An in-depth analysis of activities in relation to their specific actions is a follow-up study needed. In addition, examining actual student activities in the classroom in relation to those in the curriculum is an important study to conduct, since activities presented in the written curriculum are only "envisioned" activities, not actual student activities.

EFFECT OF PROFESSIONAL DEVELOPMENT ON TEACHERS' IMPLEMENTATION OF A REFORM ORIENTED CURRICULUM

Erin E. Krupa
Montclair State University
krupae@mail.montclair.edu

Transitioning to reform mathematics curricula presents a difficult challenge for many teachers. Often professional development is targeted to help teachers implement curricular materials and can include many different components. This paper presents results from a quantitative study of teachers' implementation of an integrated mathematics curriculum based on their varying levels of participation in a targeted professional development. Results show that participation in workshops increased teachers' textbook implementation. Also, absent workshop participation, instructional coaches did not increase teachers' implementation. These results have important implications for the design of professional development and for researchers conducting curricular evaluations and studies of teaching effectiveness.

Keywords: Curriculum; Professional Development; Curricular Implementation

Implementing reform mathematics curricula represents a challenging transition for many teachers (Ziebarth, 2003), especially for those whose perceptions of mathematics education are grounded in traditional views of teaching mathematics. Although many view the textbook as the most important catalyst for changing what occurs in mathematics classrooms, the adoption of the curriculum alone will not likely transform teachers' instructional practices (Arbaugh, Lannin, Jones, & Park-Rogers, 2006; M. S. Wilson & Lloyd, 2000). Teachers typically use the same instructional practices used by their teachers (Ball, 1988; Tyack & Cuban, 1995), and in order for them to change their instructional practices to reform instruction they need ongoing and sustainable support (Ball & Cohen, 1999; Loucks-Horsley, Love, Stiles, Mundry, & Hewson, 2003; Putnam & Borko, 1997; S. M. Wilson & Berne, 1999). The NRC (2004) contends teachers need adequate professional development (PD) *before implementing* new curricular materials, continued support *while implementing*, and time for reflection *during and after implementation* (p. 46). PD designed to assist teachers before, during, and after implementing reform curriculum has been shown to be effective (Krupa & Confrey, 2010); however, teachers still face difficulties when implementing curriculum for the first time (Krupa, 2011).

Objectives

While it is apparent that ongoing support can help teachers change their instructional practices, it is yet to be determined *how* this type of support impacts implementation of curricular materials. The purpose of this paper is to report quantitative findings on the impact different components of a PD model have on teachers' implementation of the reform mathematics textbook, *Core-Plus Mathematics* (Coxford et al., 2001). This research is an important first step towards determining: the extent to which textbooks are used for instruction and the significance different components of PD have on textbook implementation. Specifically, the research question to be addressed is: *Are there quantitative differences in teachers' implementation of Core-Plus based on varying levels of participation in a specialized professional development?*

Theoretical Perspectives

In its report about curricular effectiveness, the NRC (2004) noted the importance of documenting the faithfulness of implementation and recommended researchers document the "implementation fidelity" of the curricular materials. Implementation fidelity measures the extent to which textbook materials are used for instruction, which is important for documenting the opportunity to learn students are given, but are not indicative of the quality of teaching (McNaught, Tarr, & Grouws, 2008; National Research Council, 2004).

The Comparing Options in Secondary Mathematics: Investigating Curriculum (COSMIC) research team was designed to evaluate high school students' mathematics learning from different curricular programs (COSMIC, 2005). They have provided methodological approaches and instruments to document and measure implementation fidelity. They have created indices for *opportunity to learn* (OTL), *extent of textbook implementation* (ETI), and *textbook content taught* (TCT).

The COSMIC team measured the OTL, ETI, and TCT through Table of Contents Records (TOC-logs), which were self reported by the teachers and customized for the textbook they were using (McNaught et al., 2008). For each lesson of the textbook, teachers indicated if they taught the content (a) primarily from the textbook, (b) primarily from the textbook with some supplementation, (c) primarily from an alternative source, or (d) not at all. The OTL index measured the percentage of textbook content that was taught, either solely from the textbook or through supplemental materials. The ETI index weighted the options in the TOC-logs, giving the content taught primarily from the textbook the a weight of one, content with some supplementation a weight of two-thirds, content mostly from alternative sources a weight one-third, and content not taught a weight of zero. The weights were then summed and divided by the total number of lessons contained in the textbook. This measured the degree to which the textbook was used directly to teach the content. Similarly, the TCT index used the same weighted sum but divided by the total number of lessons taught through any means. This is a measure of how the textbook was used to teach content in the textbook and ignores the topics students were not taught. Each of these three indices was measured at the course level.

Methods

Context and Sample

The North Carolina Integrated Mathematics Project (NCIM) was developed to create and support a community of teachers using the reform oriented *Core-Plus* integrated curriculum materials, particularly in high needs schools. Spread throughout rural parts of the state, the seven partner schools in the NCIM project were identified as low-performing based on North Carolina accountability measures. To prepare teachers to implement *Core-Plus*, in order to strengthen STEM education at these schools, the project directors and evaluation team designed four components for the NCIM PD: (1) a summer workshop providing in-depth education on use of curricular materials (one or two weeks), (2) a web-based environment supporting information exchange, (3) two face-to-face follow-up conferences, and (4) instructional coaches who visited each site monthly. The context of the NCIM project, non-field test sites and ones with a high percentage of minority students, supports research in areas that have not been well researched. For more information about the PD components (see Krupa & Confrey, 2010, 2012).

The sample included groups of teachers with various NCIM PD experiences. Group A teachers participated in all facets of the PD (n = 7), Group B teachers participated in the workshop only (n = 6), Group D teachers were not involved in any aspect of the NCIM PD (n = 6), and Group F were classified as NCIM project teachers but only had an instructional coach and were not part of the summer workshops (n = 2).

Data Sources and Analysis

Each teacher completed a TOC-log for each unique course they taught during the 2009–2010 year. The OTL, TCT, and ETI indices were computed using the COSMIC approach (McNaught et al., 2008) for the 41 logs completed by this sample of teachers ($n_A = 17$, $n_B = 11$, $n_D = 8$, $n_F = 5$). Due to the sample sizes, to determine quantitative differences in teachers' implementation across PD exposure, an ANOVA for unbalanced data was used, followed by Scheffe's Test to determine differences among specific groups (Hollander & Wolfe, 1999). The TCT measures were not normally distributed and the non-parametric distribution free tests, Kruskal-Wallis and Dunn's Test (Dunn, 1964) were used to determine differences in TCT among groups.

Results

Teacher Implementation Indices Disaggregated by NCIM Participation

Opportunity to learn. The OTL index across all *Core-Plus* teachers indicates that on average just over half of the content in the textbook was covered (52.30), though there was considerable variation among teacher's OTL indices (13.93), ranging from 27.69 to 81.71 (Table 1). Teachers who participated in the project workshops have higher OTL indices than non-workshop participants. Scheffe's post hoc test found significant differences in the mean OTL between Groups B and F and Groups A and F ($\alpha = 0.05$). These data suggest the importance of workshop attendance on textbook implementation. The two teachers who were provided with an instructional coach, absent workshop attendance, had significantly lower textbook OTL.

Table 1: Mean (and Standard Deviations) of the Implementation Indices

	OTL	ETI	TCT
Group A (All NCIM components)	56.19 (14.31)	51.21 (15.13)	90.65 (8.32)
Group B (Workshops only)	58.79 (9.90)	57.69 (8.44)	98.48 (3.83)
Group D (No NCIM exposure)	46.67 (9.74)	33.85 (14.90)	70.58 (17.99)
Group F (Coaches only)	33.80 (6.30)	26.18 (6.54)	77.98 (17.14)
Entire Sample	52.30 (13.93)	46.51 (16.73)	87.29 (14.94)

Extent of textbook implementation. Recall the ETI index is a weighted measure describing the degree that the textbook, rather than other materials, was used to teach the content. There was a significant difference in the mean ETI across teachers in all four groups ($F = 10.31$, $p < 0.0001$). Scheffe's post hoc analysis determined differences in Groups B and D, B and F, A and D, and A and F ($\alpha = 0.05$). These data indicated that participation in the workshop significantly increased teachers' ETI indices. Teachers involved in the NCIM PD supplemented the textbook less frequently and rarely used alternative sources. Group D teachers used alternative sources more frequently than others groups.

Textbook content taught. Recall that the TCT index restricted the ETI to consider only the *Core-Plus* content that was taught. The nonparametric Kruskal-Wallis test showed differences in location for the groups ($\chi^2 = 17.02$, $p = 0.0007$). To determine which groups had significantly different TCT indices, Dunn's nonparametric post hoc test for multiple comparisons was utilized and showed differences in the TCT indices for Groups B and D and Groups B and F ($\alpha = 0.05$). When Group B teachers taught content in the textbook, they were directly using the textbook for their instruction instead of supplements. Group D teachers used alternative sources for instruction more frequently than teachers who took part facets of the NCIM PD. Groups with teachers attending the summer workshops rarely used alternative sources for instruction and utilized the textbook as the primary resource in their instruction.

Significance

The TOC-logs provided evidence of the variance in teachers' implementation of textbook content among teachers with varying levels of NCIM PD experience. It was clear that teachers who participated in the NCIM summer workshops utilized the textbook for teaching content in the *Core-Plus* curriculum more frequently than teachers who did not attend the workshops. Next steps in this research will be to report qualitative findings from classroom observations and teacher interviews to understand *how* different components of the PD model shaped teachers' textbook implementation. As teachers navigate the transition between different curricula and standards, it is imperative researchers understand how PD offerings effect instruction so that high-quality, targeted PD can be designed and implemented to meet teachers needs.

EDUCATIVE SUPPORTS FOR TEACHERS IN MIDDLE SCHOOL MATHEMATICS CURRICULUM MATERIALS

Lorraine M. Males
University of Nebraska
maleslor@msu.edu

In this paper I describe opportunities for teacher learning present in four middle school curricular series in the areas of introduction to variable and geometric transformations. I focus on one part of my analysis, the description of the opportunities present for developing Subject Matter Knowledge, Pedagogical Content Knowledge (for Topics and Practices), and Curricular Knowledge. My results indicated that opportunities for teachers' development of Pedagogical Content Knowledge for Practices or Curricular Knowledge were most prevalent, whereas Subject Matter Knowledge was the least prevalent. In particular, opportunities lacked rationale guidance, or guidance that enables teachers to develop an understanding of why particular mathematical or pedagogical approaches might be appropriate.

Keywords: Curriculum Analysis; Mathematical Knowledge for Teaching; Teacher Knowledge; Middle School Education

There have been many efforts to reform mathematics teaching, but for pedagogical change to be realized there is the need for substantial teacher learning (Remillard, 2000). Educative curriculum materials, or materials for Grades K–12 that are "intended to promote teacher learning in addition to students' learning" (Davis & Krajcik, 2005, p. 3), are a potential source for opportunities for teacher learning. Ball and Cohen (1996) advocated for such materials because curriculum materials are used on a daily basis, affording them a "uniquely intimate connection to teaching" (p. 6).

Focus of Study

The focus of my study was to describe opportunities for teacher learning embedded in written middle school mathematics curriculum materials. In particular, I examined the opportunities for teacher learning by investigating the *content* of the teachers' guides and how this content was *expressed*. In this paper, I describe the results related to my analysis of the *content*.

Theoretical and Analytical Framework

The teacher plays an active role in designing and enacting the curriculum in their classroom. Furthermore, the curriculum is a guide not only for students, but for teachers. Dewey (1902) argued that "its primary indication, is for the teacher, not for the child. It says to the teacher: Such and such are the capacities, the fulfillments, in truth and beauty and behavior, open to these children" (p. 39). Curriculum materials continue to be guides for teachers and research indicates that teachers do learn from using materials (see Males, 2011, for a detailed review). Although empirical work has rarely investigated the features of written materials and how these features promote learning, research on teachers' use of materials and what and how they learn from using materials indicates that they may play a role in this learning.

Towards a Framework for Investigating the Content Supports in Curriculum Materials

To analyze content supports I adapted a framework from Beyer, Delgado, Davis, and Krajcik (2009) that allowed me to describe the types of *knowledge* and *guidance* available in the teachers' guides. Due to space limitations I do not include the entire coding scheme in this paper, but instead include the four knowledge domains with some explanatory text in Figure 1.

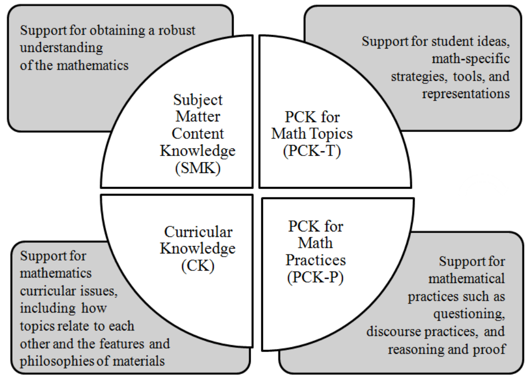

Figure 1: Four domains of knowledge

Knowledge. To develop expertise in teaching mathematics one must have many types of knowledge and be able to integrate these in ways that help one productively promote students' learning of mathematics. In essence, teachers require a specialized type of knowledge of their discipline, knowledge that allows them to teach, not just know their subject matter (Shulman, 1986). First, *Subject Matter Content Knowledge* involves having an understanding of subject matter that goes beyond the "mere subject matter major" (Shulman, 1986, p. 9). Teachers must be able to understand that something is so and also why something is so. Second, *Pedagogical Content Knowledge* can be described as subject matter knowledge for teaching. This includes knowing the most useful forms of representing content in ways that allow for its comprehensibility by others, knowing when and how students may excel or struggle, and knowing strategies for working with students' ideas. Finally, *Curricular Knowledge* is knowledge about the range of programs for the teaching of subject matter, the instructional materials available, and the knowledge related to making decisions about the fruitfulness of using particular materials in particular situations.

Guidance. Unlike materials that merely described what to teach, educative curricula go beyond this and provide opportunities for teacher learning through two types of support: *Enactment Guidance* and *Rationale Guidance* (Beyer et al., 2009). *Enactment Guidance* includes more than just knowing *what* to teach, but also knowing *how* to teach it. For example, this might include a sample of a class discussion in which the teacher asks specific questions to elicit students' justification for their reasoning or to evaluate the reasoning of their classmates. Such examples provide support for how teachers might pose questions in related contexts to elicit similar student responses. *Rationale Guidance* enables teachers to know why particular mathematical or pedagogical approaches might be appropriate. Supports such as this allow teachers to make sense of their curriculum materials and develop what Drake and Sherin (2009) call "curriculum vision," or a sense of where the curriculum materials are going and an understanding of the "particular kinds of learning and teaching practices described in the curriculum materials" (p. 324). An example might include a discussion of why having students create multiple representations for a particular situation is important by describing how the facility between representations will help students develop a stronger concept of linearity.

Method

Sample and Procedures

I mindfully choose four series with large market share in the United States and varied design principles. I included curriculum materials that are categorized as "Standards-based" (Senk & Thompson, 2003), and those that were not. I purposefully chose multiple curricular series within the Standards-based category because we know little about the differences between curricula in the same category. I chose the

Connected Mathematics Project 2 (CMP), *Math Connects* (Glencoe), *Mathematics in Context* (MiC), and *Transition Mathematics* (UCSMP).

Since the structure and features were repeated throughout the texts I chose to analyze units related to the introduction to variable and geometric transformations because these topics were addressed heavily in standards documents and research indicates that these topics are typically problematic for students or teachers (Clements, 2003; Kieran, 2007).

On each page of each unit I examined each sentence and assigned one or more content codes, if applicable, and also coded the location of the content support (i.e., *Unit*, *Section*, *Lesson*). Sentences were coded for multiple supports if it was warranted. I entered all codes into a spreadsheet for ease of calculating frequencies and percentages across all units and curricula and used relative frequencies on summaries sheets to explore themes. In addition, I had a second coder code a random sample of 10% of the corpus, stratified by unit. Percent agreement was calculated at the sentence level and an agreement of at least 85% was reached for each unit.

Results and Discussion

I present my clearest and most significant findings here. For more details, see Males (2011).

Types of Guidance

For all curricula and units, content supports more often provided *Enactment Guidance*. *Rationale Guidance*, or guidance that helps supports teachers in developing a sense of why particular mathematical or pedagogical approaches might be appropriate, accounted for no more than 6% of support in any unit. CMP and Glencoe were consistent in their distribution across the two units. MiC and UCSMP included a higher percentage of *Rationale Guidance* in their variable unit than in their transformations units, however this difference was modest.

Knowledge Addressed

Figure 2 shows the percentages of support for the four types of knowledge for both the variable and transformations units in each curriculum.

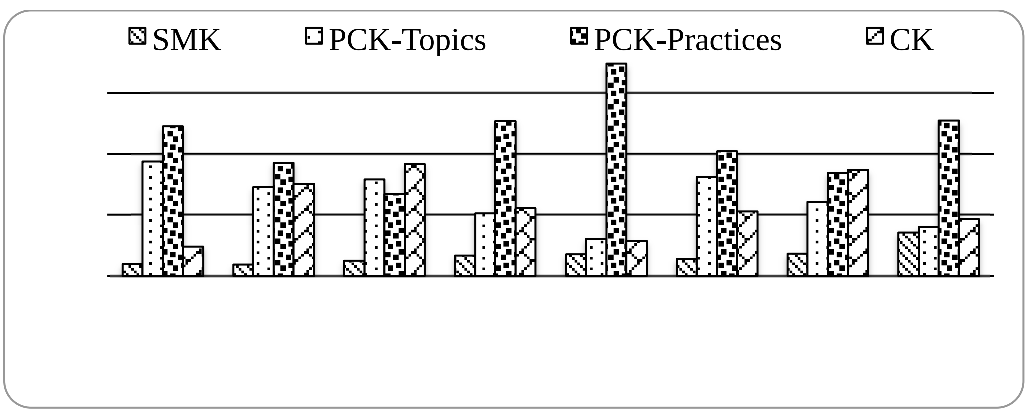

Figure 2: Percentages of content supports by unit and curriculum

The most prevalent content supports in three out of four curricula addressed *Pedagogical Content Knowledge for Practices*, accounting for over 37% of the support in CMP, Glencoe, and UCSMP. These supports included those designed to help teachers engage students in mathematical practices such as questioning, reasoning and proving, and using terminology. MiC, on the other hand, split its attention more evenly between *Curricular Knowledge* and *PCK for Practices* or *Topics.* Supports included those related to developing an understanding of the curricular features and storyline. Of the 31 individual content supports in my framework, 15 were infrequent or unobserved across at least three of the curricular series.

Location of Content Supports

Although most supports were located at the *Lesson* level, a substantial amount of support, particularly for CMP and MiC, was located at the *Unit* or *Section* level, accounting for 28–53% of their support. These results are important because the location of educative supports may impact whether teachers use them. Schneider and Krajcik (2002) found that teachers learned from support located at the lesson level, rather than support located in other sections of the textbook.

Opportunities and Implications

Although each curriculum provided access to some content supports, this access might not be sufficient. Of the 31 content supports, 15 were infrequent or unobserved across at least three of the curricular series and the supports that were present did not often provide *Rationale Guidance*. The lack of this type of guidance may diminish the ways in which teachers engage with and learn from the support. When curriculum authors discuss their rationale they open up a space in which teachers can engage with them around the underlying principles on which the curriculum is designed and. Generally, this space was not provided. In order for teachers to be able to learn from materials, authors need to speak *to* rather than *through* teachers (Remillard, 2000). For this to be realized more attention is needed on content supports, guidance, and where this is located.

MEETING A NEW STANDARD: USING SAXON MATHEMATICS FOR GRADE 8

Melissa McAninch
University of Iowa

Taehoon Choi
University of Iowa
taehoon-choi@uiowa.edu

As Common Core State Standards are adopted, assessment in the United States will soon change as a result, and school districts will turn to use textbooks that best align with these standards. This study examines range of knowledge and depth of knowledge, outlined in Webb's criteria for alignment (1997), to compare Saxon's Course 3 textbook with the Common Core State Standards for seventh and eighth grades. By analyzing the alignment between these sources, judgment can be made about whether the curriculum set forth in Course 3 aligns with the mathematics students are now expected to know how to do in the eighth grade. Results of alignment will inform teachers in seventh and eighth grades as they make instructional decisions. Results show 31% alignment of Course 3 material with the eighth-grade standards.

Keywords: Curriculum Analysis; Middle School Education; Policy Matters

Introduction

As states adopt the Common Core State Standards (CCSS), much attention has been focused on comparing previous state documents to the new CCSS with regard to curriculum and assessment (Cobb & Jackson, 2011; Porter, McMaken, Hwang, & Yang, 2011). Textbooks will become outdated with changes to the CCSS, and studies that compare existing textbook curricula to the CCSS will help teachers and school administrators in their transition to CCSS compliance. Kilpatrick (2011) acknowledges the critical role of teachers in implementing curriculum changes by understanding the intended curriculum and better implementing it in the classroom.

Through comparing Range of Knowledge (ROK)—the span of mathematical topics, and DOK—the complexity of knowledge required to meet the objectives, included in Saxon's *Course 3* with outlined objectives in the 7th and 8th grades CCSS (Common Core State Standards Initiative, 2010), we will provide information regarding the presence of a coherent and challenging written curriculum for 8th grade. In particular, the examination of older textbooks such as *Course 3* gives a way of evaluating programs from school districts that are unable to purchase new textbooks after CCSS implementation. Results will provide information to teachers regarding usable curriculum for students in middle school mathematics. With the eventual goal of studying student achievement data from CCSS assessments, these results can form a basis for future work examining teacher instruction, the second important component in judging a program's effectiveness (NCTM, 1995; Tarr, Chavez, Reys, & Reys, 2006). The Saxon text was chosen because of its unique lesson design and incremental sequencing (Hake, 2007).

This study will address the following research question:

How closely do the mathematical topics and depth of knowledge of the content in *Saxon Math: Course 3* and in the Common Core State Standards for grades 7 and 8 align?

Theoretical Framework

The Webb model was designed to analyze the alignment of state assessments and content standards and uses a combination of "qualitative expert judgments" and "quantified coding and analysis" of standards and assessments (CCSSO, 2010). The model is extended in this study to analyze the alignment between objectives in the CCSS and instructional content (as shown in the Saxon Course 3 textbook). By utilizing Webb's framework, this study will judge the alignment of ROK and DOK of the CCSS to Saxon's Course 3.

Range of Knowledge

One way to judge alignment between standards and assessments (or in this case standards and curriculum) is to examine whether both address a similar span of knowledge within content strands. Webb's ROK criterion is met if the full range of each major concept appears in both documents (Webb, 1997, 2007). This study matches textbook topics with CCSS objectives.

Depth of Knowledge

One factor to examine when judging alignment of standards, curriculum, and assessment is the alignment according to complexity of knowledge. Webb's framework gives a four-point hierarchy system. The first, *recall and reproduction*, requires the learner to recall information (e.g., a fact, definition, term or simple procedure). The second level, *skills and concepts/basic reasoning*, requires the learner to provide a non-habitual response that requires some thinking. The third level, *strategic thinking/complex reasoning*, involves higher-order thinking skills, reasoning, explaining, and using evidence. The fourth level, *extended thinking/reasoning*, requires critical thinking, planning, reasoning, and explanation over a long period of time, which must signify some higher-order thinking over the long period of time.

Method

Data Sources

The CCSS Initiative was coordinated by the National Governors Association Center for Best Practices (NGA Center) and the Council of Chief State School Officers (CCSSO). These standards will provide consistent and appropriate benchmarks for students nationwide and enhance global competitiveness (CCSS Initiative, 2010a). Work is underway to develop assessments for field testing in 2013-2014 that are aligned to these standards.

Saxon Math: Course 3 includes distributed instruction, practice, and assessments and contains 132 lessons that are not organized by chapters like traditional textbooks. This text is a part of the middle school series of Saxon's Courses 1–3, for students in sixth through eighth grades. The organizing principle in this text is mathematical thinking, with skills, concepts, and problem solving all connected by consistent mathematical language (Hake, 2007).

Procedures and Instruments

Webb's criteria were used to judge the alignment of ROK and DOK of those topics in Saxon's Course 3 to that of the CCSS for grades 7 and 8.

To analyze ROK, two raters with middle school educational experience and extensive mathematics knowledge matched mathematical topics as stated in lesson titles and subtitles with CCSS objectives. We matched key words from CCSS objectives with the same key words in lesson titles and subtitles. Examples of key words used include *represent proportional relationships*, *compute unit rates*, and *area and circumference of a circle*. If no lessons aligned with an objective by key words alone, raters looked through the instructional material and example problems in each lesson to find instances of alignment with the objective.

For those lessons that matched a CCSS objective, DOK was analyzed. We first coded the CCSS objectives in terms of the DOK levels as described in the previous section. Next, the level of instructional content and examples in the textbook were coded according to DOK. Content in the textbook and in the CCSS was analyzed using key words, verbs, and objects.

Thirty-eight CCSS objectives for grade 7 and 32 CCSS objectives for grade 8 were transferred to a spreadsheet for analysis. There are 132 lessons in the Course 3 textbook including investigations (application or exploration activities). All lessons that matched with an objective for either grade 7 or 8 were recorded, as well as the DOK level of each objective and each lesson corresponding to the objective.

Results

Raters had perfect agreement for number of lessons matching CCSS in grade 8 and differed slightly for three strands in grade 7 (Ratio/Proportion and Number Systems differed by 2 lessons, and Expressions/Equations differed by 4 lessons). The discrepancies resulted from disagreement about standards for *rational numbers*. Raters disagreed about lessons using whole numbers or integers as a match to standards referring to rational numbers. All results were based from the matches agreed upon by both raters. Results of alignment showed 41 of 132 lessons matching the CCSS standards for grade 8 and 51 matching the standards for grade 7 (see Figures 1 and 2). Looking closer at the CCSS objectives for each grade, it was found that 5 of 32 eighth-grade CCSS objectives (in Geometry, Functions, and Expressions/Equations) failed to match with any Course 3 lesson. For seventh grade, 2 of 38 CCSS objectives (both in Geometry) failed to match. Combined, 7 of 70 total CCSS objectives failed to match with the textbook, which still shows acceptable alignment with regard to ROK according to Webb's criterion (Webb, 1997).

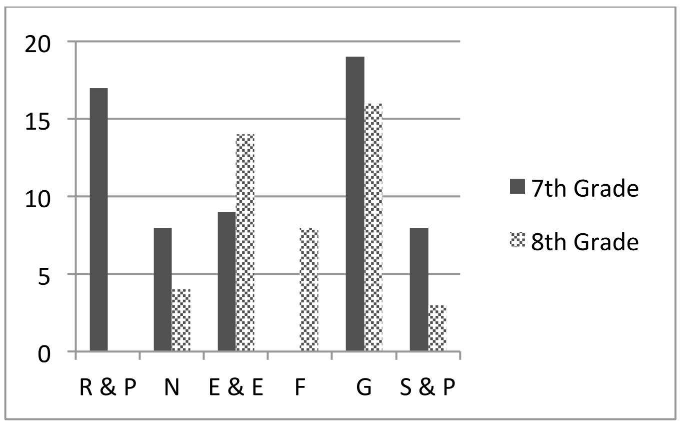

Figure 1: Number of aligned lessons for grades 7 and 8

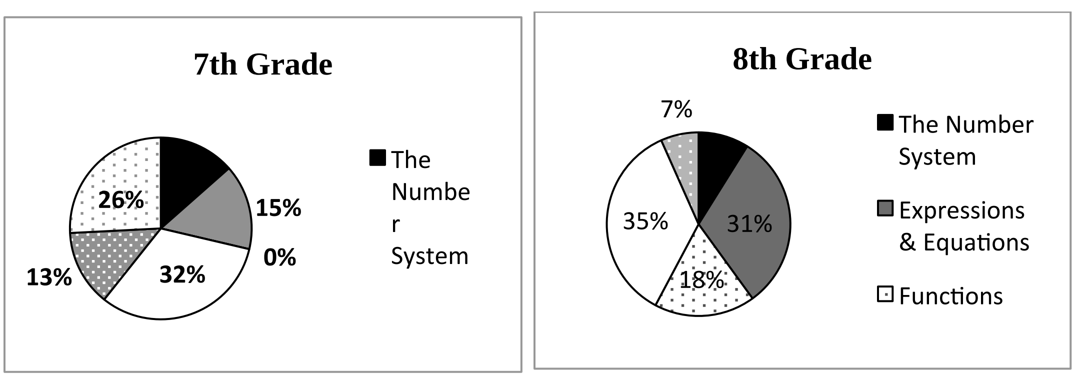

Figure 2. Proportion of aligned lessons in each domain for grades 7 and 8

An examination of DOK shows that over half of lessons were matched at the appropriate DOK level given by the CCSS objectives as Webb's criterion requires at least 50% of matches to be at or above the DOK level given by each standard (Webb, 1997). For example, if a CCSS standard is coded as level 2, the corresponding lesson objective must be coded as level 2 or above. Thirty-one of 38 seventh-grade CCSS objectives, and 22 of 32 eighth-grade objectives were found to be in alignment for both ROK and DOK.

To provide a completely CCSS-aligned, challenging written curriculum, teachers need to supplement from other sources to address these objectives. Other Saxon textbooks, such as *Algebra 1* and *Geometry*, contain lessons that provide a match to these CCSS objectives.

Discussion

As the CCSS become an important source for a consistent national framework for grades K–12 curriculum, assessment will be aligned to the standards. Future studies regarding instructional curriculum will be needed to ensure alignment between expectations, curriculum, and assessment, and these studies will provide assurance of equity among students nationwide.

This study provides a comparison of *Saxon Math: Course 3* to the CCSS for grades 7 and 8 in terms of ROK and DOK. Results of this study are important for school officials who make program decisions regarding curriculum and for teachers who must implement the school-provided textbook. Furthermore, results of this study provide important background for alignment studies of enacted curricula and of assessment relating to the CCSS, which will ultimately give ways to examine middle school achievement.

This study revealed a 69% match of DOK levels to the eighth-grade CCSS objectives, but future study is needed to examine teacher instruction and use of the textbook in the classroom. The matches between lessons and CCSS objectives may be much different than study of enacted curriculum. An alignment study between enacted curricula and CCSS objectives could provide more information about how learning is aligned to these objectives.

INTENTIONALLY INTEGRATING STEM: A PROPOSED FRAMEWORK

Allison W. McCulloch
North Carolina State University
allison_mcculloch@ncsu.edu

Jeremy V. Ernst
Virginia Tech
jvernst@vt.edu

The goals of this study were to articulate a framework for the development of integrated STEM projects for middle school students in which mathematics is meaningfully represented. Analysis of teachers' mappings of processes central to each of the STEM fields was used to develop the proposed Integrated STEM Process Framework. Here we present the framework and provide an example of a project that was designed through its use.

Keywords: Informal Education; Modeling; Problem Solving

Introduction

STEM has become a very loaded buzzword in education, especially as it relates to policy and as a result of that, funding. STEM stands for *science, technology, engineering, mathematics* and is interpreted by some as an "and" statement and others as an "or" statement (i.e., the former pointing to the integration of the disciplines and the later to the disciplines as independent, but important). NCTM president Michael Shaughnessy's recent editorial (February 2, 2012) noted both the strength of STEM and the problem with STEM. Its strength being an advocacy for investing resources in these disciplines to remain "globally competitive and scientifically and technologically innovative" which is critically important for the field of mathematics education. Yet at the same time he notes that because of this advocacy position STEM has taken on a "generalist" meaning (e.g., STEM programs, STEM schools, and STEM curricula) in which mathematics often takes a back seat and there is real concern of important mathematics content being lost. This is very troublesome when you consider the role that mathematics plays in all scientific, technological and engineering fields.

STEM-based understandings and experiences that prepare learners beyond the classroom are of imminent need, as today's STEM students are tomorrow's leaders in science, technology, engineering, mathematics and education (Prabhu, 2009). National standards for mathematics, science and technology education all highlight the importance of preparing students for college and careers through the integration of science, technology, engineering and mathematics concepts. The *Principals and Standards for School Mathematics* (NCTM, 2000) noted, "The need to understand and be able to use mathematics in everyday life and in the work place has never been greater" (p. 4), emphasizing the importance of students being able to recognize and apply mathematics to science and engineering. This has been emphasized more recently in the Common Core State Standards for Mathematics (CCSSI, 2010) through the articulation of mathematical practice standards that state, "students can apply the mathematics they know to solve problems arising in everyday life, society, and the workplace" (p. 7). Such calls point to the importance of integrative STEM experiences for all students; however, as noted by Shaughnessy, this cannot be done at the expense of important mathematics content.

Integrative STEM education signifies the intentional integration of science and mathematics with the processes, content and procedure of technology and engineering education (Sanders & Wells 2010). Though there is an obvious need for opportunities for students to participate in integrative STEM experiences, designing such experiences for classroom use is not easy. Last year a STEM project team brought together prospective science, mathematics, and technology teachers to design a *purposefully* integrated STEM project for middle school students. The term "purposefully" is used because of the central intent aimed at assuring that each discipline was incorporated to into the project in a *meaningful* way. For example, the aim was not for the effort to turn into a science project in which students used minimal mathematics. Nor was the intention for the project to become a "real world" math problem simply using a superficial science setting. What was needed was a framework that would provide both structure and a common language to guide the work. In this article, a framework for the development of purposefully integrated STEM projects is proposed. The framework includes guidelines for identifying a context and the actual design of the project. Finally, we conclude with an example of a purposefully integrated STEM project that was designed using this framework and suggestions for future work.

Proposed Integrated STEM Framework

Science, Technology, Engineering and Mathematics Processes

At the outset of our project there was an understanding that in order to design a project for students that was truly integrated the teacher team would have to work collaboratively to understand the content and common pedagogical practices of each discipline. The science teachers were pushing for the students to be expected to use the scientific method. The technology/engineering teachers were thinking in terms of engineering design principals (NASA, 2010). Finally, the mathematics teachers wanted to make sure that mathematical concepts were not relegated to just being a "tool" within STEM work, but that students were engaged in meaningful mathematical processes such as modeling. The search began for this common language by comparing and contrasting existing processes. Immediately, the cyclical nature of each process became evident and the team began to map them to one another.

The mapping was promising, so the next step was to meet with a group of approximately 30 middle school science, technology/engineering, and mathematics teachers at a statewide conference (many of whom taught at STEM schools). The idea of finding a common language that would capture the processes of each of the STEM disciplines was presented. The participants were provided a copy of NASA's engineering design process (the process with which we knew they were least familiar). Then they were asked to identify how the processes of scientific inquiry and a models and modeling prospective of mathematical problem solving (Lesh & Doerr, 2003) related to the engineering design process. Finally, they noted phrases that captured the intent of each phase.

Social Relevance as a Context

One of the first choices that must be made when designing an integrated STEM project is the context in which it will be set. STEM oriented connections that engage learners based on interest and direct relevance form effective educational efforts (Tate et al., 2007). As such, while the context needs to be related to content standards it should also have social relevance. This can be achieved through the investigation of real problems facing practitioners and researchers in STEM fields. It is recommended that teams of STEM teachers partner with local experts (e.g., informal educators, businesses, researchers) to identify contexts that are both personally and socially relevant to students to design a STEM project within. These emphases on context along with the mappings above were used to inform the development of what we refer to as the Integrated STEM Process Framework (Figure 1).

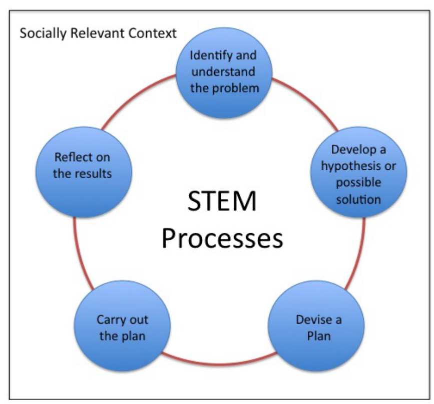

Figure 1: Integrated STEM process model

Proposed Integrated STEM Process Framework

We propose that the Integrated STEM Processes provide a framework for thinking about the development of purposefully integrated STEM projects. Notice that the processes are situated within a socially relevant context. The processes are represented as cyclical, consistent with mathematical modeling/problem solving processes, the scientific method, and engineering design processes. Language that was common among all three existing processes was used, while attempting to reduce the processes to a concise quantity of steps that still captured the essence of each. The intent is that teachers use this framework to inform project designs. In doing so, the goal is that projects should be designed such that students have opportunities to move through this cycle *at least* once within the context of each of the STEM disciplines. This will ensure that each of science, technology/engineering, and mathematics is being incorporated in a thoughtful and meaningful manner. An example of an integrated STEM project designed for middle school students utilizing this framework follows.

An Example: Inquiry on the Neuse River

A team of five prospective science, technology/engineering, and mathematics teachers chose the context of estuarine ecology for this project since it is a component of the state standard course of study for middle school science and recent research that shows that there is a need to be concerned about the effect of estuarine ecology on our nation's drinking water and fish supply. In addition, this was a particularly relevant context for local middle school students given the project team's proximity to an estuary. As such, a partnership was formed with the NCSU Center for Applied Aquatics Ecology (CAAE) in order to offer the project team and prospective teachers CAAE researcher expertise as support in this endeavor.

The prospective teachers began by meeting with the CAAE researchers to discuss their work in a local estuary. During this conversation the researchers noted the problems they had with their very expensive instrumentation, notably keeping the instruments free from the attachment of harmful barnacles. The barnacle issue ended up being the impetus for the design of their integrated STEM project—to design a way for the scientists at the CAAE to protect their instrumentation, used for water sampling, from destructive barnacles. The project was piloted with a small group of students in an out of school setting.

The project was designed to be integrative but with particular goals set within each discipline. Within the context of science, students would learn about estuaries and barnacles. For example, since barnacles live in salt water it is important that students understand that the salinity in an estuary can vary dramatically, depending on depth and the direction of wind currents as well as water temperature. Most importantly, they would then take what they have learned and design an experiment to determine whether or not a protective covering is effective. Within the context of technology/engineering, students would design and construct a protective covering for the water-sampling instrument. Finally, with respect to mathematics students would naturally be drawing on their knowledge of measurement and data analysis when designing and constructing their protective coverings and when designing and carrying out their scientific investigation. At this point in the design process all of the STEM disciplines were represented in the project. When the teachers compared the project to the proposed framework they felt as if mathematics was used as a tool within the design of the protective covering and the scientific experiment. However, they did not feel as if students would have gone through the STEM framework cycle with mathematics. To rectify this the students were also asked to compare the effectiveness of each of the protective coverings, which required them to also draw on their understanding of area (including composition of area), surface area and percents. The prospective mathematics teachers piloted this project with a small group of students in two half-day meetings outside of school.

Reflections and Future Work

Our goal at the outset of this project was to delineate a framework to help teams of teachers from STEM fields find a common language and goal for designing integrated STEM projects. Again, for us that meant a project in which all four STEM disciplines are at the forefront. While this was a preliminary investigation, we feel confident that the framework we have proposed will be helpful for teams of teachers attempting to do this kind of work. Teachers were instrumental in the development of this framework. The project team received overwhelmingly positive feedback from the STEM teachers that participated in the framework workshop that suggested that they were themselves in search of a framework to guide their project development. Furthermore, teachers from each of the disciplines saw their project goals illustrated in the framework. Even so, the mathematics incorporated into the project was somewhat "forced." By that we mean, analysis of the data collected during the experiment was the most obvious mathematics to include, but in order to be sure that mathematics was represented as a process and not solely a tool the teachers added additional prompts to compare the effectiveness of the designs. Further work needs to be done to see if this framework does in fact help to guide teachers toward more meaningful incorporation of mathematical concepts through the models and modeling perspective of problem solving incorporated with the other STEM processes.

The example provided was designed and piloted by a group of preservice teachers in an out of school setting. It is unclear how such a project would—or even could—fit within a school setting. Future research should focus on how integrated STEM projects, that seem to more naturally fit in informal settings (where the disciplines are not split into classes), might be incorporated into schools without losing important mathematics instructional time. While some have expressed understandable concern about the generalization of STEM, we propose that through the use of the Integrated STEM Process framework, integrated STEM projects can be designed in such a way that important mathematical concepts are addressed meaningfully.

A MISSED OPPORTUNITY: AN EXAMINATION OF MULTIPLICATION AND DIVISION IN A CANADIAN ELEMENTARY MATHEMATICS CURRICULUM

Vanessa Rayner	Nadine Pomilio	Helena P. Osana
Concordia University	English Montreal School Board	Concordia University
v_rayner@education.concordia.ca	NPomilio@emsb.qc.ca	osana@education.concordia.ca

We present preliminary results from our analysis of multiplication and division tasks included in the teachers' manuals of the Nelson curriculum series. Our analysis of tasks from 14 manuals for grades 1 through 6 focused on (a) the relative proportion of tasks that require problem solving, (b) the ways in which the tasks were presented, (c) the relative frequency of Partitive and Measurement division problems, and (d) the relative frequency of different multiplication and division problem types (Carpenter et al., 1999). The results demonstrated an emphasis on the development of students' conceptual understanding of the operations in the context of word problems. In addition, we observed a greater emphasis on understanding multiplication as repeated addition, suggesting that opportunities to develop multiplicative understanding may be limited. We conclude with additional analyses we are currently conducting.

Keywords: Curriculum Analysis; Elementary School Education; Problem Solving

According to Doyle (1983), "Tasks influence learners by directing their attention to particular aspects of content and by specifying ways of processing information" (p. 161). The potential, however, for mathematical tasks to positively impact students' level of mathematical understanding largely depends on the quality of the task itself (Osana et al., 2006). Given the important role of mathematical tasks in student learning, the types of tasks presented in elementary curricula warrants attention. Accordingly, the primary goal of the present study was to analyze an elementary curriculum series used extensively in Canada (*Nelson Mathematics*; Kestell & Small, 2004) with a specific focus on multiplication and division. More precisely, we focused our analysis on the *context* and *content* (i.e., the problem type) of multiplication and division activities as outlined in the teachers' manuals of the curriculum series.

Theoretical Framework and Objectives

Our decision to focus on these two features of mathematical tasks is supported by the literature on making mathematics "problematic" (Hiebert et al., 1996) and the developmental research on multiplication and division (e.g., Carpenter et al., 1993). Research has shown that tasks situated in a problem solving context[1] promote a more meaningful understanding of mathematics content because it involves applying knowledge versus simply acquiring it (Hiebert et al., 1996). Thus, it is important to consider the *contexts* that are used with students to introduce and explore concepts of multiplication and division.

In addition to the task context, the *task content*, or problem type, should align with students' mathematical development. Multiplication, for instance, is often introduced to children using an additive model in which it is conceptualized as repeated addition. Park and Nunes (2001), however, demonstrated that children's concept of multiplication originates in a schema of correspondences, not addition; therefore, Park and Nunes conclude that instruction should emphasize multiplicative reasoning rather than repeated addition. To develop an understanding of division, it is important to address two models of division: partitive and measurement. Indeed, although children's initial understanding of division is rooted in the action of sharing (Correa et al., 1998) an understanding of the concept of division also involves understanding the relationships between the dividend, divisor, and quotient (Correa et al., 1998). Developing this relational view requires a multifaceted view of division, which includes conceptualizing it as the inverse of multiplication (Greer, 1992).

This paper presents preliminary results from our analysis of multiplication and division as it is treated in the *Nelson* curriculum. Our first objective was to examine the **contexts** in which these two operations are used. More specifically, we examined the relative proportion of tasks in the Nelson series that require problem solving, as well as the ways in which the tasks were presented (i.e., word problems, equations). The next two objectives addressed task **content**: (a) to examine the relative frequency of both *models* of division (Partitive and Measurement), and (b) to examine the relative frequency of different multiplication and division problem *types* (Carpenter et al., 1999). We are currently analyzing the data to describe the ways in which frequency patterns change over the grade levels, the results of which will not be reported here.

The teachers' manuals that accompany the curriculum contain highly scripted descriptions of classroom lessons and activities. Thus, while the manuals clearly describe the intended mathematics curriculum, they also give some indication of what teachers are actually doing in their classrooms. Accordingly, our results paint a picture of the types of activities experienced by a large number of Canadian children in the area of multiplication and division, which can serve to provide an important context for examining their mathematical performance locally and internationally.

Method

The Nelson Mathematics Series

The Nelson Mathematics (NM) series is K–8 mathematics curriculum that is in use in the provinces of Ontario and in several English language school boards in Québec. The NM series was designed for use in the context of major curricular reforms in both provinces (e.g., *Quebec Education Program*; 2005). With respect to mathematics, the core of these reform initiatives corresponds to key principles in the NCTM (2000), such as problem solving and communication. The teacher's manual, called the *Teacher's Resource,* includes 14 color chapter booklets with accompanying resource materials for teachers' use in the classroom.

Coding and Analysis

Data sources. To examine the presentation of multiplication and division in the NM series, we analyzed all the printed material in the Teacher's Resource manuals at each grade level 1 through 6. We coded 14 manuals at each grade level (one manual for each chapter in the student text), for a total of 84 manuals. Each manual is further divided into lessons. For each lesson, the teacher is provided with information about the lesson's goals and required materials for implementing it, and is also provided with scripts and activities on how to introduce the concepts related to the lesson, problems for students to work on in class, and assignments to foster reflection on what was learned.

Task selection. Each lesson consisted of a series of tasks. We defined "task" as any activity assigned by the teacher to the students. Our first round of coding involved classifying the tasks as Multiplication, Division, or Other. Only Multiplication and Division tasks were included in the analysis. Multiplication tasks included those in which (a) the multiplication symbol was used, (b) the student was specifically told to use multiplication, or (c) the structure implied multiplication in a word problem context. A similar classification was used for division tasks.

Coding rubric. All Multiplication and Division tasks were then further classified as Problem Solving (PS) and Non-Problem Solving (NPS). A PS task involved solving for an unknown quantity. This included word problems such as, "Each basket has 5 apples. There are 6 baskets, how many apples are there altogether?" An NPS task is one where there is no unknown to find. In general, the goal of these tasks is to model a mathematical relationship (e.g., use these blocks to show the different ways you can represent $3 \times 2 = 6$).

PS tasks were further subdivided into those that situate models of multiplication and divisions in word problem contexts. In these tasks, the operation is not specified, so the student needs to rely on his or her conceptual understanding of the problem structure to solve it. We called these tasks PS-Not Specified (or PS-NS). There were also PS tasks that were coded as Specified (PS-S), and these were tasks in which the operation was either specified symbolically (i.e., calculate: 7×3, $48\div6$) or in the context of a word problem (e.g., “0.3 of the 400 students in the school are going to Montreal. Multiply to find how many students are going on the trip.”)

The PS-NS tasks were further classified according to problem type (i.e., Grouping/Partitioning, Rate, Price, and Multiplicative Comparison; see Carpenter et al., 1999). Grouping/Partitioning problems describe scenarios that involve collections of discrete objects that are grouped or partitioned into equal parts. An example of a Partitive Division Grouping/Partitioning problem is, “*Robert has 15 stamps that he would like to give to 3 of his friends. He would like to give each friend the same number of stamps. How many stamps does each friend get?”* In contrast, the other problem types (Rate and Price problems) often involve continuous quantities, such as those related to distance and weight. Rate problems, for instance, describe one quantity in relationship to another (e.g., 3 miles per hour), and often the quantities used are continuous. Multiplicative Comparison problems are unique in that a relationship of two quantities is described. That is, the size of one of the quantities (i.e., the referee) is based on how many times bigger or smaller it is compared to another quantity (i.e., the referent).

Results

Context of Multiplication and Division Tasks

Multiplication and division tasks only began to appear in the second grade. In addition, the use of Problem Solving (PS) tasks increased steadily between grades 2 and 6. The ratio of PS tasks to Non-Problem Solving (NPS) tasks started at 1.24 in grade 2 and ended at 2.9 in grade 6. A further analysis indicated that all the PS tasks at the second-grade level were of the PS-NS variety, meaning that all the activities on multiplication and division in grade 2 were couched in word problem contexts. We also found that although the frequency of PS-S problems increased with grade level, the frequency of PS-NS problems was always greater, suggesting that there is an emphasis on the development of students’ conceptual understanding of the operations in the context of word problems across all grade levels.

Content of Tasks: Problem Types

To analyze task content, we further coded (1) the PS tasks involving division according to the model represented (Partitive or Measurement), and (2) all the PS tasks according to problem type. We found that the frequency of Measurement Division problems compared to Partitive Division problems differed across grade levels. In particular, 66.7% of the division problems in Grades 2 and 5 were Partitive; in the other grades, this percentage was lower (48.15% in third grade; 41.67% in fourth grade; and 43.48% in sixth grade).

In general, the frequencies of problem types other than Grouping/Partitioning were relatively low. More specifically, for each grade level, the Grouping/Partitioning problems were the most frequent and Multiplicative Comparison problems were the least frequent. The frequency of Grouping/Partitioning problems was proportionally highest in Grade 2 and Grade 3, representing 86% and 81%, respectively, of the total number of tasks at each level. The high frequency of Grouping/Partitioning problems continues in Grade 4, 5, and 6, accounting for 64%, 72%, and 61%, respectively, of the total. The frequency of Rate and Price problems did increase as the grade level increased. The frequency of the Multiplicative Comparison problems, on the other hand, declined after Grade 4 and did not appear at all in Grades 2 and 3.

Conclusion

The results addressing the relative proportion of problem-solving tasks and their presentation suggest that the NM series introduces multiplication and division with a focus on conceptual understanding. As students experience with multiplication and division progresses, the frequency of modeling tasks decrease to promote more experience with problem solving. While the high frequency of problem-solving tasks suggests that the NM series engages students in reform-orientated mathematical reasoning and facilitates conceptual understanding, the results from the task content analysis demonstrate that the task context results are somewhat misleading. Indeed, the paucity of multiplicative comparison, rate, and price problems, compared to grouping/partitioning problems, demonstrates an emphasis on understanding multiplication as repeated addition. From a developmental perspective, these results suggest the orientation in the NM series toward repeated addition may hinder the development of children's multiplicative reasoning (Park & Nunes, 2001). Currently, we are conducting further analyses to determine whether there is a significant difference in the frequency of Partitive Division and Measurement Division problems and examining changes in these frequencies over the grade levels.

Endnote

[1] Our conceptualization of "problem solving" involves engaging students in the process of determining an unknown quantity. While a more traditional definition associates problem solving with tasks that do not provide an obvious solution method (Hiebert et al., 1996), our definition was broader and even included tasks where the solution method was made explicit.

CONVINCE ME: AN INVESTIGATION OF ARGUMENTATION IN A MATHEMATICS COURSE FOR IN-SERVICE TEACHERS

Lisa Rice
University of Wyoming
Lrice4@uwyo.edu

This study investigates the forms of argumentation a mathematics professor intends for in-service teachers to learn and the forms addressed in the course. The teachers are enrolled in a graduate level mathematics course intended for practicing teachers. Additionally, teacher's perceptions of mathematical argumentation and the forms they employ in course activities will be explored. Both case study and grounded theory approaches will be used to guide the data collection and analysis. Interviews with the professor and teachers will be conducted, along with observations of the mathematics course and of teachers' classrooms.

Keywords: Mathematics; Argumentation; Proof; Teacher Education–Inservice/Professional Development

Introduction and Literature Review

Mathematical argumentation is part of curriculums, for example in the teaching of two-column proofs in geometry. Proof, as Hanna (2000) claims is "prominent" in curriculum, but it is not the only form of argumentation in mathematics. Researchers Pedemonte and Reid (2011) claim that further research is needed in the area of abduction, which can be thought of the process of developing a certain form of argument. Models developed in other disciplines, such as Toulmin's model of argumentation, have been used by researchers to study argumentation (e.g., Giannakoulias, Mastorides, Potari, & Zachariades, 2010; Krummheuer, 2007; Pedemont & Reid, 2011). Both proof and argumentation are explicitly addressed in the NCTM Reasoning and Proof Process Standard (2000). Not only that, but they acknowledge in their recommendations that there are multiple forms of argumentation. The NCTM states that students should have the ability to:

- recognize reasoning and proof as fundamental aspects of mathematics;
- make and investigate mathematical conjectures;
- develop and evaluate mathematical arguments and proofs;
- select and use various types of reasoning and methods of proof.

For teachers, the ability to develop well-formed mathematical arguments is important for a few reasons. First, it supports curriculum and mathematics standards; teachers are expected to teach and ask students to engage in mathematical argumentation. They must respond to students' mathematical claims or explanations. Walshaw and Anthony (2008) claim, "effective pedagogy is inclusive and demands careful attention to students' articulation of ideas" (p. 527). Thus, teachers' experiences in mathematical argumentation are an important part of pedagogy. Further, Krummheuer (2007) who assumes that student mathematical learning is predicated on engagement in argumentation practices considers mathematical argumentation as an everyday activity in the mathematics classroom. Kennedy (2009) discusses the importance of mathematical argumentations stating "The ideal mathematical inquiry proceeds through a form of argumentation…" (p. 73). If teachers are not familiar with developing and evaluating mathematical arguments for themselves, it is unlikely they would feel comfortable asking their students to do so and assessing students based on their arguments. Additionally, considering Kennedy's remarks, deficiency in knowledge of mathematical argumentation could hinder efforts to incorporate inquiry practices in the classroom. Mathematical argumentation of teachers is an indicator of their mathematical content knowledge. Developing a valid mathematical argument, such as a proof, can show one can connect mathematical ideas together to verify, discover, explain, and achieve other purposes as listed by Hanna (2000).

Lastly, mathematical arguing is a way for teachers to "do" mathematics. Teacher education programs around the country vary in their structure, but in general programs have modest requirements regarding proof-based mathematics courses or courses which might have a variety of argumentation types, yet mathematical argumentation is a teaching expectation. Giannakoulisa, Mastorides, Potari, and Zachariades (2010) advise that refutation is a form of argumentation that needs greater emphasis in teacher education.

The focus of the research is to study the mathematical argumentation of a professor and in-service teachers enrolled in a master's program. The research pursued here is motivated by the following research questions: What forms and in what ways does the professor intend for teachers to learn mathematical argumentation? What are teachers' perceptions of mathematical argumentation in the course and what forms do they use? How do in-service teachers employ mathematical argumentation in their instruction?

Methodology

The research study's subjects will include one professor from the mathematics department at a university in the Rocky Mountain region and in-service middle and high school mathematics teachers enrolled in a master's program designed for practicing teachers. The professor is the instructor of an algebra course offered in the program, which the in-service teachers (henceforth called students) are enrolled for Spring 2012. This is the second time this professor has taught the course in the program. The format of the course is online and all course meetings are offered through the synchronous software package called Elluminate. This course was chosen for several reasons. First, it is an advanced level mathematics course and so forms of argumentation such as proof and counterexamples are likely to be encountered. Second, the researcher's previous experience working with the program has helped to gain a sense there exists a wide range of mathematical backgrounds and varying degrees of experiences with forms of mathematical argumentation. Thus, this might provide more opportunities to see the variety of ways students argue in a course they take. Third, the instructor of the course expressed enthusiasm at the prospect of conducting this research study in his course.

Data will consist of field notes from observing course meetings, which are audio and video recorded with Elluminate software, the recordings, interviews with the professor and selected students, written work collected from students, and observations of classroom visits to see the students teach in their own classrooms. Interviews throughout the semester with the course instructor will be based on observations of the course and written work produced by in-service teachers. Questions posed during interviews with the professor will seek to draw out information regarding ways the instructor plans to address argumentation, how he intends to engage students in argumentation, and forms of argumentation he perceives students employing. Potential students for interviews will be chosen based on the forms of argumentation they may have employed, questioned, or in the way in which they responded to a given mathematical argument. Interviews with students will be focused on their perceptions of mathematical arguments, forms they have used in the course, and exploring why they chose to argue a certain way.

Both techniques from grounded theory and case study approaches will be employed. Because a small number of students are expected to be selected (possibly two or three) to participate in interviews and observations of their teaching practice, this satisfies one of Merriam's criteria that case study is an appropriate approach when the phenomenon is "intrinsically bounded" (2009, p. 41). The professor and each student will be considered as separate cases. The interactions between the professor and students will provide valuable data concerning the teaching, use, and development of mathematical arguments. As asserted by Grbich (2007), in such cases when "interactions between persons or among individuals and specific environments" is under investigation, grounded theory is a suitable approach (p. 70). Also, because little is known how teachers develop arguments in mathematics, it is another reason why grounded theory is an appropriate approach (Grbich, 2007). While Toulmin's model of argumentation has been used by numerous researchers (e.g., Giannakoulias, Mastorides, Potari, & Zachariades, 2010; Krummheuer, 2007; Pedemont & Reid, 2011), it seems better suited to analyzing single episodes or instances of argumentation than to analyze the process of constructing and argument and documenting someone's forms of argumentation over a period of time to see if any changes occur.

Data collection began in the spring semester of 2012 and will continue through May 2012 and so I will continue to collect data after submission of the proposal. Observations of the course meetings and opinions from the professor will be taken into account for inviting particular students to participate in interviews and classroom observations. Open and in-vivo coding will be conducted for initial coding stages of the interview data of the professor and students, which will be partially or fully transcribed, depending on what is determined to be pertinent to the study. As Merriam (2009) states, "triangulation remains a principle strategy to ensure for validity and reliability" and so this is one strategy I will employ in analyzing data (p. 216). Also, member checks, and efforts to establish researcher reflexivity (e.g., Cho & Trent, 2006; Merriam, 2009) will be used.

Preliminary Findings and Discussion

My data set will consist of what I have gathered at this time and data I will continue to collect throughout the semester. Data I currently have consists of field notes of course observations and links to recorded class sessions. Preliminary analysis of observations indicates there is a variety of ways the professor engages students in argumentation practices. Also, students appear to be diverse with respect to arguing mathematically, providing arguments of various forms, from giving an example to respond to the professor's prompt for an argument to citing a theorem.

One of the goals of this research is to develop a scheme for examining argumentation in mathematics. Ideas or elements from Toulmin may be used in the formation of this scheme, as it is a well-established tool for analyzing mathematical arguments. Based on what I observe happening in the course I may use the data to modify Toulmin's model of argumentation so that it helps follow a person's use of argumentation over time. By developing a scheme for analyzing mathematical argumentation it is hoped that a better understanding of how teachers develop mathematical arguments and of forms they is achieved.

REASONING-AND-PROVING TASKS IN A GEOMETRY AND MEASUREMENT TEXTBOOK FOR PROSPECTIVE ELEMENTARY TEACHERS

Kimberly Cervello Rogers
Michigan State University[1]
cervello@msu.edu

Michael D. Steele
Michigan State University
mdsteele@msu.edu

Although elementary teachers are expected to engage their students in the process of reasoning-and-proving in everyday mathematics learning, many prospective teachers have had limited experiences with this process. College mathematics courses for prospective teachers and the mathematics textbooks chosen for these courses can play an important role in prospective teachers' opportunities to learn about reasoning-and-proving as undergraduate students. In this article, we examine the opportunities in a geometry and measurement textbook for prospective teachers to engage in reasoning-and-proving. The findings have implications for how instructors might choose to implement a textbook in ways that support the development of rich conceptions of reasoning-and-proving with prospective teachers.

Keywords: Reasoning and Proof; Curriculum Analysis; Teacher Education–Preservice

Introduction

Reasoning-and-proving (RP) is fundamental to the work of doing authentic mathematics, both in mathematics and classroom. Descriptions of mathematicians' practice and K-12 standards documents alike note that the proving process involves exploration of patterns, which can lead to the generation of conjectures, and can then be tested and revised or proven informally or formally (Lakatos, 1976; NCTM, 2009). The hyphenated term *reasoning-and-proving* (Stylianides, 2008) denotes the range of activities including investigating patterns, formulating conjectures, generating arguments, evaluating others' arguments, and communicating mathematical knowledge, which are "frequently involved in the process of making sense of and establishing mathematical knowledge" (Stylianides, 2009, p. 259).

Proof in K–12 classrooms is often restricted to verifying given statements using a two-column format (Herbst, 2002). This emphasis represents only one aspect of the RP processes, and contributes to the pervasive difficulties and limited views of proof held by K–12 students and their teachers (Balacheff, 1988; Martin & Harel, 1989). The full range of RP processes can be accessible at the elementary level, and as such, elementary teachers should be equipped to teach RP in meaningful ways. It is crucial, therefore, to help transition prospective teachers of elementary grades (PTEs) from conceptions of proof as empirical arguments, towards understandings of the RP as a process in which one engages to make meaning in mathematics.

Mathematics for elementary teachers courses are the primary site for supporting this development of PTEs' knowledge for teaching. Geometry and Measurement is a common content slice for these courses, with explicit attention to the work of proof (Cannata & McCrory, 2007; McCrory, Siedel, & Stylianides, 2008). Analyses of popular math for elementary teachers texts suggest that RP opportunities are sparse (McCrory et al., 2008), but those analyses used broad approaches involving key word searches of the table of contents and indices of texts. In this study, we use Stylianides's (2009) analytic framework to examine the treatment of RP in a textbook used in teaching PTEs Geometry and Measurement to characterize the opportunities for PTEs to learn about RP. Specifically, we analyzed the Geometry and Measurement chapters of a popular text used in teaching mathematics content courses in the United States, a text designed to help PTEs to "*explain why* mathematics works the way it does" (Beckmann, 2008, italics added, p. xix), make sense of mathematics, and carry those abilities into their future classroom.

Analytical Framework

The unit of analysis used in considering the text was the mathematical instructional task (Henningsen & Stein, 1997), as tasks are a key determinant of students' opportunities to learn (NCTM, 2000). A mathematical task is a set of questions or text segment oriented that develops a particular idea. Analyzing the textbook at the task level, we identified opportunities to create or evaluate conjectures and/or provide mathematical justification within each task.

Table 1: Reasoning-and-Proving Framework (adapted from Stylianides, 2009)

	Reasoning-and-Proving					
	Mathematical Generalizations			*Mathematical Arguments*		
	Investigate Mathematical Relations	*Conjecture*	*Evaluate Claim*	*Evaluate Argument*	*Provide a Non-proof Argument*	*Provide a Proof*
Components & Subcomponents of RP	• Provided Examples • Generate Examples	• Make a Conjecture	• Evaluate a Mathematical Claim	• Evaluate a Mathematical Argument	• Empirical Argument • Rationale	• Proof

To characterize the RP opportunities afforded by tasks in the text (Beckmann, 2008), we applied a modified version of Stylianides's (2009) analytic framework. This framework identifies a task as related to RP if it provides opportunities for students to create or evaluate mathematical generalizations or mathematical arguments (Table 1).

Method

In the Geometry and Measurement chapters of Beckmann's (2008) textbook, we first grouped questions together into tasks and identified all tasks with RP opportunities. The textbook contained 115 tasks related to these four chapters. We coded the questions within tasks using the analytical framework (Table 1). The definitions for each subcategory (detailed further in Stylianides, 2009) guided the coding of each question, and a single question could be coded with multiple categories, when applicable. If a question did not fit the criteria for any categories of the framework, then it was coded as not RP-related. Two trained raters conferred to refine the descriptions and procedure for applying this framework; double-coding 31% of questions, reaching agreement on 81% of the codes, and resolving any disagreements through discussion.

Results

One goal of this analysis was to examine the extent to which the textbook provided opportunities for PTEs to engage in RP; understanding the ways in which RPTs were distributed informed this purpose. Of the 115 tasks, about 57% contained at least one question related to RP, and these RPTs were distributed across the four chapters. Figure 1 shows the ways in which RPT and nonRPT distribute across sections of these four chapters. There were a number of sections in these chapters for which RPTs were prevalent, accounting for at least 50% of the tasks in sixteen of the 26 sections in the textbook. Moreover, the later subsections in some chapters (8-10) tended to have more RP tasks than earlier sections or there was an even spread among subsections (11). It could be problematic if the chapter frontloaded RPTs in the beginning subsections. The sections of the textbook with fewer RPTs were also spaced out so that PTEs could arguably have opportunities to encounter RPTs at various points throughout a course using this textbook.

We also aimed to identify the nature of RP opportunities afforded in the text by investigating the types of RP processes elicited in RPTs. Figure 2 shows the ways in which the tasks were distributed with respect to the six types of RP processes. The most common category was *providing nonproof arguments* in which 47 of the 66 RPTs (71%) contained at least one question prompting students to provide mathematical explanations, not explicitly proofs. Two categories especially relevant to teaching, evaluating claims and arguments, accounted for the fewest tasks.

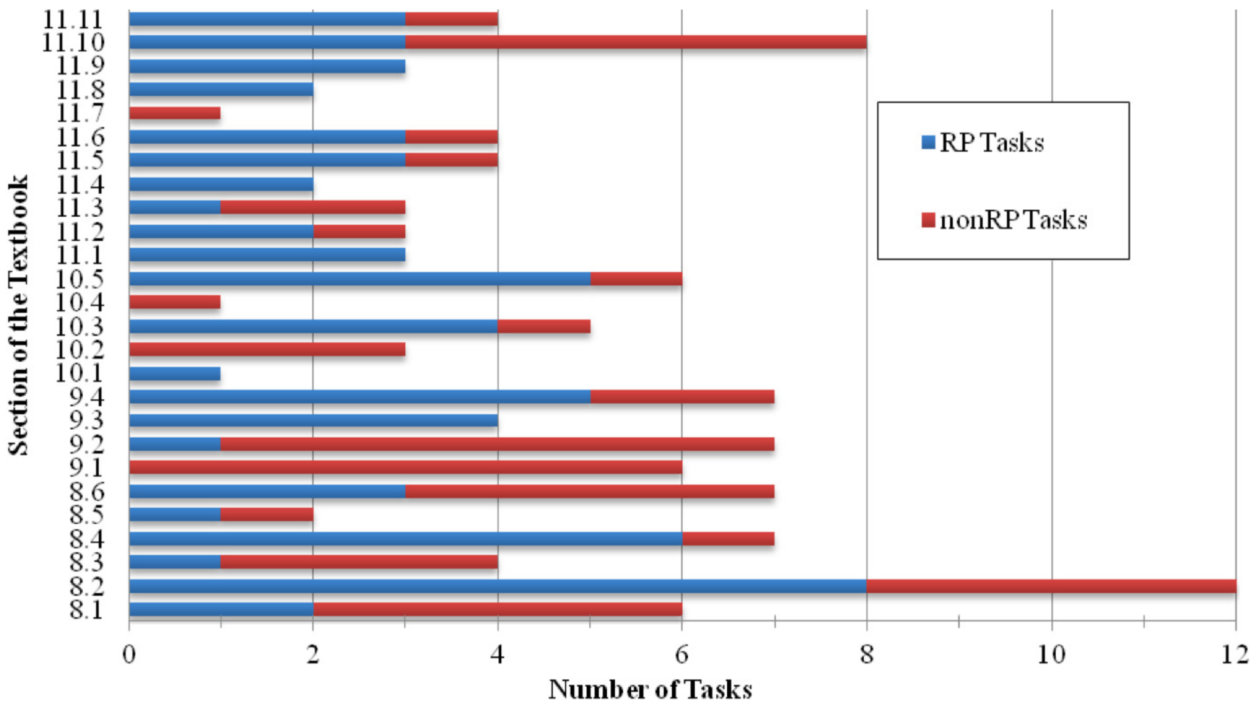

Figure 1: Breakdown of RPTs and nonRPTs in the textbook

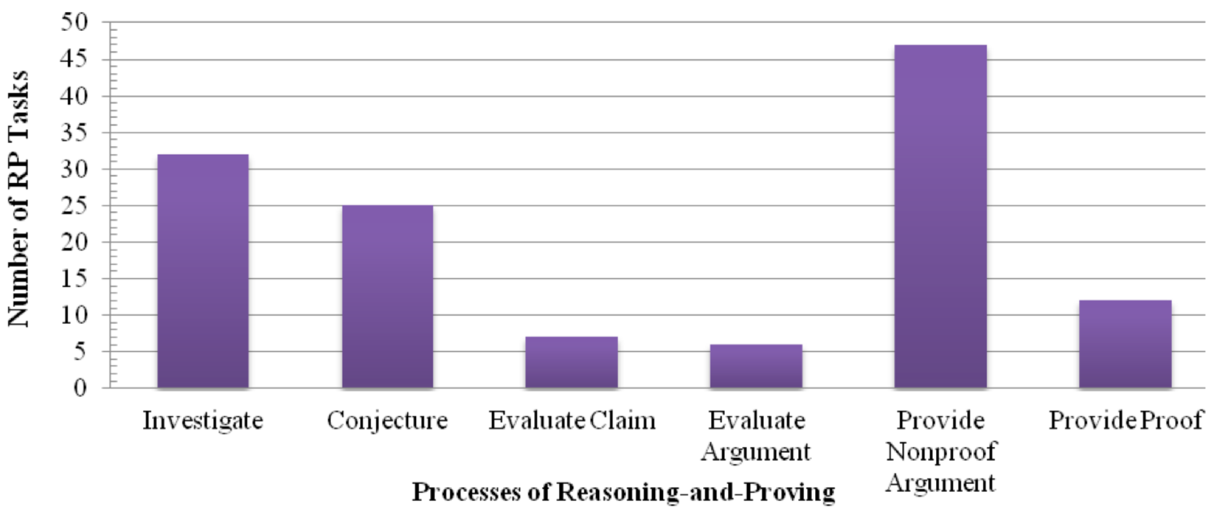

Figure 2: Number of Tasks Addressing RP Processes

Discussion

This analysis indicated that Beckmann's (2008) textbook provided a range of opportunities for PTEs to engage in RP. Throughout the geometry and measurement chapters, students investigate patterns, generate conjectures, and justify mathematical claims with rationales or with proofs. There were also opportunities to engage in many RP processes within one task, meaning they could potentially experience the process of generating and refining arguments. This analysis provided a more detailed view of RP opportunities in this textbook than previous research (McCrory et al., 2008) by identifying PTEs' opportunities to engage in specific RP processes.

As was particularly apparent in Figure 2, however, a majority of these RP opportunities were about generating nonproof arguments. This prevalence of nonproof arguments suggests that the textbook would likely be implemented to provide opportunities for PTEs to generate informal arguments for why mathematical statements were valid. Such a focus could provide helpful opportunities for PTEs to practice communicating their mathematical reasoning more clearly, which is important to demonstrate their understanding of mathematical idea and to prepare them to explain mathematical ideas to students in the future. Since many prospective and practicing teachers maintain the misconception that empirical arguments are proofs (Knuth, 2002; Steele, 2006), however, it is also important to help PTEs transition from this way of thinking to a more robust view of the role of proof in mathematics. Although the inclusion of rationales, explanations, and empirical arguments could potentially help PTEs articulate how they are thinking about the mathematical ideas, without some contextualization and thoughtful implementation on the part of the college instructor, PTEs may walk away from a course using this textbook with that conception maintained or reinforced. An instructor, on the one hand, could modify a task by pressing PTEs to provide a proof even though the task did not explicitly call for one. An instructor, on the other hand, could contextualize the fact that the argument PTEs generated was not a proof, facilitating class discussions about features of proofs and nonproofs. Modifying and contextualizing tasks from the textbook is an important aspect of instructors' teaching practice that needs to happen to broaden PTEs' experiences with and conceptions of RP. Supporting college instructors in their teaching of RP and studying the way in which RP tasks from this textbook were enacted are important avenues of further study.

Endnote

A CROSS-NATIONAL STANDARDS ANALYSIS: QUADRATIC EQUATIONS AND FUNCTIONS

<u>Tuyin An</u>

Keywords: Standards; Curriculum Analysis; Curriculum; Algebra and Algebraic Thinking

The newly released national curriculum standards, *Common Core State Standards (CCSS),* have aroused wide interests in the field of education. As claimed by the founders, the standards emphasize the correlation with the real world, attempt to reflect the knowledge and skills that students need for success in college and careers, and eventually help them to compete successfully in the global economy (Common Core State Standards Initiative, 2011). Undoubtedly, the new standards have pushed all K–12 teachers, students, researchers, policy makers, and even parents into a crucial transition phase. People are eager to learn the features of the new standards and much concerned about how they can make a smooth transition while adapting the *CCSS* into their daily work.

As a group of international researchers studying mathematics education in the United States (authors are from Caribbean, China, Turkey, and U.S.), we decide to investigate the *Common Core State Standards for Mathematics (CCSSM)* through an international lens. We designed a cross-national comparative study to investigate the similarities and differences among curriculum standards of the four countries with different education systems, specifically, how one of the most conceptually challenging topics, quadratic equations and functions (e.g., Vaiyavutjamai, Ellerton, & Clements, 2005), is introduced in different countries. Comparing to the previous studies (e.g., Reys, Dingman, Nevels, & Teuscher, 2007; Reys, 2006), a more comprehensive theoretical framework was created, which is the three dimension comparison of characteristics of standards: content, mathematical reasoning, and cognitive level. The results show that all the standards introduce students to the foundational concepts of quadratic functions, however, with various procedural and conceptual expectations. Our ultimate goal of doing the cross-national comparison is not to simply rank nations, but to provide a basis for considering current practice and possible alternatives and to help teachers improve their students' learning of mathematics.

Acknowledgments

Sincere gratitude is hereby extended to our thesis advisor, Dr. Jill Newton, for her unwavering guidance.

UNDERSTANDING HOW AN ELEMENTARY TEACHER RECOGNIZES AND USES CURRICULUM FEATURES

Napthalin Achubang Atanga
Western Michigan University
achubang.a.napthalin@wmich.edu

Teachers' use of curriculum materials is in great variation (Remillard, 2005). So is the way in which teachers read curriculum materials (Sherin & Drake, 2009). The relationship between teachers' reading and use of curriculum materials has not been articulated, and little research examined how teachers recognize and use curriculum features (CFs). The purpose of this case study is to understand how a fifth-grade teacher, Caroline, recognizes and uses curriculum features as she teaches mathematics using the *Investigations in Number, Data, and Space* curriculum.

I observed two lessons that Caroline taught using *Investigations*. Each lesson lasted one hour twenty-five minutes. Data collected include her written plans for the two lessons, associated notes, classroom videotapes, pre- and post-interviews, and the curriculum materials used. Caroline's lesson plans, associated notes, and interviews helped identify CFs she had recognized and planned to use during instruction. The videos enabled me to identify which CFs recognized during planning were actually used in her teaching and how they were used.

Caroline recognized and used CFs such as key representations and models, instructional approaches and mathematical tasks, as well as support and guidance provided for teachers. While reading/skimming the *Investigations* lessons, Caroline recognized the significance of certain CFs, by using her knowledge of CFs and benefits they offer, which she gained from the professional development (PD) she participated in. Such recognition led her to evaluate those CFs' suitability and appropriateness for her classroom and plan how to use them during instruction. For example, when reading "teacher notes," Caroline recognized the different methods students might use and the importance of discussing these methods during the lesson. Also, Caroline recognized the importance of "dialogue boxes" because of the guidance they provided, such as the type of questions to ask and the kinds of responses students might give.

Caroline's use of CFs was evident during instruction. For example, Caroline made connections among the multiple strategies students generated based on guidance from the dialogue boxes, leading to productive classroom discussions. These connections fostered students' understanding of the different strategies as well as their efficiency. When using the CFs that she recognized, she made some adjustments based on students' needs. Therefore Caroline's recognition and use of CFs was influenced by what her students knew and were able to do. Using Forbes and Davis's (2010) framework, I classified her adaptations as distributed improvisation. However, some CFs, such as "ongoing assessment," which elaborated kinds of students' thinking to look for, were neither recognized nor used explicitly. These findings suggest that PD programs should consider in-depth explorations of CFs to build teachers' capacity in recognizing and using them in productive ways.

THE INFLUENCE OF VISUAL REPRESENTATIONS ON LEARNING FROM MATHEMATICS LESSONS

Virginia Clinton

vclinton@wisc.edu

Mitchell Nathan
Univ. of Wisconsin–Madison
mnathan@wisc.edu

Martha Alibali
Univ. of Wisconsin–Madison
mwalibali@wisc.edu

The inclusion of information that is interesting, but irrelevant to the lesson, has been found to distract learners and diminish comprehension in a phenomenon referred to as the *seductive details effect* (Lehman, Schraw, McCrudden, & Hartley, 2007). Math textbooks often contain images, either decorative (i.e., for aesthetic purposes only) or contextual (i.e., related to the background of the lesson) that are irrelevant to the mathematical concepts being taught.

There is empirical evidence that decorative images have a negative influence on learning (Levin, Anglin, & Carney, 1987), likely because of the seductive details effect. In contrast, contextual images have been shown to help with aspects of reading comprehension for some populations (cf. Pike, Barnes, & Barron, 2010), although the effects of contextual images on learning from math lessons have not been explored. It is unknown whether contextual images would distract from mathematics learning or if they would benefit mathematics learning through assistance with reading comprehension. The purpose of this study is to examine the influence of contextual and decorative images on learning from a mathematics lesson. Eye-tracking methodology was used to determine if the inclusion of these images, which are mathematically irrelevant, caused diminished visual attention to the lesson text and graphs, which are mathematically relevant.

Forty-one undergraduate students participated by reading four mathematics lessons on functions. The data indicated that there was little visual attention to either decorative or contextual images. Including decorative or contextual images did not influence visual attention towards math relevant information in the lesson (i.e., the graph and lesson text). Therefore, it can be inferred that the students tended to ignore the images in the lessons. There were no differences in written recalls of lessons or answers to questions across image conditions. Compared to the lesson text, little visual attention was directed towards the graphs, which were mathematically relevant visual representations. This is unfortunate because graphs can assist in mathematics learning (Shah, Mayer, & Hegarty, 1999). An important direction for future research may be to develop methods to direct learner attention towards graphs.

ACTIVITY THEORY: THE THEORETICAL FRAMEWORK THAT GUIDES THE ACTIVITY OF GENERALIZATION FROM KINDERGARTEN TO COLLEGE

Gabriela Dumitrascu
Eastern Michigan University
gdumitra@emich.edu

In this poster I present the results of a research project in which activity theory informed the analysis of the design of some curricula materials. Through examples, I will present to what extent the curriculum tasks and accompanying teacher material included in specific lessons in the teacher's edition for the third grade textbooks create the potential for teachers to mediate students engagement in describing, extending, and making generalizations. The same theoretical analysis may inform curricula designers and educators about their integral role in creating the learning environment, the goals, and the development of a generalization activity.

Keywords: Activity Theory; Generalization; Curriculum Analysis; Advanced Mathematical Thinking

The practice of generalization is a powerful process that should be present in mathematical learning from kindergarten to college. In order to be able to investigate how curricula from elementary, middle, high school and undergraduate courses create contexts in which students may perform different forms of generalization, we need a theoretical framework. Activity theory provides basic principles that allow us to understand generalization as an activity that is socially and historically developed through tools and artifacts mediations, internalization of social knowledge, and that is transformed through learning and development. I propose that the generalization process in mathematics to be considered an activity system. I will present the means of the generalization activity using Leontiev's activity theory interweaved with Rubinshtein's description of the generalization process. The theoretical definition of the activity of generalization will be used to critique examples of task from textbooks designed to target generalization activities. Moreover, this theoretical approach of the process of generalization definition may bring a new perspective on how to organize mathematics instruction in its transition from elementary school level to high school and college levels.

ARTICULATING HOW GEOMETRIC THINKING RELATED TO CIRCLES IS DEVELOPED IN HIGH SCHOOL MATHEMATICS CURRICULA

Alden J. Edson
Western Michigan University
alden.j.edson@wmich.edu

Jason Gauthier
Western Michigan University
jason.p.gauthier@wmich.edu

Secondary school mathematics topics examining circles are found in standards, assessments, and college entrance examinations. Typically, circle-related topics are found at the end of high school textbooks (Donoghue, 2003). The implementation of curriculum using these textbooks often leads to limited-to-no coverage of circle topics and missed opportunities for student learning. Senk (1989) suggests that geometry courses alone cannot transition students from low to high levels of geometric thinking in one high school course. The Common Core State Standards for Mathematics (CCSSI, 2010) articulates that circle topics are important for college and career readiness by advocating for the understanding and application of theorems about circles. In CCSSM, all students are also expected to find arc lengths and areas of sectors of circles. Based on these findings, it is clear that curricula across high school grade levels must develop student thinking in a clear and deliberate manner, the ultimate goal being to transition students to higher levels of geometric thinking, including attention to mathematics topics related to circles.

This poster focuses on understanding the nature of geometric thinking related to circles found in three different high school curriculum programs. The researchers identified two research goals:

1. What levels of geometric thinking are required for the treatment of circles found in secondary school mathematics?
2. How do high school curriculum materials develop students' geometric thinking concerning circles?

In our analysis, a framework using van Hiele levels of geometric thinking (Fuys, Geddes, & Tischler, 1988) provided a lens for describing the development of curriculum tasks focused on addressing the CCSSM domain of circles. Using this framework, the researchers classified related tasks found in the Core-Plus Mathematics Project, Kendall Hunt Discovering Series (formerly Key Curriculum Press), and University of Chicago School Mathematics Project.

For the indicated curriculum projects, the analysis focuses on the nature of curricular efforts to develop the levels of student thinking related to circles. The results inform classroom practice across different courses when supporting students as they transition from lower to higher levels of geometric thinking. In addition, the results of this study inform curriculum developers as they strive to create a focused and coherent school mathematics curriculum.

IN PURSUIT OF A COHERENT CURRICULUM – WILL COMMON CORE STATE STANDARDS DO IT?

Dae S. Hong
Hostos Community College
dhong@hostos.cuny.edu

Jae Ki Lee
Borough of Manhattan Community College
jaelee@bmcc.cuny.edu

Recently, Common Core State Standards (CCSS) have been adopted by more than forty states in the United States. One of the goals of CCSS is to have consistent and coherence standards because of criticism that U.S. curricula are "a mile wide and an inch deep" (Schmidt, Wang, & Mcknight, 2005) and that there is little consensus regarding when and how certain mathematical topics should be introduced and developed across the K–12 mathematics curriculum (National Council of Teachers of Mathematics Research Committee [NCTM], 2011). Curriculum coherence was found in countries that performed well on the Trends in International Mathematics and Science Study (TIMSS) while American curriculum does not have such coherence (Schmidt et al., 2005). Does CCSS show a similar pattern as top performing countries? How did CCSS and other state standards introduce mathematical topics prior to or without adoption of CCSS? This study attempts to answer these questions.

In previous studies, researchers analyzed TIMSS curriculum frameworks, textbooks, and standards from different states (Schmidt et al., 2005; Valverde & Schmidt, 2000). We will use a similar approach. First, we will use a method called "General Topic Trace Mapping" (GTTM) where experts from different countries are asked to identify all grade levels that certain topics are covered. The result shows a map reflecting the grade-level coverage of each topic for each country (Schmidt, et al., 2005). The results of this mapping will be compared in regards to similarities and dissimilarities to Schmidt et al.'s (2005) comparison of top performing countries. This will partially answer coherence of CCSS compared to other countries. Second, we will choose four states—two who have adopted CCSS (New York and California) and two who have not (Virginia and Texas)—and compare the state mathematics standards before New York and California adopted CCSS (their 2005 and 2007 standards, respectively) and the state standards from Texas and Virginia. By comparing these documents to CCSS and curricula of other countries, we will determine how coherent these standards are prior to or without adoption of CCSS. This would give us better ideas on whether adopting CCSS will bring us more coherent mathematics curriculum or not. Analysis will be conducted and data will be ready for PME-NA 2012.

EQUITY IN MATHEMATICS TEXTBOOKS: A REPORT ON PROGRESS

Matthew Madison
Central Michigan University
madis1mj@gmail.com

Katrina Piatek-Jimenez
Central Michigan University
k.p.j@cmich.edu

Analyzing textbooks can provide insight into the way society views certain groups and individuals. The images portrayed in textbooks have the ability to influence students' beliefs about self, ethnicity, social class, or sex, and hence produce what is known as "stereotype threat." Good, Woodzicka, and Wingfield (2010) define stereotype threat as "a phenomenon by which individuals, fearful of confirming a negative stereotype about their group, display decreased performance on a task relevant to the negative stereotype" (p. 135). Research examining the effects of stereotype threat suggests that images producing stereotype threat can have a negative impact on student achievement (Good et al., 2010). Zeldin and Pajares (2000) assert that "individuals' beliefs about their competencies in a given domain affect the choices they make, the effort they put forth, their inclinations to persist at certain tasks, and their resiliency in the face of failure" (p. 216). In order to avoid stereotype threat, it is critical that textbooks represent a variety of individuals doing mathematics. Several studies in the 1980's and 1990's (e.g., Heintz, 1987; Allen & Ingulsrud, 1998) documented the lack of equity in mathematics textbooks with respect to gender, though few studies have been conducted recently. Research with a focus on minority representation in mathematics textbooks is even more sparse.

This study examines equity in mathematics textbooks with a focus on race and ethnicity. We analyzed three middle school mathematics textbooks series commonly used in the United States. Middle school textbooks were chosen because children in the early adolescent years are highly susceptible to outside influence and are beginning to find their personal identities (Baker & Leary, 1995). The series selected were the most recent editions of Pearson's *Connected Mathematics 2*, Saxon Publishers' *Saxon Math*, and Holt McDougal's *Mathematics*. These books were chosen to provide a range of both traditional and reform-based textbooks. Every image in each of the textbook series was examined with respect to race and ethnicity. Our categories were Asian, black, Hispanic, Middle Eastern, Native American, and white. Persons for whom we could not determine ethnicity were classified as unknown. Our goal was to compare the representation of ethnic groups in the textbooks to that of the U.S. population. We also examined how these groups are being portrayed with a focus on activities and careers by analyzing trends found in the photos. Activities were classified using modified versions of classification schemes used by Heintz (1987) and Allen and Ingulsrud (1998). Analysis is ongoing and results will provide a detailed update on the progress made by mathematics textbooks with regards to equity.

Beginning in the early 1970s, a flood of research in textbook analyses produced data demonstrating gender bias in mathematics textbooks (e.g., Winifred, 1973). Most word problems and pictures depicted men in prominent roles, while women were placed in passive roles or stereotypical roles, such as sewing and cooking (Garcia, 1990; Winifred, 1973). As a result of these findings, research from the 1990s showed significant improvement in balancing gender representation throughout the pictures and word problems in mathematics textbooks; however overall equality had not been reached in terms of numbers or in the types of roles portrayed by men and women in the texts (Clarkson, 1993). Some scholars noticed that one response to earlier studies has been to remove people and therefore gender from the texts leading to a depersonalization of mathematics (Garcia, 1990; Parker, 1999). Little research has been done in this area since the early 1990s. This led us to the following research questions: Are there an equal number of males and females in recent mathematics textbooks? Are males and females still portrayed stereotypically? Are textbooks removing people altogether, depersonalizing mathematics, to avoid the situation?

We chose to analyze textbooks used in middle school mathematics classes specifically because between the ages of nine and thirteen, children are beginning to define themselves and are more receptive to social influences (Baker, 1995). We selected popular textbooks based on varying approaches to teaching mathematics. Thus, we chose three series ranging from more traditional to more reform: *Saxon Math, Holt McDougal Mathematics,* and *Connected Mathematics 2*. We examined every image in each of the 6th, 7th and 8th grade textbooks, comparing the number of images that had people, animals, and objects. The pictures that included people were further examined to determine the gender of each person, which careers and roles were being portrayed by each gender, and which famous people were depicted. We categorized roles using an adaptation of classifications by Heintz (1987) and Allen and Ingulsrud (1998). In this poster, we provide our results regarding the stated research questions.

INSTANCES OF MISCOMMUNICATION BETWEEN CURRICULUM AND TEACHER

Dustin Owen Smith
Western Michigan University
dustin.o.smith@wmich.edu

An important goal for developers of mathematics curricula is to clearly communicate with the teacher the key mathematical ideas and the ways that those key ideas can be the basis for effective lessons. In the language of Gehrke, Knapp, and Sirotnik (1992), developers create a “formal curricula” filled with their intentions about the key ideas and how to teach them; there also exists an "intended curricula" of the teacher who plans what to use and how. This poster will highlight instances of miscommunication of key ideas between curricula and teachers.

This poster uses data gathered as a part of a project investigating teacher curriculum use. Within this project, 6 teachers were observed using two different curricula. The example chosen for this proposal is from Juliet (pseudonym), a third grade teacher using the 2nd edition of *Investigations in Number, Data, and Space* to teach multiplication and division stories. After observations of Juliet’s classroom were conducted, an interview was given that centered on how she read the curriculum and that influences the decisions she made while planning. The example below details an activity whose purpose is to help students realize how you can determine whether a particular story requires multiplication or division. Students are expected to work through stories by acting them out, using drawings, or cubes. Student thinking should be focused on looking for numbers of groups and numbers in each group. The following is an excerpt from the teacher guide description of the activity, “Highlight for students that this problem identifies the number of groups and the number of items that are in each group. Because they need to find how many there are altogether, this is a multiplication problem” (Unit 5, Lesson 4.2). Juliet said how she interpreted this passage, and its impact on her planning and teaching.

> This is kind of the basis for everything that you observed. The keywords for recognizing what multiplication and division are, and how to pull those out of the story problem and use them to the advantage for the kids. So, yeah. This right here (pointing to the passage above) was the meat and bones of what this pack of lessons was about.

Juliet took from the curriculum passage above that the “meat and bones” of the activity was the identification of keywords. These keywords are the basis for deciding between multiplication or division. The curricula, however, focuses on identifying groups and items within groups. There is only this one sentence that hints towards a keyword approach. The observers and Juliet both found these lessons difficult for students. The researchers attribute this to the keyword approach, which represented a miscommunication between the text and teacher.

The disparity that exists between the formal curricula and the intended/enacted curricula illustrates the need for teacher learning. Certainly, careful and precise writing on behalf of the developers is necessary, but the examples provided in this poster session facilitate discussion on teacher knowledge and capacity needed to design and enact lessons. This can also inform teacher education and professional development programs.

The need to reform undergraduate Science, Technology, Engineering, and Mathematics (STEM) programs has been prominent in recent years (Ferrini-Mundy & Gu̇çler, 2009). The Programme for International Student Achievement (PISA, 2003) defines mathematical literacy as "an individual's capacity to identify and understand the role that mathematics play in the world, to make well-founded judgments and to use and engage with mathematics in ways that meet the needs of that individual's life as a constructive, concerned and reflective citizen" (p. 24). Mathematics is seen as a language with which STEM students must gain fluency. Two subtleties are overlooked when using this metaphor: (1) Translation implies that one moves between two different languages when, throughout history, mathematical formalism has been used to articulate natural phenomena in both science and in every day life. (2) Literacy in mathematics entails both the dexterity and the resourcefulness to recognize and employ mathematical principles and structures. As history has shown, reforms in STEM education do not succeed through instructional modifications alone. Instructional models must be grounded in a deep reconceptualization of the skills and knowledge bases necessary for productive functioning within various disciplines, and this perspective change must precede the development of curricula (Niss & Hojgaard, 2011). Our research was directed towards development of such conceptualization by examining the relationship between mathematical competencies and mathematical literacy. In doing so, we collected and analyzed data sources from two investigations (1) the STEM professors' perceptions about the essential mathematical concepts necessary for first year engineering students, and (2) review of reports on an interdisciplinary task force whose aim is to define indicators of mathematical literacy for engineering students to be used in the creation of a first year mathematics course for engineering students.

Data sources consisted of audio-recorded interviews designed specifically to document participants' responses to key issues identified by the literature including: mathematics as it applies to their discipline and what they consider as mathematical competence pertaining to their own specific needs. We utilized the competencies put forth by the Danish KOM project to tag and describe mathematical content mentioned in interviews (Niss & Højgaard, 2011). Common and distinguishing patterns of skills and goals identified by different participants were identified using discourse analysis.

ALGEBRA I PREPAREDNESS AND THE MEASURE UP PROGRAM: IMPLICATIONS FROM A THEORETICAL MODEL

Linda Venenciano
University of Hawai‘i
lhirashi@hawaii.edu

Hannah Slovin
University of Hawai‘i
hslovin@hawaii.edu

Keywords: Algebra and Algebraic Thinking; Assessment and Evaluation; Curriculum Analysis

Here we present a model based on theoretical implications from studies of El’konin-Davydov mathematics implementation (i.e., Davydov, 2008; Slovin & Venenciano, 2008; Dougherty & Slovin, 2004; Morris & Sloutsky, 1995) and developed through structural equation modeling. The Measure Up (MU) project developed elementary curricula grounded in concepts of measurement and quantitative reasoning. MU experience, prior mathematics achievement, age, and logical reasoning capability were used as predictors of algebra preparedness. Logical reasoning was simultaneously used as a mediating variable.

The sample consisted of 129 fifth or sixth graders, 40 MU and 89 non-MU students, from a research laboratory school. Test items measuring logical reasoning were identified using exploratory and confirmatory factor analyses. Fit indices χ^2 (5) = 7.20, p = 0.21, CFI = .97, RMSEA = 0.06, WRMR = 0.57, and a composite reliability (Raykov, 2007) of .76 confirmed the conceptual relatedness of the items. Similarly, items measuring algebra preparedness were identified using factor analyses and resulted in a model, χ^2 (5) = 5.25, p = .39, CFI = 1.0, RMSEA = 0.01, WRMR = .45, with composite reliability of .89.

The development of the final SEM model [χ^2(30) = 39.4, p = .12, CFI = .94, TLI = .93, RMSEA = .05, WRMR = .96] implied that algebra preparedness was strongly mediated by logical reasoning capabilities, to the extent that effects from prior achievement could only be observed through logical reasoning. MU experience was the only variable that made a significant, direct contribution to algebra preparedness. Age and prior mathematics achievement were found to be positive, significant, indirect contributors to algebra preparedness. The path coefficient from the MU experience to algebra preparedness was positive, supporting earlier findings that MU experience leads to greater algebra preparedness. The path from prior achievement to algebra preparedness was negative and not significant, suggesting that only a particular aspect of prior achievement contributed to a preparedness for work with variables.

COGNITIVE DEMAND OF MAIN NAEP MATHEMATICS ITEMS

Crystal Walcott	Rick A. Hudson	Doris Mohr
IUPU Columbus	University of Southern Indiana	University of Southern Indiana
walcottc@iupuc.edu	rhudson@usi.edu	djmohr@usi.edu

Keywords: NAEP; Cognition; Assessment and Evaluation

To understand the connections between student achievement and teacher demographic information as measured by the National Assessment of Educational Progress (NAEP), we analyzed the cognitive demand of fourth- and eighth-grade NAEP mathematics assessment items. Using the item classification frameworks developed by Stein and Smith (1998) and Webb (1997), we analyzed and aligned released NAEP items based on the cognitive processes necessary to engage in the task. This work served as precursor to a larger study in which we are building clusters of items that will form achievement score sub-scales.

To investigate these connections, we initially sought to determine which items placed higher demands on students. NAEP items are classified by complexity level as defined by the NAEP assessment framework. The NAEP complexity level classification was designed as an indication of the level of demand that a particular item places on a student. We considered using the existing NAEP complexity level as a basis to build clusters of items, but were concerned about the wide range of types of student thinking necessary to engage in tasks classified at the same complexity level. Consider the following two task descriptions as an example of a situation that highlights this discrepancy in the complexity level classification. Both of these items were administered as part of the 2009 fourth-grade Main NAEP mathematics assessment. In the first item students were asked what number should be placed into the blank to make the following number sentence true: $\_\_ - 8 = 21$. In the second item, students were asked to use several provided shapes (four parallelograms and two triangles) to cover a composite figure. Both items were classified by NAEP as low complexity items. When considering using the NAEP classification for our research purpose, we became troubled because of the difference in the types of thinking in which students would need to engage in order to attempt these tasks. For some students the solution of the first task may be immediately obvious (recall or mental manipulation); for others, perhaps employing a simple procedure would determine the solution. In our opinion, the problem-solving path is clearly defined with no pre-planning necessary. However, the second item requires students to make a plan for solving the problem, even if the plan employed is trial and error. The answer is not immediately obvious, and the problem-solving pathway is defined by the child, not by the item prompt. This example supports the statement in the most recent mathematics framework that “Mathematical complexity deals with *what* the students are asked to do in a task. It does not take into account *how* they might undertake it” (NAGB, 2010).

Although students' difficulties in developing and understanding proofs in mathematics is well documented, less is known about how students' example use may support their proof practices, particularly at the middle school level. Research on example use suggests that strategic thinking with examples could play an important role in exploring conjectures and developing appropriate justifications. This paper introduces a framework of middle-school students' example exploration, distinguishing between the types of examples students use and the uses examples play in making sense of and proving conjectures. Drawing from clinical interviews with 20 students, we present thirteen categories of example types and seven categories of uses, followed by a discussion of each set of categories and their connections to one another.

Keywords: Middle School Education; Problem Solving; Reasoning and Proof

Objectives: The Importance of Supporting Proof in School Mathematics

Proof in school mathematics has received increased attention over the past decade, with researchers arguing that it must be a central part of the education of all students at all grade levels (Ball, Hoyles, Jahnke, & Movshovitz-Hadar, 2002). Both the *Common Core State Standards for Mathematics* (Common Core State Standards Initiative, 2010) and the *Principles and Standards for School Mathematics* (Naitonal Council of Teachers of Mathematics, 2000) argue that a central hallmark of mathematical understanding is the ability to prove, and that the mathematics education of students from pre-kindergarten through grade 12 should enable all students to develop and evaluate mathematical conjectures, arguments, and proofs. Middle school in particular is a critical time for students to develop the ability to reason deductively, resulting in recommendations for curricular and pedagogical changes emphasizing proof in beginning algebra classes (Epp, 1998; Marrades & Gutierrez, 2000).

These recommendations pose serious challenges, however, given that many students struggle to recognize, understand, and produce deductive arguments (e.g., Chazan, 1993; Harel & Sowder, 1998). Researchers have posited that a critical source underlying students' struggles to understand proof is their treatment of examples. On the one hand, students tend to engage in example-based proofs, pointing to a few successful examples as justification that a mathematical statement is true (e.g., Healy & Hoyles, 2000; Porteous, 1990). On the other hand, deliberate exploration of examples is not explicitly supported as a strategy to foster deductive reasoning; students have few opportunities to strategically analyze examples in order to make sense of a mathematical statement or to gain insight into the development of its proof.

We suggest that providing students with opportunities to carefully analyze examples may contribute to their abilities to develop and make sense of conjectures and their proofs. Studies of mathematicians suggest that the process of experimenting with examples is a critical aspect of proof development (Epstein & Levy, 1995). Although scholars have noted a number of potential roles of example use, little research has focused on characterizing these roles with regard to facilitating students' learning to prove. In fact, very little is known about how middle school students think with examples, whether their example use can facilitate deeper mathematical understanding, or whether and how examples can support students' attempts to develop proofs.

This paper presents the results of a study aimed at identifying the roles of middle school students' example use. We introduce a framework that distinguishes between the *types* of examples students use and the *uses* examples play in making sense of and proving conjectures. Our findings indicate that students made use of a variety of example types and used examples in different ways in order to check a conjecture's correctness, convince themselves and others that it held true, better understand a conjecture, and develop justifications to support their statements.

Theoretical Background

One common model of students' mathematical reasoning is that their understanding of mathematical justification is "likely to proceed from inductive toward deductive and toward greater generality" (Simon & Blume, 1996, p. 9). [For this discussion, inductive refers to generalizing from examples, and is not to be confused with mathematical induction, a valid method of proof.] This expected progression is reflected in various mathematical reasoning hierarchies (Balacheff, 1988; van Dormolen, 1977; Waring, 2000) as well as in many curricular programs (e.g., Lappan et al., 2002). However, not only do students find this transition difficult to navigate, studies also suggest that their development may not be as straightforward as the induction-to-deduction model; in fact, students may follow a "zig-zag path" (Polya, 1954) between example exploration, conjecture, proof, and back again (e.g., Ellis, 2007).

One approach to helping students navigate the transition to deductive reasoning involves emphasizing the limitations of examples as proof, thus helping students recognize the need for deductive arguments. It has, however, proven difficult to help teachers leverage this technique in order to successfully foster their students' proof abilities (Bieda, 2011). In addition, this approach positions example-based reasoning strategies as stumbling blocks to overcome. We suggest an alternative stance by positioning strategic thinking with examples as an important object of study in its own right. From this perspective, reasoning with examples is viewed as a potential foundation for the development and understanding of conjectures and proofs.

The Roles of Examples

Examples play a critical role in mathematical practice, and the time spent analyzing particular examples can provide not only a deeper understanding of a conjecture, but also insight into the development of its proof (Epstein & Levy, 1995). The role examples play in the work of middle and high school students, however, is less well understood. Although research has demonstrated students' overwhelming reliance on examples as a means of verification and justification, less is known about how students think strategically with examples.

Research on students' thinking does suggest that examples can have different potential roles and uses. For instance, Buchbinder and Zaslavsky (2009, 2011) introduced four different types of examples (confirming, non-confirming, contradicting, and irrelevant) and examined their status in determining the validity of mathematical statements. Other studies have identified different example types as well, including start-up examples, boundary examples, crucial experiments, reference examples, model examples, counterexamples, and generic examples (Alcock & Inglis, 2008; Balacheff, 1988; Michener, 1978; Watson & Mason, 2001). Studies examining the role of examples in understanding conjectures have found that analyzing structural similarities across examples can support proof development (Pedemonte & Buchbinder, 2011).

This body of research suggests that example use plays an important role in understanding conjectures and potentially supporting the development of valid proofs. However, there remains much to be learned about what types of examples students exploit, particularly at the middle school levels, and how they use them when developing and exploring conjectures. In this study we accordingly characterize the roles and strategic uses of examples in terms of a more comprehensive framework for developing, exploring, and proving conjectures.

Methods

Participants and Instrument

Participants were 20 middle-school students (12 sixth-graders, 6 seventh-graders, and 2 eighth-graders), each who participated in a semi-structured 1-hour interview. Eleven students were female and 9 students were male. Seventeen students were in general 6th, 7th, or 8th-grade mathematics courses using the Connected Mathematics curriculum, while 2 students were in algebra and 1 student was in geometry.

The interview instrument presented students with seven conjectures (see Table 1 for sample conjectures). The interviewer asked the participants to examine the conjectures, develop examples to test them, and then, when they could, provide a justification. The conjectures addressed ideas in number theory and geometry that were accessible to a middle-school population, and every conjecture except Conjecture 6 was true. Fifteen out of the 20 participants viewed only the first four conjectures; the remaining 5 participants had extra time to view all seven conjectures, resulting in 95 total responses to code. After the students worked with examples for each of the conjectures, they were asked why they chose the examples they did.

Table 1: Sample Interview Conjectures

Conjecture 1	Eric thinks this property is true for every whole number. First, pick any whole number. Second, add this number to the number before it and the number after it. Your answer will always equal 3 times the number you started with.
Conjecture 4	Bob thinks this property is true for every parallelogram. The angles inside any parallelogram add up to 360 degrees.
Conjecture 6	Kathryn thinks this property is true for every whole number. First, pick any whole number. Second, multiply this number by 2. Your answer will always be divisible by 4.

Data Analysis

Coding began by identifying each of the examples students produced for each conjecture. We then developed emergent codes to identify example types and uses. *Types* refer to the different characteristics of examples students used, and *uses* refer to the roles that the examples played in students' investigations. The research group discussed the codes and clarified uncertainties as emergent codes solidified. Codes to determine example types depended on the participant's discussion of the example, rather than on a determination based only on the example itself. For instance, the same number, 1, could be considered "common" from one student's point of view or a "boundary case" from another student's point of view. Furthermore, the same example could be coded in multiple ways based on the participant's explanation. Three different researchers on the project team coded portions of the conjecture responses so that each conjecture response was ultimately coded independently by at least two different team members.

Results and Discussion

We found 13 categories of example types (Table 2) and seven categories of example uses (Table 3). Each table introduces the category name with the number of instances in which the example type or use occurred in the data set, its definition, and a representative example to illustrate each example type and use. We discuss the example types first, and then present example uses.

Table 2: Types of Examples

Example Type	Definition	Data Example
Dissimilar Set (41)	An inclusion of examples that are all different from one another.	"I tried to pick both prime numbers…composite numbers and then odd numbers and even numbers. So just have a variety of different kinds of numbers."
Generic (28)	An example with unimportant specific characteristics. These examples demonstrate a general idea about the conjecture.	[Uses 50 to explain why Conjecture 1 works]: "So this one [51] is 1 more, and this one [49] is 1 less. So if you take this one [the 1 from 51] over to that one [49] it turns into 50. And then that one goes into 50, and 50."
Common (24)	An example described as typical or one that many would think of.	[After choosing 10 and 15 as example cases]: "I picked a more uncommon number [15] and a more common number [10], and they both worked out."
First Thought Of (22)	Example is the first that came to mind; no evidence of thoughtful decision about example selection.	"I just…kinda what popped into my head."
Unusual (21)	An example that does not occur often and may have odd or strange characteristics.	[To explain using 1,028 as an example]: "Well, the 1028's kind of like a little stand-out number because it's – it's large."
Random (12)	Example is arbitrarily chosen, with the "randomness" intentional to highlight the likelihood of the conjecture being true.	This code refers to what students consider random, rather than true mathematical randomness: "For a problem like this you want to pick random numbers. Not selected numbers."
Conjecture Breaking (11)	Example chosen to disprove the conjecture; counterexample.	"I wanted to do numbers that were hard for it…it was less likely for them to be divisible by 3, I think."
Easy (11)	Examples that are easy to operate on or compute with.	[*Prompt: So why did you try it out with 15?*] "Because it's an easy number to use."
Known Case (9)	Student picks an example in which properties or features pertaining to the conjecture are already known.	"A rectangle is a parallelogram, so that is four 90 degree angles, which is 360."
Boundary Case (5)	An extreme example or a special case example, such as the identity.	[Explaining the use of 0]: "You kind of have to try it with every not possibility like, not like 3, you know, to, you know, 100, but kind of like get down to the origin of the number. Like 1 and then, you know, 0."
Similar Set (3)	Deliberate inclusion of examples similar to one another.	[*Prompt: Are these two (triangles) different or similar from each other?*] "Similar, because they have same numbers in two of the sides and different numbers in this side."
Progression (2)	First one type of example is chosen, then student deliberately switches to a different type, and may continue switching to new types.	"You would first test a typical number to just see, like, okay in general was this going to be true. And then if that – if he was true on that, then you say, okay, then I would test a more unusual number to just, like, to test his property."
Favorite (2)	Example represents a favorite number or shape.	"The only reason I picked 6 is because that's my lucky number."

Unsurprisingly, we found evidence that students chose example types that were not always deliberate or thoughtful: For instance, the categories *first thought of*, *favorite number*, and *easy* represented example types that were not necessarily connected to the content of the conjecture at hand. These example types also did not typically support the development of deductive arguments. However, these categories only represented 18% of all of the example types. When examining the participants' discussion of their examples, we also found many cases of deliberate and thoughtful example choices, which we discuss below.

By far the most prevalent type of examples was the *dissimilar set* type; many participants indicated a belief that choosing a variety of examples was a more reliable method of testing a conjecture. For instance, one student explained the importance of choosing a dissimilar set:

> You should find numbers that maybe aren't as alike to test just so you have all kinds of differences covered. Like when you're maybe testing students for a survey, you want to have as many different students and maybe different race, different families, and everything. Just a bigger background so maybe you'll get more accurate information.

The two students who used a *progression* of example types demonstrated similar reasoning by first picking common numbers, then deliberately shifting to less common numbers.

The inclusion of a dissimilar set often resulted in a discussion about the importance of picking both *common* and *unusual* examples. Some students indicated that unusual examples are more convincing than other types of examples. For instance, one student, Eva, tested a conjecture that every even number added to half of itself would be divisible by 3. She explained that she deliberately tested numbers that could only be divided by 2, such as 10. Eva tested those unusual numbers because "it was less likely for them to be divisible by 3, I think." It is worth noting that in this case, a number such as 10 was unusual in Eva's eyes in relationship to the conjecture, even though 10 might not be an unusual number for her in general. Unusual examples and boundary case examples both played an important role: they could lead to *conjecture breaking* example types, and they were particularly convincing because if a conjecture held for an unusual or extreme example, it may be more likely to be true overall.

There were some example types that were more strongly connected to proof development, such as *known cases* and *generic* examples. Although deductive arguments were not solely developed through these example types, known case examples and generic examples helped students reason through the structure of the conjectures. For instance, Rodrigo examined Conjecture 4 (Table 1), and in order to better understand the conjecture, he began with a known case example, the rectangle. Rodrigo knew that the conjecture held true for a rectangle: "A rectangle is a parallelogram, so that is four 90-degree angles, which is 360." He then took the rectangle and adjusted it to think about how a new example would work with the conjecture (Figure 2):

Figure 2: Rodrigo's adjustment of the "known case" rectangle into a new parallelogram

After examining the new example, he said, "Oh yes it would work for every one – this doesn't really matter any more." Developing a generic example, Rodrigo explained further: "That's just a random drawing (Figure 3). It is a rectangle in disguise because you cut this off and you put this, over here, ta da! And it becomes a rectangle. And rectangles, well, see, equals 360."

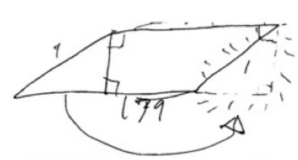

Figure 3: Rodrigo's generic example

By "random," Rodrigo indicated that the particular nature of his example was not important because it illustrated a more general point; hence, this example type was coded as *generic* rather than *random*. Across the participant group, it is notable that 15% of the example types were generic in nature; it was the most prevalent code, second only to *dissimilar set*. In general, the types of examples students chose in order to foster their understanding of the conjectures suggest that middle school students can and do engage in deliberate and strategic example choices.

Example Uses

Students also demonstrated a variety of example uses. Each of the seven categories in Table 3 includes a frequency, a definition, and a representative data example.

Table 3: Example Uses

Example Use	Definition	Data Example
Check (69)	Student selects examples to test whether the conjecture holds.	"Just, you know, test, just to see if it actually does work or not."
Support a General Argument (28)	Student uses a generic example to describe a more general phenomenon in support of a deductive proof.	"When you're taking half of it, then that number is, because it ends up being thirds. So it's always going to be true because if you do…514. That's always going to be 1208, which means that it's broken up into thirds, so no matter what it's going to be divisible by 3."
Convince (25)	After checking the conjecture, student tries additional examples in order to convince oneself or others that the conjecture must be true.	"You can't be sure if you only test one number because one number, because in almost every case there is exceptions to the stuff if it's not true."
Understand (21)	Student uses an example to make sense of the conjecture; may lead to insights that support deductive proof.	"Let's try 5…okay. Those are the two that I needed. Now I kind of know the logic behind it."
Asked (19)	Student was asked to choose and example; the only evidence that a student produces an example is because s/he was explicitly asked to do so.	S: "I'm totally convinced it's true." I: "You don't even need to – do you need to test out any examples?" (Student shakes head.) I: "Okay. Let's say that you didn't know it was true. Are there any kinds of rectangles you would want to test it out on?"
Support Empirical Proof (9)	Student offers examples as a justification of the truth of a conjecture.	I: "Say that you wanted to show that this was always true." S: "I would use these examples, and probably a few more."
Disprove (6)	Student tests an example in an attempt to disprove the conjecture.	S: "Any whole number? Oh, I thought you just meant even numbers. I wouldn't think that's true then." (Tries 9 to disprove). "Nine times 2 equals 18. 18 divided by 4 equals question mark."

The most prevalent use of examples was in *checking the correctness* of a conjecture; 39% of the example use instances occurred when students used examples to test conjectures. Part of this prevalence may be due to the fact that students were encouraged to test examples during the interview. Checking correctness occurred with many different example types, ranging from the first number thought of to unusual examples to dissimilar sets. Among the other example uses, there were some connections between how students used examples and the types of examples they employed. The strongest connection was between generic examples and the *support a general argument* use. This link is unsurprising because the purpose of a generic example is to illustrate a broader point. Similarly, using examples to *disprove* a conjecture typically relied on conjecture breaking example types, but also occasionally made use of boundary cases or unusual examples.

Another set of links emerged when students used examples to convince and understand. The example types that students viewed as more convincing, such as dissimilar sets, unusual examples, and boundary cases, were often the ones they employed when continuing to further check examples after an initial test. For instance, Alyssa tested Conjecture 1 with the number 4, and found that it worked. She then explained that she was not convinced: "I think I need to try it a few more times to make sure." She indicated that she should try different numbers, such as both even and odd numbers, in order to really be sure the conjecture would work. While testing a dissimilar set of examples in order to further convince herself that the conjecture held true, Alyssa began to use the examples to understand the structure of the conjecture. Through this process, she was then able to produce a general argument, using the initial example, 4, as a generic example: “When you add the number before and the number after, those two numbers will equal twice the first number I guess. Because, like, for 4 + 3 + 5, if you drop one off the 5…then 3 would kind of be 4. So it’d be 4 + 4 + 4. Which would be, like, 12, or 4 times 3.” Alyssa’s general argument was not unusual amongst the 20 participants; we coded students’ justifications as part of a larger study and found that after exploring examples, students who attempted justifications were able to produce deductive arguments or valid counterexamples a little over half the time.

It is worth noting that in 19 responses, students did not see a need to produce an example at all; this typically occurred because the student already believed the conjecture to be true, and therefore not in need of testing. For example, Andre was asked to consider the conjecture that for any triangle, the sum of the length of any two sides are greater than the length of the third side. Andre did not see a need to test this property because “That’s a property already proven by the, you know, the community.” This finding is in contrast to previous results suggesting that students want to test conjectures even when presented with their proofs (e.g., Chazan, 1993).

Conclusion

This study presented a framework of the example types and example uses middle school students employed when making sense of, exploring, and attempting to prove conjectures. Our findings support earlier studies suggesting that students’ uses of examples can play an important role in exploring and understanding conjectures, as well as in potentially supporting the development of valid proofs (Alcock & Inglis, 2008; Buchbinder & Zaslavsky, 2011; Pedemonte & Buchbinder, 2011). Moreover, our study suggests that distinguishing between example types and example uses may be an important component in better understanding students’ thinking with examples; this distinction can also provide a potential structure for more in-depth analysis of how example type may be linked to example use in future studies.

One compelling finding was that many of the students who explored conjectures with multiple examples were able to produce deductive arguments, valid counterexamples, or general arguments that relied on generic examples. These results run counter to the many studies demonstrating K–16 students’ difficulties in producing valid mathematical proofs (e.g., Chazan, 1993; Healy & Hoyles, 2000). The fact that the students were able to produce valid arguments after in-depth example exploration provides initial evidence that strategic and thoughtful use of examples can indeed support the development of mathematically appropriate proofs, even at the middle school level. This suggests the importance of continuing to study the roles examples can play in supporting middle-school students’ learning to prove.

TWO FORMS OF REASONING ABOUT AMOUNTS OF CHANGE IN COVARYING QUANTITIES

Heather L. Johnson
University of Colorado Denver
heather.johnson@ucdenver.edu

This paper addresses how secondary students might reason about amounts of change in covarying quantities. Two empirically based forms of covariational reasoning are distinguished. The first form—reasoning about quantities as varying simultaneously and independently—supports tandem comparison of amounts of change. The second form—coordination of change in one quantity with change in a related quantity—supports coordinated comparison of amounts of change. By expanding the mental actions of Carlson et al.'s (2002) covariation framework, these forms of reasoning provide finer grained distinctions in the "Quantitative Coordination" level of covariational reasoning. Distinctions made between these forms of reasoning might help to explain how students could begin from informal reasoning to transition to more formal reasoning about average and instantaneous rate of change.

Keywords: Algebra and Algebraic Thinking; Reasoning and Proof; High School Education

A student reasoning covariationally would be mentally "coordinating two varying quantities while attending to the ways in which they change in relation to each other" (Carlson, Jacobs, Coe, Larsen, & Hsu, 2002, p. 354). By conducting fine-grained investigations with secondary students, researchers have articulated the nature of relationships that students might make between covarying quantities (Johnson, 2012; Saldahna & Thompson, 1998). These articulations provide landmarks within a continuum of reasoning about covarying quantities.

This paper draws on two empirically based forms of secondary students' reasoning about amounts of change in covarying quantities to expand the mental actions of Carlson et al.'s (2002) covariation framework. These forms of reasoning make finer grained distinctions in the "Quantitative Coordination" level of covariational reasoning. Distinctions made between these forms of reasoning might provide insight into how students could begin from informal reasoning to transition to more formal reasoning about average and instantaneous rate of change.

A Brief Overview of the Covariation Framework (Carlson et al., 2002)

Consideration of undergraduate and beginning graduate students' responses to tasks involving recognizing and characterizing how changes in one variable affected change in another variable (Carlson, 1998) led to the development of a covariation framework. The covariation framework (Carlson et al., 2002) provides a continuum of mental actions supporting five levels of covariational reasoning, with each level increasing in sophistication: Coordination, Direction, Quantitative Coordination, Average Rate and Instantaneous Rate. Researchers infer underlying mental actions from certain behaviors associated with each level of covariational reasoning. Classifying a student as reasoning covariationally at a particular level means that the student is able to perform mental actions supporting not only that level, but also all preceding levels of covariational reasoning (Carlson et al., 2002).

For the purposes of this paper, I focus on the Quantitative Coordination (QC) and Average Rate (AR) levels. The QC level supports the mental action of coordinating an amount of change in one quantity with the change in another quantity (Carlson et al., 2002). For example, a student who related amounts of change in volume to changes in height would provide evidence of reasoning at the QR level. The AR level supports the mental action of coordinating an average rate of change in one quantity with uniform change in another quantity (Carlson et al., 2002). For example, a student who related the rate of change in volume with respect to height to uniform changes in height would provide evidence of reasoning at the AR level. In a study of college calculus students, Carlson et al. (2002) found that even after students took a course focusing on rate and varying rate, students consistently applied covariational reasoning at the QC level, but not at the AR level. Further explication of the QC level of covariational reasoning might help to account for variation in the students' reasoning and suggest whether or not students' reasoning might advance to levels of Average (AR) and Instantaneous Rate (IR).

A key distinction between the QC and AR levels is the consideration of an amount of change (QC) versus the consideration of a rate of change (AR). In this paper, I provide two distinct forms of QC level reasoning that seem to support the addition of finer-grained mental actions to the covariation framework. These additional mental actions further explicate what it could mean to coordinate an amount of change in one quantity with change in another quantity.

Two Forms of Reasoning about Amounts of Change in Covarying Quantities

In this section I articulate both forms of reasoning, providing empirical support for each. I draw on three secondary students' (Austin, Jacob, and Hannah—names are pseudonyms) work on a task relating the typical high temperature of a city to the day of the year (see Fig. 1). Austin and Jacob were 11th graders enrolled in a Precalculus course and Hannah was a 10th grader enrolled in a Geometry course. The task required students to investigate how the typical high temperature varied as the day of the year varied. Each student worked on the task during an individual clinical interview (Clement, 2000), for which I served as the interviewer.

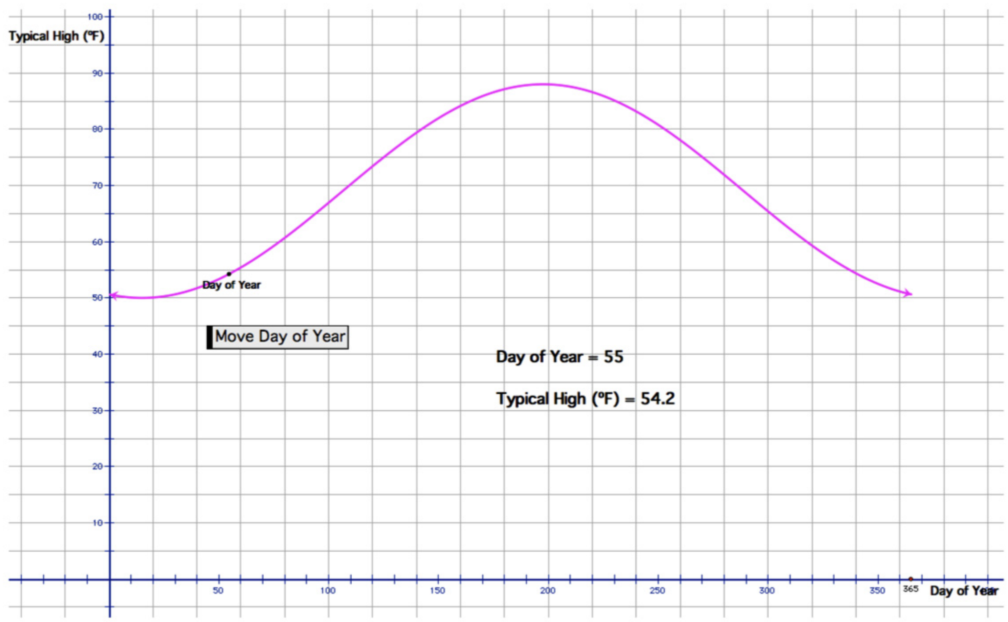

Figure 1: Dynamic Cartesian graph

The task incorporated a dynamic Cartesian graph (see Fig. 1) created using Geometer's Sketchpad Software (Jackiw, 2001). A student interacting with the graph could click and drag on the active point or press one of the animation buttons. As the day of the year changed, the corresponding typical high temperatures changed accordingly. As part of this task, I asked each student to use the graph to make a prediction about how the typical high temperature would continue to increase or decrease as the day of the year changed. Because the interviews were semi-structured, the actual prompt varied from student to student based on his or her individual work.

I employ an actor-oriented perspective (Lobato, 2003) when investigating students' reasoning about covarying quantities. By quantity, I mean an individual's conception of a "quality of an object in such a way that this conception entails the quality's measurability" (Thompson, 1994, p. 184). For example, a student could conceive of area as a quantity measuring an amount of flat surface being covered. By covarying quantities, I mean quantities that are changing together. For example, as a square is being enlarged, its side length and area are varying together. Drawing on students' explanation, written work, and gestures, I make claims about the mental actions involved in students' reasoning.

Changing Simultaneously and Independently

In the excerpt that follows, Austin used amounts of change in temperature and days to make claims about how the decreasing temperature is changing as the day of the year varied. When Austin used the word slope, he was referring to an association of an amount of days with an amount of degrees.

Interviewer: And when it decreases, if you had to describe for me, as it's going along, how is it decreasing as it's going along?

Austin: It just starts, like it's kind of rounded, or it's going more days for the temperature. It's kind of staying hot for a while and then once it starts to get close to say two hundred forty, two hundred thirty days, then it starts to decrease pretty much at that same constant rate as the other side as it increased.

…

Interviewer: And so, when you talk to me about decreasing, can you tell me what's decreasing?

Austin: The temperature is decreasing with the amount of days you go on from that top two hundred days.

Interviewer: So in the top here, how is that temperature decreasing?

Austin: From day two hundred to my line there *[longest horizontal segment shown in Fig. 2]*, it's close to about two hundred fifty, so in fifty days it's decreasing about seven degrees, which isn't that much. I'll write that down. It's fifty degrees in seven days there. *[Writes* $\frac{\text{50 degrees}}{\text{7 days}}$*]*

…

Interviewer: So suppose I were to ask you to consider the interval between day two hundred and day two twenty. How do you think that change would compare to this fifty days and seven degrees?

Austin: I'd say it'd be, it would change a little less because there's more or, there's less of a slope in those twenty days compared to that section there.

Interviewer: Can you show me? You can use the card *[Austin had been using a note card as a straightedge]*, or just show me what you mean by less.

Austin: You could just say like if I drew a line here, *[Draws in the upper left set of horizontal and vertical segments shown in Fig. 2]* it's changing a little, a lot less than compared to that. *[Draws in the lower left set of horizontal and vertical segments shown in Fig. 2.]*

Interviewer: And how does that affect the, how does that relate to the changing temperature?

Austin: It's just going to have a steeper slope, which means the more days, or the least, the lesser amount of days, compared; it takes for the temperature to drop a certain amount.

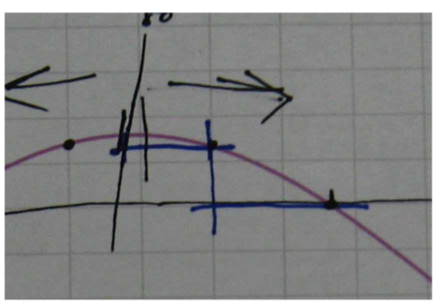

Figure 2: Line segments Austin drew to represent the changing amounts of temperature and days

To determine how the temperature might continue to decrease, Austin specified an interval of days and then compared the amount of change in temperature to the amount of change in days. He determined particular numeric amounts of change because he could compare the lengths of horizontal and vertical segments. With either specifying or not specifying numerical amounts, he used an interval, determined amounts of change in each quantity, and compared those amounts of change in the interval. Although not included in this excerpt, he did use division to compare the amounts of change in temperature and days. However, even when he used division, he interpreted the result as an amount of days per one degree of change in temperature, thereby preserving both individual quantities. Using Carlson et al.'s (2002) covariation framework, Austin was reasoning at the QC level, because he related amounts of change in covarying quantities.

Austin's reasoning shared similarities with Jacob's reasoning. In the excerpt that follows, Jacob determined an average rate of change in temperature per day for a five-day interval. He chose other five-day intervals that he predicted might have the same average rate of change, and then calculated the average rate of change on those intervals to make comparisons.

Interviewer: So if you were to determine an average change per day between days one ninety and one ninety-five, how would you figure that out, between one ninety and one ninety-five?

Jacob: Okay, well I'd take um, minus one ninety and I'll just do one ninety-five. Day one ninety-five has the high of eighty-seven point eight-nine, nine eight, (87.98) and one-ninety is a change of eighty-seven. Er, it doesn't have a change it has a temperature of eighty-seven point eight four (87.84). So to find change, ninety-eight minus eighty-four is point one four (0.14) that is for five days worth. So I would take point one four (0.14) divided by five to find the change in days, like per day so it changes point zero eight, two eight per day (0.028).

…

Interviewer: Are there any other time periods on the graph when you might expect an increase of point zero two eight (.028) degrees per day?

Jacob: Uh huh. Whenever, I'll go back to the beginning. Um, I'd say maybe somewhere around here. We'll say, we'll make it nice and make it forty. We'll try this.

Interviewer: Can you tell me why you picked this day?

Jacob: I just thought it looked like it wasn't moving up much.

Interviewer: And can you tell me how you determine if something looks like it's not moving up much?

Jacob: Um, yeah, it moves over a lot more than it moves up, so it means that it is not getting that much hotter as the days go on. But since it's curved inwards instead of outwards, I don't know if that is going to affect it, but I'm just going guess and write it down. Day, I would write day for the rest and the high was fifty-one point seven four (51.74). Day thirty-five, fifty-one point one (51.1), point six four (.64) difference for five days that is a lot bigger than this, point six four (.64) divided by five is somewhere around, yeah, point one two eight (.128) so that is a lot bigger I was wrong then, I'll go five more days, I hope so, I will be right this time.

Interviewer: Why are you moving left?

Jacob: Because if I went right it's getting greater, the intervals between each five days is getting bigger, because earlier I forget where I said it, yeah, here, it is moving up by about six point two degrees (6.2) every twenty days. … Six point two (6.2) divided by twenty, about point three one (.31), and up here it is just point zero one five (.015), so I don't, I don't see what's the point of even trying to go up because I know it is just going to get greater. So I will try, what day is this, thirty, fifty point, fifty point six one (50.61)… Fifty-one point one four (51.14) minus fifty point six one (50.61), point five three (.53). I don't know what that was—and so that's for five days so divide that by five so per day it changes point one zero six (0.106), that's still not even close. Let's go all the way back to the beginning day, it starts at day one and day six, I'll make another chart. How many do I have now, five? Yeah. Day one, day six, we have fifty point five three (50.53). Day six, fifty point two two (50.22), difference of, I am just going to use the calculator because I know what I want to say, point three one (.31) divided by five, point zero six two (.062). So I was wrong, we are probably not going to have a change like this. But that is kind of close, I guess, but that is as close as it is going to get. It just gets bigger and bigger as it is going, until it gets up to the top.

To determine how the average rate of change in temperature given a five-day interval might compare to 0.028 degrees per day, Jacob calculated the average rate of change in different five-day intervals. As indicated by his comment about being "curved inwards instead of outwards," he identified curvature as a physical attribute of the graph. He could use the shape of the graph to make some informed choices about where to begin his calculations. However, he was not able to use curvature to make sense of the varying average rate of change in temperature per day because his focus was on the results of his calculations. When his calculations did not support his hypotheses, he assumed that it was not possible to have another interval with the same average rate of change in degrees per day. Using Carlson et al.'s (2002) covariation framework, Jacob was reasoning at the AR level, because he considered the rate of change of temperature with respect to time for equal amounts of time (five-day intervals).

Together, Jacob and Austin's responses provide empirical support for reasoning about covarying quantities as changing simultaneously and independently (see also Johnson, in press). This way of reasoning involves the simultaneous varying of quantities such that both are changing in tandem. Using this form of reasoning, a student could compare amounts of change in one quantity with amounts of change in another quantity in uniform or nonuniform intervals. A student could also use this way of reasoning to compare average rates of change in one quantity with respect to another quantity in uniform or nonuniform intervals. When using this form of reasoning, a student begins by forming intervals. In doing so, a student can compare amounts of change (or average rates of change) across intervals. Comparing variation in amounts of change in an interval would not be the student's goal. Instead, the student's goal is to find an amount of change (or average rate of change) in an interval, making varying change in the interval irrelevant.

Changing with Respect to Another Quantity

In the excerpt that follows, Hannah attended to variation in the intensities of increases and decreases in typical high temperature with respect to changes in amounts of days. Her reasoning stands in contrast to Austin's and Jacob's because she did not work from calculations to make claims about changes in the typical high temperature. Instead, she used descriptors such as "increases are increasing," "steady increase," and "increase its decrease" to indicate the variation in the intensity of an increase or decrease.

Interviewer: And so if you were to take a look over the whole year and talk to me about when the temperature, the typical high is changing the most or the least?

Hannah: The typical high changing the least would be like at the peak *[Makes a circling motion around the maximum of the graph shown in Fig. 1]* like near the one hundred ninety-seventh day, but like the least, or the most change would be around right here *[Motions to the part of the graph near day 60]*, like where the steady increase is going *[Slides her finger along the graph until about day 120]*, and like same on the other side, like around in there. *[Motions to the part of the graph near day 300.]* The peak is more like the least change.

Interviewer: And if you also had to talk about a range of days, and you talked about increasing increases,

Hannah: Mhmm.

Interviewer: When do you think, does it seem like those increases are increasing?

Hannah: Um, it looks like the increases are increasing right here *[Motions to the part of the graph between days 60 and 120.]* and then like the increases decreasing would be up closer to the point *[Referring to the active point which is on day 197]*.

Interviewer: When does it seem like the change happens from increasing increases to decreasing increases?

Hannah: It seems like it really changes before the steady increase. It's where the increase increases and after the steady thing is where it starts to change to decreasing the increase.

Interviewer: And what about the decreases?

Hannah: The decreases is pretty much the same, like as the increases, except this is where *[Points to the part of the graph to the right of the maximum]* it starts to decrease its increase, or decrease its decrease, or no, increase its decrease, so that the other side towards the end *[Points to the right* *most portion of the graph]* would be where it's, the smaller decreases come.

Interviewer: Could you explain to me increase its decrease, just to make sure I'm understanding how you are thinking about these things?

Hannah: Like for, on the decrease side, around, like right after the point *[the maximum]*, like where the highest high is. Right after that the decrease is larger than what's after it. So the decrease starts off bigger and then as it goes on the decrease gets smaller. And then it goes into that steady one and then eventually the steady one goes smaller.

To determine how the intensity in the increases and decreases might vary, Hannah drew on the curvature of the graph to make claims regarding the intensity of the change. Hannah's work extends beyond noticing a physical attribute of the graph, because she could use an attribute (curvature) to make claims about variation in the increases and decreases in amounts of temperature. Using Carlson et al.'s (2002) covariation framework, Hannah was reasoning at the QC level, because she related amounts of change in covarying quantities. Although she attended to variation in the intensity of increases and decreases, she provided no evidence of considering average rate of change in temperature with respect to change in days.

Hannah's response provides empirical support for reasoning about covarying quantities such that one quantity changes with respect to changes in another quantity (see also Johnson, 2012). Using this way of reasoning, a student could vary one quantity (using uniform or nonuniform increments) and investigate how another quantity is changing with respect to that variation. Unlike a student reasoning about covarying quantities as changing simultaneously and independently (e.g., Austin & Jacob), a student reasoning about covarying quantities such that one quantity changes with respect to changes in another quantity (e.g., Hannah) does not necessarily form intervals to determine and compare amounts of change.

Expanding Carlson et al.'s (2002) Covariation Framework

Reasoning about covarying quantities such that one quantity changes with respect to changes in another quantity supports students' consideration of variation in intensity of quantity indicating a relationship between varying quantities. At the heart of this way of reasoning is the coordination of the covarying quantities such that one quantity is changing with respect to another quantity. In contrast, reasoning about covarying quantities as changing simultaneously and independently supports students' linearization of nonlinear situations, but does not support students' consideration of variation in intensity of a rate of change in a single interval. As evidenced by Jacob's work, reasoning about covarying quantities as changing simultaneously and independently could support covariational reasoning at the AR level. However, it seems unlikely that a student's mental actions would support reasoning about instantaneous rate of change.

I propose that the Carlson et al.'s (2002) covariation framework be expanded to account for students' reasoning about covarying quantities as changing simultaneously and independently (e.g., Austin & Jacob) or about covarying quantities such that one quantity changes with respect to changes in another quantity (e.g., Hannah). Using the current framework, Hannah and Austin were both reasoning at the same level (QC). However, these students were coordinating amounts of change in covarying quantities in very different ways. Making distinctions between the ways in which students coordinate amounts of change in covarying quantities can create two paths to the subsequent levels of Average (AR) and Instantaneous Rate (IR). Table 1 indicates two distinctions (Type 1 and Type 2) in the QC level of the covariation framework.

Table 1: Expanding the Covariation Framework

Level of Covariational Reasoning	**Mental Action**	**Behaviors**
Quantitative Coordination: *Existing*	"Coordinating each amount of change of one variable with changes in the other variable" (Carlson et al., 2002, p. 357)	• "Plotting points/constructing secant lines" • "Verbalizing awareness of the variable amounts of change of the output while considering changes in the input" (Carlson et al., 2002, p. 357)
Quantitative Coordination *Expansion: Type 1*	Coordinating amounts of change in quantities such that the quantities are varying simultaneously and independently	• Specifying intervals (uniform or nonuniform), determining amounts of change in those intervals, and comparing those amounts of change • Using amounts of change to make claims about covarying quantities
Quantitative Coordination *Expansion: Type 2*	Coordinating amounts of change in quantities such that change in one quantity depends on change in another quantity	• Allowing one quantity to change with respect to another quantity • Describing variation in the intensity of change in covarying quantities

By making these distinctions in the QC levels, students' transitioning to more advanced levels of covariational reasoning might be more closely examined. Students engaging in QC Type 1 covariational reasoning seem likely to advance differently to the levels of AR and IR than would students engaging in QC Type 2 covariational reasoning. For example, Jacob reasoned in a way consistent with QC Type 1 and provided evidence of reasoning at the AR level. To extend to the IR level of covariational reasoning, a student could begin by shrinking the interval on which average rate of change is being determined. In Jacob's work on the task, he was able to shrink the interval when prompted. However, his goal was not to shrink the interval because his focus was comparing average rates of change in different intervals. In contrast, it made sense for Hannah to consider smaller intervals because for her the change in temperature was dependent on the change in the day of the year. Future research might investigate how students using these different types of QC covariational reasoning advance to AR and IR levels of covariational reasoning.

Examples play a critical role in mathematical practice, particularly in the exploration of conjectures and in the subsequent development of proofs. Although proof has been an object of extensive study, the role that examples play in the process of exploring and proving conjectures has not received the same attention. In this paper, we present a framework that characterizes ways in which mathematicians utilize examples when investigating conjectures and developing proofs. The data consist of 133 mathematicians' responses to two open-ended survey questions. The framework offers categories for the types of examples, uses of examples, and example strategies that mathematicians discussed in reference to their work with conjectures. In addition to presenting the framework, we also discuss potential educational implications of the results.

Keywords: Advanced Mathematical Thinking, Reasoning and Proof

Introduction

A perennial concern in mathematics education is that students fail to understand the nature of evidence and justification in mathematics (Kloosterman & Lester, 2004). Mathematics education scholars have suggested that students' struggles with understanding the nature of evidence and justification may be due, in large part, to their views concerning the role of examples; in particular, students tend to be overly reliant on examples and often infer that a (universal) mathematical statement is true on the basis of checking a number of examples that satisfy the statement (e.g., Healy & Hoyles, 2000; Knuth, Choppin, & Bieda, 2009; Porteous, 1990). One approach designed to help students overcome their overreliance on examples is to help them understand the limitations of examples as a means of justification and thus appreciate the need for a proof (e.g., Harel & Sowder, 1998; Stylianides & Stylianides, 2009; Zaslavsky, Nickerson, Stylianides, Kidron, & Winicki, in press). Although such an approach may indeed help students understand the limitations of example-based reasoning as well as appreciate the need for proof, it characterizes example-based reasoning strategies as obstacles to overcome. Given the essential role examples play in the exploration of conjectures and in subsequent proof attempts, we suggest that example-based reasoning strategies should not be positioned only as barriers. The field may benefit from a greater understanding of the ways in which those who are adept at proof, such as mathematicians, leverage examples in order to support their thinking and activity.

Although the role of examples in learning mathematics has received attention in the literature (cf., Bills & Watson, 2008), considerably less attention has been directed toward the specific roles examples play in exploring and proving conjectures. In this paper, we present a framework that serves to characterize the variety of ways in which examples arise in mathematicians' exploration of conjectures and development of proofs. In particular, the framework characterizes the *types* of examples mathematicians may choose, the ways in which they may *use* examples, and their described *strategies* for utilizing the examples. We also discuss potential implications of this work for the teaching and learning of proof in school mathematics.

The Interplay Between Example-Based Reasoning and Proof

Epstein and Levy (1995) contend that "Most mathematicians spend a lot of time thinking about and analyzing particular examples," and they go on to note that "It is probably the case that most significant advances in mathematics have arisen from experimentation with examples" (p. 6). Clearly, examples play a critical role not only in mathematicians' development of and exploration of conjectures, but also in their subsequent development of proofs of those conjectures. Indeed, there is often a back-and-forth interplay between mathematicians' example-based reasoning activities and their deductive reasoning activities (e.g., Alcock & Inglis, 2008). Several mathematics education researchers have accordingly examined various aspects of the interplay between example-based reasoning activities and deductive reasoning activities among both mathematicians and mathematics students (e.g., Buchbinder & Zaslavsky, 2009; Iannone, Inglis, Mejia-Ramos, Simpson, & Weber, 2011; Knuth, Choppin, & Bieda, 2009).

Antonini (2006), for example, asked advanced mathematics graduate students to generate examples with specific mathematical properties. The results of this work led to an initial categorization of the students' strategies for producing examples. Antonini hypothesized that the categorized strategies may play an important role in the production of conjectures and proofs. Building upon this research, Iannone et al. (2011) used Antonini's framework to categorize the strategies undergraduate mathematics students used to generate examples during their attempts to produce proofs of conjectures. They were surprised to find that example generation did not seem to have a positive effect on proof production tasks, and they called for more research to be done in studying examples. Finally, Buchbinder and Zaslvsky (2009) also provided a framework for categorizing high school mathematics students' uses of examples when evaluating the validity of mathematical statements; they specifically classified examples as confirming, non-confirming, contradicting, and irrelevant. Although the preceding studies did not focus explicitly on the role examples play in exploring conjectures and developing proofs (or counterexamples), the research underscores the nature of the interplay between example-based reasoning activities and deductive reasoning activities, and it thus serves to inform the research presented in this paper.

Methods

Participants consisted of 133 mathematicians who responded to an online survey sent to the mathematics departments at 27 U.S. universities. The focus of this paper is on these experts' responses to the following open-ended prompt: *If you sometimes use examples when exploring a new mathematical conjecture, how do you choose the specific examples you select in order to test or explore the conjecture? What explicit strategies or example characteristics, if any, do you use or consider?* Approximately 58% of the experts were completing PhDs in mathematics, 30% had PhDs in mathematics (in a variety of different mathematical areas), and 12% had advanced degrees in other STEM-related fields; 67% were male. The data consist of these mathematicians' self-reported responses about their work with examples; while we acknowledge limitations to such data, they led us to an initial framework for experts' example-related activity.

Members of the research team independently examined the expert responses to the questions with the intent of identifying the various types of examples the mathematicians reported. During this initial coding of the data, however, it became clear that *types* of examples alone did not sufficiently capture the richness of the responses; in particular, we also coded the data with respect to the mathematicians' *uses* of examples and their *strategies* for using examples. After codes for types, uses, and strategies emerged, two members of the research team re-coded all of the responses; any discrepancies were resolved through discussion with the entire research team.

It is important to note that a particular response often could be coded in multiple ways simultaneously, both within a category (e.g., receiving multiple example-type codes), and across categories (e.g., coded as a particular example-type and as a particular use of examples). For instance, the response "I first do examples that are easiest to test. If those are consistent with the conjecture, I try more general examples, focusing on those for which the conjecture might fail." received the following codes (defined in the following section): ***Types****: Easy to Compute, General/Generic, Counterexample/*

Conjecture Breaking; ***Uses****: Check, Break the Conjecture;* ***Strategies****: Multi-Stage Example Exploration: Increasing in Generality.* The total frequencies thus do not necessarily sum to 133, the total number of respondents to the prompt.

Results

In the three sub-sections that follow, we present the components of the framework that characterize the mathematicians' example-related activities when exploring and proving conjectures. Given the page limitations of the conference proceedings, we do not go into great detail about the framework; however, we do provide representative verbatim data excerpts to illustrate the various framework categories (italics in the excerpts indicate researchers' rationale for the respective codes). We examine the results further in the Discussion section.

Types of Examples

Mathematicians described a variety of types of examples that they use when exploring conjectures (Table 1). *Simplicity* was the most frequent type of example discussed by the experts, and they also often considered counterexamples and complex examples in their work.

Table 1: Types of Examples

Type (Frequency)	Definition	Representative Data Excerpt
Simplicity (72)	Expert appeals to an easy, simple or basic example. Includes "trivial" and "small."	*Easy* ones! Start with toy cases and slowly build up the complexity.
Counterexample /Conjecture Breaking (36)	Expert picks an example that might disprove the conjecture. The expert might explicitly say "a counterexample," but this can also be inferred.	Likewise, I might also check *an example for which I believe the conjecture is most likely to fail* (sort of like a stress test).
Complex (36)	Expert picks a complex example in order to test whether the conjecture holds for tricky ones; synonyms include "non-nice," "non-trivial," or "interesting."	I try to find examples that include all of the (foreseen) barriers to a proof. *The "hardest" examples in the sense of what I'm trying to prove.*
Easy to Compute (32)	Expert chooses an example that is easy to manipulate. The difference between this code and "Simple" is that the expert says something about computing or working the example out.	I usually use appropriate low-level examples. For example, those that may be *easy to compute* and/or for which it is reasonable to check the conjecture.
Properties (26)	Expert takes into account some specific mathematical property – he or she might reference a "property" or "features," or might mention particular properties.	… For number-based conjectures, *I choose 0, numbers close to 0 (both positive and negative), very large and very small numbers, for examples, both integers and non-integers.*
General/Generic (22)	Expert states that he or she uses general or generic examples, or describes examples that are viewed as representative of a general class of cases or otherwise lack special properties.	Try the *most general example* which is still practical to test.
Boundary Case (19)	Expert picks an extreme example or number, or a "special" case, such as the identity.	…I will next try to test some strange or pathological examples, *to really push the boundaries of what might be possible in this situation*.
Familiar/Known case (18)	Expert chooses an example with which he or she is familiar, or in which properties related to the conjecture are already known.	Use examples *I'm familiar with* and see if everything still holds.

Type (Frequency)	Definition	Representative Data Excerpt
Unusual Examples (13)	Expert picks an unusual number, which would be described as something that does not come up often. "Rare," "obscure," "strange," and "weird" are also synonyms.	Next, I try something slightly more *obscure*.
Random (10)	Expert describes the example as randomly chosen; this includes genuine mathematical randomness, such as cases in which examples are chosen with a random number generator.	Try *"random"* examples in cases where that makes sense.
Exhaustive (9)	Expert looks for "all" of the examples in an exhaustive manner. This can be by testing all possible examples or by using a computer.	If it is difficult to find examples, write a computer program to find *all examples with specific characteristics*.
Common (9)	Expert describes the example as typical, common, or one many would choose.	Ones that are not special, *ones that I judge to be typical*.
Dissimilar Set (9)	Expert indicates that he or she purposely selects a variety of different types of examples.	If there are too many, I would try to select examples with *widely different properties*.

Uses of Examples

Table 2 highlights the ways in which the mathematicians discussed how they use examples as they examine conjectures; these ranged from using an example to check whether a conjecture is true to carefully selecting examples that might provide insight into how to prove the conjecture.

Table 2: Uses of Examples

Use (Frequency)	Definition	Representative Data Excerpt
Check (41)	Expert selects examples to make a judgment about the correctness of a conjecture; "test," "verify," and "check" are all synonyms.	I would start with an example that is easy to *check*. If that example works out and agrees with the conjecture I would *check* a less trivial example then.
Break the Conjecture (35)	Expert tries examples to break the conjecture; this can include specifically looking for a counterexample.	Then once I'm more comfortable with it, *try it with some example I regard as less likely to verify the conjecture and keep looking for a counter-example*.
Make Sense of the Situation (16)	Expert uses an example to deepen his or her understanding of why the conjecture might be true or false, or to gain mathematical insight.	First test for the most simple cases, *also to understand the conjecture a little better*. …
Proof Insight (8)	Expert indicates that his or her production of examples (or counterexamples) might have a direct bearing on understanding how to prove the conjecture.	Eventually, if I figure out the conjecture is true for all the examples tested, the search for a counter-example *should have given me some insight in how to prove it*.
Generalize (5)	Expert mentions using the example to generalize or to allow the expert to work in a more general situation.	… Hopefully it's obvious why what you're looking for is true in the easiest case. *You can then see if that reason generalizes.*
Understand Statement of the Conjecture (3)	Expert uses an example to better understand the statement of the conjecture.	I use simple examples first, *so I understand what the conjecture says* and then build up to more complicated ones.

Example Strategies

Table 3 displays the strategies that mathematicians said they employ when using examples to explore and/or prove conjectures. In order to be coded as a strategy, a mathematician's response had to explicitly describe a systematic approach for how he or she used examples when exploring a conjecture; simply listing one or two actions one would take or examples one would try did not constitute a strategy unless the actions or examples were explicitly connected. The *Multi-Stage Example Exploration* strategy occurred when mathematicians indicated a progression in their choices of examples; typically they described starting with simple examples, and moved toward more complex, more general, or more extreme examples. The *Property Analysis* strategy involved an examination of particular properties of the chosen examples, and insights about these properties provided further insight into the conjecture or the proof. In the *Analysis of Related Proof Activities* strategy, mathematicians described engaging in proof activities that subsequently affected how they chose and used examples. In these cases, the mathematicians' choices and uses of examples were explicitly linked to attempts to prove or to disprove the conjecture. Finally, the *Systematic Variation* strategy occurred when mathematicians suggested that they would start with an example, but would then carefully modify it in some way to further their progress in exploring or proving a conjecture.

Table 3: Example Strategies

Strategy (Frequency)	Subcategory (Frequency)	Definition	Representative Example
Multi-Stage Example Exploration (62)	*Increasing in Complexity (29)*	Expert begins with simple or easy examples and shifts to more complex or complicated examples.	*I use simple examples first*, so I understand what the conjecture says *and then build up to more complicated ones.*
	Increasing in Extremity (17)	Expert begins with simple or typical examples and builds to boundary cases, special cases, or conjecture-breaking cases.	*First look for the easiest examples. Build sophistication, and look for extremal cases.*
	Increasing in Generality (16)	Expert begins with simple or special examples and shifts to more general or generic examples.	Following Polya's suggestions, *looking at simplest examples first*. *Then try to choose a few representative/generic/random examples.*
Property Analysis (12)	*Supporting or Non-Supporting Examples (11)*	Expert attempts to determine the properties of examples that either support the conjecture in particular ways, or to determine the properties of examples that do not support the conjecture.	I try *to find specific properties* of my guess examples that prevent them from doing what I want them to do. *Sometimes this allows a slow building up of properties that can eventually say something useful about the conjecture.*
	Test Cases (1)	Expert analyzes special test cases depending on the critical properties of the examples related to the conjecture.	Also, depending on what I think will be important in proving (or disproving) the conjecture, *I will include some special test cases.*

Strategy (Frequency)	Subcategory (Frequency)	Definition	Representative Example
Analysis of Related Proof Activities (11)	*Generalize From Attempts to Prove (6)*	Expert proves related conjectures or lemmas and attempts to generalize to the conjecture at hand. Or, proves the conjecture for specific examples and then attempts to build to a general proof. Or, attempts to generalize from examples related to unsuccessful proof attempts.	Based…*on an unsuccessful proof of the conjecture* (the point where I got stuck may give me suggestions of where to look for negative examples).
	Generalize From Attempts to Disprove (5)	Expert attempts to generalize from examples that disprove related conjectures. Or, attempts to generalize from properties of examples that failed to disprove the conjecture.	I also *try to guess counterexamples*. This guessing typically fails, and if it does, *I try to find specific properties of my guess examples that prevent them from doing what I want them to do.*
Systematic Variation (10)	*Known Case Adjustment (7)*	Expert takes a known case and makes small adjustments to the example's properties, inputs, or characteristics.	Take an example *I've already done and perturb it a bit.*
	Multiple Property Variation (3)	Expert varies multiple properties or characteristics simultaneously or independently in a systematic fashion.	If there are *multiple properties, I often try to vary them independently* to see if I can discover their individual effects.

Discussion

The three-part framework highlights the complex roles examples play in the work of mathematicians, identifying multiple types of examples, uses of examples, and example-based reasoning strategies that mathematicians take into account as they engage in exploring and proving conjectures. What may not necessarily be evident in the presentation of the framework, however, is the ways in which the mathematicians' extensive domain knowledge plays a critical role in conjecture-related activity. Through our analysis, we identified four ways in which mathematicians' domain expertise appears to influence both their example choices and the ways in which they think strategically with examples when making sense of conjectures.

First, mathematicians noted that their approaches to exploring and proving a conjecture were dependent on whether or not they thought the conjecture was true. Their initial instincts about a conjecture's likelihood to be valid influenced the types of examples they chose and the strategies they employed. For example, one expert said, "If I am not sure whether the conjecture is true, I start by considering an example for which I believe it will be true … If I think it is not true, I choose the simplest example for which I believe the conjecture will fail. If I am fairly certain it is true, I usually try to consider the most general case." Second, mathematicians indicated that for many conjectures, constructing an example was not necessarily trivial (or even possible) in certain mathematical domains. One expert said, "In my work … the invariants I work with are incredibly hard to compute," and another noted that, "In my mathematical experience, the trick is to FIND examples" (expert's emphasis). Third, mathematicians implied that prior experience and intuition often played a part in their choice of examples. They described ways in which they capitalize on their prior experiences with a given area in order to access examples that would be most relevant to particular types of conjectures. One expert described choosing examples, "Based on the intuition, on the experience (examples already present in the literature may give a feeling)."

Finally, the mathematicians exhibited a meta-awareness in which they were able to see their example-related activity in terms of a broader context of their mathematical activity. In other words, the mathematicians showed intentionality about their work with examples—they were aware of what their examples could do for them and were often explicitly deliberate about their example choices. In the following response, the expert displays a clear strategy and cognizance when it comes to choosing examples when exploring a conjecture: “First test for the most simple cases, also to understand the conjecture a little better. Then once I'm more comfortable with it, try it with some example I regard as less likely to verify the conjecture and keep looking for a counter-example. Eventually, if I figure out the conjecture is true for all the examples tested, the search for a counter-example should have given me some insight in how to prove it.”

The role that examples play in the work of mathematicians stands in contrast to the role examples typically play in the work of mathematics students. For instance, some studies suggest that experts’ meta-awareness of examples described above differs from students’ example use. Knuth et al. (2011) suggest that middle school students may have difficulty considering the characteristics of their examples in the way mathematicians do. Additionally, while other studies have shown that, like mathematicians, students make use of similar types of examples (such as *Simple, Common*, or *Unusual*) (Cooper et al., 2011), the ways in which students and mathematicians appear to use examples may differ. Using examples to check a conjecture’s accuracy and then as a justification of its truth is common in student populations (Healy & Hoyles, 2000; Knuth, Choppin, & Bieda, 2009; Porteous, 1990), whereas mathematicians indicated that they rely on examples not only to check conjectures, but also to better understand them and to gain insights into their proofs.

The domain expertise that the mathematicians possess also clearly contributes to the differences between the roles examples play in the work of mathematicians and in the work of students. In the latter case, for example, the majority of conjectures with which students are charged with proving are true (and students often know this in advance as well); example uses such as *Break a Conjecture* are thus rarely employed. Students are also often unable to build upon familiar examples and on their intuition due to their relatively limited mathematical experience. This may be one reason why students seldom demonstrate the meta-awareness that mathematicians demonstrate. Our results point to the power of intentional example exploration in supporting one’s understanding of conjectures and their proofs. By better understanding mathematicians’ strategies when thinking with examples, we can uncover and elaborate ways to more effectively support students’ example exploration and subsequent proof development.

Concluding Remarks

Our findings suggest some implications for the teaching and learning of proof in school mathematics. Mathematicians’ practices of engaging in systematic, multi-stage example exploration suggest that students may benefit from learning how to vary their example use and to assess the relative merits of different types of examples when exploring conjectures. Teaching practices that encourage exploration of multiple example types, and that require students to clarify and justify their use of examples, could support a greater understanding of the conjectures. Also, during a classroom discussion, comparing different sets of examples across groups of students could highlight the ways in which some types and uses of examples may be more beneficial than others in supporting both understanding and proof development. In this sense, a stronger understanding of the strategies mathematicians employ as they use examples to develop, explore, and prove conjectures may ultimately inform the design of instructional practices and curricula that effectively foster students’ abilities to prove. Mathematicians clearly possess an awareness of the powerful role examples can play in exploring, understanding, and proving conjectures, as well as the ability to implement example-related activity in meaningful ways. Thus, in order for students to develop such awareness and ability, it is important to help them learn to think critically about the types of examples, uses of examples, and associated strategies they can employ as they engage in exploring and proving conjectures. Building on both our findings and on others’ prior work, the exploration of students’ example use could inform a new approach to conjecture development and proof, one that highlights the power of strategic example-based reasoning and activity.

alfinio@udel.edu

This paper explores how textbooks address two central concepts in differential calculus, derivative at a point and derivative function, make the transition from one concept to the other, and establish connections between them. We analyzed how the three most widely used calculus textbooks present these two aspects of the derivative, focusing on visual means and word use in the books. In contrast to their thorough discussion on the limit process for the derivative at a point, the books make a quick transition to the derivative function by "letting a point ***a*** *vary" and changing "f '(a) to f '(x)." Then, they graph f '(x) using several values of the derivative at a point. In addition, the books often use the term "derivative" without specifying which of the two concepts is meant, and are inconsistent in the use of letters, so that it is unclear whether a letter (a or x_1) denotes an arbitrary but fixed number or a variable.*

Keywords: Advanced Mathematical Thinking; Post-Secondary Education

Introduction

With a gradual growth in research in teaching and learning calculus, there have been several studies about students' thinking about the derivative. Most studies have reported students' conceptualizations about the derivative (e.g., Tall, 1987; Thompson, 1994), and their notations (e.g., Hahkioniemi, 2005; Zandieh, 2000) by addressing several mathematical aspects. This study focuses on two aspects: the derivative at a point as a specific value, and the derivative function as a function. Other researchers have emphasized these aspects (e.g., Oehrtman, Carlson & Thompson, 2008), but few studies have been done especially about the derivative as a function, nor about the transition and connection between derivative at a point, and the derivative function.

Motivation of this study came from Park's (2011) study about calculus instructors' and students' discourses on the derivative. The results showed that instructors addressed some aspects of the derivative implicitly in class using the word "derivative" without stating whether it was "derivative at a point" or "derivative function," and how these two concepts are related. During the interviews, students also used the word "derivative" without specifying and often to support incorrect notions such as "derivative as tangent line." From these results, we started wondering how to help students realize the relation and difference between derivative at a point and derivative function, make a transition from one to the other and build connections between them. As a first step, we decided to explore how widely-used calculus textbooks address the derivative as a point-specific concept and as a function. Specifically, we address the following questions:

1. How textbooks for Calculus I address the derivative at a point?
2. How textbooks for Calculus I address the derivative of a function?
3. Whether and how textbooks for Calculus I make a transition/connection between the derivative at a point and the derivative of a function?

This study is important for several reasons. First, it focuses on a central, but not yet sufficiently analyzed, relation between two main concepts of differential calculus, derivative at a point and derivative as a function. By studying students' opportunities to establish such relation through the material presented in the textbooks, if the analysis shows gaps or inadequacies in the presentations, we will be able to suggest ways instructors may complement how the books presented the idea. The textbooks analyzed in this study, which are used by over 70% college calculus instructors, share many similarities in their approaches to derivative. Second, exploring the relation between derivative at a point and derivative function is important because it offers calculus students an opportunity to revisit central aspects of function, namely a relation between thinking about function pointwise and across an interval. Though the concept of function is fundamental to understand calculus concepts, many students who received A's still have incomplete conceptions of function after their second calculus course (Oehrtman et al., 2008).

Theoretical Background

Function at a Point and Function on an Interval

There is a rich body of research on how students understand function, which also has provided several conceptualizations of functions. The studies, which address developmental stages of understanding functions, have made a clear distinction about function at a point and function on an interval (e.g., Breidenbach, Dubinsky, Hawks, & Nichols, 1992). Most studies describe the first stage of understanding function as being able to generate an output value of a function when an input value is given. A person at this stage would think of function as a value for a given input. Monk (1994) called this view of function "*pointwise understanding,*" and Dubinsky and McDonald (2002) called it "Action." The next stage is described as being able to see dynamics of a function. Monk (1994) called this stage "*across-time understanding,*" and described it as an ability to see the patterns in change of a function resulting from patterns in input variables. Dubinsky and McDonald (2002) called it "Process." Breidenbach et al. (1992) found that a transition from the first to the second stages is not natural, and some calculus students are at the first stage, and thus they have trouble seeing calculus concepts dynamically.

Derivative at a Point and Derivative as a Function

Existing studies on students' thinking about the derivative can be divided regarding the two views of functions. Studies about the derivative as a point-specific value showed that students' thinking about the limit is related to their thinking of local linearity (Hahkioniemi, 2005) and tangent line (Tall, 1987). Studies about the derivative as a function that mainly address co-variation showed the importance of what is varying in a function. Oehrtman et al. (2008) compared the rate of change of the volume of a sphere with respect to its radius (its surface area) and the rate of change of the volume of a cube with respect to its side (not its surface area). Thompson (1994) related the rate of change to students' thinking of the derivative.

However, few studies have been done about the relation between these two types of understanding of the derivative. Monk (1994) addressed these two types based on students' written answers on four survey problems, but did not give much detail about whether and how students related these two concepts. Park (2011) interviewed 12 calculus students and found that using one word "derivative" for both "the derivative function" and "the derivative at a point" was related to their conception of the derivative as a tangent line. The students were changing what the word "derivative" refers to in various contexts and used it as a mixed notion of a point-specific concept but a function, which the tangent line represents. They also used this idea to justify an incorrect statement, "a function increases if the derivative increases." Analysis of their class lessons about the derivative showed that the instructors were not explicitly addressing the derivative at a point as a number, and the derivative function as a function. In this current study, whether and how the calculus textbooks relate these two mathematical aspects will be explored.

Words and Visual Mediators

This study is based on the communicational approach to cognition (Sfard, 2008), which views mathematics as a discourse characterized by four features: word use, visual mediators, routines, and endorsed narratives. This study focuses on the first two features. A *word* in mathematical discourse can be used differently in a different context. For example, the word "derivative" is used as the derivative at a point and the derivative function (e.g., "is the derivative positive here?"). Quantifiers (e.g., one & any) play an important role to determine if "derivative" is a point-specific value or a function. *Visual mediators* refer to visual means of communication. This paper focuses on various notations of the derivative and letters for a point and variable. For example, if the derivative at a point is denoted as $f'(a)$, and the derivative function as $y = f'(x)$, "a" is used as a number, and "x" is used as a variable. The derivative at a point can be visually mediated by the slope of the tangent line and the derivative function by its graph.

Method

Based on Bressoud's (2011) study, we chose three textbooks that are widely used by Calculus I course instructors in the United States: one edition by Stewart (43%), Hughes-Hallett et al. (19%), Thomas et al. (9%). In each book, we explored the sections about the rate of change, and the derivative. We developed an analytical tool using an existing framework (Park, 2011). Though there were slight differences in each book, we identified five phases: (a) rate of change, (b) the derivative at a point, (c) transition, (d) the derivative function, and (e) connection. The first phase addresses the rate of change without using the word "derivative." The derivative at a point is defined in the second phase. In the third phase, the books make a transition to the derivative function, and define it in the fourth phase. Last, they connect back to the derivative at a point graphically. We examined book descriptions through their visual mediators and word use (Table 1). We focused on whether key terms—slope, rate of change, and derivative—were used as static or dynamic based on whether it is defined at a point, multiple points, or on intervals with a variable. Because books have limitations showing dynamics, we carefully looked at the descriptions for the figures including quantifiers and letters.

Table 1: Analysis Table

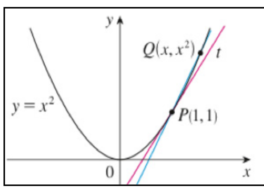
Stage	Visual Mediator			Word Use			
	Table	Graph	Symbolic Notations	Key Term	Static		Dynamic
					A point	Multiple points	

Results

In this section, we focus on the most-widely used book (Stewart, 2010) with the details of how we used the key words and visual mediators to reach our conclusions. The analysis of other books is addressed in the Discussion.

Velocity and Slope of Tangent

Stewart's (2010) *Calculus* addresses the slope and velocity in the chapter of Limit without using the word *derivative*. First, it shows how to obtain the slope of tangent line to a curve $y=x^2$ at $P(1, 1)$ using the point $Q(x, x^2)$ approaching P (Figure 1).



x	m_{PQ}
2	3
1.5	2.5
1.1	2.1
1.01	2.01
1.001	2.001

$m_{PQ} = \frac{x^2-1}{x-1}$ …for the point $Q(1.5, 2.25)$… $m_{PQ} = \frac{2.25-1}{1.5-1} = 2.5.$
The table…shows the values of m_{PQ} for several values of x close to 1. The closer Q is to P, the closer x is to 1 and, it appears from the tables, the closer m_{PQ} is to 2.

Figure 1: Graph of $y = x^2$ and values of slope of secant lines (p. 45)

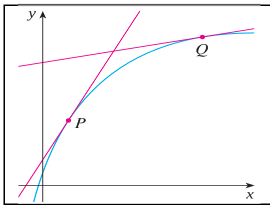
Using the same method, the book calculates the velocity of a ball after 5 seconds as *49 m/s* (the distance: $s(t) = 4.9t^2$), and relates its velocity at $t = a$ to the slope of tangent to the curve, $s(t)$. Here, the book addresses the slope of the tangent line to a curve and the velocity as point-specific concepts, at $x = 1$, $t = 5$, and $x = a$. The book used a as if a were a number rather than an arbitrary value or multiple values without stating that a could be any point. The dynamic aspect of the concepts was only addressed in the limit process finding the slope of tangent from secant lines. Thus, this section addressed the velocity and slope of a tangent line at a *specific* (single) point.

Derivative at a Point

The book calls the "special type of limit" in the slope and velocity "a *derivative*," and uses the word with phrases, "of a function," "at *a*," or an equation in this section. It rewrites the slope of the tangent line of $y = f(x)$ at $x = a$ as $m=\lim_{h\to 0}\frac{f(a+h)-f(a)}{h}$, and defines "the *derivative* of a function *f* at a point *a*" as the same limit (p. 107). The letter *a* is used only for a point until the book calculates "the derivative of a function $f(x) = x^2-8x+9$ at the number *a*" as "$f'(a) = 2a-8$" and finds the slope at (3, -6) as "$f'(3) = 2(3)-8=-2$." Though this calculation implies that *3* is one value of *a,* the book does not explicitly state it or write $a = 3$ (p. 107).

Rate of Change

The book defines the instantaneous rate of change of $y = f(x)$ with respect to *x* at $x = x_1$ as $\lim_{x_2\to x_1}\frac{f(x_2)-f(x_1)}{x_2-x_1}$, interprets it as "the derivative $f'(x_1)$" and changes it to "the derivative $f'(a)$." It then gives two interpretations, "the slope of tangent line to a curve when $x = a$" and "the instantaneous rate of change…at $x = a$," and makes a connection between them (Figure 2, p. 108).



[On] the curve, $y = f(x)$…the instantaneous rate of change is the slope of the tangent to this curve at the point, where $x = a$. This means that when the derivative is large (and therefore the curve is steep, as at the point *P*), the *y*-values change rapidly. When the derivative is small, the curve is relatively flat (as at point *Q*). and the *y*-values change slowly.

Figure 2: Graphs of two tangent lines (p. 108)

For the cost of producing *x* yards of fabric, $C = f(x)$, the book explains "the derivative, $f'(x)$" as "the rate of change of the production cost with respect to the number of yards produced" in dollars/yard and asks to find or compare the meaning of $f'(1000) =9$, $f'(50)$, and $f'(500)$ (p. 109).

In this section, the book uses the word "derivative" three times. "The derivative, $f'(x_1)$" indicates that it is defined at a "fixed point x_1" (p. 109). In Figure 3, "derivative" is used to describe the function behavior as in "when the derivative is large, the *y* value change rapidly" (p. 108). Because the book specified the point *P*, it is clear that the sentence is about the local function behavior near P, but it can be true anywhere on the interval if "the derivative" is used as a function. At the end, the book calls all rates of change of various functions at several points "derivatives." It uses the notation, $f'(x)$ for the first time. In the fabric problem, it interprets $f'(x)$ as if it were a point-specific value, but gives its units in general terms using the units of different quotients without making a connection to its interpretation. In the second problem, it interprets "$f'(1000) = 9$," as "when $x = 1000$, C is increasing 9 times as fast as *x*." Though $f'(1000)$ was used as a value of $f'(x)$ at $x = 1000$, the relation between notations, $f'(1000)$ and $f'(x)$, was not stated.

Transition from the Derivative at a Point to the Derivative of a Function

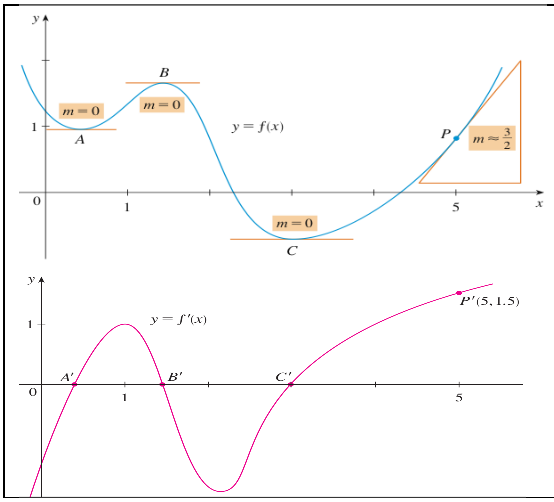
The book summarizes that all previous discussions were about "a fixed point," which confirms the word, "derivative," "*x*" in the fabric example and "*a*," in graphs as point-specific values. Then, in $f'(a)=\lim_{h\to 0}\frac{f(a+h)-f(a)}{h}$, the book changes the "point of view and let[s] the number *a* vary, … replace[s] *a* by a variable *x*, and…obtain[s] $f'(x)=\lim_{h\to 0}\frac{f(x+h)-f(x)}{h}$" (p. 114). Here, the nature of "*a*" was specified as "vary[ing]" and connected to the "variable, *x*."

The Derivative Function

The book defines "$f'(x)$ as a new function" that assigns to "any number *x*…the number $f'(x)$," and connects it to "the slope of the tangent line to the graph of *f* at the point $(x, f(x))$" (p. 114). It also emphasizes that the variable *x* in $f(x)$ and $f'(x)$ are the same by comparing the domain of f', $\{x| f'(x)$ exists$\}$ that may be smaller than the domain of *f* (p. 114).

Connection from the Derivative Function to the Derivative at a Point

The book then graphs *f '(x)* using slopes of tangent lines to the curve, *f(x)* (Figure 3).



We can estimate the value of the derivative at any value of *x* by drawing the tangent at the point (*x*, *f(x))* and estimating its slope. For instance, for *x* = 5 we draw the tangent at *P* in [the] Figure and estimate its slope to be about 3/2 , so *f* '(5) ≈1.5. This allows us to plot the point *P' (*5, 1.5) on the graph of *f* ' directly beneath *P*. Repeating this procedure at several points, we get the graph shown in Figure 2(b). Notice that the tangents at *A*, *B*, and *C* are horizontal, so the derivative is 0 there and the graph of *f* ' crosses the *x*-axis at the points *A*', *B*', and *C*', directly beneath *A*, *B*, and *C*. Between *A* and *B* the tangents have positive slope, so *f* '(*x)* is positive there.

Figure 3: Graphs of a function and its derivative function (p. 115)

In Figure 3, the book makes a connection from the derivative function to the derivative at a point by stating the value of the derivative at "any" point of *x* using the slope at the point, finding the slope 1.5 at *x = 5*, and plotting (5, 1.5) for *f '(x)*. It again uses the point-wise approach to find the zeros for "the derivative." Then, it uses the interval-wise approach to determine whether *f '(x)* was positive or negative between these zeros. Here, the word, "derivative" first is used as *the derivative function* because it was defined "at any value." The second one in "the derivative is zero there and the graph of *f '* crosses the *x*-axis" is used as a point-specific value. To refer to the function that the second graph represents, the book consistently used the notation *f '(x)*. When it describes the sign of the "slope" of "tangents" on intervals, it used the singular "slope" instead of "slopes." Though "the slope" can be inferred as "the slope" as a function because the book was using "the slope" for several values, it would have been "the slopes of the tangents."

Summary

To address the concept of the derivative, Stewart (2010) (a) uses the velocity and slope at a point, (b) defines the derivative of a function at a point, (c) interprets it as the instantaneous rate of change, (d) makes a transition by letting point *a* vary and replacing it with variable *x*, (e) defines the derivative of a function, and (f) constructs the graph of *f '(x)* using the slope of tangents to *y = f(x)*. Table 2 shows key words and visual mediators used in each of these phases.

Table 3: Visual Mediator and Word Use in Stewart (2010)

Phase	Visual Mediator			Word Use			
	Table	Graph	Symbolic Notations	Key Terms	Static		Dynamic
					A point	Multiple points	
(a)	Fig. 1	Fig. 1	$\frac{x^2-1}{x-1}$	The slope	At the point (1, 1)		Limit. "Values close to 1"
			49m/s	The velocity	After 5 seconds		
			$\frac{4.9(a+h)^2-4.9a^2}{(a+h)-a}$	The velocity The slope	At time $t = a$ At point P		Limit. "As h approaches 0"
(b)			$f'(a)=\lim_{h\to 0}\frac{f(a+h)-f(a)}{h}$	The derivative of a function f	At a point a		
			$f'(a) = 2a-8$	The derivative of $f(x) = x^2-8x+9$	At the number a		
			$f'(3) = 2(3)-8=-2$	The slope of the tangent line	At (3, -6)		
			$\lim_{x_2\to x_1}\frac{f(x_2)-f(x_1)}{x_2-x_1}$	Rate of change The derivative $f'(x_1)$	At $x = x_1$		
(c)		Fig. 2	$f'(a)$	Derivative		At the points P & Q	
			$f'(x)$	Derivative Rage of change of C	With respect to x		
			$f'(1000) = 9$,	The rate of increase	After 1000 yd		
			$f'(50)$, $f'(500)$	The rate of increase		After 50 & 500 yd	
(d)			$f'(a)=\lim_{h\to 0}\frac{f(a+h)-f(a)}{h}$	Derivative	At a fixed point a		Let a vary
(e)			$f'(x)=\lim_{h\to 0}\frac{f(x+h)-f(x)}{h}$	Derivative			[of] variable x
(f)			$f'(x)$	A new function			Any number x
		Fig. 3	f'	Derivative Graph of f'	At $x = 5$	Where f' crosses the x axis	Any value of x

As shown in Table 2, Stewart (2010) develops the concept of the derivative from a number to a function by showing graphical representations of the slope of a single tangent line, the slopes of multiple tangent lines, and the derivative of a function. It also uses the slope, the rate of change, the derivative at a specific point, multiple points, and any points by using numbers and letters with or without subscripts and changing what those key words represent. Graphical notations were consistent with such development: first a single tangent line, then multiple tangent lines, and graph of $f'(x)$ in turn (see Figures 1, 2, & 3). However, other visual mediators, letters for a point and variable were not consistent. Though the book mainly used a for a single point or multiple (discrete) points, and x for the variable, in the second and third examples in phase (b), "a" was used as if it were a variable, because 3 is substituted in a in the next step. The book does not mention that a can be any value. In a later section, it calls "a" "the fixed point." Then, in phase (c), it again uses "a" for multiple points, which seems to transfer what "a" represents from a single value to any values. However, in the next step, it uses "$f'(x)$" as if it were one value of the rate of change of a cost function and interprets $f'(1000)$, $f'(50)$, and $f'(500)$ without making a connection back to $f'(x)$ or mentioning they are the specific values of $f'(x)$.

The word "derivative" is also used inconsistently. First, it is used as *"the derivative* $f'(x_1)$*"* as the rate of change at a point, and again in "the derivative $f'(x)$ with respect to x" as if it were a point-specific concept (before the book defines the derivative function, $f'(x)$). Then, in Figure 3, the book uses the word "derivative" twice: one for the derivative of a function (at any points), and the other one for the derivative at points where f' crosses the x axis. The word is used without its referent–the derivative function or the derivative at a point–or notation–$f'(x)$ or $f'(a)$. The book relates these two concepts twice. First, it makes a transition from the derivative at a point to the derivative function by letting "a" vary and changing "a" to "x." Second, after defining the derivative of a function, it makes a connection back to the derivative at a point based on the slopes of several tangent lines to the original function at discrete points.

Discussions and Conclusions

As mentioned earlier, the textbooks address the concept of the derivative first as the velocity and slope without using the word "derivative," define the derivative of a function at a point, and then the derivative function. With slight differences in representations, the books we analyzed have some common characteristics in connecting the derivative at a point and the derivative of a function. First, the use of numbers and letters with or without subscripts is not consistent. For example, Thomas et al. (2010) uses $t = 1$ and $t = 3$ in a problem statement and $t_0 = 1$ and $t_0 = 3$ in its solution. It also uses a letter with a subscript x_2 for a value approaching a fixed value x_1. Second, the word "derivative" is not used explicitly; most times, it is used without its referent, the derivative at a point or the derivative function. Especially, when the word is used after defining both concepts, it is not clear whether "derivative" is used as a point-specific value or as a function. With this implicit use of the letters and key words, the derivative at a point as a value of the derivative function is also not consistently addressed. For example, all three books use notations $f'(x)$ and $f'(a)$, and substitute a number in x or a before mentioning that the concept of the slope or the rate of change can be considered at more than one (or any) point on an interval or defining the derivative function. To define the derivative function, they all change the view to let "a" or "x_0", which used to be a fixed value, "vary" and change it to "x." After the definition, they show the graphing process of the derivative function based on the slopes to the curve $y = f(x)$. In this process, the word "derivative" is also used implicitly, which is problematic because they are graphing "the derivative function" based on "the derivative" at discrete points. Hughes-Hallet et al. (2010) even draws the graphs of a function and its derivative function on one x-y plane, which does not show that they represent different values, such as distance and velocity.

Calculus I is a first college course, in which students practice abstract mathematical thinking and prepare for upper level mathematics courses. Mathematicians, including textbook authors, may think that students have mastered the concept of function before they start the course. However, many studies show that this is not necessarily true; calculus students do not always have complete understanding of function in secondary level, and thus have trouble seeing the derivative as a function (Park, 2011). Calculus books cannot and need not include all the explanations of a function, which should be addressed in the previous mathematics classes. However, inconsistent use of key words and visual notations supporting the concept of the derivative as a point-specific value and as a function may confuse calculus students who do not have a solid understanding of a function. The way the concepts of the derivative are built—(a) heavy discussion on the limit process in the derivative, obtaining the slope of the tangent from a sequence of secant lines; (b) a simple transition from the derivative at *a*, $f'(a)$, to the derivative function $f'(x)$; and (c) graphing $f'(x)$ based on several values of $f'(a)$– is not consistent with the way the concept of function was built before. Changing a view of seeing "*a*" as a fixed value to any values may not be *simple* to students and graphing $f'(x)$ after giving its definition may not be ideal. Constructing the derivative function based on the derivative at discrete points before defining the derivative function may remind students about how a function was constructed and thus help them guess what those values represent and how they change as *x* values change, and finally think about the derivative as a function before they see the formal definition.

RELATIONSHIPS BETWEEN MATHEMATICAL PROOF AND DEFINITION

David Plaxco
Virginia Tech
dplaxco@vt.edu

This article discusses results from interviews with two undergraduate students in an introductory proofs course. The researcher assessed the participants' general proof schemes and built models of the participants' conception of probabilistic independence and mutual exclusivity. The participants were then tasked with asserting a relationship between independence and mutual exclusivity and trying to prove the asserted relationship. The results discuss possible interactions between students' conception of mathematical ideas and their approaches to proof.

Keywords: Proof Scheme; Definition; Concept Image; Probability

Mathematical proof and mathematical definition are two areas of research that have recently gained heightened attention from researchers (Edwards & Ward, 2004; Harel & Sowder, 1998; Ko, 2010; Vinner, 1991). These two areas, though generally studied separately, are intrinsically related (Edwards & Ward, 2004; Weber & Alcock, 2004). Little research, however, has explicitly explored relationships between proof and definition. The purpose of this research is to explore the connections and relationships between undergraduate students' proof schemes and their understanding and use of definition.

Theoretical Framework

A Framework for Discussing Proof

Harel and Sowder (1998, 2007) have provided a fundamental framework for research in students' conceptions of proof. This framework begins by defining proof as a two-part process: ascertaining and convincing. A student's notion "of what constitutes ascertaining and persuading" is called that student's proof scheme (Harel & Sowder, 1998, p. 244). There are varying levels of proof schemes described in the literature. Broadly, these proof schemes are External, Empirical, and Analytical — an External proof scheme includes validations by authority, ritual, or symbolism, an Empirical proof scheme is inductive or perceptual, and an Analytical proof scheme is more rigorous and logical. It is important to note that, at a given time, no person completely displays evidence of exactly one proof scheme. Because of this, a student's proof scheme is a generalization of the types of proof schemes evident through his or her work. For example, a student could exhibit both Empirical and Analytical proof schemes within a short period of time or even within a single proof; such a student could be said to have an "emerging Analytical" or "Empirical/Analytical" proof scheme.

Weber and Alcock (2004) also contribute a framework for discussing students' semantic and syntactic proof productions. This framework draws distinctions between students' use of instantiations in proof (syntactic) and the formal manipulation of logical mathematical statements (semantic). While this framework is constructed outside of Harel and Sowder's (1998) proof schemes, the two classification systems for students' mathematical tendencies seem as though they could work successfully together as neither excludes the other.

A Framework for Discussing Definition

Vinner (1991) distinguishes between the ideas of concept image and concept definition. He defines the concept image as a non-verbal entity such as a "visual representation of the concept… [or] a collection of impressions or experiences" (p. 68) which our mind associates with the concept. In contrast, the concept definition is the formal mathematical definition of a concept. These two ideas are not necessarily—and, one could argue, seldom—the same thing. Vinner uses the sentence, "my nice green car is parked in front of my house," as an example of concept image (p. 67). He argues that the reader or listener does not necessarily consider the definition of each word in the sentence, but that each word invokes a generic concept image in his or her mind, the collection of which allows the sentence to take form as a whole impression.

Probability as a Context

Manage and Scariano (2010) provided a useful context in which this research was conducted. The authors found that most of the students in their study thought that two events being independent implied that they were mutually exclusive and vice versa. Although one's initial reaction may be to conclude this exact relationship, after careful consideration of the two concepts one realizes the two terms have almost exactly opposite meanings. This "almost" is attributed to cases in which one or both of the events has zero probability. Otherwise (i.e., if two events have nonzero probability), independence implies that two events are not mutually exclusive and mutually exclusive events are not independent. When asked to prove this relationship between independence and mutual exclusivity, one must address his or her own conceptions of independence and mutual exclusivity, compare the two concepts, ascertain the relationship between the two, and try to convince others. So, this relationship between mutual exclusivity and independence will provide a context for exploring the use of definition in proof.

Methods

The researcher conducted semi-structured interviews with three undergraduate students—Alex, Betty, and Caroline—who were enrolled in an Introduction to Proofs course. All three students were mathematics majors in their third year and were chosen randomly from a group of volunteers. None of the students were compensated for their participation. Each participant completed three interviews, each lasting approximately one hour.

Each of the three interviews had its own unique goal: (Interview 1) to gauge the participants' general proof schemes, (Interview 2) to gain insight into the participants' concept definitions and concept images of specific mathematical terms, and (Interview 3) to observe and analyze the participants' use of definition and imagery while proving relationships about the mathematical terms discussed in the previous interview.

Data Collection

All interviews were recorded using both video and audio devices. The researcher kept notes throughout the interviews and all participant work was collected. The first interview was designed to gather a general understanding of each participant's proof scheme. The interview consisted of each participant assessing a "matrix of proofs," which is a 3-by-3 grid of mathematical proofs. Each row in the matrix contained three variations of proof of the same mathematical relationship, reflecting Harel and Sowder's (1998) three major proof schemes—Analytical, External, and Empirical. The participants were asked to assess each proof for mathematical and logical correctness. From these responses, the researcher determined the aspects of mathematical proof that the participants considered important and/or necessary or, conversely, unimportant and/or unnecessary. In turn, the researcher used the participants' responses and reasoning in order to form a notion of each participant's general proof schemes.

In the second interview, the researcher collected the participants' definitions of mutually exclusive events and independence. The researcher also asked the participants to consider several events in various sample spaces and determine whether pairs of events were mutually exclusive and/or independent. Participants were also invited to introduce their own events and sample spaces to elaborate points that came up during discussion. This was intended to provide the interviewer with insight not only into how the participants defined each of the two terms, but also how these terms were applied in various probabilistic contexts. The researcher could then distinguish between the participants' concept definitions (collected directly) and concept images (drawn from examples, phrasing, etc.).

The third interview was designed to provide a context wherein the participants could assert a mathematical relationship between independence and mutual exclusivity and then attempt to prove this relationship. The participants were asked to assert two main relationships: given that two events have nonzero probabilities in the same sample space, does independence imply mutual exclusivity and does mutual exclusivity imply independence? These questions were posed as two separate multiple-choice questions, as in Manage and Scariano (2010).

Data Analysis

The researcher analyzed each video and audio recording after each interview in order to determine the participants' proof schemes, identify major themes in the participants' reasoning, model participants' understanding of mutual exclusivity and independence, draw quotes from the dialogue to support such models, and develop individualized clarifying tasks for the subsequent interview. Throughout the video analysis, video clips were taken that supported or challenged working models of participant thinking. These videos were collectively re-analyzed in order to confirm or reevaluate a model. The researcher would then develop questions for the subsequent interview that would be used to help clarify conflicts within the model.

Results

For the sake of depth and limited length, we discuss only Alex and Betty here.

Alex

Throughout the first interview, Alex exhibited a predominantly Analytic proof scheme. Eventually he correctly supported all Deductive proofs and refuted all Empirical and External proofs, citing appropriate flaws in logic or reasoning. In a few instances, he showed signs of relying on a proof's form rather than content, signifying an occasional tendency toward a Ritual (External) proof scheme. Alex was also very pedantic about precise details, reflecting a skeptical point of view and checking for logical progression in each proof.

Alex displayed a deep understanding of examples and their use in proof. This was quickly evident in the first example in the matrix of proofs. This proof, applying an Inductive (Empirical) proof scheme, used an example of a large random number that exhibited the desired result. After reading the argument, Alex immediately said, "Yeah, this is bogus." He later refuted other inductive proofs very similar to the first. These examples highlight Alex's ability to refute proofs that inappropriately use examples.

Another interesting aspect of Alex's proof scheme is his emphasis on the axioms of real numbers and considering the space in which he was working. These qualities were evident in three instances. In the first two cases, Alex explicitly applied the axiom of the closure of integers under addition and multiplication. In the second case, Alex also invoked the associativity axiom for real numbers. In the third case, Alex suggested that the sum of the interior angles of a triangle might not be 180° in non-Euclidean space. While this could be a manifestation of the rigor required in his Introduction to Proofs course, it is evident from these examples that Alex had internalized a mindset that considers the system in which a proof is argued and its fundamental axioms. It should be noted that Alex's use of axioms in this interview reflects Harel and Sowder's (1998) Intuitive-Axiomatic proof scheme.

These qualities of Alex's proof scheme combine to support an initial emphasis on the form of a proof and then careful investigation of motivation and justification at each line of an argument. This emphasis was manifested in his pedantic discussions of the proof writer's justification, his use of axioms, and refutation of proofs by example. We see Alex used the form of a proof to make initial judgments, but his skepticism forced him to evaluate a proof based on its line-by-line merit. From this, we can conclude that Alex generally displays an Intuitive-Axiomatic (Analytical) proof scheme with tendencies toward a Ritual (External) proof scheme.

In the second interview Alex explored two sample spaces and discussed a few other examples that he used to help describe his understanding of mutual exclusivity and independence. As we will see, Alex displayed an extremely internalized and powerful conception of independence. Alex defined independence as, "[when] the outcome of one event does not affect the outcome of a subsequent event." This definition implies an emphasis on a sequence of events, where one of the events being considered must occur prior to the other.

With regard to mutual exclusivity, however, Alex was less certain of a formal definition—changing his definition twice throughout the interview until eventually declaring, "[Mutual exclusivity is when] performing an event or series of events causes a subsequent event to have zero probability of happening." Again, Alex uses the word "subsequent" in his definition, which implies that this relationship is defined over a period of time. It is important to note that Alex's initial definition of mutual exclusivity (consistent with the mathematical definition) was not defined over time, but rather instantaneously. It was not until he had considered examples in the two given sample spaces that he changed this definition to more closely resemble his definition of independence.

When prompted for an example of independent events, Alex gave two examples: a die and a coin. He stated that rolling a six on the first roll of a die does not affect rolling a six on the second roll of a die and gave an analogous explanation for the coin. These examples are consistent with his definition of independence, implying that the two events in consideration take place at separate times. His initial examples of mutually exclusive events exhibited what he described as "well-defined states" including raining versus not raining, sides of a die ("you can't roll both a 5 and a 1"), and a coin ("it's either heads or tails"). These examples support his original definition, which considers the two outcomes instantaneously in that it cannot both rain and not rain at the same time. Later in the interview, however (after changing his definition of mutual exclusivity), Alex described repeatedly drawing "any card" without replacement until all spades were exhausted. In this case, drawing "any card" and drawing a spade were mutually exclusive since drawing "any card" can eventually cause drawing a spade to have probability zero. This example seems much more convoluted than the first three examples, but supports Alex's newer definition of mutual exclusivity.

We can see that Alex's conception of independence was so strong that it not only influenced how he defined mutual exclusivity, but also caused him to reject three different examples and develop a new concept image for mutual exclusivity wherein one event must cause a subsequent event to be impossible. This new concept image was so strong that, when asked to reconcile this new definition with his original examples, Alex reneged on their mutual exclusivity (e.g., heads on a coin does not cause "not tails" later).

Equally intriguing is the fact that Alex independently asserted a corollary to his new definition of mutual exclusivity. In this corollary, Alex stated that if the two events are mutually exclusive, then they cannot be independent. This reflects the (almost) exact relationship outlined in Manage and Scariano (2010) and investigated in the third interview of this research. Alex used an explanation analogous to that described in Manage and Scariano (2010). He asserted that, since one event causes the second event to have zero probability, the first event changes the probability of the second event and therefore the two events are not independent. It should be noted, however, that Alex did not consider the case when the second event in the sequence already had zero probability.

In the third interview, Alex responded that if two events were mutually exclusive this implied that they were not independent. This claim was made using his final definition of mutual exclusivity. He directly referenced his own corollary from the second interview in which he made this exact assertion. Alex also claimed that if two events are independent then they are not mutually exclusive. He supports his answer choice by saying, "one event's not affecting the other event at all so, I mean, it's not going to cause it to have zero probability cause it's not changing the probability of the next event." As with the first question, this answer choice supports the relationship between the mathematical definitions of independence and mutual exclusivity for nonzero events.

Betty

Betty displayed a predominantly Analytic proof scheme with the exception that she accepted one proof based on its appearance and another proof based on its form. Betty correctly refuted the three examples of Inductive (Empirical) proofs, but accepted one Deductive proof because it "seem[ed] more mathematical." Her refutation of the inductive proofs shows her understanding of the importance of a general proof for all cases. Betty's acceptance of a proof based on its seeming mathematical qualities and acceptance of a false proof by the principle of mathematical induction, however, indicate a tendency toward External (Ritual) and Empirical (Perceptual) proof schemes.

Betty showed an insistence on understanding very specific aspects of a proof rather than drawing any assumptions about the proof's process with the exception of one case. She quickly accepted a proof by mathematical induction. Here, she was likely preoccupied with the form (or "look") of the proof, rather than its mathematical validity. This idea was supported when Betty stated that her class had recently discussed the principle of mathematical induction. When asked which of the first three proofs she preferred, Betty chose the last proof because the processes in the second proof were not obvious to her. This reflects a need to understand connections in a proof, even though this need was temporarily suspended in the case of mathematical induction. This need was also addressed later in the interview, when Betty described the process of verifying for herself relationships she felt she did not understand in class.

Throughout the rest of the first interview, Betty correctly refuted Empirical and External proofs and accepted Analytical proofs. She rejected the false proofs with little hesitance. At one point, Betty described combinations of negating the hypotheses statements of the Inductive proofs, showing a clear understanding of logical proof, counterexamples, and proof by contradiction. She also reflected an ability to identify false proof by example. These examples show a healthy skepticism of Authoritarian and Ritual proof, both of which are External proof schemes. Additionally, Betty's explanations in refuting Inductive proof schemes support an emphasis on proof for all cases.

When asked what it meant for two events in a sample space to be independent, Betty responded, "The intersection is zero. Is it? That's what I'm asking. I don't remember." Betty almost instantly changed this to, "Two events are independent if the probability of A occurring does not affect the probability of B occurring." Betty then described the independence of events A and B using the equation $P(A) = P(A|B)$. Neither of these representations necessarily implies a chronological distinction between events A and B (as was seen with Alex's use of the word "subsequent"). But, when prompted for an example of independent events, Betty described the act of picking a card from a deck of fifty-two cards and putting it back so that the probability of picking a second card is not affected. Similarly, when asked for an example of events not being independent, Betty provided the case of picking a card and not replacing it. These examples are consistent with a conception of independence in the context of a "with replacement" and "without replacement" conditioning event.

In contrast, Betty defined mutually exclusive events with the statement, "you can't have both at the same time." This definition explicitly states that the events can be compared instantaneously. Here, Betty gave the example that the choosing the queen of hearts and choosing the jack of diamonds are mutually exclusive because they cannot both occur when one card is drawn. We notice that this definition is consistent with the mathematical definition and that this example is consistent with Betty's definition. Betty did spend much more time defining mutually exclusive events compared to her definition of independence, but once she determined this definition, she held firm to its accuracy saying, "I'm sorted now." This reflects her need in first interview to prove relationships in order to understand them.

Betty's initial confusion of independent events as events that "don't happen at the same time" reflects the most common misconception in Manage and Scariano (2010). Although she quickly changed her mind about the definition of independence, this confusion was apparent in her use of mathematical notation to represent the ideas (discussed below). Also, when explaining her conditional notation of independence, Betty described two independent events as "completely separate," which one could argue is a descriptor more applicable to mutually exclusive events since their intersection is empty.

More than once, Betty wrote an equation involving probabilities saying, "That's just something I remember from probability." For instance, she initially used "$P(A \cap B)=0$" to represent independence and used the equation "$P(A \cap B)=P(A)*P(B)$" to define mutual exclusivity. These equations were quickly erased. The former, however, was eventually used to describe mutual exclusivity. For the latter, Betty admitted, "[I have] no idea where that came from or if that's even mutually exclusive. And I would not be able to come up with [it]." We notice that Betty's second description of independence, $P(A)=P(A|B)$, is true unless the probability of B is zero. In this case, the statement $P(A|B)$ makes no sense, although it could be adapted to say, "two events A and B are independent if both have nonzero probability, $P(A)=P(A|B)$, and $P(B)=P(B|A)$."

In this interview, we see that Betty's concept definitions, though initially inconsistent, are each strongly internalized when evaluating the independence and mutual exclusivity of specific events in specific sample spaces. This is evident because once Betty defined each term, she was "sorted" on how to verify them and seemed to develop quick checking schema in order to do this (e.g., "Can these happen at the same time?"). Her spoken reasoning for two events' independence and mutual exclusivity reflected these quick checks.

In response to each of the two questions in the third interview, Betty concluded that there was not enough information about the sample space and that two mutually exclusive events can be both independent and not independent. This led her to respond that there was not enough information about the sample space or the context of selecting events in the sample space to determine a relationship. She explained that in the previous interview she had seen mutually exclusive events that were both independent and not independent (a copy of her responses from the second interview was presented to her). She also explained that she saw independent events that were both mutually exclusive and not mutually exclusive in the second sample space. From this, Betty reasoned that more information was needed about both the sample space and the actions taken between the occurrence of the first event and second (e.g., replacement, non-replacement). Again, we see independence is affected by the context in which the events take place.

Betty's proof scheme showed that she is more inclined to want to verify mathematical relationships on her own. This was evident as she "sorted" herself about the definitions of independence and mutual exclusivity. During this process, Betty successfully reconciled her definitions of the terms with symbolic representations (about which she was admittedly unsure) that she had recalled from her statistics course. Betty used these definitions to investigate the sample spaces in the second interview, the results of which had a direct affect on her reasoning in the third interview. Because Betty's definition of independence relied so heavily on the sample space and whether replacement occurred, she had examples of all different combinations of independence and mutual exclusivity.

Conclusion

We see that proof schemes can be both restricted and enhanced by students' definitions of the mathematical ideas they consider. Though her reasoning was logically based on her previous experiences in the samples spaces, Betty's conception of independence and mutual exclusivity caused her to require more information about the sample spaces in question, in turn restricting her ability to draw conclusions between the two concepts. On the other hand, Alex's ability to adapt his concept image and concept definition of mutual exclusivity allowed him to logically conclude both directions of the relationship between mutual exclusivity and independence, however correct or incorrect his definition may have been.

In his proof, Alex claimed from his concept definition of mutual exclusivity that each mutually exclusive event would cause the other to have zero probability. This would make the two events "not independent" since his definition of independence necessitated each event to "not affect a subsequent event." Using similar reasoning, Alex concluded that independence implied "not mutual exclusivity." It should be noted however that, despite Alex's focus on "proof for every case" in the first interview, he failed to assert a relationship for the case when one or both events were given to have zero probabilities. The contrast between his assertions about proof and his actions in proving this relationship reflects the "pathological" nature of zero probability cases pointed out by Kelly and Zwiers (1986). Interestingly, this also points to a characteristic of his definitions that may have influenced his thought process: an event with zero probability cannot "happen first" and therefore can neither cause nor affect any other event, as the definitions require.

Betty's was unable to logically assert any certain relationship between the two concepts. This resulted from such strong concept images of independence and mutual exclusivity. More specifically, Betty's personal experiences in the sample spaces allowed her to provide counterexamples to any explicit relationship between the two concepts. Since specific characteristics of sample spaces affected two events' independence, she required information about a sample space in order to make inferences about the events in question. This prevented Betty from generalizing to all cases an explicit relationship between mutual exclusivity and independence, which her proof scheme required.

Recalling the Alex and Betty's general proof schemes (mostly Analytical with slight Empirical and External tendencies), we consider how these related to their use of definition. Alex's dynamic concept image and unsolicited production of the lemma for the definition of mutual exclusivity reflect an Analytical frame of mind that is also geared toward finding and asserting relationships between the two concepts. We see with Betty, however, that a mostly Analytical proof scheme alone is not sufficient to connect the relationships between mutual exclusivity and independence. This is because her conceptions of the two ideas were so powerful that she was comfortable using the four cases from her exploration to show that no relationship existed. From these two cases, we see that little inference can be made about how a student uses definition relative to Harel and Sowder's (1998) proof schemes.

But we can also consider these cases with respect to Weber and Alcock's (2004) semantic and syntactic proof productions. Because he produced it immediately after changing his concept definition of mutual exclusivity to more closely resemble his concept definition of independence, we see that Alex's lemma (and therefore responses in the third interview) was a direct result of his comparing the two concept definitions. A syntactic approach to the relationship was not fruitful, however, until he changed his definition. Conversely, Betty's use of previous instantiations (a semantic approach) prevented a definite relationship between the concepts from forming. It is unclear, though, whether Betty even thought her concept definitions might need to be changed. From this, we see some indication that a syntactic approach may play some role in aiding the adaptability of definition and that a semantic approach could be more restrictive.

From this research, we have seen how the adaptability of a student's concept image allows him or her to compare seemingly disparate concepts in new contexts. Here, the phrase "seemingly disparate" reflects the understanding of the concepts from the students' initial points of view. This action reflects Vinner's "interplay between definition and image," but is different in that the participants were not comparing a definition and image of a single mathematical concept, but rather two different but related images (1991, p. 70). This interplay is not addressed in his work, but yields a result similar to that of Vinner's interplay where an adaptation of image allows one to make sense of a perceived relationship. In this case, the adaptation of two images allowed a relationship to be perceived. Conversely, in Betty's case, rigidity restricted her perception of a relationship between independence and mutual exclusivity.

Middle school students bring with them to the classroom powerful, informal resources for reasoning about mathematical ideas. However, little research has examined how these resources can interact with or support skills of mathematical justification. Here, we explore how middle school students consider inductive strategies—the use of examples in proof—when confronted with conjectures. We discuss ways in which these students might reason about mathematical objects like numbers and shapes strategically as they test examples. We argue that critical to such strategic reasoning is flexible application of mathematical and everyday ways of knowing.

Keywords: Reasoning and Proof; Middle School Education

Students bring with them to the mathematics classroom powerful intuitive ways of reasoning based on their everyday experiences interacting with the world. An important goal in mathematics education has been to find ways to leverage these resources or "funds of knowledge" (Moll & Gonzalez, 1997) to support mathematics learning. However, this search has proven to be problematic. Students not only have trouble applying their "school math" knowledge to complex, situated real world problems (e.g., Masingila, Davidenko, & Prus-Wisniowska, 1996; Walkington, Sherman, & Petrosino, 2012), but they struggle to productively use knowledge from their everyday experiences in school-based tasks (e.g., Reusser & Stebler, 1997; Walkington, Nathan, Wolfgram, Alibali, & Srisurichan, in press). A situated perspective on learning acknowledges that the interplay between the practices valued in school and everyday activity is complex, and that these two sets of practices will not always overlap. However, recent work has uncovered ways for students' concrete, situated experiences to support the learning of mathematical formalisms (e.g., Walkington & Sherman, 2012).

One area in which the interaction between everyday experience and formal mathematical knowledge has not been well-examined is mathematical justification. Here, we define justification or proving as "the process employed by an individual to remove or create doubts about the truth of an observation," and emphasize that this process is often based on intuition, internal conviction, and necessity (Harel & Sowder, 1998, p. 243). The importance of the construction and evaluation of mathematical arguments is accentuated in both the Common Core and NCTM standards (CCSSI, 2010; NCTM, 2000). But how are children's intuitive ways of reasoning important when considering mathematical justification, which has been traditionally characterized as a formal and disembodied chain of axiomatic, deductive statements?

Recent research has revealed the *inductive* or *example-based* reasoning strategies that children use when considering mathematical conjectures (Knuth et al., 2011). For instance, when presented with the conjecture "the sum of any two even numbers is even," a student might test different even numbers, like 2 and 20. Some studies have suggested that this kind of reasoning might allow students develop more general arguments (Knuth et al., 2011). Here we will examine how students' everyday and mathematical knowledge interacts with their evaluation of example-based justifications. We argue that students must navigate along a learning continuum as they gain expertise with mathematical arguments, which ultimately leads to flexible and appropriate application of everyday and mathematical knowledge. Gaining an understanding of this continuum, of the ways in which students think about the nature of evidence in inductive justification, may help mathematics educators in better supporting students' learning to prove.

Theoretical Framework

Use of Example Objects in Justification

Many of the problems people face in life resist formal solution. There is no deductive proof for beliefs about friends, nor a valid algorithm for picking a spouse. Instead people must employ inductive reasoning strategies. Some of the most well studied inductive strategies in the cognitive science literature are example-based (see Feeney & Heit, 2007). One way to decide if a person will be a good friend is to compare them to others. But which others? Children and adults employ a number of strategies for selecting good examples in their everyday lives, strategies that often are in line with formal principles of inductive inference.

In mathematics, students also tend to use inductive reasoning when confronted with conjectures (Chazan, 1993; Knuth et al., 2011; Harel & Sowder, 1998). Such reasoning has sometimes been identified as problematic because students may use *only* examples, without moving towards more powerful general arguments. However, examples may still play a critical role in understanding conjectures and constructing more general justifications. For instance, mathematicians use examples as tools when confronted with conjectures (Alcock, 2004). Expert mathematicians (N = 133) indicated they use examples to verify and understand conjectures, generalize from examples to a proof, and seek counter-examples or try to "break" the conjecture (Lockwood et al., 2012). Examples play an important role in the development of proofs.

Typicality and Example Choice in Non-Mathematical and Mathematical Domains

In scientific domains, three principles of example selection (see Osherson et al., 1990) have been identified as useful when drawing conclusions about a class or type: *quantity*—more examples are better than fewer, *diversity*—a wide variety of examples are better than a set of very similar examples, and *typicality*—generic or "average" examples are better than special or "weird" examples. Thus in trying to decide whether all birds have hollow bones, one would want to check many birds, a diverse set of birds, and relatively typical birds. Here we focus on typicality—a typical example shares properties with many members of its class and has few distinctive properties. One challenge in developing accounts of example-based inference is identifying which features are used to compute typicality. In science, people have robust intuitions about features that are "biologically relevant." That cats and goldfish are both kept as pets does not seem relevant in determining their biological relatedness. However, untangling everyday notions of typicality from typicality based on properties of *mathematical* objects may be more difficult.

In previous work, we found it useful to distinguish two types of mathematical typicality (Williams et al., 2011). The *everyday typicality* of an object is how common it is in everyday life—i.e., how many experiences a person has with objects of that kind in their day-to-day activity. The *mathematical typicality* of an object is how typical it is when its mathematical properties are considered in relation to the properties of *all* objects of that type. The number "0" would be a mathematically *atypical* number because it has properties that no other integers share (e.g., additive identity). The number 322 might be a *typical* number in a mathematical context because it does not have many properties that make it distinct from the set of whole numbers. Middle school mathematics is an interesting site for exploring these two types of typicality, as many of the objects that are highly *atypical* mathematically (e.g., numbers like 0 or 1) are highly *typical* in everyday life. Students may struggle to reconcile these two different conceptions of typicality. But do typicality judgments really matter when considering mathematical justifications?

When the expert mathematicians (N = 133) were asked how they choose examples when exploring conjectures, many responses referenced the typicality of their examples. They reported choosing common examples with no special properties or generic or general examples, unusual, obscure, or "tricky" examples, examples with special properties, and examples that are boundary cases (Lockwood et al., 2012). These mathematicians seemed to have found ways to use typicality *strategically*—to allow typicality judgments to support and inform their exploration of mathematical conjectures. But what about middle school students? Do they consider typicality when exploring conjectures with examples, and if so, what type of typicality?

We presented middle school students (N = 20) with conjectures about numbers, and students reported purposefully varying the typicality of the examples they chose when testing conjectures. Students reported trying to test both typical and atypical numbers, or trying to test unusual numbers to see if the conjecture would hold (Cooper et al., 2011). Students' reports of what made a number typical varied—some were attuned to whether the number was prime or the relative size of the number, while others identified typical numbers based on their everyday experiences. Overall, it seemed that students were reasoning strategically about the typicality of their examples. In the present study, we implement a large-scale survey to assess how students use mathematical and everyday typicality when considering examples in justification.

Research Questions

Our research questions are: (1) How do middle school students use typicality *strategically* when considering examples? and (2) How are students' conceptions of mathematical typicality consistent or at odds with their everyday notions of typicality?

There are two dimensions along which middle school students might demonstrate using mathematical typicality strategically. First, students might realize that conjectures that hold for mathematically atypical objects (i.e., objects with mathematically special properties) may not hold for all objects. For instance, a conjecture holding for the number "1" may not be strong evidence that the conjecture would hold for all numbers, since 1 has special properties (e.g., multiplicative identity). However, this conception of mathematical typicality might be directly at odds with students' everyday notions of typicality, because although 1 is highly atypical in a mathematical context, it is highly typical in students' everyday life. Thus if typicality is used strategically, we might see a reversal. Students may recognize that a number like 1 is highly *atypical* in a mathematical context, despite being highly *typical* in an everyday context.

Second, students might use mathematical typicality strategically if they realize that superficial features of a mathematical object are not particularly important when considering whether conjectures that hold for that object will hold for most objects. Students might realize that when a parallelogram is in a non-standard orientation, this is unlikely to impact most mathematical conjectures in middle school mathematics. Similarly, a student might realize that the relative size of a number (e.g., 3 or 103) or the cultural significance of a number (e.g., 13) might not be particularly important. This strategic use of mathematical typicality may be at odds with everyday notions of typicality—in daily life, students are accustomed to seeing shapes in standard orientation and working with relatively small numbers, so objects that do not conform to these experiences might be considered atypical. Thus we argue that strategic use of typicality requires students to flexibly switch between their "everyday" and "mathematical" lenses.

Methods

A total of 475 middle school students (46% female) from a suburban middle school in a Midwestern state were included in the study. Students were distributed across grades 6 (144 students), 7 (160 students), and 8 (163 students), and mathematics classes used reform texts. The school demographics were 48% Caucasian, 21% African American, 14% Asian, 11% Hispanic, and 1% Native American, with 37% low income, and 10% English Language Leaners (ELL).

A survey was administered to all participants during their normal math classes. Each survey contained questions relating to two of four different domains: numbers, parallelograms, triangles, and birds (birds are omitted here). For each domain, students were presented with mathematical objects or items in that domain (e.g., a small equilateral triangle or the number "6") and asked to rate each item's typicality on a 1–7 scale in a mathematical context and in an everyday context. Figure 1 gives an example of the instructions students received on the survey (left) and actual survey items (right). Mathematical objects were selected by the researchers to either cover the space of possible mathematical properties in the domain (e.g., the parallelogram in Figure 1 is a rectangle; we also included squares, rhombi, etc.), or to be completely devoid of any property that would distinguish the object mathematically (e.g., a long, skinny rhomboid with no 90 degree angles). The order of the 9 items within each context and the 2 domains was randomized.

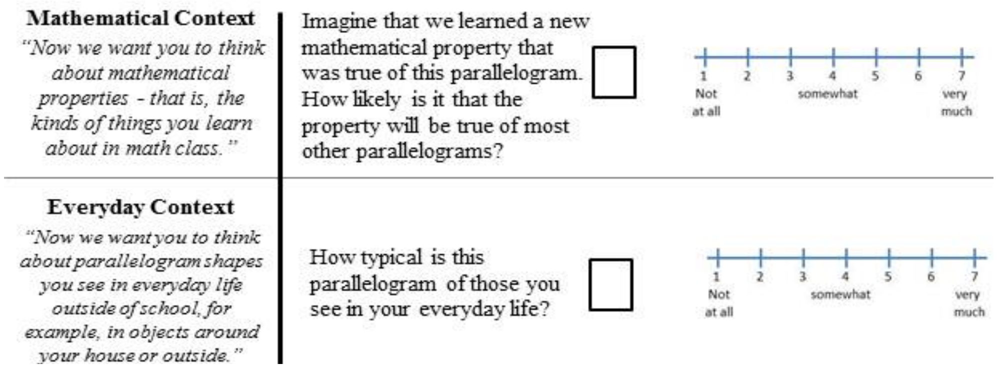

Figure 1: Example of questions on middle school survey

Table 1: Mathematical (italics) and Everyday (underline) Properties Entered into Model

Numbers	Parallelograms	Triangles
Prime or perfect square *Power of 2 or 10* *Multiple of 5 or 10* *Identity properties (i.e., 0 or 1)* Relative magnitude (small or large)	*Square, rectangle, or rhombus* Size (small, large, "skinny") Orientation (standard, non-standard, left-leaning)	*Isosceles, equilateral, scalene* *Obtuse, acute, right* Size (small, large, "skinny") Orientation (standard, non-standard)

The data were analyzed using hierarchical linear regression models (Snijders & Bosker, 1999) where repeated observations were nested within students nested within teachers. Three different models, one per domain, were fit to the data. Random effects included student, teacher, and which mathematical object (i.e., which specific number or shape) the question referenced. Fixed effects included context (Figure 1), the mathematical and everyday properties of the object (Table 1), and the interaction of these two terms. Properties that did not have significant main effects or interactions with context were removed. Fixed effects for gender and grade were not significant in any of the models. Mathematical and everyday properties of numbers, triangles, and parallelograms entered into the model are in Table 1. These properties were chosen based on the mathematical knowledge of a team of mathematicians, psychologists, and mathematics educators and former K–12 teachers, as well as based on previous results from our studies of inductive reasoning (Knuth et al., 2011; Cooper et al., 2011).

Results and Discussion

Number

As can be seen from Table 2, across mathematical and everyday contexts, students rated small numbers ($p < .001$), numbers ending in 5 ($p = .020$), and powers of 10 as being more typical ($p < .001$). This suggests two ways in which students might *not* be considering mathematical typicality strategically. First, students seemed to believe that conjectures that hold for mathematically-special numbers, like powers of 10 or multiples of 5, would be *more* likely to hold for other numbers. From a mathematical standpoint, properties that hold for these numbers may be *less* likely to hold for other numbers. Second, students rated that conjectures that held for small numbers were *more* likely to hold for other numbers. Here, students may have been considering a superficial or mathematically irrelevant feature when considering mathematical conjectures. In both cases, students' everyday notions of typicality, their familiarity encountering small numbers, multiples of 5, and powers of 10 in their lives, may have influenced their mathematical notions of typicality—whether it makes sense for properties that hold for these numbers to hold for most other numbers. We also see no evidence of the desired reversal for mathematical typicality that might evidence strategic thinking. Students did not indicate that numbers with special properties—like prime numbers—were atypical in a mathematical context.

Table 2: HLM Analysis of Students' Typicality Ratings for Number

	Estimate	**S.E.**	***t***	***p***	Sig.
(Intercept)	3.61	0.46	7.70	< .001	***
Mathematical Context	(ref.)				
Everyday Context	0.19	0.17	1.10	0.274	
Large	(ref.)				
Small	0.77	0.17	4.42	< .001	***
Ends with 5	0.68	0.27	2.55	0.020	*
Power of 10	1.32	0.25	5.39	< .001	***
Prime	-0.17	0.22	-0.76	0.445	
Identity (0 or 1)	-0.37	0.35	-1.05	0.298	***
Everyday Context: Small	0.59	0.09	6.67	< .001	***
Everyday Context: Prime	0.33	0.11	3.07	0.001	**
Everyday Context: Identity	0.55	0.16	3.44	< .001	***

* $p < .05$. ** $p < .01$. *** $p < .001$.

However, looking at the interaction terms in Table 2, we do see evidence that students are at times using mathematical typicality strategically. First, although students rated small numbers as typical regardless of the context, being small had a larger impact on typicality in an everyday context ($p < .001$). This suggests that students may realize that superficial characteristics, like relative size, are less important when considering a number mathematically. Second, students found both prime and the identity numbers more typical in an everyday context ($p = .001$ and $p < .001$). Thus although students expressed their familiarity with these numbers by giving them high everyday typicality ratings, this familiarity did not inflate mathematical typicality ratings.

Parallelograms

Across mathematical and everyday contexts, students rated squares as being more typical (Table 3; $p = .015$). This again suggests that students might not be considering mathematical typicality strategically—these ratings suggest that properties that hold for squares are more likely to hold for other parallelograms. Students' everyday familiarity with squares might be interfering with viewing a square as a mathematical object that has special properties (e.g., 90° angles). We again do not see evidence of the desired reversal—students do not rate mathematically special parallelograms (like squares) as being less typical in a mathematical context.

Table 3: HLM Analysis of Students' Typicality Ratings for Parallelograms

	Estimate	**S.E.**	***t***	***p***	Sig.
(Intercept)	2.88	0.61	4.7	< .001	***
Mathematical Context	(ref.)				
Everyday Context	0.39	0.27	1.41	0.165	
Standard Orientation	0.43	0.24	1.78	0.080	
Large	(ref.)				
Small	0.19	0.55	0.34	0.710	
Leans Left	-0.51	0.34	-1.52	0.134	
Square	0.88	0.34	2.58	0.015	*
Rectangle	0.63	0.32	1.99	0.055	
Rhombus	0.57	0.40	1.44	0.154	
Everyday Context: Standard Orientation	0.49	0.11	4.49	< .001	***
Everyday Context: Small	-1.04	0.25	-4.20	< .001	***
Everyday Context: Leans Left	0.52	0.15	3.48	< .001	***
Everyday Context: Square	0.55	0.15	3.64	< .001	***
Everyday Context: Rectangle	1.31	0.14	9.30	< .001	***
Everyday Context: Rhombus	0.56	0.18	3.14	0.001	**

* $p < .05$. ** $p < .01$. *** $p < .001$.

However, looking at the interaction terms, we see considerable evidence that students can use mathematical typicality strategically. Although students rated squares as being typical regardless of the context, squares were considered even more typical in an everyday context ($p < .001$). Similarly, students rated rectangles and rhombi as more typical in an everyday context ($p < .001$ and $p = .001$). Students seemed to recognize that although these shapes were common in their everyday lives, this consideration should not inflate their ratings when determining whether properties that hold for these shapes will hold for other shapes. Students also allowed superficial properties of parallelograms—like size and orientation—to influence their everyday typicality ratings ($p < .001$), but not their mathematical typicality ratings.

Triangles

Across mathematical and everyday contexts, students found equilateral, isosceles, and standard orientation triangles more typical (Table 4; $p = .037$, $p = .004$, $p < .001$, respectively) and skinny triangles less typical ($p = .002$). This suggests that students may not be using mathematical typicality strategically. Students expressed that conjectures that hold for special triangles like isosceles and equilateral triangles are more likely to hold in general, and that conjectures that hold for skinny or non-standard orientation triangles, superficial considerations, are less likely to hold in general. Here, again, students do not seem to be differentiating between everyday typicality (the commonness of equilateral and isosceles triangles in their everyday life, and the rarity of skinny and non-standard orientation triangles) and mathematical typicality (whether conjectures that hold for certain triangles are likely to hold for other triangles). We also see no evidence of the desired reversal—students did not rate mathematically special triangles as atypical in a mathematical context. However, looking at the interaction terms, students seem to sometimes reason strategically about mathematical typicality. Although students rated equilateral triangles as typical regardless of context, they were even more typical in an everyday context ($p = .002$). Further, right triangles were typical in an everyday context ($p = .004$), but students did not let everyday familiarity inflate ratings in a mathematical context. Students may realize that although these triangles are highly salient in their everyday experiences, this familiarity should not affect whether conjectures that hold for these triangles will hold for other triangles.

Table 4: HLM Analysis of Students' Typicality Ratings for Triangles

	Estimate	S.E.	*t*	*p*	Sig.
(Intercept)	4.98	0.41	12.16	< .001	***

Summary and Conclusions

We examined whether middle school students use typicality *strategically* when considering conjectures, and found mixed results. When numbers or shapes had special mathematical properties, students considered them *more* typical in a mathematical context. However, properties that hold for these special objects should be *less* likely to hold for other objects. In other cases, superficial characteristics impacted whether students thought that conjectures that held for an object would hold for other objects. Both behaviors suggest that students might be conflating everyday typicality with mathematical typicality. Despite these results, students did sometimes distinguish mathematical and everyday contexts; they appropriately recognized the relevance of mathematically special and surface-level properties in each domain. This suggests that students have important resources for using typicality strategically, and for differentiating how objects should be considered in the math classroom and everyday life. But are these behaviors really characteristic of mathematical expertise? We recently presented the survey to 339 mathematicians. Initial analyses suggest that mathematicians do use typicality strategically in the ways we predicted, and they recognize everyday and mathematical typicality as two distinct entities that are often in opposition. This stands in contrast to how middle school students considered typicality, as they had difficulty reconciling mathematical and everyday contexts.

Our results suggest that students must negotiate an important learning continuum regarding mathematical conjectures. Initially, students appear to have difficulty reconciling their mathematical experiences with numbers and shapes with their concrete, salient everyday experiences. However, expertise in mathematics is characterized by flexible application of formal mathematical knowledge and everyday experience, based on the features of the problem and the social context. Thus students should be encouraged to critically reflect on how mathematical objects like numbers and shapes are considered differently in the mathematics classroom when exploring conjectures, compared to interacting with these objects in day-to-day life. Our work suggests that mathematicians are able to move flexibly between each of these two viewpoints, and use both examples and typicality judgments as resources in their work. Strategic use of examples and considerations of typicality may thus be important in helping students think more critically about the nature of mathematical evidence and in moving students towards making important generalizations about why mathematical conjectures hold, both of which ultimately could support deductive reasoning and formal mathematical proof.

The role of reasoning and proof in mathematics is undeniably crucial, and yet research in mathematics education has repeatedly indicated that students struggle with proof production. Our research shows that proof activities can be illuminated by considering action and gesture as a modality for crucial aspects of mathematical communication. We share two examples that highlight the importance of gesture and action in supporting students' mathematical proof production. We conclude by discussing the implications of our work for already existing schemes for classifying proof.

Keywords: Geometry and Geometrical and Spatial Thinking; Reasoning and Proof; Instructional Activities and Practices

Research in mathematics education has consistently shown that students, as well as pre-service and in-service teachers, struggle with constructing, interpreting, and evaluating proofs (Knuth, 2002; Healy & Hoyles, 2000; Chazan, 1993). Such research is deeply concerning, as proof is "an essential component of doing, communicating, and recording mathematics" (Schoenfeld, 1994, p. 74). Yet these results are perhaps unsurprising, as only recently has mathematics education begun to emphasize proof in the curriculum (e.g., National Council of Teachers of Mathematics [NCTM], 1989, 2000). NCTM recommends that proof and reasoning be taught from prekindergarten to 12th grade. The reasoning and proof Process Standards most relevant to our research include: the investigation of mathematical conjectures; the development and evaluation of mathematical arguments and proofs; and the use of "various types of reasoning and methods of proof" (NCTM, 2000, p. 322). Building upon NCTM's work, the new but widely-adopted *Common Core State Standards for Mathematics* identify constructing viable arguments and critiquing the reasoning of others as critical skills for students to learn across grade levels, while the standards for high school geometry specifically call for students to construct mathematical proofs of theorems (Common Core State Standards Initiative, 2010).

As the field continues to struggle with teaching proof, it is worth considering alternative forms of support for students. Healy and Hoyles (2000) found that correct proof production is easier for students when they can engage in building narrative forms, rather than algebraic ones. Various authors have examined the role of digital geometry environments in supporting the development of proof (Chazan, 1993; Hoyles & Jones, 1998). Here, we take a novel approach by looking to theories of embodied cognition, examining alternative methods of supporting proof production and communication through the modalities of action and gesture. We place ourselves on PME-NA's learning continuum, as we are using an innovative method of examining ***student learning*** during proof production. This paper makes no claims as to the newness of action and gesture in supporting mathematical learning and communication—in fact, it is the ubiquitous yet overlooked role of action and gesture to which we wish to draw attention. Consequently, we contribute a new lens in order to reveal heretofore invisible proofs.

In this paper, we begin by briefly defining the practice of mathematical proof, and then explore relevant research on embodied cognition, action, simulated action, and gesture. We then share two excerpts of students using gesture and action to support proof from a recent study we conducted. In these excerpts and others, we find that the practice of proof is greatly enriched by considering both verbal and physical modalities. Finally, we share our future plans for this research, and examine the potential implications for teaching proof.

Theoretical Framework

Mathematical Proof and Justification

We conceptualize mathematical justification using Harel and Sowder's (1998) proof scheme, and our intended "mode of thought" (e.g., the modality of mathematical observation and reflection; p. 240) is body-based action and gesture. Harel and Sowder define *proving* as "the process employed by an individual to remove or create doubts about the truth of an observation" (p. 241). They further identify two subprocesses of proving: ascertaining (the proof activities an individual engages in when attempting to convince themselves); and persuading (the proof activities an individual engages in when attempting to convince others). As proof occurs in a social context where the argument must be communicated to an audience effectively and convincingly, we argue that each subprocess is essential when considering the learning of proof.

Harel and Sowder's (1998) proof scheme includes multiple categories and levels for classifying mathematical proofs. For our purposes, we focus on the *analytical>transformational* proof scheme, which involves "operations on objects and anticipations of the operations' results" (p. 259). In particular, when students are utilizing the analytical>transformational proof scheme, they are *transforming* a mathematical object or concept by varying some relationships purposefully in anticipation of certain results, observing the resulting changes, and deducing mathematical properties accordingly. Although this is a powerful and effective method of proving for students to learn, until now little research has examined how gesture and body-based action can play a role in supporting these dynamic transformations.

Gesture and Action

Theories of embodied cognition suggest that cognitive processes are not algorithms acting upon amodal mental systems, but rather they are bound up with the action and perception systems of the thinker (Barsalou, 1999; Barsalou, 2008; Glenberg & Robertson, 2000; Wilson, 2002). These action and perception systems, in turn, are not only guided by cognitive processes, but they also constitute and transform those processes. In other words, gestures and actions are not simply byproducts of cognition—they are coupled to cognitive processes (Shapiro, 2011) and they influence cognition. For example, gesture accompanied by speech may elaborate upon the thoughts possessed by the speaker (contributing additional information not contained by the speech acts), as well as feed back into processes that transform the speaker's cognition (Alibali & Kita, 2010; Goldin-Meadow & Beilock, 2010; Nathan & Johnson, 2012).

Gestures are a particular form of action that represent the world, rather than acting upon the world directly (Goldin-Meadow & Beilock, 2010). Furthermore, gestures are more than mere movements; as McNeill (1992) says, they "can never be fully explained in purely kinesthetic terms" (p. 105). Gesture is tied tightly to action, in our view, following Hostetter and Alibali's (2008) conceptualization of gestures as "manifestations of the simulated actions and perceptions that underlie thinking" (p. 508). Gestures are symbols that serve both to communicate and to affect the gesturer's cognition. Whether participants' gestures are produced as communicative or cognitive acts may appear to be a crucial distinction that we are in need of making. However, Hostetter and Alibali (2008) determine such a distinction to be somewhat false:

> … gestures are a natural by-product of the cognitive processes that underlie speaking, and it is difficult to consider the two separately because both are expressions of the same simulation…. [G]esture and speech may express different aspects of that simulation … but they derive from a single simulation; thus, they are part of the same system. (p. 508)

Consequently, we use verbal and gestural data side by side in our analyses for the purpose of triangulating on participants' cognition. By considering multiple modalities in this fashion, we are able to gain access to elements of ascertaining (convincing oneself) and persuading (convincing others) proof activities that would otherwise remain hidden in plain sight.

Gesture, Action, and Mathematics

Learners' gestures and actions have been found to support mathematics learning in many previous studies (e.g., Glenberg et al., 2007; Nathan, Kintsch, & Young, 1992; Alibali & Nathan, 2012; Alibali & Goldin-Meadow, 1993), and are "involved not only in processing old ideas, but also in creating new ones" (Goldin-Meadow, Cook, & Mitchell, 2009, p. 271). In our research, we build upon this prior work while venturing into new territory: the role of action and gesture in supporting proof production. In the following section, we discuss gesture and mathematics in a general fashion, and draw out some threads that are particularly relevant to the domain of proof.

In some cases, gesture or body-based action may allow students to manipulate conceptual objects in a fashion similar to dynamic geometry software. In these systems, students can build objects that maintain invariant relationships even as the object is manipulated and acted upon (e.g., when a single vertex is moved on a triangle, the connected sides will stretch to meet the new location of the vertex, always keeping a triangular shape) (Hoyles & Jones, 1998). These environments can support students in generating and verifying conjectures about the relationships contained within these objects. Similarly, the real-world context within which action and gesture are produced can give feedback about the legitimacy of the constructs evoked by the mathematical conjectures. Whereas with paper and pen impossible triangles can be constructed (e.g., a triangle where the hypotenuse is labeled as longer than the sum of the remaining two sides; see Table 1 for the relevant task), using one's body to construct the triangle can constrain a student from expressing such an impossibility.

One of the features of dynamic geometry software is that it affords the possibility of testing a large number of examples while maintaining the relevant invariant features. Gesture and simulated action may have a similar affordance. Hostetter and Alibali (2008) note that, "Because mental images retain the spatial, physical, and kinesthetic properties of the events they represent, they are dependent on the same relationships between perceptual and motor processes that are involved in interacting with physical objects in the environment" (p. 499). In other words, mental simulation, as evidenced through action and gesture, also allows such testing. We hypothesize that action and gesture can influence cognition in a way that is soundly based upon the physical experience of space within the world. In this way, action and gesture may support analytical>transformational proof production.

Given the potential influence of action, gesture, and simulated action upon cognition, we designed an experiment to examine the role of action and gesture upon mathematical proof production and communication. In the following section, we share our methodology and mathematical conjecture tasks.

Methods

The data reported in this paper were drawn from a larger study of the role of action and gesture in proof. Participants were 36 students (22 F; 14 M) at a large Midwestern university enrolled in a psychology course, and they received partial class credit for participating. The average age of our participants was 20 years old (15 freshmen; 9 sophomores; 7 juniors; 4 seniors; 1 part-time student).

In one-on-one interviews, participants were asked to justify a variety of mathematical theorems from number theory and geometry; here we report on the two conjectures shown in Table 1. Our research question was: *How are gestures and actions used in the ascertaining and persuading phases of proof?* In the larger study (not reported here), we encouraged participants to produce particular sorts of gestures for some conjectures. However the analysis here focuses only on cases in which students spontaneously gestured and used action when proving (i.e., their behavior was not manipulated).

Table 1: Conjectures

Conjecture 1: Gears	Conjecture 2: Triangle Inequality
An unknown number of gears are connected in a chain. You know which direction the first gear turns. How can you determine what direction the last gear will turn? Provide a justification for your answer.	*Mary came up with the following conjecture:"For any triangle, the sum of the lengths of any two sides must be greater than the length of the remaining side." Provide a conceptual justification as to why Mary's conjecture is true or false.*

We intentionally created a context in which participants would be likely to produce gestures while reasoning mathematically by setting up the discourse context (Hostetter & Alibali, 2008) in various ways. First, we emphasized the talk-aloud nature of the experiment to all of our participants, and we verbally prompted them to reason out loud if they fell silent. For some, we removed pen and paper; and for others we also removed the chair so that they (and the interviewer) had to remain standing. Furthermore, by designing the protocol to give no feedback to the participants, we emphasized *innovative* proof instead of *imitative*, and shifted the mode of thought to mental and physical by lessening the availability of pen and paper.

Each participant was videotaped, with the camera(s) capturing both small and large gestures. The data were analyzed in Transana, a qualitative analysis software program, and team members selected various gesture segments with the units of analysis based on each mathematical conjecture. In particular, we used *multimodal analysis* techniques (Alibali & Nathan, 2012; McNeill, 1992), and coded how each student used action and gesture during the ascertaining and persuading phases of their proof (Harel & Sowder, 1998).

Results

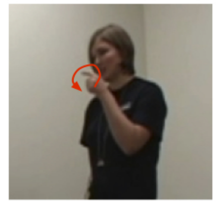
Our first example shows how simulated action (manifested through gesture) can illuminate the ascertaining phase of proof. The second example demonstrates the role of paired gesture and speech during the persuading phase. Our presentation we will provide additional examples.

Simulated Action Illuminates Ascertaining

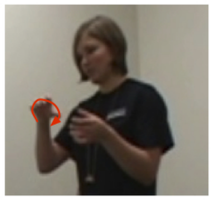
To illustrate the illumination of proof by simulated action, we share an excerpt from the Gears conjecture (Table 1), as the participant leverages her body as a tool for simulating the actions of the gears and identifying parity (shown in Figure 1). The excerpt contains both ascertaining and persuading phases of the proof, and is annotated as such.

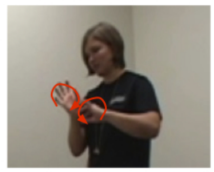
1 **Well, if you know which direction the first gear is turning, then you also know that the second gear must to be turning in the opposite direction,**

(Ascertaining) Uses her hands to replicate the turning of a gear



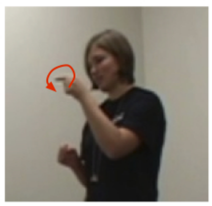
2 **Because one gear turning would push the other gear...**

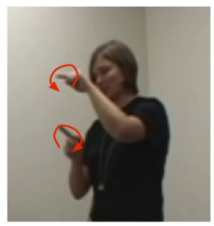




(Ascertaining) Uses both her hands to simulate the movement of two gears turning against each other

3 **See if one gear was turning this way, then the spokes on it would push...**

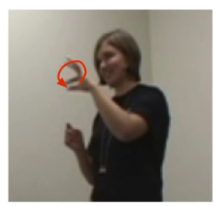


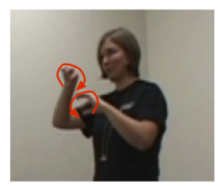


(Ascertaining) Uses her hands to simulate the spokes of one gear pushing the second gear

4 **If one gear was turning like that, then the spokes would push the other gear in the opposite direction, so you would know that every other gear from the first gear was turning the same direction as the first gear.**

(Persuading) Uses her hands to simulate the movement of two gears as she solves the conjecture.





5 **So all the odd gears would be turning in the original direction and all the even gears would be turning in the opposite direction. So if the last gear was odd it would be turning in the original direction and if the last gear was even it would be turning in the opposite of the original direction.**

Figure 4: Simulated action illuminates ascertaining

Paired Gesture and Speech Persuading

To illustrate the pairing of gesture and speech to support persuading in embodied proof, we examine an excerpt that occurs after a participant has solved the Triangle Inequality conjecture (Table 1) and has shifted into the persuading phase of the proof (Figure 2). The verbal element of the proof provides a specific example, as simultaneously the gestural components communicate the generalizability of the participant's proof.

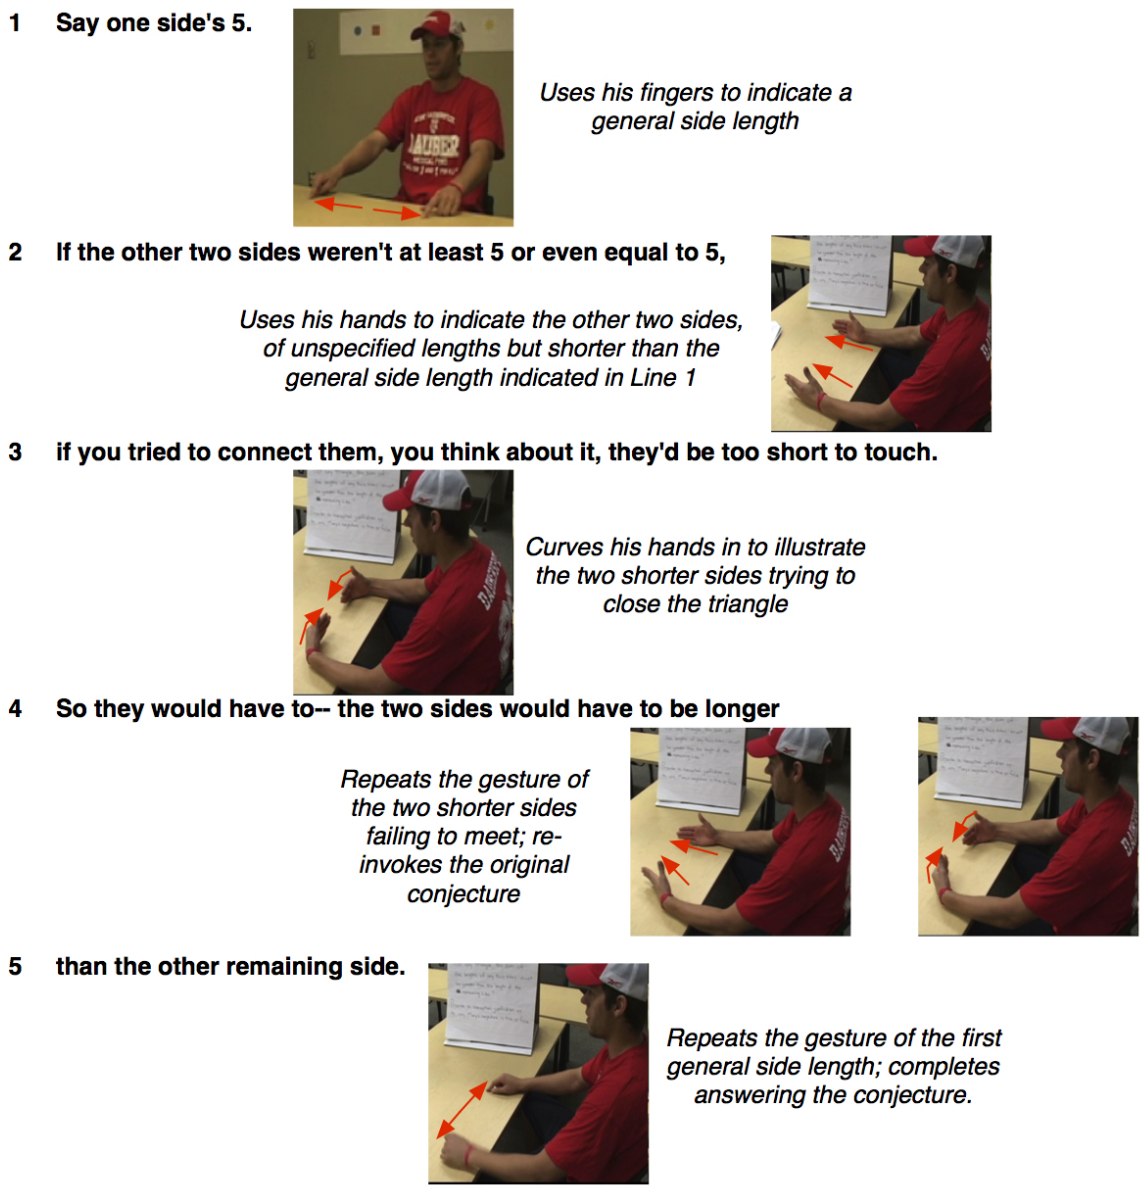


Figure 2: Paired gesture and speech persuading

In Figure 2, the verbal and gestural components are woven together to provide a complete proof. Attending only to the verbal proof elements would result in an incomplete empirical justification, as the participant would appear to be basing his entire argument upon testing a single (and incompletely described) triangle. However, in considering the gestures, we gain insight into the participant's full argument that goes beyond empirical, into analytical and even axiomatic proof schemes—the realms of a mathematically legitimate proof. It is through multimodal communication of gesture paired with speech that the student presents the most compelling and persuasive case for supporting his conjecture.

Discussion

These two examples highlight the multi-modal nature of proof, and show that understanding proof production can require attending to more than just students' verbal and written work. In Figure 1, the participant's embodied account reveals how she relies on an early instance to establish a conjecture about gears that is sufficiently general to support a deductive proof scheme. In Figure 2, the persuading phase offered might seem superficial (overly empirical) as a strictly verbal account. However, the participant's accompanying gestures reveal a corroborative proof scheme that is analytical in the sense that it relies, not on the particular lengths or topology, but their structural role. At the same time, it is transformational in how it utilizes actions to support the goal of portraying the impossibility of any triangle that rejects the premises.

These are not rare examples from our data, but rather they are characteristic of many other proof schemes we observed. Alongside our exploration of the different modalities of proof, we are examining various ways that gesture and action can support mathematical learning and, consequently, proof production. Although the data reported here come from proofs that participants spontaneously generated, interventions that manipulate action and gesture show promise for supporting analytical>transformational proof production (Walkington et al., 2012). As many students have difficulty producing traditional deductive proofs, preferring inductive empirical reasoning (Chazan, 1993; Healy & Hoyles, 2000; Hoyles & Healy, 1999, 2007), gestures and actions may provide an accessible bridge between the two. The potential of simple physical movements to support mathematical understanding is vast—and a crucial new area of study, given the importance of proof to the mathematical community and the general difficulty of engaging students in proof practices.

Conclusions

The implications of this emerging research on embodied cognition are profound for mathematics education in general, and the teaching of mathematical proof in particular. Action and gesture provide another modality for mathematics learning and expression, which may particularly support those students who struggle with the abstract notation traditionally used with proof. Extending the examination of proof production into gesture and action allows us to conceptualize a more complete model of cognition (Shapiro, 2011), and consequently allows us to design new activities that more coherently account for different strategies of proof production.

Our research provides a starting point for those examining mathematical proof through the modalities of action and gesture, and we continue to research the impact of action and gesture upon proof production. This work raises an important question: How does an embodied account influence earlier proof frameworks (e.g., Harel & Sowder, 1998; Healy & Hoyles, 2000)? Our next step is to answer exactly that question, and provide a multidimensional framework that incorporates a proof scheme with a spectrum of gesture, action, and proof.

Acknowledgments

Many thanks to Dan Klopp for his video camera and digitizing skills during this project! This work is funded by the National Science Foundation (REESE) grant no. DRL-0816406 to the last two authors.

A DEVELOPMENTAL PERSPECTIVE INTO STUDENTS' CONTEXTUALIZATION OF PROBLEM SOLVING

Jonathan Bostic

bosticj@bgsu.edu

Sean Yee
California State University – Fullerton
syee1@kent.edu

The purpose of this paper is to investigate students' contextualization of problem solving, not the problems. This study draws on the naturalistic paradigm and uses a developmental perspective to explore students' representations and metaphors used during problem solving. Students of comparable abilities employed similar representations, tended to use analogous metaphors during problem solving, and perceived solutions as outside of a problem's context.

Keywords: Linguistics; Problem Solving; Reasoning and Proof

Introduction

Problem solving is central to mathematics and instruction should give students daily experiences with it (Kilpatrick, Swafford, & Findell, 2001). Prior problem-solving experiences including teachers' scaffolding or suggestive language influence students' problem-solving behaviors and perceptions (Lesh & Zawojewski, 2007). The aim of this paper is to understand how students' contextualize problem solving. We illuminate relationships between students' problem-solving performance and experiential expressions via metaphors and representations employed during problem solving.

Related Literature

Embodied Cognition

The theoretical framework for this study stems from the embodied cognition perspective (Lakoff & Núñez, 2000). Students' problem solving is influenced by the cognitive network (i.e., beliefs and academic knowledge) and external relationships with the environment and other individuals (Lesh & Zawojewski, 2007). Prior experiences are difficult to communicate at times for teachers and students, but linguistic tools, such as metaphors, used by students can be rich with representational elements (Kövecses & Benczes, 2010). Metaphors denote one figure of speech as another figure of speech (Merriam-Webster, 2011). They embody experiences and are a means to support transfer through language, thought, and action.

Problem Solving and Representations

A problem is a developmentally appropriate challenge for which a problem solver has a goal but the means for achieving it are not immediately apparent (Schoenfeld, 2011). It requires making sense of the problem and the involved decisions to achieve the desired goal (Schoenfeld, 2011). When solving a problem, the existence of "a" solution or "the" solution is uncertain. Moreover, a pathway to such solutions is unclear (Schoenfeld, 2011). Research on students' problem solving indicates that prior experiences and knowledge, beliefs and dispositions, and culture play a huge role in how individuals approach problem solving (Lesh & Zawojewski, 2007).

Representations characterize a product or process (Goldin, 2002), or more specifically "an item that corresponds in an iconic sense to another item, an 'original' to which it refers" (von Glasersfeld, 1985, p. 2). Re-presentation characterizes a "conceptual construct that has no explicit reference to something else" (von Glasersfeld, 1985, p. 2). This distinction is critically linked to a contextualized understanding of mathematics (Goldin, 2002). Learners encode familiar contexts as internal representations such as beliefs, competencies, and expectations (Goldin, 2002). These internal representations are (a) based on everyday experiences, (b) shared by many, (c) extensively linked within one's cognition, (d) developed prior to learning mathematics in a context, and (e) supported by one's culture (Goldin, 2002). Thus, prior experiences greatly impact students' perceptions (i.e., representations) of problem solving (Schoenfeld, 2011).

Metaphors

As representations associate one item to an iconic other, the linguistic, cognitive counterpart is the conceptual metaphor. Current conceptual metaphor theory includes the literal component and conceptual component (Lakoff & Johnson, 2003). The literal component is the actual literal expression, while the conceptual metaphor is a mapping between two objects: the source and the target domain. The source domain is the experientially known domain and the related concept is the target domain. For example, "Your theoretical framework has a solid foundation" would involve the conceptual metaphor of "THEORIES ARE BUILDINGS." The target domain is theoretical framework and source domain is building. Variations of being (e.g., are and were) indicate unidirectional flow from the target to source domain. Conceptual metaphors can be classified in one of three hierarchical categories: structural, ontological, and orientational (Kövecses & Benczes, 2010; Lakoff & Johnson, 2003). Structural metaphors tend to describe a complex concept, such as time or understanding, in terms of a concrete experiential object, such as a limited resource (i.e., "DON'T WASTE MY TIME"). Ontological metaphors employ less structured target domains and necessitate a new defined reality to understand the shared experience. Personifications are regularly ontological. Orientational metaphors broadly conceptualize a specific direction inherent in human development. For example, the literal expression, "Things are looking up" demonstrates the conceptual metaphor of GOOD IS UP. Conceptual metaphors are used to map how individuals' cognitive domains are related to expression of their experiences (Lakoff & Johnson, 2003).

The relationship between the experiences of the teacher and student are vital to mathematics education. Teachers and students share an experiential set: solving mathematics problems. However, the student's and teacher's perspectives of what constitutes mathematical problems and/or solutions are complex in structure (Lakatos, 1976). Metaphors are culturally designed to articulate these implicit perspectives, and they have been found to encourage and incite cognition (Lakoff & Núñez, 2000).

Research Questions

The two research questions are: (1) How do middle and high school students' problem solving compare? (2) How do middle and high school students contextualize problem solving?

Method

Research Design

This study drew on a naturalistic paradigm and phenomenological inquiry to closely examine students' contextualization of problem solving (Short, 1991). Researchers employed a developmental perspective to explore students' problem solving.

Participants

Six participants for this qualitative study were representatively selected from investigations with larger samples. Data from sixth-, tenth-, and eleventh-grade students were collected during a think aloud conducted during two prior studies. Three middle and high school students from each study were selected. One sixth- and eleventh-grade pair (i.e., Theta and Kappa) performed above average compared to participants in the larger samples. A second pair had average performance (i.e., Beta and Lambda) and a third pair performed below average compared to peers (i.e., Gamma and Mu). Pairs two and three involved sixth- and tenth-grade students.

Data Collection

All participants completed a think aloud during a 40-minute period, which was video recorded. Sixth-grade participants completed four problems and high school participants responded to three problems. All participants were asked to solve developmentally appropriate problems using materials (e.g., manipulatives and markers) provided during the interview.

Data Analysis

Three analyses were conducted with videotapes and interview transcripts. First, students' responses were scored as correct or incorrect/no response by two mathematics educators. Correct responses had (a) solutions that answered the problem, and (b) representation(s) that supported the solution. Interrater agreement (IRA) was used for the first and second analyses and calculated using r_{wg}. Second, correct responses were coded using a representation coding protocol (Lesh & Doerr, 2003). Representation categories included symbolic, pictorial, tabular, verbal, concrete model, and mixed. IRA for these analyses was ideal, $r_{wg} = 1$. The third analysis was conducted by one researcher and intended to categorize students' conceptual metaphors used during the think aloud. The three conceptual metaphors were structural, ontological, and orientational (Kövecses & Benczes, 2010; Lakoff & Johnson, 2003).

Results

Participants with comparable performance tended to use similar representations. Theta and Kappa answered more problems than peers and also employed a variety of representations. Moreover, they did not immediately implement a symbolic approach like other participants. Gamma wrestled with symbolic expressions to explore one problem. Similarly, Mu read the problem and immediately combined numbers. Beta's attention focused on manipulating a concrete approach for one task, and then tried, albeit unsuccessfully, to employ symbolic representations with other problems.

Participants' metaphor use offered insight into their contextualization of problem solving. Theta and Kappa tended to use action verbs more often than their peers. For example, Kappa used "equals" more often than Lambda and Mu, who tended to use variations of "to be." As a whole, middle school participants employed metaphors far less than their high school counterparts. Kappa, Lambda, and Mu said "got" and variations of "to be" frequently whereas high school students' language was more complex in vocabulary and grammar structure. For example, Gamma stated that he was "going in the other direction" and "getting off track." These literal metaphors align with the structural conceptual metaphor of PROBLEM SOLVING IS A JOURNEY. Concomitantly, Theta had the literal metaphor, "my mind hit a wall" indicating the same conceptual metaphor as Gamma. Less successful students said "(verb) out" more often than their peers. Lambda frequently made comments like "figure out this problem," "take him [number] out," and "draw it [representation] out." These types of ontological metaphors indicated that students perceived the solution as outside of the problem's context. Thus, problem solving, as interpreted by students, can be characterized as working from within one context and outward to another where the solution lies.

Conclusion

The aim of this study was to examine students' representations, contextualizations, and metaphors of mathematical problem solving. A common theme emerged across grade levels: effective problem solvers tended to use nonsymbolic representations and more conceptual metaphors to support their problem solving. Students' contextualization suggests that problem solving is moving towards a solution, which is not readily associated with the task's context. Kappa and others' strategies often employed symbolic representations, which divorce mathematical symbols from their context. These results aligned with Santos-Trigo's (1996) findings that students perceived symbolic representations as more appropriate than others during problem solving, and students were reticent to explore nonsymbolic representational approaches. The perception of mathematics as abstract due to its highly symbolic nature may have encouraged students to disassociate the problem's context from the problem and solution. Thus, practical considerations are necessary to enhance learners' contextualization of problem solving.

This exploration also suggested a new model to draw on students' experiences. The student-described experiences with problem solving indicated that students perceived problems ontologically as containers.

Linguistically, students contextualized problem solving with the ontological conceptual metaphor of PROBLEMS ARE CONTAINERS. This result was surprisingly natural as Kövecses and Benczes (2010) argue, the experiential understanding of in and out is inherent with human existence. The ontological metaphor of container is powerful and intimately involved with our perception of the world. The container (i.e., problem) held all knowledge needed to “solve” the problem. Therefore, the action of “solving” the problem was to use the given knowledge to move one’s understanding from inside to outside the container.

This research led to a transition along a developmental continuum of students’ perceptions of problem solving via the compass of contextualization. The proposed model can support future investigations into enhancing students’ nonsymbolic representation use during problem solving and their problem-solving outcomes.

TO PROVE OR DISPROVE: IN WHAT WAYS DO UNDERGRADUATE STUDENTS USE INTUITION TO DECIDE?

Kelly M. Bubp
Ohio University
bubp@ohio.edu

In this study, students used their intuition to decide whether to prove or disprove mathematical assertions. The investigation involved individual task-based interviews with three undergraduate students in transition-to-proof courses and analysis to determine students' various uses of intuition to decide on the truth of a statement. Tall's three worlds of mathematics—embodied, symbolic, and formal—provided categorization for students' intuitions, and the intuitions were situated along three continua of mathematical thinking. The students' use of intuition and the categorization of their intuitions suggest that the students were at various points in the transition to advanced mathematical thinking. Thus, differences in students' intuitions may correspond to differences in students' competence in making valid decisions and translating their intuitions into counterexamples.

Keywords: Advanced Mathematical Thinking; Post-Secondary Education; Reasoning and Proof

"The move from elementary to advanced mathematical thinking involves a significant transition" (Tall, 1991, p. 20). Intuition is necessary for deciding on the truth value of a mathematical assertion and producing proofs and counterexamples (Fischbein, 1987; Hersh, 1997; Wilder, 1967). Undergraduate students, however, often lack intuitive understandings that support effective reasoning during proof productions (Harel & Sowder, 2007; Moore, 1994). Preliminary results from a study of how undergraduate students decided whether to prove or disprove a mathematical assertion will illustrate in what ways (a) they used their intuitions to decide, (b) they used their intuitions to support formal reasoning, and (c) their intuitions can be situated in Tall's (2004, 2008) *three worlds of mathematics*.

Theoretical Framework

Student intuitions can be categorized using Tall's (2004, 2008) three worlds of mathematics—the *embodied*, *symbolic*, and *formal* worlds—and situated along three continua of mathematical thinking. According to Tall, these worlds are distinct yet overlapping, allowing them to intertwine in various ways as individuals mature mathematically. Development of mathematical intuition begins with initial experiences with mathematics and is nurtured by further experience and mathematical knowledge (Fischbein, 1987; Wilder, 1967). Intuitions can be rooted in any of the three worlds and often span them, being influenced by experiences that overlap worlds.

The embodied world encompasses "perceptual representations of objects" and visuo-spatial reasoning (Tall, 2008, p. 7). Embodied intuitions may be based on vague mental representations that are acquired through repeated experiences with mathematics (Davis & Hersh, 1980; Fischbein, 1987). These mental representations may connect to prior knowledge that resides in any of the three worlds (Burton, 2004; Hadamard, 1945).

The symbolic world incorporates symbolic manipulations, including arithmetic and algebraic reasoning. The symbols in this world "allow us to switch effortlessly from processes to *do* mathematics to concepts to *think* about" (Tall, 2004, p. 285). Symbolic intuitions may develop from repeated and various experiences with computational mathematics that allow for generalizations and abstractions based on recognizing iterative reasoning.

The formal world comprises formally defined objects, deductive reasoning, and mathematical proof. Formal intuitions build on experiences with mathematical logic and assist with reasoning about formal mathematical statements and constructing mathematical proofs (Hadamard, 1945; Tall, 1991).

In this paper, intuition is situated along three continua of mathematical thinking based on the degree of students' use of (a) intuition to make sense of formal statements and decide on their truth value; (b) links among intuitions, proofs, and counterexamples; and (c) formal intuition. Intuitions of lower-division undergraduate students often reside in the embodied and symbolic worlds because of their limited experience in the formal world. However, in order to advance their mathematical thinking, they must develop formal intuitions and learn to use their embodied and symbolic intuitions to make sense of formal mathematical statements and build bridges to mathematical proofs. Thus, in order for students to develop the intuition of mathematicians, they must make "a fundamental transition in their thinking processes" (Tall, 1991, p. 7).

Method of Inquiry

The data in this paper come from a larger exploratory study that (a) investigated how students decide whether to prove or disprove mathematical assertions, (b) identified difficulties students have in making these decisions, and (c) examined connections between students' decision procedures and their success in constructing associated proofs and counterexamples.

Data Collection

The participants were four undergraduate students in transition-to-proof mathematics courses at two private liberal arts institutions in Ohio and West Virginia. I asked each instructor to choose two high-achieving students to participate, but this was not feasible at one institution. I conducted individual, semi-structured, task-based interviews with each student (Goldin, 2000). Each interview was audio-recorded and transcribed. Participants completed three prove-or-disprove tasks, including the following:

> *Injective-function task*: Let $f : A \to B$ be a function and suppose that $a_0 \in A$ and $b_0 \in B$ satisfy $(a_0, b_0) \in f$. Prove or disprove: If $(a, b) \in f$ and $a \neq a_0$, then $b \neq b_0$.

I instructed the students to think aloud during the tasks and to clarify or expand on their thinking as necessary. Upon completion of the tasks, I asked the students about difficulties they had with the tasks and general strategies they used for prove-or-disprove tasks.

This paper focuses on three students, called Ann, Dave, and Chris, whose intuitions represent increasing degrees of development of mathematical thinking. Each student reported using their *intuition*, *instinct*, or *gut feeling* when deciding on the truth value of the statements in the tasks. Dave and Chris are from one institution, and Ann is from the other.

Data Analysis

The main goal of the analysis was to determine the various ways that students were reasoning while deciding whether a mathematical assertion was true or false. Consequently, I performed a content analysis on the transcripts in order to detect themes in the data (Patton, 2002). The transcripts were coded and intuition emerged as a theme. I classified intuitions by reasoning type and situated them in the three worlds of mathematics. Intuitions categorized as *embodied* involved visuo-spatial reasoning, verbal phrases that invoke a visual image or action, and visual representations of objects. Intuitions categorized as *symbolic* involved symbolic manipulations, equations, operations, and properties of operations. Based on the above characterizations, I situated examples and informal definitions in either the embodied or symbolic worlds. Intuitions categorized as *formal* involved logical reasoning and formal definitions. Many intuitions contained combinations of these reasoning types and were situated in multiple worlds.

Results

I present below snapshots of three students, Ann, Dave, and Chris, whose intuitions resided in various combinations of the embodied, symbolic, and formal worlds and represented increasing degrees of development of mathematical thinking. The students used their intuitions in distinctive ways to determine the truth value of the injective-function task.

Ann

Ann's general intuition involved the use of numbers, equations, or graphs, but she had a difficult time getting started on the tasks. For the injective-function task, Ann said, "Well, when I think functions, I just always think of like a graph. That's just where my thought instantly goes. . . . I think like, everything like algebra, so I just gotta, hmm, I like equations." Ann's intuition on this task combines the visuo-spatial concept of graphs with a symbolic characterization of functions as equations, thus it is embodied-symbolic. When I asked Ann if she had a particular equation in mind, she replied, "Not really. That's what I'm trying to figure out." Ann was unable to use her embodied-symbolic intuition to determine a suitable function, graph, or equation to make sense of or decide on the truth or falsity of the injective-function task.

Dave

Dave's general intuition stemmed from "experience with problems" which helped him recognize tasks that are similar to ones he had seen before. On the injective-function task, Dave's intuition was in the formal-embodied world: "That sounds just like the definition of a function, one thing can't map to two, one element of the domain can't map to two elements of the codomain. So I guess I'm probably trying to prove that." However, he hesitated to begin a proof, and said "I'm just wondering if I'm confusing vertical line test with horizontal line test, and confusing not a function with not one-to-one." Thus, his formal intuition of the definition of a function was coupled with an embodied visual intuition related to the definitions of function and one-to-one. He reread the assertion, decided the definition was for one-to-one, and quickly produced and verified the counterexample $f(x) = x^2$. Dave's embodied-formal intuition was off target at first, but then led him to construct a correct counterexample.

Chris

Chris depended on his intuition to help him construct proofs and counterexamples: "I find it really difficult to start unless I have an idea. . . . I'm pretty sure it's this. Why do I think that? I think that because of this, this, and this, and eventually that kinda leads me through." For the injective-function task, Chris's embodied-formal intuition invoked a visual image of a function related to the definition of one-to-one. "Well my intuition so far is that it can be. It seems like if it were a function from **R** to **R**, then if it's just not a one-to-one function, or something, then it can double back on itself." He quickly wrote $f(x) = x^2$ and proved it was a counterexample by noting that different inputs result in the same output. Thus, he combined his visual embodied intuition with the formal definition of one-to-one, resulting in an embodied-formal intuition. This intuition was decisive in his ability to complete the injective-function task successfully.

Discussion

The ways in which Ann, Dave, and Chris used their intuitions and the categorizations of their intuitions suggest that the students were at various points on the three continua of mathematical thinking detailed above. Ann's embodied-symbolic intuition did not help her make sense of the assertion, decide on its truth value, or construct a proof or counterexample. Although Dave struggled to understand the assertion and decide on its truth value, his symbolic-formal intuition led him to construct a correct counterexample. Chris's embodied-formal intuition helped him successfully understand the assertion, decide on its falsity, and construct a counterexample.

Each student used intuitions from overlapping worlds when deciding on the truth of the task, but the similarities in the categorization of the students' intuitions may conceal differences that influenced their success. Dave and Chris linked their formal intuitions to the formal definition in the task, and Ann's lack of formal intuition limited her ability to make sense of the task. Thus, students using formal intuitions may be better equipped to make decisions and translate their intuitions into counterexamples than students using only embodied and symbolic intuitions.

However, it was the differences in the students' embodied intuitions that seemed to affect their success the most. Each student had a distinct embodied intuition that played a key role in their work on the task.

Ann's superficial correlation of graphs and functions was not helpful to her because she was unable to draw a graph corresponding to the function in the task. Dave's embodied version of the definitions of function and one-to-one as the vertical and horizontal line tests made it clear to him that he was confusing these definitions, thus leading the way to a counterexample. Chris's vague image of a function doubling back on itself and violating the definition of one-to-one provided the key idea for his counterexample to the task. Chris said that when he has an intuition of a definition related to functions, "I feel like I can kind of have a function in my mind, which, it's a very strange function that does whatever I want it to." Thus, differences in students' embodied intuitions may correspond to differences in students' competence in making valid decisions and translating their intuitions into counterexamples.

Although this paper explored the intuitions of only three students working on one prove-or-disprove task, it presents differences in their intuitions that may warrant consideration in future work. How can Ann's graphical intuition be refined so that it can help her relate to the formal aspects of the task? How did Dave come to think of definitions in both embodied and formal terms? And how can we teach students to invoke vague images in the way that Chris does?

EXPLORING THE SECONDARY–POSTSECONDARY TRANSITION WITH TEACHERS: THE CASE OF SYMBOLIZING

Claudia Corriveau
University of Quebec in Montreal
corriveau.claudia@uqam.ca

This research is interested in considering teachers' view in issues of transition between school levels. As a framework, ethnomethodology enables us to take teachers' "ways of doing" mathematics (symbolizing, using representation, proving, etc.) as key elements to those issues. Using this concept, we present data from a one-year collaborative research project involving secondary and postsecondary teachers. We analyzed data from a task the researcher and the teachers examined together in one of the meetings, highlighting teachers' ways of doing in relation with transitional issues around the use of symbolism to represent exponential functions.

Keywords: Secondary-Postsecondary Transition; Collaborative Research; Symbolism

Introduction

Several researches highlight difficulties due to new demands and new knowledge's organization when moving from secondary to postsecondary mathematics (see Robert, 1998). Researchers commonly address this issue from the perspective of advanced mathematics (e.g., Robert & Schwarzenberger, 1991), identifying potential problems, but without studying the transition as such. Others compare mathematical organizations of tasks at both levels (e.g., Bosch et al., 2004; Gueudet, 2004; Praslon, 2000; and Winslow, 2007). For instance, Artigue (2004) starts from secondary level to examine transitional issues by characterizing the culture of high school mathematics based on its curriculum. According to Hall (1959), it is, however, the implicit "ways of doing" that lead to greatest cultural differences. In classrooms, teachers do, and make their students do mathematics in a certain way. Transitions in mathematics education have yet to be examined from the perspective of those ways of doing. This project aims at exploring the transition from secondary to postsecondary mathematics with teachers through their ways of doing mathematics. The study anchors in our previous researches showing several students' difficulties with symbolism when transitioning from high school to college (Corriveau, 2007).

A Collaborative Research Taking Account of Teachers' Perspectives

Collaborative research is founded on the idea of researchers and teachers working together on issues directly related to the practitioners' practices (Desgagné et al., 2001). An idea is to conduct research "with" teachers rather than "on" or "about" them. In this project, we engaged the issue of transition with a group of six participants: 3 secondary schools teachers and 3 college teachers (12th to 14th year of study). They join a collaborative research focusing on issues around the transition from secondary to postsecondary mathematics.

There were regular meetings (7) between the researcher and teachers to work around the participants practices (their ways of doing mathematics). Except for the first, informational meeting (Nov. 2010), they were full "one-day" reunions (Jan. 2011 to Nov. 2011). Typically, the teachers alternatively worked in teams and as a group around a task submitted by the researcher. The task itself was designed around actions-situations teachers face in their daily practices, but also *breaching* from their ordinary (an ethnomethodological method used to reveal everyday hidden insights and/or "ways of doing"). All meetings were recorded and transcribed, and are now analysed using qualitative emergent analysis methods and softwares.

Conceptual Framework Underlying the Analysis

Ethnomethodology (Garfinkel, 1967) is a perspective enabling us to explore “ways of doing” mathematics by teachers. Ethnomethodology’s research interest is to study everyday methods people use to accomplish and constitute a socially organised activity (such as teaching math at a specific level). For the analysis, we are interested in what we call ***mathematical ethnomethods*** which are *ways of doing mathematics* that are mobilized by teachers in their daily working life. These ethnomethods are *indexed* to situations and certain *circumstances* which allow them to be shared among teachers of a given level. In this perspective, the actor (the teacher) is assumed to be knowledgeable, meaning that those ethnomethods also concerns teachers’ *rationale* for his/her ways of doing. Hence, actors in a social activity share and create meanings that show common ways of doing and saying, because they allow the participants to understand one another.

In a first phase of the analysis, we identify and describe ways of doing shared by teachers of a same level, the circumstances, indexicality, rationality of these ways of doing. This categorization (ways of doing, circumstances, indexicality and rationality) leads to a description of mathematical ethnomethods.

Results: Symbolizing an Exponential Function

We illustrate the analysis with an example about ways of symbolizing an exponential function at secondary and post-secondary levels. We gave teachers excerpts from textbooks showing different ways of symbolizing an exponential function (see Figure 1, for example). We ask them to comment what is done at the other level.

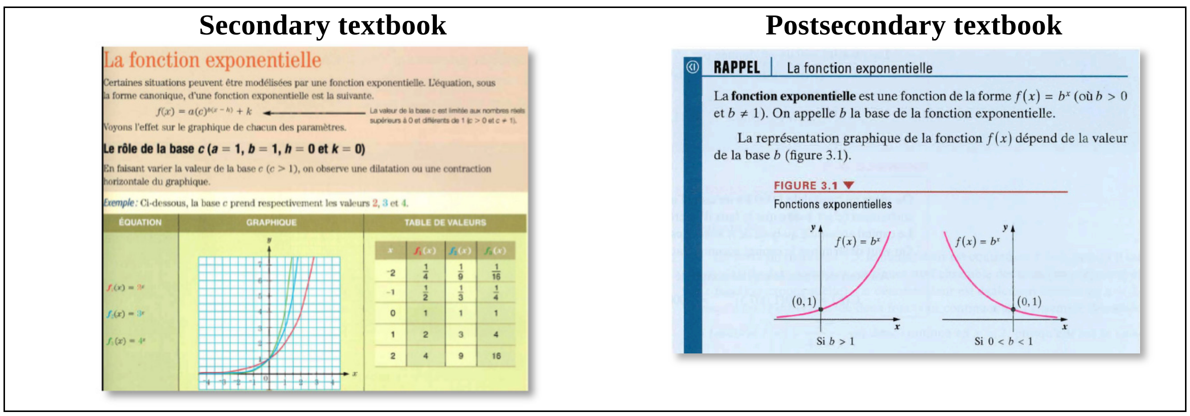

Figure 1: Example of symbolization of an exponential function

The choice of this situation is significant. It had been thought so the question immediately puts teachers in their practice (using their textbook, working on a function they both study and use with their students). This task also led to unfamiliarity: teachers were faced with ways of symbolizing presented in textbook from the other level (inspired by the concept of breaching we mentioned earlier). In the interaction between teachers, many ways of doing around symbolism emerged. The following fragment gives an example, involving Paul and Patricia, from postsecondary level, and Sean, Sam and Sandra, who work in secondary schools, reacting on the formula presented in a secondary textbook $f(x) = ac^{b(x-h)} + k$:

Paul:	Do you really present the exponential function this way? Really?
Patricia:	You don’t like it? This writing? It’s heavy, hey? I also find it really heavy.
Paul:	Ah very heavy.
Sean:	But we will eventually simplify this writing.
Paul:	Maybe but even if you do it, why is it written this way? Students will be afraid right away, they will be scared.
Sam:	It’s because of the 4 parameters...

Sandra: There is a basis to that...
Sean: Students are already pros [with parameters] when we study this function [exponential]. It's true, they are very comfortable working with the parameters.

From the conversation, we understand that the use of parameters (a, b, h, and k) as presented in the textbook ($f(x) = ac^{b(x-h)} + k$) is not a familiar symbolization for postsecondary teachers. Secondary teachers express familiarity with this symbolization and do not recognize the heaviness pointed out by Paul and Patricia. Sam explains to them the *circumstances* of the use of this particular symbolization and the ways of using (introducing) it:

Sam: I start with $f(x) = c^x$ and then, I present the four parameters one by one […]…
Patricia: You don't show this [$f(x) = ac^{b(x-h)} + k$] right away.
Sean: No…
Sam: No. We always start with the function $f(x) = c^x$, the basic function, and we see some properties in the graphic. Then, we transform it. We use parameters and draw the graphic and we ask "what is interesting here".

Sam explains he starts with something like $f(x) = c^x$, a basic function, and then, progressively adds complexity by introducing parameters (a, b, h and k) until it becomes $f(x) = ac^{b(x-h)} + k$. This progression in the symbolization is also associated with the graphic of the function: each parameter is related to an effect when compared to the basic function (a translation, a reflection and dilatation/shrinkage). In reaction, Patricia explains the way of symbolizing an exponential function at postsecondary level:

Patricia We use b^x in the review. We will work with this writing when we teach the derivative, when we demonstrate properties. But then, we can change it, we can play with it in applications. It doesn't have to be x. x can become $\sin(x)$, we can play with it, it can become $a^{\sin x}$.

At postsecondary level, teachers use the basic function $f(x) = b^x$ as a reminder of what is an exponential function, in definitions and theorems, and the teacher explain to students that x can become something more complex. Then, in applications, the complexity of the symbolization shows when the letter x becomes $sin(x)$, $x + \Delta x$, etc. This results in another way of using symbolism (to vary the meaning of the letter/variable): "we can play with x, with the symbolism" said a teacher from postsecondary level. When secondary teachers heard how symbolization is used in applications at the postsecondary level, they asked why not use something like $g(x) = a^{f(x)}$ as a basic symbolization rather than $f(x) = b^x$: it would be "more logic!" To this, postsecondary teachers explained that it is also important for them to graphically represent the function, which would not be possible with the first, more general, case.

From the symbolization point of view, it is interesting to notice that these ways of using symbols leads to different meaning in relation with generalization. In the way teachers from the secondary level use the symbols, the function $f(x) = c^x$ represents one specific type of functions, a function which can be represented in a graphic (*indexicality of the symbolism*). The symbolization $f(x) = ac^{b(x-h)} + k$ then represents every other case. This second symbolization is thus more general then the first one. Also, considering this notation as more general is linked with a certain way of using "letters." Letters are indexed on the one hand to numbers (variables and parameters), and on the other hand, to an effect in the graphic (parameters). Contrastingly, from the way teachers use symbols at postsecondary level, $f(x) = b^x$ is considered the most general function because b and x can become something more complex. Letters are not indexed to numbers but to more complex algebraic expressions. At the same time, when representing the graphic of the function $f(x) = b^x$, the symbols have other signification, closer to what they are used for by the secondary level teachers. Thinking in terms of transition, student then have to deal a meaning for the letters which is partially the same as in secondary school, but also have to abstract and expand the possibilities of these symbols.

Conclusion

By contrasting ways of doing at each level, we highlighted important aspects of teachers' ways of using symbolism to represent an exponential function. Teachers explained their ways of symbolizing but also pointed out *circumstances* (e.g., $f(x) = c^x$ at secondary level to represent a particular function that will become more complex, $f(x) = b^x$ at postsecondary level as a reminder, in definitions and theorems), and *rationales* (e.g., $f(x) = b^x$ is used rather than $g(x) = a^{f(x)}$ to be able to represent the graphic) for these ways of doing. And we can also see how symbolism is *indexed* to specific meanings (a symbol can relate to numbers and effects in the graphics at secondary level; a symbol can relate to a complex algebraic expression at postsecondary level). Such analysis take us to conceptualize symbolism as a *process*, in the way it is talked about and use by high school teachers, and/or as a *pregiven object*, from the perspective brought forth by the teachers at the postsecondary level.

Such analysis take us to conceptualize symbolism as a *process*, in the way it is talked about and use by high school teachers, and/or as a *function*, from the perspective brought forth by the teachers at the postsecondary level. We believe this shift can be an interesting tool for researchers to address secondary-postsecondary transition from the student's perspective.

INVESTIGATING THE RELATIONSHIP BETWEEN TASK DIFFICULTY AND SOLUTION METHODS

Erhan Selcuk Haciomeroglu
University of Central Florida
Erhan.Haciomeroglu@ucf.edu

The present study sought to investigate the role of task difficulty in students' preference for visual or nonvisual methods as they solved calculus tasks. Data were collected from 498 high school students enrolled in Advanced Placement Calculus courses. Results indicate that the mode of representation and task difficulty were factors influencing the students' preference for visual or nonvisual methods. The students used more visual methods when presented with graphic calculus tasks and more nonvisual methods when presented with algebraic calculus tasks. As task difficulty increased, the number of visual methods increased significantly, and the number of nonvisual methods decreased significantly.

Keywords: Advanced Mathematical Thinking; High School Education; Calculus; Visual and Nonvisual Methods

Background

Research on differences in students' preference for solution methods has been of considerable interest to educators for many years (e.g., Krutetskii, 1976; Kozhevnikov, Hegarty, & Mayer, 2002; Lean & Clements, 1981). Most previous studies investigating differences in students' preferred methods have concentrated on gender and cognitive abilities and failed to take into account the role of task difficulty (e.g., Lowrie & Kay, 2001). Thus, the purpose of this study was to investigate the relationship between task difficulty and preference for visual and nonvisual methods.

Krutetskii (1976) identified types of mathematical giftedness based on students' preferences for or verbal-logical (or nonvisual) or visual thinking. Following the work of Krutetskii, Lean, and Clements (1981), Moses (1977), Suwarsono (1982), and Presmeg (1985) have recognized that individuals could be placed on a continuum (i.e., degree of mathematical visuality) according to their preference for visual processing. Visualizers are considered as learners who prefer to use visual-pictorial processes, and verbalizers as learners who prefer not to use visual-pictorial processes when there is a choice on a specific task.

Individual differences in solution methods have been reported by a number of researchers (e.g., Fennema & Tartre, 1985; Hegarty & Kozhevnikov, 1999; Lean & Clements, 1981). Battista (1990) and Bremigan (2005) showed that low achieving students used more visual solutions (i.e., drawing strategies without visualization) than nonvisual. Ben-Chaim, Lappan, and Houang (1989) investigated the effect of instruction on middle school students' preferences for visual and nonvisual methods. There were significant differences in preferences among students by grade level prior to the instruction. In the studies with high school students, Gallagher and De Lisi (1994) and Gallagher, De Lisi, Holst, McGillicuddy-De Lisi, Morely, and Cahalan (2000) identified strategy use and flexibility as factors contributing to differences in mathematical performances. In a study with sixth grade students, Lowrie and Kay (2001) found that task difficulty was related to preference for visual or nonvisual methods, and that the students used more visual methods as the task difficulty increased. From the review of literature, it appears that research findings regarding preferred solution methods have been inconclusive, and few studies investigated students' preference for visual or nonvisual methods in calculus. Therefore, this study sought to investigate the role of task complexity in students' preference for visual or nonvisual methods as they solved calculus tasks presented graphically and algebraically.

Methods

Participants

The participants were 498 high school students who were enrolled in Advanced Placement (AP) calculus courses at seven high schools in two districts in Florida in the United States at the time of the study. Of the 498 students, 290 were males and 208 were females. Approximately 59% of the sample were White, 18% were Hispanic, 15% were Asian, 5% were African American, and 1% were Multi Racial. The remaining 2% indicated "Other" as their ethnic group.

Materials and Procedure

Over a 2-year period, 498 students were asked to complete 20 calculus tasks. All students received standardized instructions and were tested in their intact classrooms. All participating students gave their informed consent and were debriefed at the end of the study.

The calculus tasks, which could be solved by visual or nonvisual methods, were administered in a packet. The calculus packet contained 14 graphic (7 derivative and 7 antiderivative) and 6 algebraic (3 derivative and 3 antiderivative) tasks and a corresponding questionnaire consisting of a visual and a nonvisual solution for each task. In each task, the students were presented with the graph or the equation of a function and were asked to draw a possible derivative or antiderivative graph. Upon completion of the tasks, the students were given the questionnaire and were asked to choose for each task a method of solution that most closely described how they solved the tasks.

First, the calculus tasks were divided into two groups as graphic and algebraic. Then, each of the two groups was divided into two subgroups. That is, eight graphic tasks (4 derivative and 4 antiderivative) were classified as relatively easy, and six graphic tasks (3 derivative and 3 antiderivative) as more difficult. Easy tasks require sketching derivative or antiderivative graphs of continuous functions (i.e., linear, quadratic, cubic, exponential, and trigonometric), whereas difficult tasks sketching derivative or antiderivative graphs of functions with an infinite discontinuity or a corner (e.g., $1/x$, $1/x^2$, and $|x - 1|$). Two algebraic tasks, which require sketching derivative or antiderivative graphs of quadratic or cubic functions, were classified as relatively easy. Four algebraic tasks, which require sketching derivative or antiderivative graphs of absolute and logarithmic functions, were classified as more difficult.

Students' responses for each task were categorized into four subgroups: (a) visual and correct, (b) nonvisual and correct, (c) visual and incorrect, or (d) nonvisual and incorrect. A score of 1 was given for each response category on each test (i.e., Easy Graphic, Difficult Graphic, Easy Algebraic, and Difficult Algebraic). It is important to note that few students chose both visual and nonvisual methods for a task on the questionnaire, and these responses were not included in the analysis.

Results

The mean number of responses for each of the response categories derived from easy and difficult tasks is reported in Tables 1 and 2. A paired-samples t-test was conducted to compare the total number of correct responses for easy and difficult tasks presented graphically and algebraically. As expected, there was a statistically significant decrease in the number of correct answers from Easy to Difficult tasks presented graphically, $t(1, 497) = 15.19$, $p < 0.001$. The eta squared statistic (0.32) indicated a large effect size. Similarly, on the algebraic tasks, the number of correct responses for easy tasks was significantly higher than difficult tasks, $t(1, 497) = 24.35$, $p < 0.001$. The eta squared statistic (0.54) indicated a large effect size. The results indicate a statistically significant difference in the task complexity between the tests.

Table 1: Means and Standard Deviations for Graphic Tasks

	Easy		*Difficult*	
	M	*SD*	*M*	*SD*
Response Category				
Visual and correct	0.30	0.28	0.31	0.33
Nonvisual and correct	0.24	0.21	0.06	0.13
Visual and incorrect	0.21	0.21	0.35	0.29
Nonvisual and incorrect	0.22	0.23	0.23	0.28

Table 2: Means and Standard Deviations for Algebraic Tasks

	Easy		*Difficult*	
	M	*SD*	*M*	*SD*
Response Category				
Visual and correct	0.09	0.21	0.10	0.17
Nonvisual and correct	0.48	0.36	0.08	0.16
Visual and incorrect	0.10	0.24	0.24	0.26
Nonvisual and incorrect	0.31	0.34	0.53	0.32

A paired *t*-test revealed significant differences in the number of visual (correct and incorrect) and nonvisual (correct and incorrect) between easy and difficult tasks. On the graphics tasks, the number of visual methods significantly increased, and the number of nonvisual methods significantly decreased as the task complexity increased. When the tasks were presented algebraically (see Table 2), the students used more nonvisual methods than visual on easy and difficult tasks. However, with the increasing level of task complexity, the number of nonvisual methods significantly decreased while the number of visual methods significantly increased.

Discussion

The present study examined the relationship between task difficulty and preference for visual and nonvisual methods. Although the mode of representation (i.e., graphic vs. algebraic) was not of primary interest to this study, the results indicate that the mode of representation influenced the students' preference for visual or nonvisual methods. That is, the students used more visual methods when presented with graphic calculus tasks and more nonvisual methods when presented with algebraic calculus tasks.

The results also suggest that task difficulty was related to preference for visual or nonvisual methods. This finding supports the conclusions of Lowrie and Kay (2001), who found that that task difficulty has an influence on the way students represent mathematics problems. As task difficulty increased, the number of visual methods (correct and incorrect) increased significantly, and the number of nonvisual methods (correct and incorrect) decreased significantly, suggesting that the students were likely to use visual methods for more difficult tasks. Visual solutions are image-based and involve determining the shape of derivative or antiderivative graphs based on visual estimates of slopes. On the other hand, nonvisual solutions are generally equations-based and involve translation to an equation, computing the derivative or integral of the equation, and then using this new equation to draw the graph. Although the design of the study does not enable this finding to be inferred from the data, the results support the hypothesis that students are likely to use visual methods in more complex tasks because increasing complexity makes it difficult for students to estimate the equation of a function and might influence their tendency to use visual methods.

STUDENTS' WAYS OF THINKING ABOUT COMBINATORICS SOLUTION SETS: DELETION AND EQUIVALENCE CLASSES

Aviva Halani
Arizona State University
Aviva.Halani@asu.edu

Students' ways of thinking about combinatorics solution sets, the sets of elements being counted, were investigated in a study that engaged fourteen undergraduates with no formal experience with combinatorics in individual task-based interviews. This paper focuses on two ways of thinking that emerged from the data analysis: Deletion and Equivalence Classes. Both involve creating a related combinatorics problem and finding a relationship between the solution set of the new problem and that of the original problem. The relationship is additive in Deletion and multiplicative in Equivalence Classes.

Keywords: High School Education, Post-Secondary Education, Problem Solving

According to Piaget and Inhelder (1975) children's combinatorial reasoning is a fundamental mathematical idea based in additive and multiplicative reasoning. Indeed, as Kavousian (2008) said "without much prior knowledge of mathematics, one can solve many creative, interesting, and challenging combinatorial problems" (p. 2). This indicates that students should be able to solve combinatorial problems by employing their additive and multiplicative reasoning. However, the research shows that students of all ages often struggle to solve combinatorial problems (English, 1991; Hadar & Hadass, 1981; Lockwood, 2011)

In order to address these difficulties, much of the prior research on combinatorics education has focused on students' actions, not their reasoning and understanding. Thus, it will be foundational to understand the stable patterns in reasoning that students apply in a variety of combinatorial situations. These coherent patterns in reasoning are known as *ways of thinking* (Harel, 2008). The research study described here aims to answer the following research question: What are students' ways of thinking about the set of elements being counted in combinatorics problems?

The set of objects being counted has been called the "solution set"(Lockwood, 2011). Framed in this language, the second research question investigates students' ways of thinking about the solution set of combinatorial problems.

Theoretical Perspectives

The philosophical perspective underlying this study is that "knowledge is not passively received either through the senses or by way of communication, but it is actively built by the cognizing subject"(von Glasersfeld, 1995, p. 51). This idea that mathematical knowledge is constructed as the learner engages actively in the tasks is central to this research. Harel (2008) contends that there are two different categories of mathematical knowledge: ways of understanding and ways of thinking. Humans' reasoning "involves numerous *mental acts* such as interpreting, conjecturing, inferring, proving, explaining, structuring, generalizing, applying, predicting, classifying, searching, and problem solving" (Harel, 2008, p. 3). *Ways of understanding* refers to the reasoning applied to a particular mathematical situation—the cognitive products of mental acts carried out by a person. *Ways of thinking*, then, refer to what governs one's ways of understanding—the cognitive characteristics of mental acts—and are always inferred from ways of understanding. Reasoning involved in ways of thinking does not apply to one particular situation, but to a multitude of situations. Ways of understanding and ways of thinking thus comprise mathematical knowledge (Harel, 2008).

Research Methodology

Data for this study come from a series of "individual exploratory teaching interviews" (Steffe & Thompson, 2000) conducted at a large southwestern university in the USA. Fourteen students from a second-semester Calculus for Engineers course participated in individual task-based interviews. Each student participated in 2 hour-long interviews with the researcher (the present author) in a two-week period in spring 2011. None of the students had formal experience with combinatorics. The purpose of these interviews was to catalogue students' ways of thinking the elements of solution sets. Each interview involved the researcher as the teaching agent, one of the students, a series of tasks, and a method of audio and video-recording the interview.

There were a few phases of retrospective analysis. The researcher discussed the data with two mathematics education researchers during the study. Content logs including summaries of the video for each task were created for each student following each interview and relevant portions of the video were transcribed as necessary. At the end of the study, the researcher used open coding (Strauss & Corbin, 1998) to identify and catalogue the ways of thinking in which each student engaged.

Results

Several different ways of thinking emerged from the data analysis. One category of ways of thinking was present as students determined the sizes of subsets of the solution set. Another, the *Odometer* category, involves holding an item constant and cycling through possible items for the remaining spots in order to generate all elements of the solution set (Halani, 2012). A third category comprised of *Deletion* and *Equivalence Classes* thinking is discussed here. Both of these ways of thinking involve creating a new, related combinatorics problems and then finding a relationship between the solution set of the new problem and that of the original problem. The relationship is additive in Deletion and multiplicative in Equivalence Classes.

Deletion

Consider the following task "Situation: A security code for a computer involves two letters. It is case insensitive, but the two letters must be different from each other. Question: How many possible security codes are there for this computer?" Sophie found the answer to be $2^{26} – 2$ and described her thought process below:

> *This time you need to take out any duplicates of the letters. So it can't be like A and A or anything else like that. Um, so let's see. [….] Like, 2 to the 26th [writes 2^{26}] and then you would end up minusing, well, yeah, you would end up subtracting [continues writing $2^{26} – 26$ because this [circles 2^{26}] would give you the total number of combinations, and this [circles 26] is the number of combinations that are invalid because they are using the same letter.*

Here, Sophie tried to count the number of security codes where repetition may be allowed, thereby creating a related problem and finding the cardinality of its solution set. Then, she identified those elements that are "invalid" because they use the same letter. She understood that she could "take out" these elements in order to find the cardinality of the solution set of the original problem. These remarks point to a way of thinking known as *Deletion* thinking.

Typically, while engaging the Deletion way of thinking, students will first consider a given task with solution set *A*. Then they will construct a related problem with a solution set *C*. This solution set will contain a subset *B* which has a bijective correspondence with *A*. By counting the total number of elements in *C* and the elements of *C* which are not in *B*, the students will find the cardinality of *B*. Since *B* corresponds to *A*, they will have found the cardinality of *A*, the solution set whose size they were trying to find. In essence, they are "deleting" the elements of the solution set *C* that are not in *B*.

The fact that Sophie incorrectly determined the number of security codes where repetition is allowed is not relevant to identifying her way of thinking. What is relevant is that even before she attempted to enumerate the elements of the solution sets, she outlined her thinking about the situation by saying "you would need to take out any duplicates of the letters." Again, one difference between a way of thinking and a way of understanding is that a way of thinking is present in a multitude of situations. Sophie's solution here is not enough to show that she is engaging in the Deletion way of thinking. However, her solutions to other tasks and the way she outlined her thinking suggest that she was in fact engaging in Deletion thinking.

Equivalence Classes

When attempting to determine the number of ways four people could sit around a circular table, Slang drew representations of different table arrangements as shown in Figure 1:

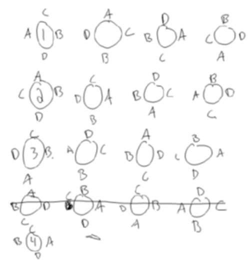

Figure 5: Slang's written work for the Table Problem with four people

From her partial representation and explanations, it is clear that Slang constructed a new problem in which rotations of the circle are considered as a different table arrangement. She then grouped the tables so that each row corresponded to a table arrangement she wanted to count. Once Slang had drawn three different rows, she realized that there would be a total of 24 different circles she would be drawing and four circles per row so there are 24/6 or 4 ways four people could sit around the table. For this reason, she only drew one representative of the fourth row.

In a similar manner to students engaging in Deletion thinking, Slang constructed a new problem and found a relationship the solution set of the new problem and the one whose cardinality she was trying to find. However, the relationship was additive in Deletion thinking but multiplicative in her case. This is a new way of thinking known as *Equivalence Classes*.

A student engaging in the Equivalence Classes way of thinking will first consider a given task with solution set *A* and then create a related problem with a solution set *S*, which can be partitioned into equivalence classes of the same size—each class corresponding to an element of *A*. After grouping elements into these equivalence classes, he or she would then quantify the size of each equivalence class and relate the size of the equivalence classes to the size of *S*, in order to find the size of set *A*. See Figure 2.

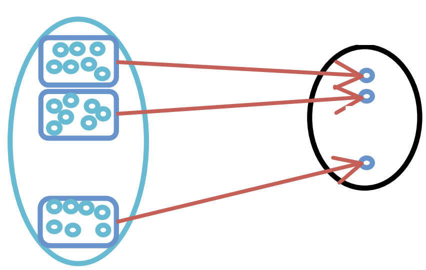

Figure 2: Equivalence classes

Discussion

In this study, students did not always engage in ways of thinking which are productive for solving certain tasks. In particular, most students were able to naturally engage in Deletion thinking, but struggled with Equivalence Classes. Some of these students could construct new questions, determine the size of the new solution set, construct equivalence classes and even quantify the size of the equivalence classes, yet they could not determine the multiplicative relationship between the new solution set and the original one. Thus, it seems as if some students need to be encouraged to develop certain ways of thinking.

This study which focused on understanding students' ways of thinking about the set of elements being counted and how that thinking expresses itself in their attempts to solve combinatorial problems can be foundational for future studies and for teaching practice. It can serve to assist teachers in implementing instructional interventions designed to help students develop productive ways of thinking about combinatorics and support curriculum developers in organizing tasks to build upon students' ways of thinking. In addition, this study could provide a framework for analyzing how the ways of thinking about combinatorics solution sets are distributed across various mathematical populations. This researcher hopes to conduct further studies to investigate how students develop their ways of thinking about the solution sets as they progress through a variety of combinatorial tasks and the instructor implements interventions designed to encourage particular ways of thinking, including Equivalence Classes thinking.

STUDENTS' PERCEPTIONS OF THE ROLE OF THEORY AND EXAMPLES IN COLLEGE LEVEL MATHEMATICS[1]

Nadia Hardy
Concordia University
nhardy@mathstat.concordia.ca

Dalia Challita
Concordia University
dalia.challita@gmail.com

Previous research has thoroughly reported on college level students' inability to deal with non-routine problems and to justify in mathematical terms the ways in which they deal with routine problems. Researchers have conjectured that these inabilities are the result of the absence of theoretical content or its dissociation from tasks and corresponding techniques in the teaching approach to college mathematics. In this preliminary research report, we present empirical evidence that, at the college level, students perceive theory exclusively as a validatory discourse and don't recognize the value of generalized examples. Students' perceptions of the role of theory and examples in mathematics have to be addressed if we want them to genuinely engage in mathematical activity.

Keywords: Post-Secondary Education; Advanced Mathematical Thinking

Recent research has shown that, at the college level, mathematical theory is either completely absent or strongly dissociated from the teaching of procedures (techniques to find limits, calculate derivatives, integrate, solve systems of linear equations, etc.; e.g., Lithner, 2004; Sierpinska, 2004; Barbé et al., 2005; Hardy, 2009). The absence or dissociation of theoretical discourses or even mathematical intuition might leave students with no resources to deal with non-routine tasks (e.g., Selden et al., 1999; Lithner, 2000) and be a contributing factor to students behaving more as *institutional subjects* than as *mathematical subjects* in front of mathematical tasks (Hardy, 2010). Studies show that this absence or dissociation is typical of the teaching approach to college mathematics: Elementary and Intermediate Algebra, Calculus, and Linear Algebra (e.g., Raman, 2004; Sierpinska, 2004; Barbé et al., 2005; Boesen et al., 2010).

What drives this research project is the question "if we were to incorporate theory in our teaching approach to Calculus, how should we do it so that we provide students with discourses to justify in mathematical terms their approaches to problem solving and with tools and strategies to deal with non-routine tasks?" As a first step towards answering this question, we investigate students' perceptions and uses of theory and examples. Bills et al. (2006) point out that students may not perceive and use examples in the ways intended by educators; based on 30 subjects we present a preliminary report on students' perceptions and uses of theory and examples.

Perspective and Educational Context

We consider that knowing mathematics includes the ability of behaving mathematically and that the process of learning mathematics requires behaving as mathematical subjects. Our understanding of mathematical behavior includes mathematical reasoning, analytic and deductive thinking, mathematical approaches to problem solving (see Schoenfeld, 1987), and a preoccupation for theoretical consistency and validation. Furthermore, a subject behaves mathematically when he or she perceives theory not only as a discourse that justifies techniques but also as a discourse that connects and produces techniques to solve different types of tasks. Our use of the notions of *tasks*, *techniques* and *theory* is to be understood in terms of the notion of *praxeology* within the Anthropological Theory of the Didactic (Chevallard, 1999; we refer to *theory* meaning the theoretical block of a praxeology).

The educational context of this project is the teaching and learning of college level Calculus courses, with particular focus on the topic of limits of functions, as they are taught in several universities across Canada, the US and different locations in Europe (e.g., Lithner, 2000, 2004, 2010; Barbé et al., 2005). In many well described cases, the routinization of tasks and a prevalent institutional normative discourse result in certain stable institutional practices that define a teaching culture in the Calculus community. This

culture can be gleaned from course outlines, assessment instruments, and textbooks. One of its main characteristics is the dissociation of techniques-to-solve-a-given-task from a theoretical-(even-intutitive)-mathematical-valid-explanatory-discourse.

Methodology

Four teaching approaches to the topic limit of functions at infinity were designed and video-taped. Forty subjects were recruited among students at the university level who have recently passed a pre-Calculus course and were randomly assigned to one of four conditions. Condition 1 corresponds to a teaching approach that consists of a list of particular (numerical) examples of finding limits of functions; techniques are presented in terms of sociomathematical norms (Voigt, 1995) with complete absence of theoretical content. In condition 2, a list of theoretical results together with some generalized examples is given first. Then, a list of particular (numerical) examples is given. In this approach, theory is present but is dissociated from particular examples. Condition 3 corresponds to a teaching approach consisting exclusively of theoretical results; these results are derived from and/or illustrated by means of generalized examples, no numerical examples are shown. The fourth condition, which will be analyzed at a later stage, focuses on theory and mathematical intuition and clearly links them to tasks and techniques. Mechanisms of generalization of some techniques are also shown.

Subjects were met individually; they completed a pre-test, attended the video-taped lecture and engaged in a task-based interview.

Results and Analysis

In this preliminary report, we present results from subjects assigned to conditions 1, 2, and 3 corresponding to three types of problems that subjects deal with in the task-based interview. Problems of type 1 consist of finding limits at infinity of particular rational functions. In conditions 2 and 3, a technique for finding such limits is discussed in general terms, while particular examples are only given in conditions 1 and 2. Subjects in condition 3 were unable to deal with most problems of type 1 while subjects in conditions 1 and 2 were able to deal with those that strongly resembled examples given in the lectures; for instance, they were able to find limits at infinity of rational functions where the value of the limit is a non-zero constant (an example shown in both conditions 1 and 2) but were unable to do so when the value of the limit was zero or infinity. Problems of type 2 consist of finding limits of rational functions with generalized constants. Only two subjects (out of the 30) engaged in these problems. They did so by experimenting with concrete values of the constants and then generalizing the results to all possible values. Only one of these two subjects was able to justify his generalization. This subject showed an explicit interest in mathematical theory and strongly criticized condition 1 for the lack of it. The remaining 28 subjects displayed a hesitant behavior and eventually refused to deal with the problems. They justified their behavior on a self-declared inability to work with generalized constants (subjects refer to these as "letters"). Problems of type 3 consist of finding limits of functions that were not discussed in any of the three conditions. In particular, subjects are asked to find the limits of the product of an exponential function and cosine function—however, examples including exponential and trigonometric functions are given in all conditions 1 and 2. Only one subject engaged and succeeded in dealing with problems of type 3 (the theory-bound subject mentioned in the previous paragraph). The other 29 subjects argued that they did not know how to deal with these tasks; they blamed this on the lack of examples of that particular type.

Table 1: Three Types of Problems Posed to Subjects in the Task Based Interview

Type 1	Type 2	Type 3
Find limits of rational functions (e.g., $\lim_{x\to\infty}\frac{3x^2-x-2}{5x^2+4x+1}$, $\lim_{x\to\infty}\frac{x^2-4}{x+2}$)	Find limits of rational functions whose expressions contain generalized constants (e.g. $\lim_{x\to\infty}\frac{x^c}{x^4+1}$ where c is a non-negative integer)	Find limits of functions not discussed in any of the three conditions (e.g. $\lim_{x\to\infty} e^x\cos(x)$)

Subjects assigned to conditions 1 or 3 criticized the approaches for their lack of theory and examples respectively. When asked about the effect of adding theory to condition 1, subjects said that they "like to know why things are true"[2] but that theory "doesn't help in knowing how to deal with problems." When asked about the effect of adding (particular) examples to condition 3, subjects said that "without examples [we] don't know what to do" and that they are "unable to apply theory to an example without being shown how to do so." Certainly, these students do not recognize generalized examples as "examples on how to apply theory."

When dealing with problems in the task-based interview, subjects assigned to conditions 1 and 2 constantly reviewed the notes they had written during the corresponding lecture, in search of examples that *matched* the proposed problem. This is more significant when we consider subjects assigned to condition 2 who ignored their notes on theoretical explanations, generalized techniques, etc. For instance, in condition 2, they had been shown a technique for finding limits of rational functions in general terms and only one numerical example; when dealing with problems of type 1, subjects only referred to the numerical example and got stuck when the function they had to deal with did not have the exact same features as those of the example. When asked why they did not use their notes apart from the example, they argued that they "wouldn't know how to apply these to a concrete problem." These students, as students in condition 1, use particular examples as templates (instead of using generalized examples).

Subjects assigned to condition 3 did not refer to their notes when dealing with problems in the task-based interview. When asked, for example, whether they thought that a technique to find limits of rational functions had been explained in the lecture, most subjects said that they "didn't remember" or that they "didn't understand the explanation." In some cases, subjects said that they "didn't pay attention to explanations in the lecture as [they] know they are not important for solving problems." When the interviewer insisted they refer to the section of their notes where a technique to find limits of rational functions is explained, subjects stated that they were uncomfortable with "expressions that use letters rather than numbers," and that they have a hard time "recognizing what the letters mean" and understanding how to use techniques explained in general terms.

Discussion

Our study highlights features of the learning culture that college level (Calculus) students share: the ways they perceive mathematical theory and particular examples. In his paper of 2004, Lithner showed how particular examples in Calculus textbooks are used as templates to solve other problems. Our data shows that students not only use particular examples as templates but that at the time when they are (institutionally) ready to start a Calculus course, they need these particular examples; generalized ones don't count as they don't know how to use them. Moreover, they do not recognize generalized examples as a tool to solve problems; the existence of generalized constants in an expression seems to act as an obstacle for them to recognize the example as such. It seems as though students don't realize that particular examples hide the limitations of a technique, and are at loss when presented with non-routine problems. Furthermore, although students perceive theory as important because "it explains why things are true," they fail to see it as a generator of techniques for solving problems. We believe that these inabilities, although they are of different natures, might have a common source in certain institutional norms that define a predominant mathematics teaching and learning culture; a culture in which if and when theory is present, it is not necessary. Thus, it won't suffice to incorporate theory into the teaching approach; it is the very essence of mathematical theory and its relation to problem solving that has to be addressed if we want college level students to engage in mathematical practices as mathematical subjects.

Endnotes

SEEING THE GENERAL IN THE SPECIFIC: A CLOSER LOOK AT STUDENTS' EXAMPLE BASED REASONING

Sean Larsen
Portland State University
slarsen@pdx.edu

Carolyn McCaffrey
Portland State University
mccaffrc@pdx.edu

In this paper, we explore distinctions among middle school students' example based mathematical justifications. This work has emerged naturally as part of a research and professional development project focused on middle school teachers' development in their understanding of mathematical justification and their ability to support their students in learning to justify. We share a selection of example based student justifications in order to illustrate a distribution ranging from pure empirical arguments to generic proofs. We observe that the most sophisticated of these generic example based arguments are but a step away from general proofs. This progression could provide a viable starting point for design research focused on developing instruction to support students in leveraging examples to produce general arguments.

Keywords: Reasoning and Proof; Middle School Education

It has been well documented that K–12 students tend to both produce and prefer empirical justifications (Chazan, 1993; Knuth, Choppin, Slaughter, & Sutherland, 2002). However, this research can suggest a dichotomy between example-based reasoning and rigorous proof. Justifications using generic examples (Mason & Pimm, 1984), which we will refer to as *generic proofs* (Selden & Selden, 2008) straddle this dichotomy. On the one hand, they involve the use of specific examples, while on the other hand, these examples are reasoned about generically (i.e., focus is on the attributes seen as common to all instances rather than attributes specific to the example being considered). Additionally, generic examples can typically be refined to be general proofs by introducing more general representations (including algebraic symbols). This suggests that it may be more productive to think in terms of a progression from pure empirical reasoning to reasoning about examples generically on the way to rigorous general proof.

The JAGUAR Project

The JAGUAR (Justification and Argumentation: Growing Understanding of Algebraic Reasoning) project is a research and professional development project focused on middle school teachers' development in terms of their understanding of mathematical justification and their ability to support their students in learning to justify. The project team worked with 12 teachers in two different states over the course of two years. The teachers were exceptional in the sense that (for most of the teachers) we had evidence that their practice was already developed to the point that their classrooms were rich in mathematical discourse. An important goal of the project was for the teachers to develop in their ability to support their students in constructing valid mathematical justifications.

Data Collection and Analysis

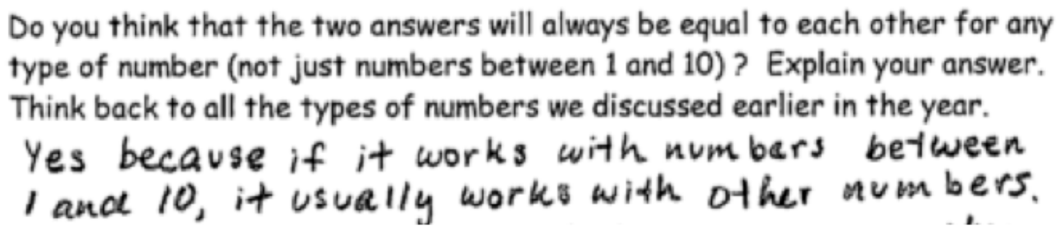
Early in the project, the research team met with the participating teachings in summer workshop. One of the questions that was considered (in collaboration with the participating teachers) was what forms of reasoning (Stylianides, 2007) were appropriate to expect and promote in a middle school mathematics classroom. Because of its prevalence in students' thinking, example-based reasoning was something that the project team and the teachers expected to see regularly in students' justifications. The project team worked with the teachers to design four lessons that both fit well into the teachers' existing curriculum and strongly featured justification. For each teacher, we videotaped the implementation of each of these lessons in two consecutive years. While the focus of our data collection was on the teachers, we were able to collect a large number of student justifications in the form of collected written assignments, poster presentations, and contributions to whole class discussions.

This brief research report is based on our ongoing analyses of the students' individual written justifications and poster presentations. A major aspect of this analysis is the categorization of the forms of reasoning employed by students in their justifications. The goal of this analysis is to construct a taxonomy of forms of reasoning that is relevant to middle school mathematics. Note that an argument can employ more than one form of reasoning, and we have found that some of our categories naturally overlap (e.g., pattern based reasoning can typically be considered to be a special case of example based reasoning). The focus here is on the distinctions we are seeing among students' example-based arguments.

Illustrative Results

Here we will present a progression of illustrative student justifications. This progression can be subdivided roughly into two levels. The first level consists of empirical justifications ranging from naïve empiricism to arguments that show evidence of awareness of the potential limitations of empirical reasoning. The second level consists of justifications in which examples are used generically to some extent. The most sophisticated justifications of this type are essentially general proofs although they contain residue of example based reasoning in their use of representations that are not fully general.

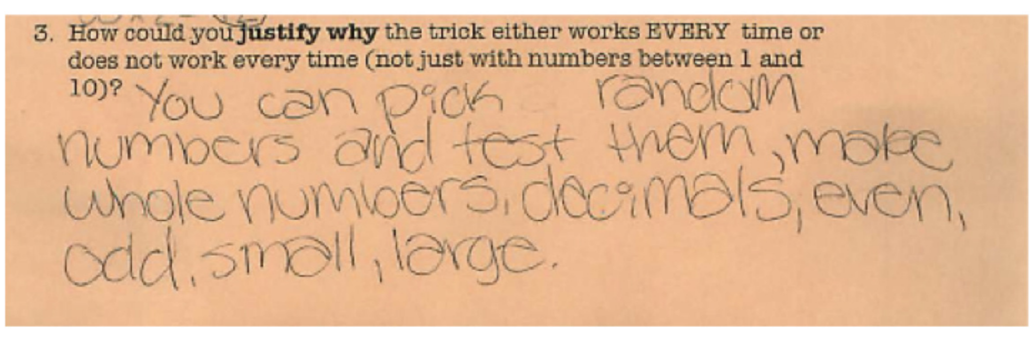
Level 1: Empirical use of examples in justifications. Not surprisingly, we identified many instances of students using empirical reasoning. For example, when asked whether a number trick (using the distributive property) worked for all numbers (after it had been verified for the numbers 1–10), one student responded as follows:



Do you think that the two answers will always be equal to each other for any type of number (not just numbers between 1 and 10)? Explain your answer. Think back to all the types of numbers we discussed earlier in the year.
Yes because if it works with numbers between 1 and 10, it usually works with other numbers.

Figure 1: Naïve empirical justification

While the justification in Figure 1 shows little awareness of the limitations of checking examples, the justification shown in Figure 2 (to a very similar task) describes a much less naïve empirical approach in which one carefully selects examples in order to verify a representative sample (apparently) in an attempt to decrease the likely hood of missing a disconfirming case.



3. How could you **justify why** the trick either works EVERY time or does not work every time (not just with numbers between 1 and 10)? You can pick random numbers and test them, make whole numbers, decimals, even, odd, small, large.

Figure 2: Less naïve empirical justification

Level 2: Generic examples. While the example shown in Figure 2 suggests an increased awareness of the limitations of checking examples, it does not address *why* the number trick works and so does not really provide a starting point for developing a general argument. However, we found many examples in which students did reason generically about examples. Some of these only showed only a rudimentary analysis of why a statement was true for a specific example. In Figure 3 we see a justification of this type.

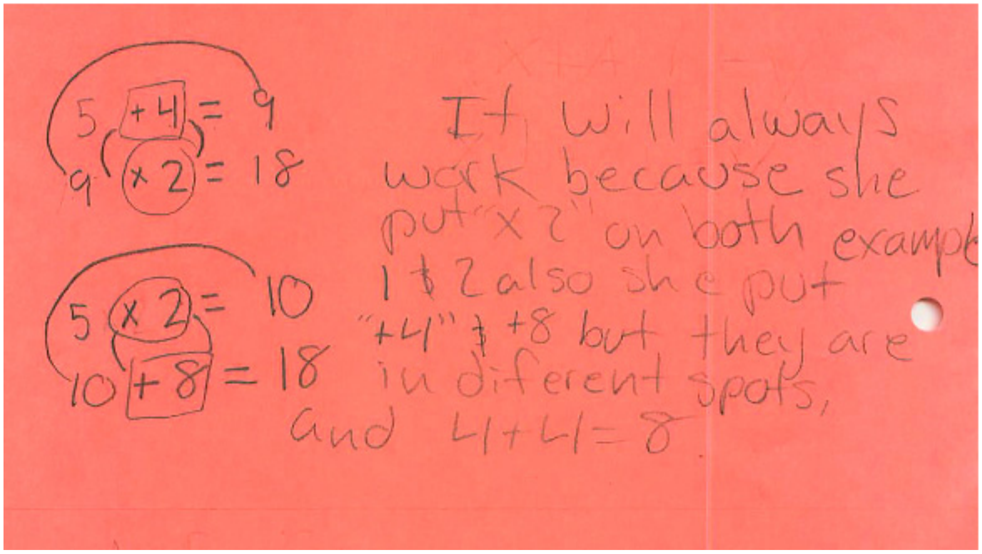


Figure 3: Slightly generic example

In the justification shown in Figure 3 we see the student analyzing the structure of the example in order to ascertain *why* the number trick works. The student has identified a type of equivalence between the two statements based on the doubling that occurs in each procedure and a compensation (doubling the four to get eight) for the fact that this doubling occurs at a different step in the two procedures. By way of contrast, the justification shown in Figure 4 (Justifying a formula for the perimeter of a chain of hexagons) fully explains why the formula works in general by carefully analyzing a specific example.

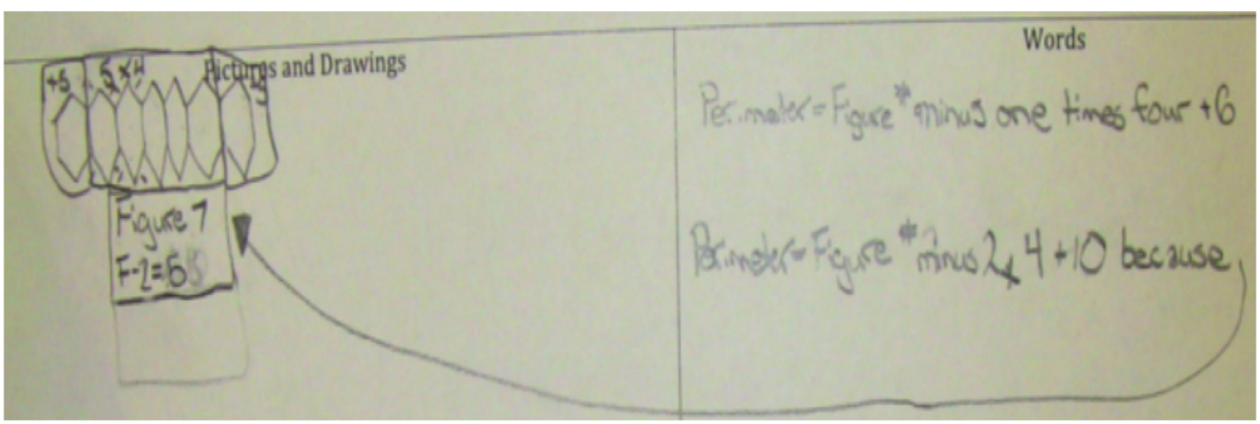

Figure 4: Generic proof

Note that a justification of the type shown in Figure 4 comes very close to being a general proof. The argument does not depend in any way on the specific nature of the example. One could make the figure more general using ellipses and make greater use of algebraic symbols. Then when accompanied by a verbal explanation, this argument would serve as a very explanatory general proof.

Discussion

The examples presented here suggest some milestones along a trajectory from pure empirical reasoning to generic proof. Further analysis will be needed to further flesh out this trajectory. Such a trajectory would be an important part of a taxonomy of forms of reasoning relevant to middle school mathematics and would provide a solid starting point for design research aimed at developing instructional approaches to supporting students in developing more powerful example based reasoning.

INFERRING IMPULSIVE-ANALYTIC DISPOSITION FROM STUDENTS' ACTIONS IN SOLVING MATH PROBLEMS

Kien H. Lim

kienlim@utep.edu

Miguel Mendoza
University of Texas at El Paso
mmendoza6@utep.edu

The research reported in this paper is part of a larger study designed to investigate the validity of the Likelihood-to-Act (LtA) survey—an Likert-scale instrument, currently under development and testing, for assessing students' impulsive-analytic disposition in mathematics. Transcripts and videos of 15 interviewees' responses to five problems, adapted from the LtA Survey, were analyzed in terms of (a) solution strategies, and (b) impulsive-analytic disposition. Two scores were derived from quantifying the codes that were assigned to the 75 problem-solving episodes. These scores were highly correlated to one another and were correlated to the LtA_Difference (impulsive minus analytic) score, obtained from the LtA Survey administered several weeks prior to the interviews. These results can be taken to support the validity of the LtA instrument.

Keywords: Cognition; Metacognition; Problem Solving

Lim, Morera, and Tchoshanov (2009) use the term *impulsive disposition* to refer to a tendency to proceed with an action that comes to mind without analyzing the problem situation and without considering the relevance of the anticipated action to the problem situation. Most mathematics educators would want their students to progress from impulsive disposition to *analytic disposition*—a tendency to study the problem situation prior to taking actions. Self-awareness of impulsive tendency is likely to propel students towards a more analytic tendency. One way to create such awareness is to have an instrument that can accurately measure one's impulsive-analytic disposition.

Lim et al. (2009) created an instrument, called the *Likelihood-to-Act* (LtA) survey, for gauging students' impulsive-analytic disposition. The LtA survey has been undergoing a few rounds of testing and revisions (Lim & Mendoza, 2010; Lim & Morera, 2011). The current version consists of 16 pairs of Likert items. Figure 1 below shows a pair of impulsive and analytic items where respondents indicate on a scale of 1 (extremely unlikely) to 6 (extremely likely) how likely they are to respond to the given mathematical situation in the described manner. Three measures can be derived from the LtA survey: (a) the impulsive subscale based on the 16 impulsive items, (b) the analytic subscale based on the 16 analytic items, and (c) the LtA_Difference score is the average difference between the impulsive and analytic scores.

3. $\frac{3}{4}+\frac{1}{10}+\frac{9}{10}$ When asked to find the answer for the above arithmetic expression without using a calculator, how likely are you to begin by finding the common denominator?	**1**	**2**	**3**	**4**	**5**	**6**
19. $\frac{3}{5}+\frac{11}{12}+\frac{1}{12}$ When asked to find the answer for the above arithmetic expression without using a calculator, how likely are you to begin by studying the fractions to see if you can predict the answer?	**1**	**2**	**3**	**4**	**5**	**6**

Figure 1

The objectives of this research are: (a) to investigate the validity of the LtA survey, and (b) to explore ways of inferring impulsive-analytic disposition from students' actions while solving math problems that were designed specifically to elicit impulsive solution strategies. In this research report, we seek to answer the following questions:

1. What solution strategies did participants use in solving those math problems?
2. To what extent does student impulsivity inferred from their problem-solving behaviors during an interview agree with the LtA score of impulsivity?

Theoretical Perspectives

Research on mathematical problem solving has been studied extensively. In particular, Schoenfeld (1992) identifies four categories of cognition that provide a framework for analyzing problem-solving behaviors: resources, heuristics, control, and beliefs. He reported that 60% of solution attempts were of the "read, make a decision quickly, and pursue that direction come hell or high water variety" (p. 356). This behavior is a consequence of one's lack of metacognitive control. The "reading and making a decision" part is suggestive of impulsive disposition.

Unlike typical problem-solving research that involve *problems* where a solution approach is not readily known to students, our study focuses on students' responses to familiar-looking tasks where they are likely to take actions spontaneously. We use tasks that are similar to those in Frederick's (2005) *cognitive reflection test*: "A bat and ball cost \$1.10 in total. The bat costs \$1.00 more than the ball. How much does the ball cost?" (p. 27). Students who have an impulsive tendency are likely to answer 10 cents, which is the difference between \$1.10 and \$1.

From a cognitive science perspective, certain impulsiveness is inevitable due to our cognitive structures. According to dual process theories, humans have two distinct cognitive systems of reasoning. "System 1 processes are rapid, parallel and automatic in nature: only their final product is posted in consciousness" whereas "System 2 thinking is slow and sequential in nature and makes use of the central working memory system" (Evans, 2006, p. 454). Mathematicians know when they can rely on System 1 and when they need to be cautious. Many math students, on the other hand, lack the control and tend to rely on the first idea that comes to mind. Helping them become aware of the need to be reflective and analytic is an important step.

Method

Among the 495 undergraduates who took the LtA survey, 90 volunteered and 16 took part in a 60-minute three-part interview. This paper focuses on the problem-solving part where participants solve five math problems and then explained their reasoning.

P1. Find the answer for $\frac{3}{4}+\frac{1}{10}+\frac{9}{10}$
P2. Solve for n: $90 + 1234n + 567 + 89n = n + 1234n + 567 + 89n$
P3. Five lampposts are spaced evenly along a street. The distance between the first lamppost and the last lamppost is 220 m apart. What is the distance between any two neighboring lampposts?
P4. Project P took 30 workers, each working 8 hours, to complete. Project Q took 20 workers, each working 3 hours, to complete. Which project was bigger in size?
P5. Paula is bicycling from home to school. At 8 o'clock she has already cycled 2.4 miles. What is her speed?

The first 12 interviews were conducted by the first author and the remaining four interviews by the second author. We analyzed 75 think-aloud problem-solving episodes (15 participants solving 5 problems each; the interviewee who spoke mainly in Spanish was excluded).

The 75 episodes were analyzed in two ways to generate two quantifiable scores. The first analysis involved data exploration and code creation, where the focus was on the solution strategies used by interviewees in solving the five problems. For each interviewee, we divided the number of instances of impulsive strategies by the total number of instances of strategies (both impulsive and analytic) to obtain the *Impulsive Strategy Percent*.

In the second analysis, the video of each episode was analyzed. Using a rubric, each episode was assigned one of five codes: "I+" (strong indication of impulsive disposition), "I-" (weak impulsive), "A+" (strong analytic), "A-" (weak analytic), and "U" (unsure). The authors and a graduate student met to go over the rubric and a training set of nine episodes. The inter-rater reliability for the remaining 66 episodes was 0.76. After discussing all discrepant cases, each code was then assigned a number (1 for "A+" and 5 for "I+"). The sum of scores for the five problems constitutes the *Impulsive Disposition Score*, which ranges from 5 to 25.

Results and Discussion

Table 1 below shows the list of solution-strategy codes and number of occurrences. Of the 102 instances (some interviewees used more than one strategy in a problem), 43 are impulsive with most of them occurring in the two non-contextualized problems (P1 and P2). The remaining 59 analytic instances occurred mainly in the three contextualized problems (P3, P4 and P5), partly because students have to read and understand the problem situation.

Table 1

Item	Strategy Code	Description	Instances
P1	CD	Uses a common denominator of 10, 20, or 40	14
	ADDLAST	Adds the last two fractions first	2
P2	COMBLT	Combines like terms	12
	CANCELTRM	Cancels any common terms found on both sides	6
P3	DIVIDE5	Divides the total distance by five	10
	DIVIDE4	Divides the total distance by four	6
	DRAWPIC	Draws a picture	12
	GUESS-N-CHK	Makes an educated guess and checks if it is correct	1
P4	RATIOCOMP	Creates and compares two ratios	4
	LOGIC	Uses direct reasoning to solve problem	4
	TOTALHOURS	Multiplies workers by hours to find total hours worked	10
P5	DIVIDE8	Divides the total distance by eight	1
	FORMULA	Uses speed = distance/time formula	1
	PROPORTION	Thinks of setting up a proportion	1
	DRAWPIC	Draws a picture	4
	MISSINFO	Believes problem is unsolvable; missing info	14

Table 2 below shows the codes we assigned to each episode as well as the Impulsive Disposition Score for each interviewee. "I+" and "I-" codes appeared mainly for P1 and P2 whereas "A+" and "A-" occurred mainly for P4 and P5.

Table 2

	S1	S2	S3	S4	S5	S6	S7	S8	S9	S10	S11	S12	S13	S14	S15
Problem 1	I+	I+	I+	I+	A+	I-	I+	I+	I+	A+	I+	I+	I-	I+	I+
Problem 2	I+	A+	I+	I+	I+	I-	I-	I+	I+	A+	A-	A-	I-	A-	A+
Problem 3	I-	A-	A+	I+	I+	I-	I-	I+	I-	A+	A-	A+	A+	I+	A+
Problem 4	I-	A+	A+	A-	A+	A+	I+	A+	A+	A+	A+	A+	A+	A+	A-
Problem 5	A-	A+	A+	A+	A+	A+	A-	A+	A+	A+	A+	U	A+	A+	A+
Imp. Disp. Sc.	20	10	13	18	13	14	20	17	16	5	11	12	11	14	10

Table 3 below lists the three measures of impulsivity for each participant, with the top three highest scores in each row highlighted. These results seem to be consistent, except S13.

Table 3

Participant	S1	S2	S3	S4	S5	S6	S7	S8	S9	S10	S11	S12	S13	S14	S15
Imp. Strategy %	62	22	33	50	40	50	71	60	50	0	33	38	33	50	43
Imp. Disp. Sc.	20	10	13	18	13	14	20	17	16	5	11	12	11	14	10
LtA_Difference	2.81	0.31	0.88	2.00	-0.56	1.13	0.44	0.81	0.44	-2.75	-0.31	0.44	1.50	0.25	0.81

Twelve out of the 15 interviewees have a positive value for LtA_Difference score; in other words, they were more likely to respond in the impulsive manner than in the analytic manner described in an LtA pair (see Figure 1). On the other hand, only three interviewees exhibited more impulsive solution strategies than analytic solution strategies, and only five interviewees have Impulsive Disposition scores that are greater than 15. These results suggest that participants are generally more analytic in an interview setting and more impulsive in a survey-taking setting.

The Pearson's correlation between Impulsive Strategy Percent and Impulsive Disposition Score is 0.927 with a *p*-value of 0.000. This high correlation can be attributed to the fact that these two scores are based on the same data source—the problem solving part of the interview. The correlation between Impulsive Strategy Percent and LtA_Difference is 0.670 with a *p*-value of 0.006. The correlation between Impulsive Disposition Score and LtA_Difference is 0.693 with a *p*-value of 0.004. These high correlations suggest that the analysis of the problem-solving part of the interviews supports the validity of the LtA_Difference score.

Concluding Remarks

There was a strong correlation between the Impulsive Strategy Percent and Impulsive Disposition Score, partly because the problems in the interview were designed specifically to elicit impulsive solution strategies. Nevertheless, it is possible for students to use an impulsive (or analytic) solution strategy but reason in an analytic (or impulsive) manner.

The two scores from the interview data are positively correlated with the score obtained from the LtA survey. These strong correlations suggest that the LtA survey is a valid instrument. However, not all LtA items are necessarily valid. The analyses of the other parts of the interview will inform the strengths and weaknesses of the LtA items; this information will be valuable for refining the LtA items.

CONVERSATIONAL REPAIR AS A SCAFFOLDING STRATEGY TO PROMOTE MATHEMATICS EXPLANATIONS OF STUDENTS WITH LEARNING DISABILITIES

Jia Liu
Purdue University
liu69@purdue.edu

Yan Ping Xin
Purdue University
yxin@purdue.edu

The linguistic concept of conversational repair is proposed to scaffold students with learning disabilities/difficulties (LD) to better transit to the reform-based discourse-oriented mathematics classroom. With a multiple-baseline-across-participants design, participants were asked to self-explain their reasoning/thinking during word problem solving, while the experimenter gives repair requests as a scaffolding strategy to elicit explanation repair from them during intervention. This study attempts to examine the effectiveness of this strategy in improving these students' reasoning ability measured by the characteristics and quality of their self-explanations, and their problem solving ability measured by performance scores.

Keywords: Elementary School Education; Problem Solving; Reasoning and Proof; Standards (broadly defined)

Pursued Problem

Self-explanation can deepen understanding and improve learning outcome (Aleven & Koedinger, 2002; Neuman & Schwarz, 2000). It plays an especially important role in current reform-based mathematical classroom discourse where *all* students are expected to learn to be clear and convincing in expressing their own ideas and to listen to, understand, and make connections with others' ideas and hence sharpen their thoughts (National Council of Teachers of Mathematics, 2000).

Students with learning disabilities (LD) encounter difficulties articulating or explaining well their reasoning processes due to the mathematical and communicative difficulties they may have. As such, they may need to repair incorrect or inaccurate articulations while self-explaining. Thus the use of repair request techniques is proposed as an intervention to elicit conversational repair from students with LD to improve their self-explanations.

Classroom Discourse and Students with LD

The importance of communication in learning stems from Vygotsky's social development theory, which emphasizes that social interaction is crucial in shaping cognition (Kotsopoulos, 2010). There are increasing interests in the role classroom communication plays in teaching and learning within academic content areas (Hicks, 1995-1996). Current reform in mathematics education calls for reasoning and communication aspects of mathematics learning to develop student competencies. Explanation is an important component in mathematics classroom discourse. Self-explanation is to explain to oneself problem-solving process and reasoning behind the process. If a student is able to make good self-explanation, s/he can also make him/herself clear when explaining to others.

According to existing literature, though it is difficult for students with disabilities to participate in discourse-oriented learning (Baxter, Woodward, & Olson, 2001; Maccini & Gagnon, 2002), they could still learn the thinking behaviors such as asking questions, disagreeing, explaining, and suggesting solutions (Berry & Kim, 2008). They can also benefit from the discourse-oriented classroom as their normally achieving peers do (Berry & Kim, 2008; Kroesbergen & Van Luit, 2002, 2003; Woodward & Baxter, 1997) if teachers use effective instructional strategies (Baxter, Woodward, & Olson, 2001).

In a constructivist learning process, to help a student produce a satisfactory explanation of thinking or reasoning, a teacher should collaborate with the student through dialogues with scaffolding techniques whenever needed for the student to achieve that goal.

Research Questions

The research questions are: (a) What are the characteristics of self-explanation utterances of students with LD, pertinent to repair frequencies and types before, during, and after intervention? (b) Will conversational repair increase the quality of self-explanation of students with LD? (c) Will the students gradually need fewer and fewer repair requests as they go through the intervention? (d) How will conversational repair help students' performance on word problem solving tests?

Methodology/Research Design

A multiple baseline design across participants was used. The experimental design included two major conditions for each participant: baseline (including pre-intervention assessment and post-intervention assessment conditions) and intervention. Chronologically, the experiment included four phases: pre-test phase, intervention phase, post-test phase, and transfer phase. When a phase ended, the next phase began the following day.

Measures

Dependent measures included students' word problem solving performance and self-explanation quality in the criterion test and the transfer test. The criterion test and its alternate forms were used in the pre-test, the intervention, and the post-test phases. The criterion test comprised 10 one-step *equal group* (EG) word problems (i.e., number of items in each group × number of groups = total number of items) with the unknown's position in a problem systematically varied. The transfer test had the same format as the criterion test except that the 10 word problems were two-step EG word problems.

Scoring. The participants' quality of self-explanation and accuracy of problem solving were scored. For each test, the quality of self-explanations was calculated as the total points earned for self-explanation statements divided by the total statements produced. Accuracy of problem solving referred to the percentage of problems solved correctly in each test. It was calculated as the total points earned divided by the total possible points.

Participants and Setting

About five students with LD from 4th grade in a Midwest urban public elementary school in the United States were selected as participants. They were pulled out to a quiet conference room four times a week to conduct the experiment. The whole process of the experiment was videotaped.

Procedures

In the baseline condition, students were asked to solve 10 one-step equal group (EG) word problems in each session. They first wrote down all of the problem-solving processes, including math equation(s) in the space below the problems, and then explained the solving steps to the investigator.

In the intervention condition, students' explanations were scaffolded by the investigator's repair requests. During intervention, participants' initial statements were evaluated for the quality of self-explanation. Also, the number of repair requests needed from the investigator to complete a satisfactory explanation of a problem was counted. When the first participant showed a clear and stable increase in self-explanation scores, a second student was introduced to the intervention condition.

Treatment components. Repair request referred to the prompts from the investigator requesting the participants to repair their explanation. The repair requests in this study were designed based on Weiner (2005): (1) requests for general information, (2) requests for specification/clarification, (3) requests for revision, and (4) direct other-repair. The forms of the requests were based on and maximally followed the basic types defined by Schegloff, Jefferson, and Sacks (1977).

1. The request for general information **"It is a good start. Could you tell me more?"** is given after a participant is given enough time to read and think about the problem, and produces a problematic initial explanation (being roughly correct but unclear, or incorrect, or offering no response at all) that needs to be

improved. After the participant repairs (or does not repair) the explanation, the following intervention will address the repaired (or initial, in case the participant does not try again) explanation if it is still problematic.

2. If repaired explanation is incorrect or offers no response at all, which reflects incorrect reasoning, the investigator will follow up to provide a hint and then request a revision by saying **"This number means…and this number means…"** (*Tells the participant the meaning of the two known numbers*.) **"So do you want to revise your explanation?"** If the following repaired explanation is still incorrect or offers no response at all, the investigator will implement direct teaching (based on Xin et al., 2008 and Xin & Zhang, 2009), and the participant will be asked to repeat what the investigator has just said; if the following repaired explanation becomes roughly correct but not clear enough, the investigator will implement the actions in "requests for specification/clarification."

3. If repaired explanation is roughly correct but not clear enough, the investigator will request specification/clarification of the unclear parts by repeating repairable parts in the participant's response and adding *a **wh-*** question word, or, by saying **"And could you tell me more about why you did so?"** If the following repaired explanation is still roughly correct but not clear enough, the investigator will do direct other repair. That is, the investigator will model a full-scored explanation to the participant. Then the participant is asked to repeat what the investigator has just said.

4. If in any place in the process the explanation is worth full score, the participant will be moved to the next problem.

Results

Prior to this study, a pilot study (Xin et al., in preparation) has shown that in a constructivistic learning environment, students with LD were still passively involved in the teaching-learning interaction when the teacher applied little scaffolding techniques. Therefore, the results of this study will show how the participants' performance in self-explanation and problem solving change from the baseline to the intervention condition. The self-explanation scores, test scores, and frequencies of repair requests will be presented in a graph and a systematic visual comparison of within- and across-conditions will be conducted to see the levels, trends, and variability of the data.

Discussion

This study has theoretical significance. First, it directly addresses the call for mathematical communication/discourse by the math education reform. It helps improve not only the achievement levels, but also articulation of math thinking and reasoning. Secondly, it focuses on students with LD. In the call for inclusive classroom, quality participation of all students (including those with LD) in classroom discourse will be crucial to the success of the whole class. Third, current research on students' verbalization in the field of special education covers various topics. However, few studies specifically examine the characteristics and quality improvement of self-explanations of students with LD. Fourth, this study enriches the research on self-explanation by extending it to the field of special education. Fifth, this study incorporates conversational repair, a concept in pragmatics, into math education with students with LD or learning difficulties. This study's practical significances include first, it provides a clearer picture for teachers and practitioners on how students with LD explain their reasoning in problem solving process. Second, it offers a strategy (conversational repair) that teachers or practitioners could easily use in conversations to work with the student by providing scaffolding to improve their explanation. Third, the repair requests and responses can also occur between students with LD and their normally achieving peers. As such, it can facilitate communication and discussion between students with LD and their normal achieving peers, and improve group work.

WHAT KINDS OF ARGUMENTS DO EIGHTH GRADERS PREFER: PRELIMINARY RESULTS FROM AN EXPLORATORY STUDY

Yating Liu
The Ohio State University
liu.891@buckeyemail.osu.edu

Azita Manouchehri
The Ohio State University
Manouchehri.1@osu.edu

In this work, using Harel and Sowder's framework as a guiding lens for data collection and analysis, we examined the proof schemes used by 16 eighth graders when validating mathematical statements from number theory, algebra, geometry and probability and statistics. We also elicited the participants' views regarding soundness of alternative explanations offered to justify the same statements. Our goal was to see what features of arguments they viewed as convincing and ways in which they reconciled differences between their own validating schemes and those of others, if any existed.

Introduction

Students' difficulty with both writing deductive proofs and recognizing them as viable vehicles for verifying validity of mathematical conjectures has long been recognized (Balacheff, 1988; Chazan, 1993; Coe & Ruthven, 1994; Knuth et al., 2002). It has also been established that students usually maintain different perspectives than those of mathematicians about the meaning of proofs and how to go about proving mathematical statements (Herbst, 2006).

Harel and Sowder (1998) posited that an individual's scheme for proving statements consists of what the person considers as ascertaining and persuading. These schemes are not built in a vacuum and are impacted by students' personal experiences, vocabulary and thinking habits. Harel and Sowder (1998) summarized the students' proof schemes to be of three types: external conviction, empirical, and analytical. External conviction proof schemes include instances where students accept the validity of an argument by referring to external sources. As such, they rely on either the appearance of the argument (instead of its content) that could include symbolic manipulation, or rely on words of an external authority such as a textbook or a teacher. Empirical proof schemes, inductive or perceptual, include instances when a student relies on examples or mental images to remove doubt about the validity of an argument. While an inductive proof scheme draws heavily on examination of cases for convincing oneself, a perceptual proof scheme is grounded in more intuitively coordinated mental procedures without realizing the impact of specific transformations. Lastly, analytical proof schemes follow logical deduction when validating conjectures, relying on either transformational structures (operations on objects) or axiomatic modes of reasoning which include resting upon defined and undefined terms, postulates or previously proven conjectures.

There is consensus that in order for students to move towards relying on analytical schemes when attempting to validate mathematical statements, they need to recognize deductive arguments as convincing statements instead of merely mechanical procedures that need to be followed. Despite this, research has shown consistently that students' misconceptions about proofs impede their capacity to recognize this critical issue (Herbst, 2006; Healy & Hoyles, 2000; Harel & Sowder, 1998). Due to the vital role that proofs and proving process play in the discipline of mathematics, the need to conceptualize ways in which students might be assisted in their development in this area is equally as important as to exam their thinking during the transitional band of moving from informal to formal mathematics. The existing body of research on students' proof schemes has focused primarily on students enrolled in upper secondary school levels or undergraduate university courses. It is not quite clear what schemes younger students, particularly those in middle grade levels might use when confronted with mathematical tasks needing validation. The purpose of our research was to address this gap in the literature.

Purpose of the Study

The goal of the study was threefold. First, we intended to examine how a group of eighth graders attempted to validate mathematical statements from four different content areas. Second, we intended to investigate the type of arguments that were most likely to be accepted by the students. Third, we explored whether exposure to various types of validation arguments (e.g., external, empirical, and analytical) motivated a reconsideration of utility of each when confronted with similar situations.

Methodology

This report is a part of a much larger, longitudinal research project in which we study the development of problem solving and mathematical reasoning skills of a cohort of approximately 150 children as they progress from eighth to tenth grade in their respective schools. All children come from urban communities, attending over 30 different middle and high schools across the state of Ohio. The sample used for analysis in the current study consists of 16 eighth graders involved in the larger project. At the time of data collection approximately one half of the children were enrolled in a geometry course and the other half in an algebra course (Integrated Algebra or Algebra I). The sample consisted primarily of children from historically underrepresented groups in STEM areas (75% Black, 15% Latino).

Data Collection and Analysis

Harel and Sowder's (1998) framework guided the development of the data-collection instrument, *Survey of Reasoning*, as well as data analysis efforts. *Survey of Reasoning* consisted of four problems that focused on proving and disproving conjectures in number theory, algebra, geometry, and probability & statistics, respectively. Each problem consisted of several parts. The participants needed to first decide on the validity of the statement of the problem and support their conclusion using their own explanations; then four different types of arguments to justify the validity of the same problem were given and students were asked to decide which argument they preferred and why. Lastly, the participants were asked to judge whether each of the given arguments was convincing and whether it was mathematically complete. Students needed to provide narrative explanations to further support their claim in answering each of the questions. The content of the problems used in the survey will be shared during the presentation.

The choice of arguments offered in the survey was essential to the results we could obtain from the survey. In order to distinguish what kinds of arguments were most accessible to the participants, we deliberately designed arguments that represented different proof schemes as identified by Harel & Sowder's (1998) model.

In analyzing the data, the participants' responses were coded according to indicators associated with each of the three proof schemes. Prominent modes of reasoning used by the participants were catalogued and tallied across the sample and problem type. Qualitative analysis of responses included identifying particular lines of reasoning participants had used when verifying statements, issues they had considered when suggesting an argument as mathematically complete, as well as whether consistency existed between problems regarding what students considered most convincing and most mathematically complete.

Results

Table 1 illustrates the proof schemes that students used in responding to each of the problems on the survey (NA indicates that either participants didn't offer a response or their work was not understandable to the researchers). Consistent with the findings of previous research the participants in this study relied heavily on empirical evidence when verifying arguments. However, the dominance of the empirical scheme varied according to the mathematical context on which they worked.

Table 1: The Proof Scheme of the Arguments Created by Students in Each Problem

	Number Theory	Geometry	Probability	Algebra	Accumulative
External	0	2	1	0	3
Empirical	12	8	3	8	31
Analytical	1	2	5	4	12
NA	3	4	7	4	18

Table 2 illustrates the proof schemes the students preferred among the 4 arguments provided in each problem. These results again depict that students' explanations can vary depending on the context. As such, the results suggest possible transitional paths for production of proof schemes learners are inspired by understandable and informative arguments. Interestingly, even the same individuals who had expressed preference of their own arguments favored a different argument type when answering the same question in another problem.

Table 2: The Proof Scheme of the Arguments Preferred by Students in Each Problem

	Number Theory	Geometry	Probability	Algebra	Accumulative
Empirical	11	4	2	0	17
Analytical	2	10	14	16	42
Own	1	1	0	0	2
NA	2	1	0	0	3

The participants indicated an analytical argument as their favorite choice in 11 of 31 cases where the explanations created by themselves followed empirical approaches; while among the 12 cases where students offered analytical explanations, only 1 indicated preference for an empirical argument given to support the same problem. This suggests that students can and do recognize the advantages of analytical approach over empirical explanations. Once students were able to produce analytical explanations they were unlikely to prefer empirically based argument in the same context.

What students considered as *convincing argument* was not always consistent with what they recognized as mathematically complete. Several participants' choice of *mathematically complete* arguments in each of the four problems could have relied more on formal appearance of statements. In particular, in explaining their choice they often suggested that while the argument they had selected was least understandable to them they felt it "seemed more mathematical than others."

Perhaps the most important result concerned the potential learning that seemingly emerged from the review of optional arguments provided in each item. In conceptualizing ways in which children may be assisted in the development of their reasoning skills and the use of formal deductive arguments when verifying statements, we had conjectured that by increasing their exposure to a variety of argument types (drawing from multiple representations and visual models) we could increase their repertoire of approaches and hence influence resources from which they could draw when working on a mathematical task. This conjecture was indeed confirmed as a large number of students suggested that by studying the four arguments, they had not only gained a better understanding of the task but also methods of proving or disproving statements. This merits further and extensive study. Samples of the content of the survey and students' responses will be shared during the presentation at the conference.

Summary

Results of the study indicated that induction from empirical evidence was the most common reasoning scheme used by the participants as evidenced on their responses on the survey. However, since the participants exhibited the tendency to use empirical reasoning mode differently when verifying statements in different content areas, we believe it is premature to assert that empirical reasoning is the natural validation method used by students at this grade level in every situation. Results of our quantitative analysis demonstrated the external, empirical and analytical aspects of participants' reasoning when justifying various conjectures and shed light on contextual factors that may encourage each type of reasoning.

Our data indicated the existence of a gap between what students considered as *mathematically complete* and *convincing* arguments, and the latter were more preferred and more likely to motivate their reconsideration of how they could justify a statement. This suggests that by offering arguments that represent different proof schemes in different contexts, we might have a greater chance of transitioning students from informal to more formal modes of reasoning by providing them the access to a greater representational repertoire that they could use to build intuition and understanding.

We focus on two pairs of students from two different guided reinvention teaching experiments where students created rigorous formal sequence convergence definitions. Neither pair had been instructed on formal limit definitions, but both pairs were able to reinvent definitions consistent with formal theory. Obvious differences existed between how each pair reasoned about absolute value to denote the distance between individual sequence terms and the value of the limit. One pair quickly conceived of absolute value as a measurable attribute of a sequence graph (i.e., a quantity), while the other pair initially conceived of absolute value as a transformation. We detail the emergence of both pairs' quantitative reasoning about absolute value and shed light on why the second pair's adoption of absolute value as a quantity came much later.

Keywords: Advanced Mathematical Thinking; Design Experiments; Learning Progression; Learning Theory

Introduction

Some recent studies have adapted the guided reinvention heuristic to detail some of the challenges students face while attempting to articulate their emerging formal definitions of limit concepts (Swinyard, 2011; Oehrtman et al., 2011; Martin et al., 2011). In the case of sequence convergence, students constructed and refined their definition primarily through iterative cycles of attempting to capture and test salient relationships among quantities they identified in graphical examples. This paper begins to detail the role of such quantitative reasoning (e.g., Thompson, 1994) during guided reinvention of limit definitions by focusing on students' reasoning concerning absolute value while constructing formal sequence definitions.

Theoretical Perspective

A *guided reinvention* approach was chosen to support students in progressively constructing formal mathematics for themselves (e.g., Gravemeijer, 1998, 1999). Oehrtman et al. (2011) described student reinvention of sequence convergence as an iterative refinement process where students wrote a definition, evaluated their definition against examples and non-examples, acknowledged problems with their definition, discussed potential solutions, and attempted to incorporate solutions into a new definition, thereby initiating another iteration. *Problems* are identified by students typically due to conflicts between their concept image and their current definition. Students' explicit resolutions of problems lead to ideas that remain stable throughout remaining iterations. During the process, a mathematician may identify other *problematic issues* with a definition that the students have yet to identify as problems. When students persist in overlooking a problematic issue, facilitators can act as *conflict producers* by, for instance, asking students to interpret their definition applied to a particular example. After students wrestle with a problem for a significant time and have sufficient understanding of solution elements, but remain unable to come to a satisfactory resolution, facilitators might also act as *solution providers*.

Quantitative reasoning involves reasoning about quantities that includes the mental actions of conceiving of an object (e.g., a graph of the sequence $\{a_n\}$), attending to measurable attributes of the object (e.g., distances on a graph), constructing representations of measurements of these attributes (e.g., $|a_n - L|$,

N, or ε), and developing and reasoning about relationships between these constructed quantities (e.g., for all $n \geq N$, $| a_n - L | < \varepsilon$) (Moore, Carlson, & Oehrtman, 2009; Thompson, 1994). The research reported here focuses on the interaction between problems and quantitative reasoning about absolute value by asking the following in the context of guided reinvention: (a) How do students come to reason quantitatively about the role of absolute value? (b) What roles do problems play in students' quantitative reasoning about absolute value? and (c) What roles can facilitators play in helping students to reason quantitatively?

Method

Participating students had experience with sequences during second-semester calculus courses, but had not received instruction on formal limit definitions. Each teaching experiment was comprised of 90- to 120-minute sessions with the objective of generating a rigorous definition for *sequence convergence*. Megan and Belinda (pseudonyms) were selected from a nonstandard calculus class using Oehrtman's (2008) instructional framework where concepts involving limits are systematized around a theme of unknowns, approximations, errors, and bounds on errors. Over eight days, they participated in six sessions at a large, southwest, urban university. Joann and David (pseudonyms) were selected from a more traditional calculus class using Tan's *Calculus* (2009). Over one month, they participated in nine sessions at a small, southwest university.

Each pair initially created what they viewed as prototypical examples of sequences converging to 5 and not converging to 5. They wrote a definition which they iteratively revised until they felt it captured all their examples and excluded all their non-examples. Facilitators steered discourse to help students progress, but at the same time were diligent to preserve their "intellectual autonomy" (Gravemeijer, 1998, p. 279).

The research team created content logs containing time-stamped descriptions of the students' and facilitators' activities and theoretical notes about how progress was being made toward a formal definition. The timeline was coded for problem(s) being addressed and for students' reasoning about absolute value. Attempts were made to determine the interactions between problems and reasoning about absolute value and why particular reasoning emerged.

Results

For each pair of students, we focus only on their quantitative reasoning concerning absolute value in relation to the problems they were engaging as they iteratively refined their definition.

Megan & Belinda

Megan and Belinda first engaged the problem of "bad early behavior" of a convergent sequence with terms moving away from the limit. Their resolution was to include their notion of "at some point *n*" into a definition to identify a point at which terms became "closer and closer" to 5. Megan explained this notion by *pointing to* individual points on their graph (**Figure 6**), and noting how points get both further away and closer to 5. While she attached descriptions of closeness to relative locations of points, she did not indicate any explicit measurable attribute of the graph or mention any formula.

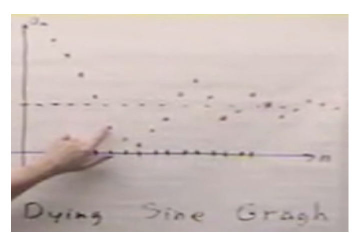

Figure 6: Pointing to individual points

Within 12 minutes of the experiment's start, Megan spontaneously rearticulated "closer and closer" in the context of errors. Both students highlighted vertical distances between points and the limit (7) and attached these vertical distances to the expression $| 5 - a_n |$, which they then included in their definition.

Afterwards, they returned to using dynamic language without reference to errors as they wrestled with another problem: "How close is close?" They made little progress during this time. However, within five minutes of facilitators guiding the students back to approximation language, they coordinated error with the emergence of error bounds and produced their next definition which contained an explicit relationship between both ("$| 5 - a_n | < .01$"). They viewed this relationship as resolving the issue of "How close is close?" provided that .01 is deemed as an "acceptable error range." Their use of error and its coordination with other quantities remained relatively stable throughout the remainder of the reinvention.

Figure 7: Highlighting error as vertical distance

Joann & David

Joann and David first discussed absolute value while engaging the problem of clarifying the meaning of "approaches" for a damped alternating graph. Initially equating "approaches" with "monotonically decreases," they voiced the following convergence test: Shift the graph down to zero, reflect the negative-valued terms over the *x*-axis, and if it "…converges to zero, it converges to 5." They expressed this in Definition 2 as "$| 5 - a_n |$ approaches or equals 0." Unlike Megan and Belinda, they took an hour to incorporate absolute value into their definition.

While testing Definition 2 against a damped oscillating sequence (as in Figure 3) where each subsequent term does not necessarily move closer to the limit, Joann and David concluded that their notion of "approaches" did not work. This led Joann to articulate ideas about "closeness" using her concept of "breaking decimal barriers" which evolved to a notion consistent with ε in the standard ε-N definition. They felt that they had resolved their problem but as they applied their definition to graphs they consistently interpreted absolute value as a transformation.

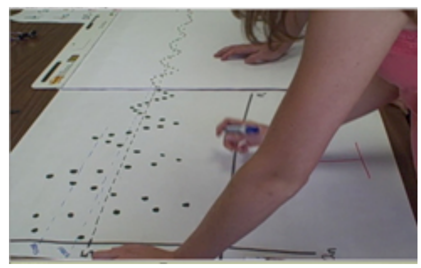

Figure 8: Decimal barriers on damped oscillating sequence

Although Joann's and David's interpretation of absolute value as a transformation was potentially viable for creating a rigorous definition, the facilitators determined that the approach would be inefficient and could create conceptual difficulties when producing limit-related proofs. Thus, on Day 3, using a ready-made graph (see Figure 3), Joann and David were asked to explain the meaning of $| a_n - 5 |$ for the sixth dot without transformations. Joann replied, "[a_1 and a_6] are the same *distance* from 5. $| a_1 - 5 |$ is the same as $| a_6 - 5 |$." David responded, "Exactly." Yet, on Day 4, when again asked to explain without transformations, Joann exclaimed: "All I can think of is shifting and reflecting!" After some time, David articulated absolute value as distance and marked the graph to show a term's distance from 5. Joann said, "So the absolute value is … your distance."

On Day 5, though David was repeatedly asked to explain $| a_n - 5 |$ without transformations, he continued to do so. He explained, "I'm not trying to reflect. This is how I would represent positive distance." Later, after Joann and David had drawn barriers around 5 on the damped oscillating graph, they no longer shifted and reflected as they coordinated absolute values with decimal barriers. From then on, they consistently referred to absolute value as distance.

Conclusion and Discussion

Graphs were essential for the constitution of relevant quantities, but addressing problems provided the context. For both pairs, absolute value as a quantity emerged as they contemplated problems involving notions of "closeness." Unfortunately, their quantitative reasoning did not emerge to resolve *explicit* problems, otherwise they would not have reverted to prior rejected interpretations. For example, Joann and David initially indicated that they *did* understand absolute value as distance but their transformation conception served them well as they were addressing early problems. Even by Day 5, David's need to shift and reflect before talking about a term's distance from 5 suggests that absolute value had not yet been reified as a quantity.

The little progress that Megan and Belinda made when using dynamic interpretations, their sudden shift to absolute value as quantity after introducing "error language," the swift incorporation of symbols, and their ability to coordinate errors and error bounds, suggest that the systematization provided by approximation instruction supported the emergence of relevant quantities not supported by dynamic interpretations. Joann and David's struggles and lack of experience with approximation activities supports this conclusion.

In contrast to Megan and Belinda, Joann's and David's eventual adoption of absolute value as a quantity resulted from *repeated* facilitator intervention, as well as the conceiving of and the repetitive coordination with other quantities such as decimal barriers. This suggests the need for other quantities to aid the emergence of related quantities. Had the facilitators been able to produce cognitive conflict causing Joann and David to identify a problem with their transformational reasoning, they may have conceived of absolute value as a quantity sooner.

IMPLEMENTATION FOR JUSTIFICATION: SUPPORTING MIDDLE SCHOOL STUDENT ARGUMENTATION

Carolyn McCaffrey
Portland State University

Sean Larsen
Portland State University
slarsen@pdx.edu

This study explores how four middle school math teachers support student justification on a "scaling" task implemented over two years. This research building on the framework developed by Stein and colleagues (1996) by providing evidence for three types of supports for justification: high level performance modeled, sustained pressure for explanation and meaning, and task specific scaffolding. In addition, this research reports three additional practices that support justification: reviewing as an opportunity to justify; cyclic iterations of investigation and discussion; and building on incomplete, incorrect or misunderstood justifications.

Keywords: Reasoning and Proof; Middle School Education; Instructional Activities and Practices

Literature Review and Theoretical Framework

Many studies have reported difficulties associated the implementation of justification tasks (Bieda, 2010; **Henningsen & Stein, 1997)**. Stein, Grover, and Henningsen (1996) studied a sample of 144 reform-oriented middle school task implementations, 61 of those tasks declined in cognitive demand between set-up and implementation stages, with a greater decline for high cognitive demand tasks. The researchers identified seven attributes that were common among the tasks that maintained faithful implementation to high cognitive demand: building on students' knowledge, appropriate amount of time, high-level performance modeled, sustained pressure for explanation and meaning, scaffolding, student self-monitoring, and teacher drawing conceptual connections. Bieda (2010) applied the mathematical task framework to examine student opportunities to prove within the middle school setting. Bieda found that student proving opportunities were limited, and student proofs were even more rare: of the 109 student conjectures 59 resulted in justifications, although 31 of those 59 were empirical or non-proof arguments. This research extends the work of both Stein and colleagues (1996) and Bieda (2010) by identifying components of task implementation that led to student justification.

Study Background

The data for this study is drawn from an NSF funded project called "Justification and Argumentation: Understanding Algebraic Reasoning (JAGUAR)." Twelve teachers in two states were selected to take part in the two year-long JAGUAR project which included two one week long summer session, four prescribed justification lessons, and three working sessions through each of the two school years. The primary research questions of the project focus on how teachers develop mathematical knowledge about justification and how teachers transform that knowledge into their classroom practice. The teachers selected to participate in the JAGUAR project were intentionally selected based upon previous professional development and are not representative of typical middle school teachers.

The analysis for this study draws upon classroom data from four of the twelve case teachers: Audrey Tompkins, Bruce Hummel, Paige Davilla, and Cynthia Littrel (all teacher and student names are pseudonyms). The analysis focuses on the implementation of a single prescribed task: "The Scaling Task." The task as presented to the teachers was: "How does scaling various 2-dimensional [and 3 dimensional] figures impact the perimeter, area, [surface area and volume]?" Data for this analysis include copies of student work, written teacher reflections on the lesson, classroom video, and classroom video transcripts.

Methodology

In the first stage of analysis justification episodes were identified. Justifications are mathematically valid and connect previously accepted facts or definitions to conclusions using valid forms of reasoning (see Stylianides & Stylianides, 2009). A simple statement of an accepted fact or algorithm did not constitute a justification. For example, when finding the perimeter of a rectangle with length 10 and width 4, "I added 10 plus 4 times 2 to get 28 centimeters" is not considered a justification because it only describes a procedure without supporting the validity of the procedure. On the other hand, the following explanation is considered a justification because it justifies the operations by connecting them to structural features of square: "Well, because *s* is like the side length, and then *k* is the scale factor, so we have *s* times *k* equals the similar side length. And then you times it by 4 because there is 4 sides."

Once the justification episodes were identified, social and environmental scaffolds leading to those justifications were identified. Identification of these factors was guided by, but not limited to, the Stein and colleagues' (1996) seven traits for maintenance of cognitive demand. In the final phase of analysis, three emergent themes were identified as independent from the original themes: reviewing as an opportunity to justify; cyclic iterations of investigation and discussion; and building on incomplete, incorrect or misunderstood justifications. This list of themes represents only a subset of the possible factors that encourage the expression of student justification within a classroom.

Data and Analysis

Support for Previously Identified Themes

High level performance modeled. Stein and colleagues (1996) found that when teachers or more capable students modeled high levels of performance high levels of cognitive demand were more likely to be maintained. In this study, three student justifications were modeled after a previous correct justification given by another student. For example, in Mr. Hummel's second implementation of the task, Rick, one of the more capable students, gave a pictorial argument for the relationship between the area of the original square and a scaled-up square. The next day of class, students explored rules for different shapes. Clay modeled his justification for the scaling of a parallelogram directly off of Rick's justification from the previous day of class (Figure 1).

Clay: Alright, I got original area times scale factor squared.
Mr. Hummel: Okay. And can you explain your picture? Why that works there?
Clay: Uh- this is the original one right there [pointing to the bottom left parallelogram]. That one is the original and then times 2, 3, 4... [outlining each scaled up parallelogram on his drawing as he counts] And then times 3 squared would be 9.

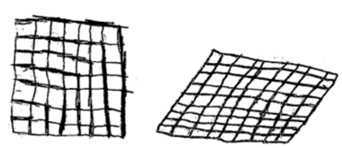

Figure 1: Clay's picture of a scaled up parallelogram

It is important to note that Clay was not simply mimicking the images from Rick's previous work. In this passage, Clay develops an independent justification for why the area of a parallelogram is 9 times bigger when the side lengths are scaled up by three.

Sustained pressure for explanation and meaning. Throughout the implementations of each of these tasks, teachers maintained strong pressure for explanation and meaning making, primarily through their use of questioning. Based upon analysis of teacher questioning patterns at the local level, four different types of teacher questions emerged. "Why" questions such as "Why is this happening?" ask students to explain a mathematical relationship or process. "Explain" questions ask students to more fully explain their work or their thinking. “Representation” questions ask students to alter, add, or improve their representation of a problem. Finally, “Skeptic” questions cast doubt on student claims and prompted students to provide further reasoning. For example, Ms. Littrel states, “I’m not totally sold yet.”

Task specific scaffolding. According to Stein and colleagues (1996), task specific scaffolding breaks a task down into smaller or more manageable tasks, while at maintaining the cognitive demand of the task in spite of the decomposition. Several teachers used representational scaffolding to help students access and reason about the task. For example, in Ms. Littrel’s first year of task implementation the class co-constructed a completely generalized diagram representing an original figure and a scaled-up figure. This diagram served as a transformational record, which is a “notation, diagram, or other graphical representation that [is] intentionally used to record student thinking and then are later used by students to solve new problems” (Rasmussen & Marrongelle, 2006).

Emergent Theme 1: Reviewing as an Opportunity to Justify

Teachers used review of pervious material as an opportunity for students to justify. For example, Ms. Tompkins noticed that many students were having trouble calculating the surface area of a rectangular prism even though surface area had been a content topic from the previous week. Tompkins asked a student to explain for the class how to find the surface area.

Ms. Tompkins: Would you come up? Would you explain to us? And again, if you've done this, this is a review, but maybe it's um, *we need to review it again* [emphasis added].

Sharon: You're just multiplying the length of the sides by the width or the height, whichever one it is. And so then you multiply it by two because there's one on the opposite side that's exactly the same. And so … each one is times two.

Students may have had better access to resources required for constructing justifications for review topics, because review contexts allow students to focus on the act of justification apart from conceptually challenging material. These findings are consistent with the results of Niemi (1996): stronger student content understanding is associated with stronger student explanation and justification.

Emergent Theme 2: Cyclic Iterations of Investigation and Discussion

In all of the task implementations across both years, all of the teachers utilized some variation of a “Think-Pair-Share” protocol in which students were given time to think individually, then work with a partner or small group, and then discuss as a whole class. Many valid student justifications emerged after multiple cycles of whole class and small group discussion time. For example, in the first year of Ms. Davilla’s scaling task implementation, students suggest that doubling the scale factor doubles the perimeter of the rectangle. Ms. Davilla asks students to consider this in small groups: “I'm not sure I'm ready to move on until people agree with this, understand this… I’m going to give you 30 seconds to a minute, discuss these questions in your group.” In the next whole class discussion, several students give empirical evidence for the rule, but fall short of a justification. Ms. Davilla again returns to small group discussion and asks the students to probe deeper into why the relationship holds. In the following small group time, several groups formulate valid justifications, one of which is shared with the class, “I think this is happening because maybe it’s the scale factor you have to multiply everything so like everything doubles, the perimeter will double as well.” The iterative cycles of student work time and whole class discussion allow the teacher to draw student attention toward increasingly sophisticated components of the task, and allow students to synthesize and build upon the ideas of their peers presented in whole class discussion.

Emergent Theme 3: Building on Incomplete, Incorrect or Misunderstood Justifications

In contrast to the previous theme of *high level of performance modeled*, eight justifications in this data were given in response to incomplete, incorrect, or misunderstood justifications given by other students. For example, in Ms. Littrel’s class there was a debate about whether $3s$ is equal to s^3. Janis offers her justification to the class, but her justification is not understood by the class. In response Zoe provides a different justification.

Janis: Because that one [points to 3*s] is multiplying 3 by s, and that one [points to s^3] is multiplying s three times.
Ms. Littrel: Ok, but I am not convinced.
Student: That's the same thing. You just said the same thing.
Janis: Ok, well Zoe can help me.
Ms. Littrel: Do you want to come support Zoe?
Zoe: Ok, so if $s = 2$, then 3 times s would be 3 times 2 which equals 6. And then 2 cubed which would be 2 cubed equals 2 times 2 times 2 which equals 8.

Although the first justification offered by Janis was correct, it was not understood by the class, and it allowed Zoe the opportunity to provide an empirical proof. Empirical reasoning is often favored by students (Stylianides & Stylianides, 2009), and although it is typically invalid, in this case it provides a valid counterexample to disprove the conjecture that $3s = s^3$. Building on student contributions is an important part of advancing the mathematical agenda as well as an important opportunity for student justification.

Conclusions and Implications for Further Research

This paper provides evidence in support of five of the themes identified by Stein and others (1996) and describes additional three elements of implementation that appear to support justification. This work has implications both for teacher practice and professional development. For example, allowing students to share incomplete, incorrect, or misunderstood justifications can provide strong opportunities for further student justifications. Many teachers are uncomfortable and resistant to using wrong answers within the classroom (Hoffman et al., 2009). A challenge in professional development is to help teachers create a critical classroom environment in which productive incomplete ideas are leveraged for deeper student learning.

PUSHING SYMBOLS: TEACHING THE STRUCTURE OF ALGEBRAIC EXPRESSIONS

Erin Ottmar
University of Richmond
erin.ottmar@richmond.edu

David Landy
University of Richmond
dlandy@richmond.edu

We describe an intervention being developed by our research team, Pushing Symbols. PS is designed to encourage learners to treat symbols as physical objects, which move and change over time according to dynamic principles. By providing students with the opportunities to physically manipulate colored symbol tiles and interact with a new touchscreen software technology, we aim to help students learn the structure of algebraic notation in general, and in particular learn to simplify like terms. We present preliminary findings from a study with 70 middle-school students who participated in the intervention over a three-hour period.

Keywords: Algebra and Algebraic Thinking; Technology; Instructional Activities and Practices

Students have great difficulty in mastering basic algebra content and notation (NAEP, 2011). Often, instruction emphasizes content while students struggle to understand basic notation (Koedinger & Alibali, 2008), which is often presented as the memorization of abstract rules. However, algebraic literacy—the fluent construction, interpretation, and manipulation of algebraic notations—involves not just memorizing, but learning appropriate perceptual processes (Landy, 2010; Kirshner, 1989; Kellman, Massey, & Son, 2010).

Our theoretical framework comes from work in cognitive psychology and perception. Successful students often use perceptual and visual patterns available in notations to solve mathematical problems. Like many skills learned from long practice, learning algebra involves perceptual training—learning to *see* equations as structured objects and chunks (Kirshner, 1989; Kellman et al., 2008). Because rigid motion is a powerful perceptual grouping mechanism (Palmer, 1999), and real-world motion is naturally memorable and easy to acquire, it is anticipated that training students to see correct algebraic structures through dynamic transformations may be a promising approach to teaching algebraic ideas (Landy, 2010). The purpose of this study is to describe and present preliminary findings from an intervention exploring this approach to improve student learning of algebra notation.

Pushing Symbols: Teaching the Structure of Algebraic Expressions

The purpose of the PS intervention is to explore an alternative method of algebra instruction that focuses student efforts on the visual structure of notation. The core idea of this approach is that symbolic strings can be usefully thought of as physical objects located in space, and that proofs or derivations can often be thought of as dynamic transformations of those objects. The intervention sustains this idea by allowing students to physically and dynamically interact with elements of algebraic expression, through a set of in-class discussions, activities, and a dynamic computer-based visualization method by which students manipulate expressions with their hands. The symbol strings respond in mathematically appropriate ways. The strong role of the expression in maintaining its own integrity is analogous to the ways that real physical objects maintain their own integrity: fluids flow when poured, while solids maintain their shape, for instance. This internal integrity allows the physical world to become intuitive and predictable. The PS program is designed likewise to build efficacy and engagement in students by creating a formal symbolic structure that can be intuitive, predictable, and even fun.

The first component of the PS manipulative system uses colored magnets and tiles to model and decompose the structure of algebraic expressions. Each color represents a specific mathematical object (number, variable, coefficient, symbol). After modeling an expression, the tiles can be rearranged, transformed, and simplified into equivalent expressions—this component is intended to help students see pieces of symbol strings as physical objects, with real-world properties. The second component of the PS system uses a new touch-based computer application*, Algebra Touch: Research (ATR),* developed in collaboration with Regular Berry software and based on the commercially available *Algebra Touch* system. In ATR, students perform arithmetic functions by tapping on a sign and carry out algebraic rearrangements by touching appropriate symbols and moving them into the desired location. An example of *ATR* can be seen at http://davidlandy.net /PushingSymbols/RPS--12-1-11-Like-Terms-Automatic-1.mov**.** ATR does not allow students to make mistakes; if they attempt to do something that violates the laws of mathematics, a brief side-to-side motion (a “shake”) provides immediate feedback that their desired action was illegal. As a result, students immediately see how the rules result in legal transformations or manipulations in a way that is impossible with a traditional lesson. Problems in ATR can be presented in either an untimed *list* mode or a *game* mode. At the end of each problem, the program provides immediate feedback to students about the number of errors they made and the speed to which they simplified the expression.

In this present study, we report preliminary results from a study implementing the PS intervention in 3 middle school classrooms. We aim to improve students’ understanding of algebraic structure through engaging students in perceptual training. We anticipated that the intervention would decrease the number of structural errors that students made on procedural problems, but not a task that required primarily bridging formal notation with situations (equation modeling). Second, we hypothesized that pre-test scores, self-efficacy, engagement, and performance on the iPad would positively contribute to post-test scores, while math anxiety would negatively contribute to post-test performance.

Methods

Participants

Seventy eighth-grade students from an urban public middle school in the mid-east United States participated in this study during their regular mathematics instruction time. Student assent and parental consent were obtained prior to participation in this study.

Procedures

The study took approximately 3 hours and occurred over three class periods. On the first day (90 minutes), students completed the simplifying expressions pretest and the self-efficacy & anxiety questionnaire. Next, the teacher led a whole-group lesson and led a series of discussions and activities using colored magnets and tiles to demonstrate algebraic structure, followed by 20 minutes of familiarization with the iPad and ATR. On the second day (90 minutes), students were given 40 minutes to simplify both simple and complex expressions, followed by the engagement questionnaire and post-test. Two weeks later, students completed a retention test assessing simplification.

Measures

Simplifying Expressions Assessments. Each child completed an 18-item pre, post, and retention test involving procedural facility with simplification (10-items) and expression construction (word problems) (6 items). For each assessment (pre, post, and retention), we calculated 2 composite scores: (1) proportion of attempted procedural problems that were free of structural errors (i.e., combining unlike terms, over-combination, or partial structural errors); and (2) proportion of attempted word problems that were modeled correctly.

ATR Performance. ATR Performance was measured by calculating total points at 2 different levels (simple and complex), using the *Algebra Speed* game. Level 1 asked students to simplify a series of 36 *simple* expressions (e.g., 5+7+3; x+2+6), while Level 2 asked students to simplify a series of 40 *complex* expressions (e.g., 7+2x+5x+4y+1+-2y). Students could receive a maximum of 3 points for each problem solved. The points system accounted both the number of errors that they made and the speed to which they simplified the expression.

Mathematics Self-Efficacy and Anxiety Questionnaire. Students were administered a set of 10-items pertaining to their self-efficacy (Midgley et al., 2000; 5 items, α=.82) and anxiety in mathematics (5 items, α=.61)

Student Engagement in Mathematics Questionnaire. Student engagement during the lesson was measured using 18 subjective rating items that were adapted from the Student Engagement in Mathematics Questionnaire (Kong, Wong, & Lam, 2003).

Results

Analysis 1: Does the Pushing Symbols Intervention Improve Student Understanding of Algebraic Structure?

On average the intervention increased students' knowledge of algebraic structure (Figure 1). At pretest only 9.4% of problems were solved without structural errors. At post-test 54% of problems attempted were solved without structural errors (Improvement of 44.6%, $t=10.48$, $p<0.01$). At retention 41.4% of the problems were solved without structural errors (overall improvement of 32%, $t=6.81$, $p<0.01$). After 2 weeks students retained 72% of their structural learning. As expected, the intervention did not appear to affect equation modeling at post-test ($t=-0.87$, $p>0.05$) or retention ($t=-0.07$, $p>0.05$).

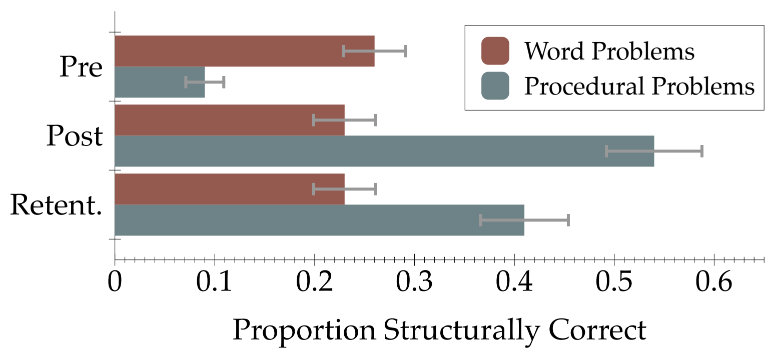

Figure 1: Performance on assessments

Analysis 2: Relations between Structural Performance, Efficacy, Anxiety, Engagement, and Performance on *ATR*.

A regression analysis was conducted to examine predictors of structural performance on the post-test. Results indicate that math efficacy was related to higher performance on the post-test (β=1.27). Second, successfully completing more problems (both simple and complex) on ATR was related to higher scores on the post-test. Further, students who reported being more engaged during the PS intervention performed higher on the post-test (β=1.80). Interestingly, neither students' performance on the pre-test or levels of math anxiety predicted post-test performance.

Discussion

We have described an approach to algebra instruction that emphasizes perceptual and manual interactions with dynamically realized models of algebraic notation. These preliminary results demonstrate that a short intervention based on this framework can help students become fluent with algebraic structure and substantially improve student performance at simplifying expressions. Furthermore, this work adds to a small literature suggesting that touchscreen-based learning tools can successfully lead to student learning (Segal, 2011).

The current findings demonstrate that using a hands-on approach to teaching the structure of algebra may benefit students. Given the clear demonstrations that students struggle to understand basic algebraic notation (Koedinger, Alibali, & Nathan, 2008) and existing evidence linking teaching algebraic structure to improved student understanding of algebraic expressions (Banerjee & Subramaniam, 2011), we believe that there is good reason to pursue manipulative systems that expressly communicate algebraic structure through engaging perceptual and motor interactions. The current system contrasts with many popular algebra manipulative systems, such as Algebra Tiles and Hands-on Equations, in its emphasis on the structure of mathematical expressions rather than models of the concepts referred to by them. It is also worth noting that the intervention seemed to increase student interest, participation, and interactions. Both observational and student reported engagement during this intervention was high. Virtually all students reported that the intervention was highly engaging, fun, and helped make the mathematics easier to understand.

These results are clearly preliminary, and the conclusions that can be drawn from the empirical results are limited. It is unclear how the learning that results this intervention differs from typical classroom learning, and how such differences may impact learning of future topics.

BECOMING A MATHEMATICAL AUTHORITY: THE SOLUTION LIES IN THE SOLUTION

Daniel Lee Reinholz
University of California, Berkeley
reinholz@berkeley.edu

This paper focuses on the development of three skills underlying mathematical authority: (1) explanation, (2) justification, and (3) assessment. An intervention was designed to help students develop these skills through explicit engagement with assessment in the classroom. Preliminary results from this ongoing study indicate that students had improved meta-level understandings of solutions, which supported greater levels of explanation in their solutions of problems.

Keywords: Design Experiments; Instructional Activities and Practices; Metacognition

Introduction

When a mathematician solves a problem or submits a proof to a journal, he or she doesn't wonder whether or not the work is correct; he or she *knows* it is. Most mathematicians self-assess using highly-internalized mathematical standards. In contrast, mathematics students routinely submit assignments with little sense of how well they did, relying on their instructor to be the arbiter of mathematical truth. For these students, mathematical authority is something that exists externally to them. This paper is focused on how students internalize mathematical standards.

Mathematical authority relates to positioning and identity (cf. Boaler & Greeno, 2000; Engle & Conant, 2002), as well as specific skills and domain knowledge. This paper focuses on three mutually supportive skills, hypothesized to be crucial to mathematical authority (as conceptualized in Figure 1): (1) explanation, (2) justification, and (3) assessment. Mathematicians use these skills to derive authority from the logic and structure of mathematics (internalized authority), rather than relying on some other authoritative source like a teacher or textbook (external authority). These skills are widely recognized as part of the multi-faceted nature of mathematical proficiency (e.g., NCTM, 2000) with explanation and argumentation specifically emphasized by the Common Core State Standards (Common Core State Standards Initiative [CCSSI], 2010).

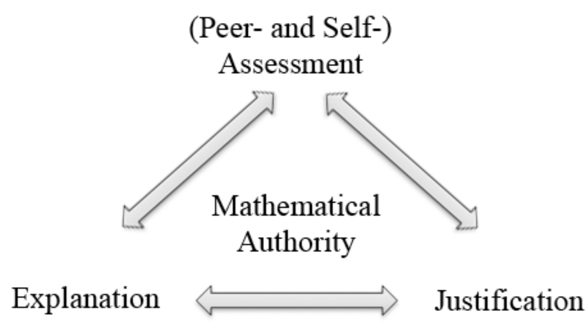

Figure 1: Three skills hypothesized to underlie mathematical authority

The design of this study's intervention draws on research showing that when students self-assess, they are unlikely to spontaneously generate information to test their understanding, which impedes accurate self-assessment (Dunlosky & Lipko, 2007). Just as perceiving constructive and deductive geometry as unrelated hinders mathematical performance (Schoenfeld, 1988), I hypothesized that perceiving explanation and justification as extraneous parts of a solution inhibits accurate self-assessment. When students are unable to use their own reasoning to justify their work, they are forced to rely on an external mathematical authority. Sadler (1989) suggests that standards of a high-quality solution should be communicated through a combination of descriptive statements, exposure to exemplars, and direct evaluative experience. Crucially, as students analyze others' work, they develop the required objectivity and skills to assess their own work (Black, Harrison, & Lee, 2003). Thus, this study used peer-assessment to promote the development meta-level understandings of solutions that are crucial to self-assessment.

Methods

This paper draws on preliminary data collected during from an ongoing design research study with elementary algebra students (N = 20) at a community college in the San Francisco Bay Area. Data were collected from classroom videos, student written work, and the instructors' daily reflections. As a pre-test, students assessed sample written work of two hypothetical students solving the problem: "*If a tortoise is traveling at an average of 1 2/3 miles per hour, how long would it take the tortoise to travel 6 miles?*" (see Figure 2). Students were presented with two solutions sequentially, and after seeing each solution were asked to explain the hypothetical student's reasoning, and why it was correct or incorrect. Finally, students were asked to reconcile the two conflicting solutions, and explain how they could determine which solution was correct.

$$1\tfrac{2}{3} = \frac{5}{3}$$
$$\frac{5}{3} \cdot 6 = \frac{30}{3} = 10$$

a.

$$1\tfrac{2}{3} = \frac{3\cdot 1 + 2}{3} = \frac{5}{3}$$
$$6 \div \frac{5}{3} = 6 \cdot \frac{3}{5} = \frac{18}{5} = 3\tfrac{3}{5}$$

b.

Figure 2: (a) Initial sample solution; (b) Sample solution presented after initial assessment

As an intervention, students were introduced to a framework for assessing mathematical solutions. The framework emphasized that a solution should answer three questions for the reader: (1) What did you do?; (2) Why did you do it?; and (3) Did you do it correctly? These relate to three parts of a solution: (1) the execution, (2) the explanation, and (3) the justification. Guided by the instructor, students discussed features of high-quality solutions to generate a rubric based on the above framework. Students also engaged in various peer- and self-assessment tasks using the student-generated rubrics.

The results presented here document students' changes in their perceptions of solutions. Because the data are preliminary, and peer-assessment can be seen as a precursor to self-assessment (Black et al., 2003), this paper focuses on the development of understandings that would support self-assessment, but not their actual application to self-assessment. This brief report considers the development of a few focal students, to highlight trends within the larger data corpus.

Results and Analysis

In the pre-test, students articulated *what* steps the hypothetical students took to solve the problem, but could not explain *why* they took them, even when pressed by the instructor (e.g., "why did the student multiply rather than divide?"). When asked to determine which solution was correct, only one student generated an answer. This student recognized that if the tortoise was traveling faster than 1 mph, then 10 hours for a travel time was much too long, so therefore the first solution must be incorrect. Other students either responded that it was impossible for them to determine which solution was correct, or that they didn't know how to figure it out. Students asked the instructor to resolve the mathematics for them.

The pre-test provided the basis for classroom discussions about important qualities of a complete mathematics solution. In these discussions, students articulated that the sample solutions lacked detail, thus providing limited access to the hypothetical students' reasoning. Students were presented with a framework for high-quality solutions, and were guided to generate a rubric using this framework. Students suggested 8 important features of a solution, such as: a written statement explaining why the solution path was chosen, checking units, and estimating what a reasonable answer would be. Students then discussed how the sample solutions would have been easier to assess if they had these features. The instructor introduced 5 additional features of high-quality solutions to the class to complete the rubric.

Two weeks later, students were once again presented with one of the sample solutions from the pre-test (see Figure 1, sample a). After analyzing the solution using the rubric they had developed, students explained how generating a more complete solution would have helped their classmate. Some students, like Tanya, focused on specific solution features:

Tanya: It would have helped him if he put the units down on his paper to check what to cancel out, since the problem gives you miles and miles per hour.

Tanya seems to understand that units are not just part of a complete solution, but actually a tool for problem solving, because they help determine which arithmetic operations are meaningful to perform. Other students, like Enrique and Jason, focused on solutions holistically:

Enrique: A more complete solution would have made him catch his mistakes.
Jason: The execution is well done, but there's no explanation of any sort. The only thing that *seems* good is the answer.

Enrique's response emphasizes that careful solutions are important because they make our thinking (and thus mistakes) more evident. Jason alludes to the fact that the lack of explanation makes it difficult to say much about the student reasoning (e.g. "the only thing that *seems* good"). In sum, students transcended the specifics of the solution given, and exhibited meta-level understandings of solutions in general. These are the types of understandings that would allow students to begin to act as authorities themselves, rather than referring to an external authority.

As students develop a sense of high-quality mathematics solutions, it should also become evident in their written work. A comparison of students' solutions to the first two homework assignments (one week apart) provided evidence of such growth. (Note: the first homework assignment had 10 problems, and the second assignment had 11 problems but was of comparable length.) In general, solutions for the second homework assignment were more verbose and began to include explanations of reasoning (the first assignments contained little to no explanations). These changes were particularly striking for two of the students highlighted above, Jason and Tanya, whose solutions doubled in length (from 2 to 4 pages) between these two assignments. The increase in length was due to an inclusion of much more significant explanations and justifications in the second assignment.

Evidence of a more sophisticated understanding a solution was also evident in students' daily reflections. At the end of each class session, students were asked to answer a number of reflection questions, both in general and specifically related to the given lesson. When asked, "What does a good explanation in a math solution look like and why is it important?" Jason cogently responded:

Jason: A good explanation can help someone understand the problem just by redoing the steps you took. After reading the steps they know why you took those steps and what you were doing.

This response seems to indicate a transition to seeing the solution to a math problem as an explanation of one's reasoning, not just "finding an answer." Jason's initial homework assignment included little to no justification or explanation, whereas his second homework assignment and responses to in-class questions were much more complete. Although we can only infer how Jason *sees* mathematics, there is evidence of changes in how he *does* mathematics. By explicitly turning students' focus to important features of solutions, it is possible to improve the quality of solutions that they submit.

Conclusion

By making the analysis of solutions an explicit focus of classroom activity, students were supported to develop meta-level understandings of solutions to mathematics problems. Students were able to articulate why including certain aspects of a solution can be essential, rather than an extraneous requirement imposed by the teacher. Evidence of growth was also apparent in students' homework solutions, which included greater explanations and justifications. Thus, preliminary results from this ongoing study show evidence of students' nascent development of internalized mathematical authority. These results provide the basis for the further refinement of classroom activities for promoting and studying students' development of skills of explanation, justification, and assessment. Moreover, the continuation of this work will allow for the study of students' application of these skills to self-assessment.

INVESTIGATING A STRATEGY FOR SOLVING INDEFINITE INTEGRATION PROBLEMS: AN fMRI STUDY

Larissa B. Schroeder
University of Hartford
schroeder@hartford.edu

Thomas C. DeFranco
University of Connecticut
tom.defranco@uconn.edu

Recently the emerging field of educational neuroscience has begun to use neuroscience methods to investigate questions of interest to both education and neuroscience. This study used behavioral measures and fMRI to examine the first step of integration problem solving—selecting an appropriate technique. In Phase 1, college-aged subjects reviewed integration techniques; in Phase 2, subjects were trained in an expert-like strategy for selecting an integration technique. Results indicated that training improved the accuracy in selecting an integration technique. fMRI results indicated increased activity in brain regions associated with visuospatial processing, attention, and working memory. This study extends what is known about the neural basis of integration problem solving and raises questions about the role of working memory and visuospatial processing in the calculus classroom.

Keywords: Post-Secondary Education; Metacognition; Research Methods

For over 100 years, efforts to reform the teaching and learning of calculus have focused on curricular, pedagogical, and technological changes to improve calculus education (Ganter, 2001). Less emphasis has been placed on how students develop expertise in calculus. Recently, education-based neuroscience research using functional magnetic resonance imaging (fMRI) has been used to complement traditional educational research into student understanding (e.g., Delazer et al., 2005; Lee et al., 2007; Qin et al., 2003, 2004; Thomas et al., 2010). Thus, exploring the neural regions associated with selecting an integration technique may ultimately provide an avenue for future research aimed at improving the teaching and learning of calculus.

Although recent calculus curriculum reform efforts placed increased emphasis on students acquiring conceptual understanding of calculus, facility with techniques of integration continues to be a goal of first-year calculus instruction (Sofronas et al., 2011). Research (Schoenfeld, 1985; Kallam & Kallam, 1996) along with anecdotal evidence suggested that while first-year calculus students may be able to successfully implement individual integration techniques, determining an appropriate technique was difficult. In contrast, college calculus instructors did not appear to have similar difficulties (Kaczmarczyk, 2005).

Schoenfeld (1985) argued that students' difficulties with integration stemmed from issues of control associated with strategy selection and allocation of cognitive resources. To test this theory, Schoenfeld (1980, 1985) developed a strategy for selecting an integration technique consisting of three broad stages: simplify, classify, and modify the integrand. Research suggested that supplemental instruction using this strategy resulted improved student performance (Kallam & Kallam, 1996; Schoenfeld, 1985). Yet questions remain about how students become more expert-like in the selection of an integration technique.

Theoretical and Methodological Framework

The work of Dehaene et al. (2005) and Arsalidou and Taylor (2011) form the theoretical foundation for this research. The triple-code model of numerical processing (Dehaene et al., 2005) posits that a three-part parietal network consisting of the horizontal part of the interparietal sulcus, the left angular gyrus, and a posterior superior parietal system is responsible for processing numbers and numerical operations. In a meta-analysis of neuroimaging studies in mathematics, Arsalidou and Taylor (2011) argued that this model should be extended to include regions (e.g., the prefrontal cortex) which are associated with executive functions such as working memory and attention. Although these regions are not part of the triple-code model, behavioral evidence has linked working memory and attention with mathematical performance (LeFevre et al., as cited in Arsalidou & Taylor, 2011, p. 2390).

Atherton and Bart (2001) proposed a methodological framework to guide research studies involving fMRI. In the *Discovery* stage, imaging studies focus on the brain regions associated with a particular cognitive function, identifying *the* brain region most strongly activated by a given task. The *Functional Connectivity* stage addresses the more complex nature of cognition and investigates the coordination of activity between brain regions (Atherton & Bart, 2001; Varma & Schwartz, 2008). Since fMRI research into calculus is in its infancy with one published study of calculus using fMRI (Krueger et al., 2008), this study takes place at the *Discovery* stage. Specifically, this study examined the brain regions identified in the literature (e.g., Arsalidou & Taylor, 2011; Dehaene et al., 2005) to determine which were significantly active while selecting an integration technique and if there were differences in the activation in these regions after subjects were trained to use Schoenfeld's (1980, 1985) strategy.

Methods

Eight right-handed, native English speaking undergraduate students who had completed Calculus II participated in this two-phase study. During the two Phase 1 sessions subjects reviewed four integration techniques (i.e., algebraic manipulation of the integrand, *u*-substitution, integration by parts, and the method of partial fractions) in a manner aligned with typical classroom instruction. At the end of Phase 1, subjects participated in computer-based test post-test and a block-design fMRI experiment. For both participants were shown an indefinite integration problem and told to select the most efficient integration technique. Response times to select a technique and proportion correct data were collected during both the computer-based test and the fMRI experiment.

Phase 2 began one week after the Phase 1 fMRI experiment, and consisted of two sessions where participants were taught Schoenfeld's (1980) strategy. After Phase 2 training, participants participated in a computer-based post-test and fMRI experiment which were identical in format to the Phase 1 post-tests described earlier. The integration problems presented in the Phase 2 post-tests were isomorphic to those used in Phase 1.

The response time and proportion correct data were analyzed using paired *t*-tests ($\alpha = .05$) to compare means for dependent groups. Analysis of the fMRI data was done in two stages. The first stage was a within-subject analysis for the contrast of interest (i.e., *integration vs. control*) using SPM8 (Wellcome Trust Centre for Neuroimaging, 2009). A second-level random effects analysis was implemented in MarsBar (Brett, Anton, Valabregue, & Poline, 2002) using the regions previously identified in the mathematics-related neuroscience literature (Arsalidou & Taylor, 2011; Dehaene et al., 2005). The second-level fMRI data analysis identified the regions for which the contrast were significant and then compared Phase 1 to Phase 2 in each of these regions for this contrast.

Results

The analysis of the response time data indicated that there was no significant difference ($p = .161$) in the mean response time between Phase 1 ($n = 32$, $\mu = 4.714$, SD = .827) and Phase 2 ($n = 32$, $\mu = 4.288$, SD = .595) during the computer-based post-test. There was also no significant difference ($p = .709$) in mean response time between Phase 1 ($n = 64$, $\mu = 3.509$, SD = .620) and Phase 2 ($n = 64$, $\mu = 3.617$, SD = .362) during the fMRI experiment. These results suggested that the training in an expert-like strategy did not have an effect on response time to select an integration technique.

The analysis of the mean proportion correct data for Phase 1 and Phase 2 computer-based post-tests indicated that there was a significant difference ($p = .035$) between the mean proportion correct in the Phase 1 ($n = 32$, $\mu = .660$, SD = .084) and Phase 2 ($n = 32$, $\mu = .746$, SD = .078). In the fMRI experiment, there was also a significant difference ($p = .014$) in the mean proportion correct in Phase 1 ($n = 64$, $\mu = .709$, SD = .112) and Phase 2 ($n = 64$, $\mu = .805$, SD = .074). These results suggest that the Phase 2 training in a more expert-like strategy had an effect on the subjects' ability to select an appropriate integration technique.

Phase 1 fMRI data indicated that there for the contrast *integration vs. control*, there was a significant difference bilaterally in 3 regions of interest: the horizontal part of the interparietal sulcus (hIPS), posterior superior parietal lobule (PSPL), and middle frontal gyrus (MFG) These results suggested that the hIPS, PSPL and MFG were more active during the selection of an integration technique than during the control task. Phase 2 fMRI results were similar to that of Phase 1. Results indicated that there was no significant difference between Phase 1 and Phase 2 in any region of interest for the contrast *integration vs. control*.

Discussion

The results of this study adds to the growing number of studies (e.g., Krueger et al., 2008; Lee et al., 2007; Stavy et al., 2006; Stavy & Babai, 2009; Thomas et al., 2010) which have begun to use neuroscience methods such as fMRI to investigate questions linked to mathematics education. The results of this study found activations in the hIPS and PSPL which were consistent with an earlier study involving integration (Kreuger et al., 2008). This study also associated activation in the posterior superior parietal lobule (PSPL) and middle frontal gyrus (MFG) with the first step of integration problem solving—selecting an integration technique. Prior neuroscience research into mathematical cognition indicated that the MFG was involved with working memory and executive functioning (Fehr et al., 2007; Kong et al., 2005; Lee et al., 2007) and the PSPL generally supported visuospatial processing, attention and spatial working memory (Dehaene et al., 2005; Delazer et al., 2003). The PSPL is also a key component in the central executive network which showed increased activation during cognitively demanding tasks (Sridharan et al., 2008). Activation in the PSPL and MFG while selecting an integration technique may be attributed to the working memory demands of the integration problems, specifically the need to maintain and manipulate information in working memory in order to select an appropriate technique.

Finally, the results of this study raise several questions for the researchers: (1) What is the difference in functional connectivity before and after training in Schoenfeld's (1980) strategy? (2) How does the visuospatial processing and working memory capacities of students impact their learning of calculus and (3) How should understanding of visuospatial processing and working memory capacity shape college classroom instruction?

ACTIVITIES WHICH FOSTER HIGH SCHOOL STUDENTS' CONCEPTUAL UNDERSTANDING OF THE NOTION OF LIMIT

Armando Sepúlveda
Universidad Michoacana de San Nicolás de Hidalgo, CECYTEM
asepulve@live.com.mx

Elizabeth Virrueta
Universidad Michoacana de San Nicolás de Hidalgo, CECYTEM
ely_virrus@hotmail.com

In this article we describe how we carried out a sequence of activities designed to foster the acquisition of the concept of limit with a group of high school students who had not taken a Calculus course. The students had the opportunity to work in small groups, to present their ideas to their peers and thus modify their conceptions as a result of the critiques and opinions made by their classmates; at the end of the sessions they again had to solve the activity individually. We present "Yaya's leaps" an adaptation of the paradox of Achilles and the turtle.

Keywords: Advanced Mathematical Thinking; High School Education

Calculus is the field of mathematics that studies change phenomena which occur in nature and in everyday life. It involves concepts and procedures such as that of the limit, which are difficult to learn by most students or in some cases, never are understood. The limit of a function is one of the most important concepts of general mathematics and specifically, of calculus; it is the cornerstone for the study of change phenomena and several important numbers are defined as limits. In addition, such concept allows one to know the performance of a function towards a point, even though its performance at that point is unknown.

Intuitively, a function has a limit *L* at a point x_o if at any point, each time closer to x_o, the function has a value which is each time closer to *L*. However, the formal definition with "epsilon-delta" becomes inaccessible for most: *L* is the limit of function $f(x)$, when *x* gets closer to *p*, if and only if for all $\varepsilon > 0$, there is a $\delta > 0$ such as for any real number *x* which complies with $0 < |x - p| < \delta$, we have $|f(x) - L| < \varepsilon$. The preceding has originated the creation of teaching strategies, such as David Tall's, who proposes that formal definitions and concepts be introduced taking into account the student's context, in subtle and "sensitive" ways which appeal to intuition for acquiring these notions, since he sustains that mathematical rigor during the early instruction phases produces unfavorable learning results. What kind of activities and experiences further the understanding of the concept of limit for high school students? What mathematical and heuristic processes do the students use when facing problems which involve the concept of limit?

Theoretical Framework

The mathematical concept of limit is an especially difficult notion. Cornu (1994) mentions that in a teaching environment it is very important to distinguish between the definition and the concept itself. Additionally, he recommends being attentive to the spontaneous ideas which students may have of the concept since they do not disappear when they move on to a new mathematics lesson. On the other hand, Tall (2010) affirms that the ideas which belong to this area of mathematics, such as variation, continuity, slope, etc., must follow a teaching route which is close to the natural way of human thought. Tall (2010) strives for a "sensible approximation to Calculus." He classifies the evolution of mathematical thought in three stages: The first is the natural growth of ideas (which corresponds to the "world of the senses" associated to the sensory cortex, of basic primitive ideas); the second stage are the actions which help us to transform such ideas into symbolic handling and computation (corresponding to the "operational world" which takes place in the secondary brain cortex and allows for control and proficiency of short term memory); and the third, in which we can formulate logical definitions and carry out formal demonstrations (related to the "formal world" which takes place in the superior cortex).

Tall (2010) proposes the use of technology so as to view a graph on the computer screen, in such a way that it is visibly flat when maintaining the same vertical scale and increasing the horizontal scale (Figure 1); that is, to get the image so close for it to be possible to view the pixels forming a single line, thus insuring that the graph is continuous.

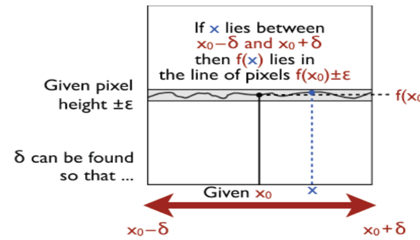

Figure 1: Tall's geometric interpretation

Participants, Research Method, Procedures

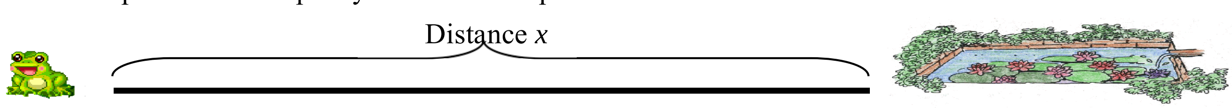
This report documents one of the four activities which were designed to offer a close approach to the concept of limit to students who had not studied Calculus. These activities were applied to students of high school (second semester) of Cecytem in the Municipality of Tzintzuntzan, state of Michoacan, Mexico who participated voluntarily in extra class sessions. The purpose of this study is to find out how these activities contribute to the initial building of such concept. The design of activities was carried out following the suggestions of the Balanced Assessment Package for the Mathematics Curriculum (2000), trying to make them attractive to the students.

Activity: **Yaya's Leaps**

Instructions: Analyze the situation and answer the questions, do not erase.

Yaya is a little frog that lives happily in a pond; she likes to count the leaps she does so as to reach the objects around her. One day, tired of always counting in the same manner, Yaya decides to modify the way in which she goes forward, and says: "From now on, every one of my leaps will be exactly one half the distance I need to cover to reach my goal."

Observe the picture and help Yaya count her leaps.



Yaya wants to reach the pond and w ith her first leap she travels half the distance required to get to it.

1. What distance did Yaya cover with the first leap?
2. What distance does she have to travel in order to reach the pond?
3. Remember that with each new leap Yaya travels one half of the distance which is missing? Yaya jumps her 2nd leap, what distance has she traveled between leaps 1 and 2? How much more does she need to travel?
4. Draw Yaya's Leaps and complete the following table according to the distance to be covered with each leap.

Leap number	1	2 3		4	5 6 7					
Distance to be covered	½	¼								
Expression	(½)	$(½)^2$								

5. Observe the table: after 5 leaps how m uch more does Yaya have to jum p to arrive at the pond? Express it algebraically.
6. If Yaya jumped "n" leaps, what distance must she still travel?
7. How many leaps does Yaya need to get to the pond? Justify your answer.
8. What happens to the distance that Yaya needs to travel as the number of leaps increases?

Results

The students worked by teams during 45 minutes. The group discussion practically started as the teams presented their results. It stands out that graphic representation seems to be the form which favors the approach to the concept of limit; when they referred to verbal representation, the students thought it was a problem of logic or guesswork.

Yaz: since this is the distance, then we have to divide it in… in half.
Dany: but, this seems almost logic, isn't it?...
Yaz: … **but** [looking at Dany], **she would never arrive.**
Dany: what I mean, she would never arrive because, it is pure logic…
Yaz: **no, because she has to get to here, mijo**, they are one, two, [counting the leaps] …, seven, she jumped seven times, **eight, no look** [counts again] **she jumped eight times**.

Apparently, the above dialogue shows the moment when Yazmin has a brilliant idea and, as mentioned by Schoenfeld (1992), the student's own experiences will lead him/her to understanding. The students that did not divide the segment have not noticed that very soon it will be physically impossible to make the partitions. Yazmín tries to explain it:

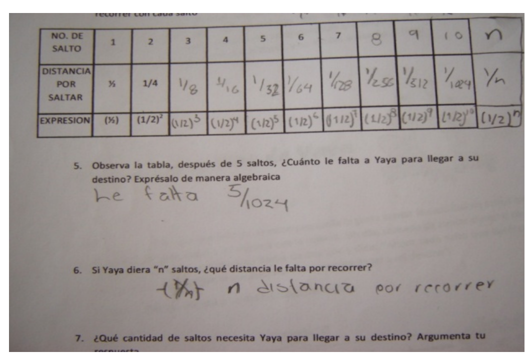
Yaz: **one half of one half is remaining, she will leave more and more space behind, have you understood me or not yet? she has to get there; she does get there, doesn't she?**
Erandi: **it reduces more each time**.
Yaz: **it's that… uhm it reduces more each time**.
Dany: **yes it's true that it reduces more and more**.
Yaz: **whether the space is large or small, she has to arrive**
Erandi: **there's no more space**.
Yaz: **there will be no more space which can be cut by half, she simply has to get there, do you or don't you understand?**

When Yazmín explains to her peers she is confronting her peer's ideas in relation to the notion that problems are solved by completing tables:

Juan C: **but then the table would only have eight boxes**…
Fidel: **Because… we only went for ten… and for completing the table**. [and shows more complex issues] **I'm telling you that here she would give two equal leaps and on this page it never says that it will jump the same distance twice.**

However, although Yazmín tries to explain by showing the partitions on the floor with the aid of markers and pencils which represent each of Yaya's leaps and the pond, she does not convince them to visualize:

Yaz: **it's that she is not jumping the same distance, there will simply be no more space to leap with her nails… it reduces and reduces until she has no more space to jump one half.**
Fidel: **but she also jumps into the water**. [laughs]
Yaz: **oh, but she has arrived at the pond.**
Ely: then how many jumps does Yaya need to get to the pond?
Dany: [very slowly] I say it is infinite.



NO. DE SALTO	1	2	3	4	5	6	7	8	9	10	n
DISTANCIA POR SALTAR	½	1/4	1/8	1/16	1/32	1/64	1/128	1/256	1/512	1/1024	1/n
EXPRESION	(½)	$(1/2)^2$	$(1/2)^3$	$(1/2)^4$	$(1/2)^5$	$(1/2)^6$	$(1/2)^7$	$(1/2)^8$	$(1/2)^9$	$(1/2)^{10}$	$(1/2)^n$

5. Observa la tabla, después de 5 saltos, ¿Cuánto le falta a Yaya para llegar a su destino? Exprésalo de manera algebraica
le falta 5/1024

6. Si Yaya diera "n" saltos, ¿qué distancia le falta por recorrer?
(1/n) n distancia por recorrer

7. ¿Qué cantidad de saltos necesita Yaya para llegar a su destino? Argumenta tu

Figure 2: Fidel's team's response

In general, there was no numerical difficulty in the teams when partitioning the segment which represented the distance Yaya had to travel; they were also able to complete the table without problems; some even added a columns for leap "n" and they answered correctly the expression on the table, however they could not answer question 6, as seen on Figure 2. This problem arose with all the teams when having to find the algebraic expression for leap "n." In some teams we even observed rejection or frustration towards algebra which does not permit them to at least make an attempt.

Juan C: which would be the algebraic answer?, would it be here? [pointing to the table]
Dany: … I don't know [takes the sheet and writes $(½)^n$].
Yaz: **but, why to the nth power? we're supposed to be obtaining…**
Dany: **one half to the 2nd, one half to the 3rd… one half to the nth.**
Yaz: **but what is the value of "n" so it can be reduced to this? and so it results in "n".**
Dany: but here it goes, and goes, and goes.
Erandi: **"n" es infinite.**
Yaz: **"n" es infinite? "n" is any number**.[laughs]

However Yazmín and many of her classmates do not identify that "n" represents the number of leaps and cannot be used to represent another variable; they understand that "n" is a variable which can have any value but they use it indiscriminately to indicate the number of leaps and the distance to be traveled.

Ely: what does "n" represent?
Mando: the distance and the number of leaps.
Ely: Both? [Armando nods affirmatively].
Fidel: well, it represents one thing in each question.
Ely: Different things?
Mando: ... because it is a distance and also the leaps.

Barbara's team did not have a problem to find the limit, although when they counted the partitions they made, they counted up to nine leaps:

Juan C: [starts to count with the aid of the drawing, followed by Penelope] one, two, three, four, five, sex, seven, **eight and from this half, it got there** [laughs], how many leaps did we do? nine [answer his peers]…, then it wouldn't need to jump anymore; [insists] **ten leaps, if you place another pencil there would be one, two, three… Ten leaps.**
Yaz: **but another pencil doesn't fit.**

Final Comments

It seems that Yazmin had the best approach to the concept of limit. At the start her thoughts were similar to those of her peers assuming that Yaya would never reach the pond; however, she discovered the contrary when partitioning the segment on the drawing. After that she tried to explain her classmates with several examples using the argument: how is she going to leap again if there is no more space to jump? She either leaps to the pond or remains in her place. This convinced most of the students since there was a consensus in the last question; all answered that the distance which Yaya had to travel was reduced inasmuch as the number of leaps increased. These are essential prerequisites to reach understanding of the concept of limit.

PRODUCTIVE STRUGGLE AND ITS ROLE IN TEACHING AND LEARNING MIDDLE SCHOOL MATHEMATICS

Hiroko Kawaguchi Warshauer
Texas State University-San Marcos
hw02@txstate.edu

Mathematics educators and researchers suggest that struggling to make sense of mathematics is a necessary component of learning mathematics with understanding. This study examined students' productive struggle as students worked on tasks of higher cognitive demand in middle school mathematics classrooms. Observations of 186 episodes of student-teacher interactions revealed types of struggles students encountered, the ways teachers responded to these struggles, and the kinds of interaction outcomes that were productive or not. A productive struggle framework was developed to examine the phenomenon of student struggle from initiation, interaction, to its resolution.

Keywords: Instructional Activities and Practices; Middle School Education; Classroom Discourse; Problem Solving

Introduction

Students' struggle with learning mathematics is often cast in a negative light and viewed as a problem in mathematics classrooms (Hiebert & Wearne, 2003; Borasi, 1996). Teachers, parents, educators and policymakers routinely look for ways to overcome the "problem," seen as a form of learning difficulty, and attempt to remove the cause of the struggle through diagnosis and remediation (Adams & Hamm, 2008; Borasi, 1996). From this one would hardly expect that focusing on students' struggle in mathematics could be viewed in a positive light and as a learning opportunity.

Mathematics educators and researchers James Hiebert and Douglas Grouws suggest, however, that *struggling to make sense of mathematics* is a necessary component of learning mathematics with understanding (Hiebert & Grouws, 2007). The idea that struggle, that is to expend intellectual effort, is essential to intellectual growth has a long history (Dewey, 1933; Piaget, 1960; Polya, 1957; Hatano, 1988). More recently, Hiebert and Wearne (2003) stated, "all students need to struggle with challenging problems if they are to learn mathematics deeply" (p. 6).

While the phenomenon we call struggle may be internal, it is also observable in most classrooms. This study identified episodes during instruction where students made mistakes, expressed misconceptions, or claimed to be lost or confused, and to which teachers responded. Interactions between students and teachers generally advanced toward some resolution of the students' difficulties and attempts at sense-making. Using an embedded case study methodology with instructional episodes as the unit of analysis, the study identified and described the nature of the students' struggle as well as the instructional practices of teachers that either supported and guided or did not support or guide the students' sense- and meaning-making of the mathematics in the lesson episodes.

Conceptual Framework

The conceptual framework was built on three main components: (1) The role of struggle in learning mathematics with understanding; (2) The nature and types of mathematical tasks and their relationship to students' struggle; and (3) The ways teachers' respond to students' struggle in classroom interactions. This study used the perspective of mathematics as a social phenomenon, where people create objects and study the patterns and relationships of these objects within a social culture (Hersh, 1997; NCTM, 2000). In addition, mathematics is viewed as a dynamic discipline that involves exploring problems, seeking solutions, formulating ideas, making conjectures, and reasoning carefully.

Methods

This exploratory case study used embedded multiple cases (Yin, 2009) in order to study the role of productive struggle in learning and teaching mathematics. Specifically, the research questions addressed were:

1. *What are the kinds and patterns of students' struggle that occur while students are engaged in mathematical activities that are visible to the teacher and/or apparent to the student in middle school mathematics classrooms?*
2. *How do teachers respond to students' struggle while students are engaged in mathematical activities in the classroom? What kinds of responses appear to be productive in students' understanding and engagement?*

Participants

The participants were 6th and 7th grade middle school students and their teachers from three middle schools located in mid-size Texas cities.

Procedure

Data collection. Each teacher was videotaped teaching six to eight classes in a one-week period with each class ranging from 60 to 90 minutes. Thirty-nine class sessions were observed among the six teachers and 327 students for a total of 52.5 observation hours.

Data analysis. An excerpt file of video clips of instructional episodes was created guided by Erickson's (1992) methods for analyzing video data. An instructional episode consisted of a classroom interaction about a mathematical task that was initiated by a student struggle that was in some way visible to a teacher or another student whether voiced, gestured, or written. The transcripts of the class observations and interviews were coded using the open-coding process (Strauss & Corbin, 1990) to identify and analyze (1) the kinds of struggle that occurred, (2) the level of cognitive demand within which each struggle occurred, and (3) the nature and kind of responses each teacher made to the students' struggle.

Findings

Students' Struggle

In the analysis of the 186 episodes, four main types of struggle emerged as students engaged in mathematical tasks. The struggles centered about students' attempts to: (1) Get started, (2) Carry out a process, (3) Give a mathematical explanation, and (4) Express a misconception or errors.

Findings confirm that occurrences of struggle depended on students' engagement in the prescribed tasks that challenged them and had some element of difficulty.

Teacher Response

Findings showed four main ways that teachers responded to student struggles situated along a continuum that includes *telling, directed guidance, probing guidance,* and *affordance*. The analysis of the teacher responses in the student-teacher interactions focused on three dimensions based on the conceptual framework: (1) level of cognitive demand of the mathematical task, (2) attention to the student's struggle, and (3) building on student's thinking.

The study found that teachers seem to constantly strike a balance between trying to sustain student engagement and maintaining the cognitive demand of the task (Kennedy, 2005).

Interaction Resolutions

Resolutions were classified as *productive* if they (1) maintained the intended goals and cognitive demand of the task, (2) supported students' thinking, and (3) enabled students forward in the task execution; *productive at a lower* if productive in points (2) and (3) above but the cognitive demand of the intended task was lowered; or *unproductive* if students continued to struggle without showing signs of making progress towards the goals of the task.

The Productive Struggle Framework below in Figure 1 incorporates the aspects of student–teacher interactions about student's struggle from initiation, interaction, to resolution.

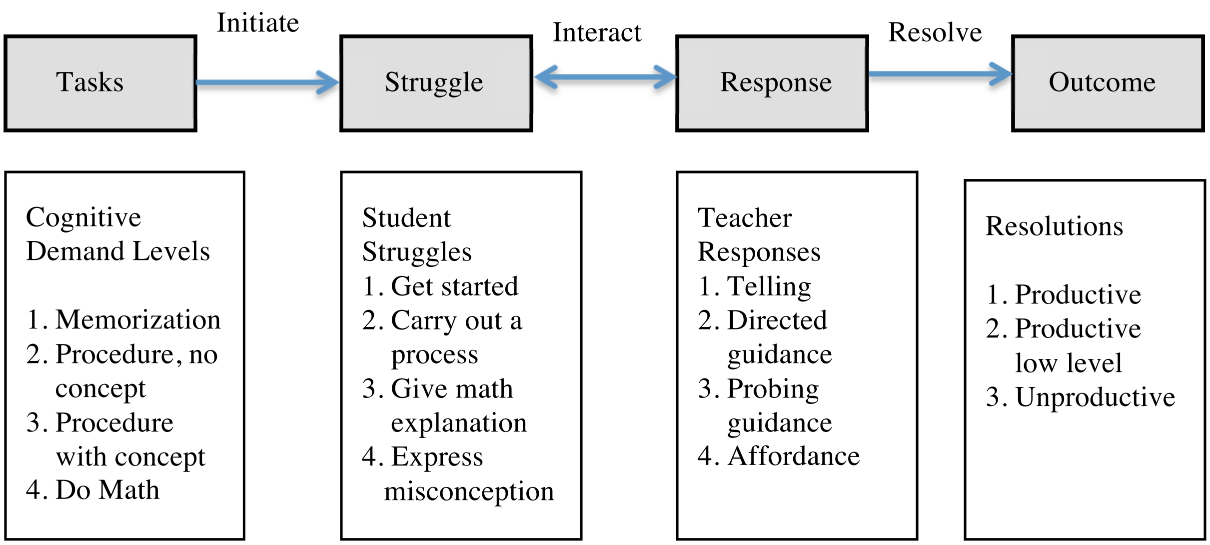

Figure 1: Productive struggle framework

Conclusion and Implications

The aspects of the interactions that helped direct and support student struggles productively and toward student understanding of mathematics was the joint student actions, teacher actions, and the physical and cultural contexts established by the norms in the class. The encouragement to communicate with teacher responses such as, "Tell me what you mean" and "Talk about it some more" or insistence on sense-making with "Why is that?" provided opportunities for students to elaborate on what they understood and clarify the source of their struggles. Responses that encouraged continued effort such as, "Try that" and "Well, what if you do…" gave positive reinforcement for engagement without student worrying about whether the result was right or wrong. Posing problems of high cognitive demand gave the students opportunities to think, reason, and problem-solve in ways that meant the students had to think deeply about the problems and not just find routine methods to apply. For future research, we can build on the descriptions of struggle, interaction, and resolution to assess how productive the students' struggles were and what the students learned through their struggle.

PROSPECTIVE TEACHERS REINVENTING INTEGRATION USING MEANS

Dov Zazkis
San Diego State University
zazkis@gmail.com

Chris Rasmussen
San Diego State University
chrisraz@sciences.sdsu.edu

The ubiquitous Riemann sum definition of integration is not the only way to define integral. Here we present an alternative mean-based definition of integration that we conjecture is more accessible to students. In support of this proposition, we first present a theoretical argument pertaining to how human beings think about infinity, followed by a discussion of results from a small-scale classroom-teaching experiment. This teaching experiment was conducted with a group of pre-service elementary school teachers all of whom had no prior calculus experience. These students, who are arguably much weaker mathematically than typical students entering college calculus, made considerable success in reinventing the mean-based definition.

Keywords: Post-Secondary Education; Curriculum; Instructional Activities and Practices; Advanced Mathematical Thinking

Toward an Alternative Pathway

The limit concept relies on notions of infinity. Núñez (2005) argued that the human mind understands the various instantiations of the concept of infinity as a conceptual blend of a finite process, which has a final state, and an ongoing process, which has no perceivable end (Fauconnier & Turner, 2002). Both of these processes are understood through real-world experiences. Students have more tangible experiences with ongoing processes of growth than processes of shrinking. One can imagine regularly depositing $100 into a bank account and watching the account balance grow without bound. However, it is much harder to imagine continually zooming in on an object. After the subatomic level is passed, there is nothing tangible left to imagine. Since we have more real-world experiences with processes of growth than processes of shrinking, if we are to accept Núñez's blending model, a natural consequence is that the concept of infinitely small is harder to grasp than the concept of infinitely big. Thus, if all other factors remain constant, a formulation of a concept that uses only notions of infinitely big is potentially more accessible to learners than a formulation of that concept which involves notions of infinitely small.

Students struggle with understanding processes that involve infinitely small quantities. Many students make sense of integration through something Oehrtman (2009) refers to as "the collapsing metaphor." This is when students reason that a dimension is lost as increments get smaller. For example, when finding the area underneath a function students may reason that to get an exact answer they need to shrink the rectangles used in the Riemann sum until they become lines. When the rectangles become lines a dimension is lost.

In light of this theoretical argument, we propose an alternative pathway to the definition of integration. Rather than relying on the concept of infinitely small, which is something students have little tangible experience with, we propose developing a definition that builds on students' understanding of mean. In this alternative approach, students reason about infinitely large sample sizes instead of dealing with infinitely small rectangles.

The Mean Based Definition of Integration

The following definition is a mean-based formulation of integration:

Uniform Sampling: $x_{i-1} - x_i = h = (b-a)/n \qquad x_i = a + ih$, $i=0,1,2,\ldots,n$

Sample Data: $y_i = f(x_i)$, $i=0,1,2,\ldots,n$

Statistical mean: $\bar{y}(n) = 1/(n+1)\sum_{i=0}^{n} y_i$

Definition of Integral: $I \equiv \lim_{n\to\infty} \bar{y}(n)(b-a)$ is the integral of *f(x)* over the interval [*a*,*b*].
This is written as $I = \int_a^b f(x)dx$.

Instead of rectangles that become infinitely narrow this definition takes a uniform sample of heights on an interval [*a*,*b*]. The mean of these heights provides an estimate for the mean height of the function. Multiplying this estimate by the width of the interval, *(b-a)*, provides and estimate for the area under the curve on the interval [*a*,*b*]. As the size of the sample is increased to infinity, the estimate of the area becomes the actual area, the integral of *f(x)* over the interval [*a*,*b*]. Unlike the Riemann sum definition, this formulation includes both end points of the interval [*a*,*b*], which is consistent with how it was reinvented by the participants in this study.

The Teaching Experiment

In the previous section we presented a theory-based argument grounded in how individuals think about infinity. Educational theory however, and the realities of classroom practice do not always line up with each other. A small scale teaching experiment was conducted to provide an existence proof of the accessibility of the definition (Steffe & Thompson, 2000). This teaching experiment was conducted with four prospective elementary school teachers who had no prior calculus experience. This lack of exposure minimized interference from previous instruction.

The first author was the instructor for all four sessions of the teaching experiment, which took place over four 50-minute sessions. Instruction focused on facilitating the guided reinvention (Gravemeijer, & Doorman, 1999) of the majority of the concepts involved.

The First Session

In the first session students were exposed to the mean height-line technique for finding areas composed of blocks. This technique involved dissecting and rearranging blocks to form an equivalent rectangular area (Figure 1). This technique was introduced in the context of students' own techniques for finding areas, all of which involved some kind of systematic counting. The technique was initially introduced as Joey's height-line technique, so that students could make their own connections between the technique and means. An exercise where students were asked to find the height-line of a shape that was described numerically, but not drawn, was the catalyst for students making this connection. This left students with some initial intuitions about the relationship between mean and area, which was exploited in the subsequent sessions.

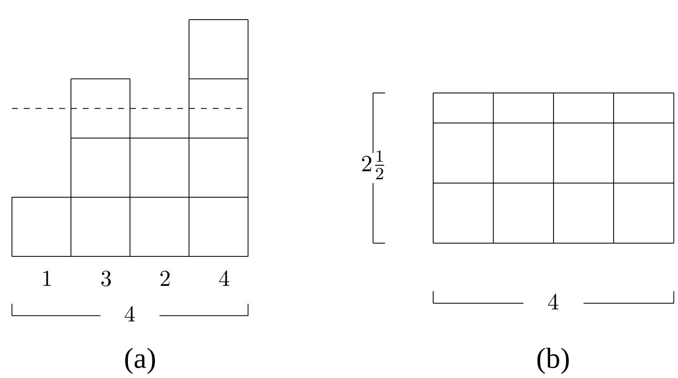

Figure 1: The mean height-line technique

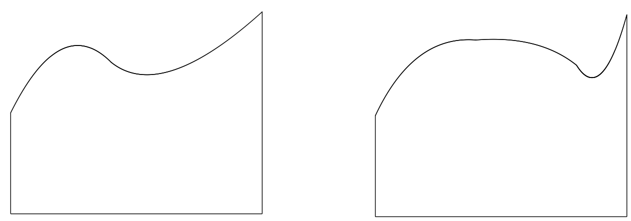
The Second Session

The focus of the second session was to extend the mean height-line technique to estimating the area of "rounder" shapes. This specifically focused on shapes that would appear, to an expert, to be the areas underneath functions. The functions context was, however, suppressed until the third session.

After several warm up exercises which involved estimating the mean height-lines for rounder shapes, students were prompted to come up with a technique that would provide consistent estimates that others could replicate. This resulted in what we view as the pivotal episode in the teaching experiment. In it the group, with some guidance from the instructor, managed to co-operatively modify the techniques that they were exposed to up to this point into one that is applicable to function-like shapes.

After several failed attempts at creating a technique that could be used to find consistent estimates of the heights of mean height-lines, two techniques emerged. The first was jointly constructed by two of the four students in the group; it involved averaging the heights of the maxima, minima and end points of the function like shape. Another student, in an attempt to understand this way of generating the estimates, inadvertently proposed a second method when she asked, "Did you add up the height or total the heights from each centimeter?"



(a) (b)

Figure 2: Deciding between two methods

The instructor drew two pictures on the white board (Figure 2a and 2b). The two shapes had the same width, maxima and minima; however, the widths of the peaks and valleys differ. The instructor noted that the maxima/minima method would produce the same estimate for the area of both of these shapes, because the high and low points were the same in both cases. Then the group was asked what would happen with the regular interval method. The group answered that this would produce a larger estimate for Figure 2b than for Figure 2a. Since the students agreed that they thought the shape in Figure 2b had a larger area than the shape in Figure 2a, the group naturally concluded that the regular interval method was more desirable. The group used this technique to estimate the mean height-lines of two more figures.

The Last Two Sessions

The last two sessions served as a formalization process of the ideas developed in the first two sessions. In the third session the technique developed in the second session was adapted to a functions context. The group successfully applied the mean height-line technique to estimate the area under a number of different functions. The group then turned to formalizing these notions. Summation notation was used to translate the step-by-step technique that the students were comfortable using into a mathematical formula.

The last session addressed the idea of increasing sample size. Students had little trouble adapting to using the technique to estimate quantities by finding a height every half unit instead of every whole unit. They quickly pointed out how tedious such calculations were in anticipation of applying them on even smaller increments. This was used as motivation for formalizing these techniques in a manner that would allow us to tell a computer how to do work for us and students' ideas were translated into a formal limit definition of integral.

Conclusion

This teaching experiment served as an existence proof that the connection between mean and area, necessary for a deep understanding of the mean-based definition of integration, could be developed in a short period of time. As such, this approach to defining integral appears promising for students entering calculus, who on average have much stronger mathematics backgrounds. The theoretical arguments posed in the first section of this paper further support the accessibility of this definition. These arguments contend that the notions of an infinitely large sample used in the mean-based definition are more accessible to students than the notion of infinitely small intervals used in the Riemann sum definition. We hope in the future to be able to study how the mean-based definition can be utilized on a larger scale in a college calculus course.

USING MULTIPLE REPRESENTATIONS AS AN ADVANCED ORGANIZER FOR SOLVING PROBLEMS RELATED TO PASCAL'S PYRAMID

Anoop Ahluwalia

Keywords: Learning Progressions; Learning Theory; Problem Solving; Reasoning and Proof

This report is a 16-year case study of the mathematical reasoning of a student who participated in a longitudinal study of the development of mathematical ideas. We trace the counting reasoning from grade 5 through young adulthood of Robert, guided by the questions: (1) What representations were used to solve the strand of counting tasks leading to problems related to the properties of Pascal's Pyramid? (2) How were the representations useful in solving increasingly challenging tasks? and (3) What connections were made to the structure of solutions of other tasks? The representations and robust counting skills that Robert used and then later elaborated unveil the growth in understanding and the increased sophistication in representing earlier ideas. We suggest how Robert's earlier ideas grew over the years. In grade 5 (1993) Robert worked on a problem where students were asked to find as many different towers, four-cubes tall, when selecting from two colors of Unifix cubes. Robert observed his classmate Stephanie share the idea of a tree diagram to keep account of all towers. In grade 11 (1998), Robert worked on extensions of the same activity and sketched a tree diagram to convince the researcher that he had accounted for all towers. Later, in a post-graduate interview (2009), Robert built a 3-D model using *Zome tools* (connecting spheres and rods) for the Pascal's Pyramid. He then extended the representation of family tree using Unifix cubes and *Zome tools* to illustrate how subsequent layers of the Pyramid are derived from the preceding ones. In grade 7 (1994) Robert was asked to find all possible five-candle arrangements choosing from two colors of candles, red and gold. He created a binary list to find sixteen such arrangements, using 0 for red and 1 for gold. Five years later, in grade 12 (1999) Robert used this same binary notation to solve the *World Series Problem*, a baseball competition asking what is the probability that a series between two equally matched teams would end in four, five, six or seven games. This time around, Robert used 0 to represent one of the teams winning and 1 to represent the other team winning. In grade 11 (1998) Robert had to find all six-tall towers choosing from yellow and blue blocks that have exactly two blue blocks in them. Robert controlled for the spaces where the two blue blocks can be placed to methodically list all towers. He repeated the same technique in grade 12 for the *World Series Problem* to list all the possible ways a series could end in six games by controlling for where the two losses of a team could be placed in his binary list. Implications for further study will be offered.

RECONSIDERING "OFF-TASK" MOMENTS

Diana Chang Blom
University of Georgia
dblom@uga.edu

Eunae Son
University of Georgia
eunaes@uga.edu

Keywords: Early Childhood Education; Elementary School Education; Instructional Activities and Practices

This poster focuses on the mathematical thinking that emerged during off-task moments in a kindergarten classroom. Research has emphasized the importance of time-on-task for student learning (e.g., Anderson & Walberg, 1993); however, there has been little attention paid to students' time-off-task and the mathematical thinking that emerges while the children are off-task. Our study focuses on the main question: In what ways can some off-task activities promote mathematical thinking?

This study is grounded on Vygotsky's socio-cultural theory (Vygotsky, 1978). He focused on children's learning within cultural context and considered that children's learning is mediated not just by others (and knowledgeable others) but also by the available cultural and material tools. We pay close attention to social and cultural contexts of children's off-task moments and explore how the tools in those moments provided learning opportunities not being made available by the teachers.

The study was situated in the kindergarten of Taylor County Public School, a small rural school with a predominantly black population. We videotaped around 40 hours of classroom time, which we transcribed into fieldnotes. Following traditional methods of ethnographic analysis (Erickson, 1986), we coded the data for formal and informal learning, mathematical topics, materials used, and off-task moments, and used these codes to make assertions.

We found that off-task moments provided opportunities for students to explore, develop and discover mathematical concepts. These opportunities arose mostly when students had manipulatives or objects to play with during a lesson or activity. For example, while Ms. Perry was teaching a lesson about measurement, Maria had her fleece jacket with her at her desk and decided to folded and unfolded her jacket three times while the lesson was taking place. As she experimented with folding her jacket in different ways, she was developing conceptual understandings for symmetry, fractions, estimation and measurement. Another example of off-task learning was during a class activity where Carter needed to create an ABC pattern using small colorful dinosaurs. Immediately after he finished his pattern, he turned his attention to his own project: he found all the purple, orange and blue Brachiosaursus dinosaurs he could and grouped them according to their color. While Carter was waiting for further instructions, he was able to experiment with sorting and patterning in his own way. Though Maria and Carter were off-task, they were still able to learn and develop mathematical concepts.

The purpose of this paper is to bring to light the learning that can happen during off-task moments especially since the academic discourse focuses mainly on the learning that happens during on-task moments. We are not arguing that all off-task moments are educational, nor are we arguing that off-task moments should take place over on-task moments. Rather, we are bringing attention to an educational moment that is often overlooked in academic discourse, a moment which educators often times see as uneducational. Through this research, we can see valuable mathematical concepts being explored and developed while children are "off-task," playing with objects and manipulatives. Rather than leaving these spaces as "off task," teachers should create a space where children can freely play and explore mathematical concepts with available social, cultural, and material tools.

TASK DESIGN TO CAPTURE MATHEMATICAL MODELING SKILLS

Jennifer A. Czocher
The Ohio State University
czocher.1@osu.edu

Azita Manouchehri
The Ohio State University
manouchehri.1@osu.edu

Keywords: Modeling; Cognition; Advanced Mathematical Thinking; Post-Secondary Education

The goal of this research was to produce a tool sensitive to both mathematical and cognitive activities attendant to mathematical thinking by adopting mathematical modeling as a lens for observing mathematical thinking-in-use. This instrument development project is embedded within a larger research endeavor designed to study influential factors on engineering students' decision making processes when engaged in mathematical modeling tasks (MM) that draw on the content of differential equations (DEs). DEs were selected as targeted content for task development for three reasons: (1) it provides a natural site to study modeling since the subject arose from the study of change in physical systems over time; (2) for STEM students, the course marks a transition from studying the fundamentals of change-over-time to using the calculus as a tool for addressing life-like problems; and (3) the course is largely populated by engineering majors—individuals who must coordinate both mathematical and non-mathematical knowledge. A cyclical schematic (e.g., Blum, 2011) is often used to describe an individual's MM activity as he develops an idealized version of the problem, represents it mathematically, analyzes the mathematical model, interprets the results in terms of the real world, and then validates the model. Using the modeling cycle as a theoretical framework, researchers have identified some of the most challenging aspects of MM for students: framing the task (Schwarzkopf, 2007), making transitions between the real world and the mathematical model (Crouch & Haines, 2004), and articulating reasons for why models are or are not valid (Borromeo Ferri, 2006). The objectives for the instrument design were to study cognitive activities associated with these challenging mathematical activities. An item pool was created based on an extensive review of literature. Each item was mapped against the modeling cycle and critiqued by a panel of mathematics educators and mathematicians, critiqued by educators at a national conference, and field tested. The items ranged from those targeting specific stages of the modeling cycle to those intended to evoke multiple cycles. The tool allows the researcher to examine how individuals move among mathematical modeling stages while explicitly acknowledging how a student's cognitive resources influence his mathematical thinking as it is being used. The instrument is suitable for use with STEM majors in one-on-one cognitive interviews.

AN INTERACTIONAL ANALYSIS OF STUDENTS' MATHEMATICAL ARGUMENT BUILDING IN AN AFTER-SCHOOL ENRICHMENT PROGRAM

Sarah Gilchrist
The Ohio State University
gilchrist.42@osu.edu

Candace Joswick
The Ohio State University
joswick.1@osu.edu

We adopted an interactional analysis perspective to examine a single class session on the development and use of argumentation among a group of 7th graders. Results indicated that students and teacher interacted in significantly different ways in the construction of mathematical meaning, which affected their learning.

In this work we focused on the development and use of argumentation in a 7th grade classroom to examine how the students and teacher develop and negotiate taken-as-shared mathematical meanings and ways in which the students and teacher viewed the use of argumentation in mathematics. For the episode, a basic transcript was produced for one whole class session. The verbal portion was divided up into message units and the timing and speaker labeled for each message unit. The nonverbal activities of the participants were recorded. The first round of analysis focused on the interactional moves at the message unit level—including who was speaking to whom as well as the discourse moves such as initiating, responding to, or closing a topic. At the second round, we used Halliday's function of language categories (1975) to catalogue the message units. We labeled message units in terms of instrumental, regulatory, interactional, personal, heuristic, imaginative, or informational in order to foreground important issues. Lastly, data was grouped into interactional units (Bloome et al., 2008) and then examined with respect to taken-as-shared mathematical meaning making, sociomathematical norms, and views on argumentation.

Findings

The students' interactional moves differed from those of the teacher's. In particular, the teacher was found initiating, validating, and closing a topic and the students responding to the topic. The students' utterances were found to function most commonly as interactional and informational, less as heuristic and imaginative. The teachers' utterances were often interactional and regulatory. The students accepted conjectures with respect to the concept of mathematical operation unless challenged either by the teacher or another student. The sociomathematical norm of re-explaining one's solution when challenged by a classmate or the teacher was prominent throughout the entire session. When discussing relational positioning in argumentation, students located themselves as dissimilar to the teacher. They interpreted argumentation in the mathematics class as something different than what they have been participating in with the other students. They also determined they are unable to challenge the teacher's power when arguing because they saw themselves lacking resources mathematically and with respect to time (i.e., the teacher controlled the time).

HOW STRATEGIES AND CONCEPTS CO-DEVELOP THROUGH MATHEMATICAL PROBLEM SOLVING PROCESSES

Mariana Levin
Michigan State University
mlevin@msu.edu

This poster focuses (at a micro-scale) on modeling transitions along the continuum of student learning by presenting a model for how strategic and conceptual knowledge co-develop in mathematical problem solving. The model was developed through a grounded analysis of six hours of videotaped interaction between a pre-algebra student and a researcher in which the student independently constructed a deterministic and essentially algebraic algorithm for solving algebra word problems of an underlying linear structure. The method he constructed, that can be recognized as linear interpolation/extrapolation, came about from incremental refinements to his earlier approaches to solving problems of similar structures, based on means-end analysis.

The analysis presented in this poster involves the development of an alternative and complementary perspective to the approach taken by the existing strategy construction literature (see Siegler, 2006, for a review). Like the existing strategy change and construction literature, this analysis tracks observable changes in strategy usage through an analysis of the problem solving actions of the individual. A novel aspect of the present analysis is the consideration of and elaboration of the nature of the knowledge needed to implement strategies. In particular, both strategies and the conceptual knowledge that undergirds their implementation are modeled as complex knowledge systems. The analysis is informed by and elaborates the Knowledge in Pieces (diSessa, 1993) theoretical perspective and the analytic methodology employed involves coordinating knowledge analysis (diSessa, 1993; Sherin, 2001) and microgenetic learning analysis (Parnafes & diSessa, submitted; Schoenfeld, Smith, & Arcavi, 1993).

In the particular case presented, the most significant class of conceptual knowledge that the solver consistently drew upon and developed over the course of the sessions was knowledge of how to control the variation of linear functions. The model of co-development of strategic and conceptual knowledge developed is one of mutual bootstrapping: (1) Strategy enactment promotes conceptual changes by seeding the development of new conceptual schemes, and (2) The creation of new conceptual schemes results in the creation of new conceptual categories and relations (e.g., and hence the creation of a new strategy).

STUDENTS' USES OF SMALLER PROBLEMS WHEN COUNTING

Elise Lockwood
University of Wisconsin – Madison
elise314@gmail.com

Research (e.g., Hadar & Hadass, 1981; Lockwood, 2011) suggests that there is a need for mathematics education researchers to examine students' work in combinatorics, attending to potential ways in which students may improve. In this poster, I report on one specific element of students' work with counting problems—the problem solving strategy of solving smaller, similar problems. Researchers in problem solving (e.g., Polya, 1945; Schoenfeld, 1979) and combinatorics education (e.g., Eizenberg & Zaslavsky, 2004) indicate that such a strategy may be effective for students as they engage in problem solving.

I interviewed 22 post-secondary mathematics students in individual, videotaped, 60–90 minute-long sessions. The students were first given five combinatorial problems to solve on their own, and they were subsequently given alternative answers of those same problems to evaluate. One such task was: "A password consists of 8 upper case-letters. How many such 8-letter passwords contain at least three Es?" A correct answer involves a case breakdown of counting passwords with exactly 3 through 8 Es. A tempting, incorrect solution first places 3 Es among the 8 positions of the letters, and then completes the password with any of the 26 letters in the alphabet (this answer overcounts). Using the methodology of grounded theory (Strauss & Corbin, 1998), data analysis included carefully reading transcripts and watching video, identifying and categorizing episodes that involved students using smaller, similar problems in their work.

I found three ways in which students used smaller, similar problems to their benefit. Students used smaller, similar problems (a) to facilitate systematic listing (which helped them to detect useful patterns in generating a solution and to identify an overcount), (b) to tackle one particular aspect of a problem, and (c) as a means of articulation and explanation. I also observed potential pitfalls of which students should be aware as they employ this strategy. Finally, I emphasize that the strategy has particular potential in the domain of combinatorics, and that the nature of counting problems makes them especially appropriate for the use of smaller, similar problems. Potential directions for further study include targeting how students think about and reflect upon their uses of smaller problems and investigating effective ways to develop this strategy among students.

ANALYSIS AND INFERENCE TO STUDENTS' RESPONSES ABOUT PROGRESSION OF UNDERSTANDING IN PROBLEM SOLVING TASKS

Pingping Zhang
The Ohio State University
zhang.726@osu.edu

Amanda Roble
The Ohio State University
roble.9@osu.edu

Keywords: Problem Solving; Assessment and Evaluation; Middle School Education

The development of problem solving ability has been among the primary goals of school instruction. In order to develop such ability, "students should acquire ways of thinking, habits of persistence and curiosity, and confidence in unfamiliar situations that will serve them well outside the mathematics classroom" (NCTM, 2000, p. 52). While this goal has been a persistent part of mathematics education community for over a century, issues regarding how to develop problem solving skills among learners through instruction continue to be a major dilemma. Schoenfeld (1992) indicated that the instruction on application of Polya-style heuristic strategies had not been proven to be successful, and further explained that it may due to the lack of knowledge about problem solving activities. In our previous study (Zhang et al., 2010), we reported a categorical analysis of problem solving schema between two transitional grade levels (5th and 8th). Improvement in the area of "understanding of problems" and preference to more "mathematical" approaches was observed, while standardized approaches and representations were identified as constraints for higher grade level.

To further contribute to the understanding of students' problem solving development, we administrated a series of problem sets to 566 students from grades 5 to 7. The content of problems concerned patterns and functions, geometry and visualization, and data analysis. These areas were selected since they have been identified as core content areas in K–8. Each set of problems was designed specifically for each grade level while coherently for the three grade levels, aiming to capture the progression of understanding for the concept exhibited on the problem items. The research questions we aim to answer are: (1) What are some different types of modes of reasoning exhibited in students' responses? (2) What factors may contribute to each type of reasoning? (3) What is the overall progression of understanding for each concept throughout the grade levels?

Two researchers will categorize half of the students' responses in each grade level separately, then discuss ambiguous responses together and finalize the categories. The modes of reasoning proposed by Stacey and Vincent (2008) will serve as the basic framework for our analysis, while any types of reasoning distinct from the model will be recorded and discussed. The second and third research questions will be analyzed based on the initial analysis.

SITUATING REVOICING WITHIN BROADER TASK AND SOCIAL STRUCTURES

Jeffrey Choppin
University of Rochester
jchoppin@warner.rochester.edu

Beth Herbel-Eisenmann
Michigan State University
bhe@msu.edu

This article explores how situating the linguistic move of revoicing within broader structures helps to explain why researchers and practitioners attribute a variety of forms and functions to revoicing, and shows how revoicing may be described as consisting of and situated within a broader set of discourse structures that represent a continuum with respect to positioning students in epistemic roles. We present analysis from classrooms of three teachers enacting the same task in both small group and whole class activity structures. The results show how revoicing took on a variety of functions within longer exchange sequences, which themselves functioned to position students as active contributors and as participants in mathematical discourse practices. The implications are that broader exchange sequences can provide the functionality that O'Connor and Michaels attributed to revoicing.

Keywords: Classroom Discourse; Teacher Practices; Positioning

Revoicing has become part of the lexicon in mathematics education since O'Connor and Michaels (1993, 1996) introduced the idea. They contended that teachers' use of revoicing created *participant structures* in which students took on serious intellectual roles with respect to mathematical argumentation (Foreman, 2003). Subsequently there has been considerable research that has focused on the various forms and functions of revoicing (Enyedy et al., 2008; Foreman et al., 2008; Moschkovich, 1999) and on the ways practitioners perceive the form and function in their classroom practice (Herbel-Eisenmann, Drake, & Cirillo, 2009). Notably, revoicing is not simply seen as creating opportunities to engage students in argumentation (Foreman, 2003) but also to create opportunities for typically marginalized students to participate in complex and valued mathematical discourse practices (Enyedy et al., 2008; Moschkovich, 1999).

A theme that has emerged from the research on revoicing is the multiplicity of forms and functions evident in practice, with Enyedy et al. (2008) identifying at least seven functions and the teachers in the Herbel-Eisenmann et al. (2009) study identifying 25 potential intended and unintended functions. These findings point to potential pitfalls of looking at a single instructional move in isolation of broader task, activity, and discourse structures: characterizing any instructional practice may portray a sense of clarity that rarely exists in practice, with consequences for how such practices are presented to and taken up by practitioners. Consequently, it is necessary to situate any discussion of revoicing (or any other instructional move) within broader chronological, instructional, and discursive structures, particularly those that contribute to the development of participant structures in which students take on serious epistemic roles (i.e., student contributions drive the development of mathematical content).

In this paper, we present analyses from classrooms of three teachers in order to show how situating revoicing within broader structures helps to portray why researchers and practitioners attribute a variety of forms or functions to revoicing, and to show how revoicing may be described as situated within a broader set of discourse structures that represent a continuum with respect to positioning students in epistemic roles. For example, moves characterized as revoicing may: serve as an extension of teacher-controlled forms of discourse (e.g., IRE-dominated exchanges) in which the teacher 'hijacks' a students' explanation to launch into a related explanation; or resemble *animation* in which the teacher narrates students' actions and explanations, squarely attributing the explanation to the students; or constitute a brief clarifying move to get students to elaborate and refine their explanations. These moves focus the discussion on students' contributions, but differ according to how the primary responsibility for explaining the mathematics shifts among the participants. These examples differ with respect to both form and to their location in longer exchanges.

We explore what we see as the primary function of revoicing relative to more constrained forms of discourse (IRE), which is to help students see themselves as knowers and doers of mathematics by creating spaces for students' contributions to serve as the focus of classroom discourse and as the primary mechanisms by which mathematical content is developed. We explore how the various shades of revoicing affect this primary functionality. We also explore moves that, in conjunction with revoicing, place the responsibility for mathematical explanations (i.e., the *work* of mathematics classrooms) almost fully on students.

In this study, we address the following research questions:

1. How do exchange sequences—broader than revoicing—influence the social task structure (i.e., position students as active contributors and participants in mathematical discourse)?
2. How do exchange sequences—broader than revoicing—develop the mathematical goals of the lesson (i.e., the academic task structure)?

Defining Revoicing

Revoicing involves a dual function of creating a social task structure (positioning students as active contributors to the development of mathematical ideas) and an academic task structure (positioning students' contributions with respect to academic content) (O'Connor & Michaels, 1993). When describing a teachers' revoicing move, O'Connor and Michaels stated:

> What [the teacher] is doing here is creating a participant framework in which (a) she herself has taken the opportunity to draw a further inference from [Student A's] utterance; and (b) [Student A] has the right to validate [the teacher's] inference and, thus, take on a position himself with respect to an aspect of the current academic task …; and (c) [Student A] has been positioned in opposition to [Student B] in an activity that involves discussion of the relative merits of two proposals. (p. 322)

Typically revoicing involves (1) rephrasing or rebroadcasting a student explanation, (2) attributing intellectual contributions to the student, and (3) checking back with the student to see if the teacher described the explanation accurately. Performing these actions puts the teacher "on relatively equal footing" with the student (p. 324) and allows the student to "challenge or affirm" any claim attributed to him. In terms of the social task structure, this allows the teacher to "induct students into a discourse community, by getting them to adopt roles in the ongoing thinking practices that she wishes them to develop" (p. 325). In effect, revoicing coordinates the academic and social task structures.

Methods

We employed discourse analysis techniques to study three teachers enacting the same task in both small group and whole class activity structures. The three teachers were selected because they displayed distinct patterns in their discursive routines and because we had data of their enactments of the same instructional sequence, providing a common mathematical and curricular context. We characterized the teachers' discourse practices in terms of the extent to which they engaged in *accountable talk* (Michaels, O'Connor, & Resnick, 2008) as operationalized in the Instructional Quality Assessment Toolkit (Boston & Wolf, 2006). Accountable talk involves discourse practices that facilitate the development of participant structures that position students in substantive epistemic roles, and includes revoicing as one of a broader set of discourse moves. Other accountable talk moves include pressing for accuracy or pressing for reasoning. We also documented occurrences of the IRE discourse pattern and similarly monologic practices (Lemke, 1990; Nystrand, 1997)—such as extensive teacher explanation and direction—that were evident. We then situated the revoicing moves for how they functioned within the broader academic and task structures by considering their functionality in the immediate turns surrounding the move and within longer interactional patterns.

The teachers were observed enacting *Comparing and Scaling* from CMP, which focuses on helping students develop methods for comparing quantities using multiple strategies, including fractions, ratios, and percents. The task that is the focus of this analysis is the *Orange Juice* task, in which students were given four water/concentrate mixtures (e.g., 2 cups concentrate to 3 cups water, 5 cups concentrate to 9 cups water, 1 cup concentrate to 2 cups water, and 3 cups concentrate to 5 cups water) and asked to determine which were the most and least "orangey" mixes. This task offered opportunities for students to choose from a range of strategies to make their comparison and to make connections between fractions, ratios, and percents as forms of comparisons.

Results

Revoicing functioned within the longer exchanges most prominently to establish *common ground* (Staples, 2008) at a given point in time, with two primary patterns in terms of what followed. The two teachers who most frequently and productively used revoicing to establish common ground either subsequently: (a) pressed the student or group of students to refine, revise, or elaborate their explanation; or (b) elicited comments from other students about the explanation. A second use of revoicing, particularly within the group activity structures, was to conclude a set of exchanges (which are analytically akin to Mehan's [1979] *Topically Related Set*), to establish common ground for one strategy before students moved to recording that strategy or developing a second strategy.

The longer sets of exchanges in which the revoicing moves were located had distinct functions in terms of the social and academic task structures. In terms of the social structure (e.g., the participant frameworks), the longer exchanges helped to make public students' explanations in ways that clearly attributed the origins of the explanations to particular students or groups of students, and marked the mathematical qualities of the explanations. At least implicitly, this positioned students as competent problem solvers and active contributors to the collective development of the core mathematical concepts. In terms of the academic task structure, the longer sets of exchanges served as the primary vehicles by which the teachers explored the mathematical ideas they identified as the primary goals for the unit.

Although we provide more detail shortly, Table 1 summarizes the exchange patterns across the three classrooms and indicates the location of revoicing within those patterns. The table shows differences in group and whole class exchange patterns. A common occurrence in the group exchanges was the use of revoice and press routines, in which the teacher revoiced the student contribution as a means to continue pressing students to clarify or revise their explanations. Granville used revoicing more sparingly, engaging instead in extended press sequences that often resulted in a fairly complete student explanation. Pless, by contrast, used revoicing to inject some explanatory features before continuing to press the students. In her class, the students' contributions were less evident, though she often explicitly attributed the content of her revoiced explanation to a student or group of students. In the classes of both Granville and Pless, the exchange sequences typically resulted in an articulation of a coherent strategy, though, as noted, the responsibility for articulating that strategy was distributed differently in those two classes. Sadosky's group exchange sequences were not as productive in terms of producing a coherent strategy, though she too employed the revoice and press routines. Below, we present examples of the *revoice and press* (Example 1) and *revoice to conclude* (Example 2) patterns.

Table 1: Occurrences of Revoicing in Exchange Sequences

Teacher	Small Group		Whole Class	
	Exchange patterns	**Location of revoicing**	**Exchange patterns**	**Location of revoicing**
Granville	Press and extended presses followed by student explanations; Exchanges conclude by revoice or teacher explanation (in 4 of 10 exchanges)	The revoicing move concluded an exchange (3 of 10 exchanges)	Student explanation, teacher press for others to interpret, with press and explanation, and revoice and press sequences (with short revoicing turns); interspersed IRE sequences	Short instances inside of longer press, revoice, and student explanation sequences (4 of 6 lengthy exchanges)
Pless	Press and extended presses followed by student explanations; Press, revoice, and more press (in 4 of 8); Press, teacher explanation, and more press (in 2 of 8)	In the midst of longer revoice and press sequences (4 of 8); The revoicing move concluded an exchange (3 of 8)	Press and student explanations; revoice and press exchanges (with long revoicing turns); interspersed IRE sequences	In the midst of longer exchanges as catalyst for press and explanation sequences (4 of 5 lengthy exchanges)
Sadosky	Press, revoice, and press (in 2 of 5); Extended known-answer press (in 1 of 5); Press followed by student explanation (1 of 5); Teacher explanation (1 of 5)	In the midst of longer revoice and press sequences (2 of 5)	Primarily IRE sequences, with some student explanation and teacher explanation	Concludes exchange (2 of 8 mostly brief exchanges)

Example 1: Revoice and Press Routine

Pless: Guys can you listen to him while we do this? So look at what he did? He wrote two over three and said it is 66.6 repeating percent but as he looked at this now he realizes, he originally thought this meant 66.6 percent was concentrate right? (She looks at Adam for confirmation. Adam nods.) [**Revoice**]

Pless: But as he looked at this he is thinking that is not really the case anymore. Do you agree with him ... that is not the case? [**Pressing for agreement**]

...

Pless: Because what do I have to do if I want to find out what percent the concentrate is that of the juice? [**Pressing for accuracy**]

Adam: You have to add them together and then do the concentrate out of the total amount.

In Example 1, Pless revoiced the student's strategy as a precursor to a further press for him to explain the strategy. In Example 2, below, Granville revoiced the student's explanation to provide the strategic context for the procedural description provided by Tim. Her revoicing marked the end of the discussion on one strategy before proceeding to discuss a second strategy.

Example 2: Revoicing to Conclude

Tim: You multiply that to get your base-90 and top of it you multiply by the same amount to get the top of it ... to get ... to get the numerator. [**Student explanation**]

Granville: So what you are saying is that since these are all different, might as well try to get all out of the same amount. [**Revoice**]

The whole class exchange sequences were oriented toward explaining and collectively reflecting on strategies developed in the small group activity structure, as opposed to developing a strategy; consequently, the exchanges reflected that difference. In Granville's class, for example, the exchanges typically began with a student explanation, followed by a press for other groups to interpret the strategy or a press back to the initiating group (sometimes in the form of multiple IRE sequences) if clarification was required. When Granville employed revoicing, it was typically a brief move serving to clarify a key feature of the explanation before a further press to the group or to other groups to interpret the strategy. Pless, by contrast, used longer revoicing moves that involved narration of the group's processes and thinking before continuing with the press back to the group or class as a whole about the strategy. In both classes, revoicing helped to focus students on a particular strategy in which there were clear attributions back to the groups that developed the strategies. In Sadosky's class, the summary discussion was poorly organized and there was little opportunity to extensively discuss a particular strategy. Furthermore, she took on a greater role in explaining strategies, using revoicing to conclude exchanges rather than as a clarification before a subsequent press. Below, we present examples of the use of revoicing in the summary discussions.

Example 3: Granville's Use of Revoicing as Short Turn Followed by Press

*Granvill*e: So first they wrote the ratio of OJ to water, and then what was the second part they did? Why wouldn't I say they got a common denominator? … So what did you get a common—what? [**Pressing for Accuracy]**

Student: Uh, we got a common uh amount of cold water. [**Student explanation**]

Granville: Common amount of cold water. Ok. So you got them all out of—or compared to 90 cups of cold water. [**Revoicing**]

…

Granville: So here's the next question. How is this strategy related to our first strategy**?** Talk in your group. How is this strategy two related to strategy one [students start to talk]? [**Asking students to interpret peer's strategies]**

In Example 3, the revoicing move by Granville was brief and primarily functioned to establish a common description for a strategy before pressing the students to compare two strategies. In Example 4 below, Pless's revoicing turn was lengthy and explained both the strategic and technical aspects of the strategy before she pressed the students on further aspects of the strategy.

Example 4: Pless' Use of Revoicing as Longer Turn with Explanatory Qualities

Pless: So you started with a fraction and what type of comparison is your fraction? [**Pressing for Accuracy]**

Student: Part to whole.

Pless: Part to whole. And what part and what whole are you talking about? [**Pressing for Accuracy]**

Student: Concentrate to juice.

Pless: Concentrate to juice okay ... So I asked [the group] to keep going because I wanted you guys to see this. Now this might not be the easiest one to do common denominators with, however, they wanted, they were having trouble finding what they thought might be the smallest common denominator so they found a common denominator, they knew it would work by multiplying all of the denominators together and they came up with a denominator of 1,680. [**Revoicing**]

Pless: Do you think that's the lowest common denominator? [**Pressing for Accuracy]**

A key feature of revoicing (O'Connor, 2009) that was not as evident in these classrooms was the move where the teacher checks back with the student to ensure that any interpretation reflects the student's intentions. O'Connor and Michaels (1993) noted that this move allowed the student "to validate [the teacher's] inference and, thus, take on a position himself with respect to an aspect of the current academic task" (p. 322). One question that our data leads us to ask is the role of such a move with respect to the norms established in the respective classes. Given the way that Granville pressed her students to fully articulate their strategies, for example, it is possible that students felt freer to disagree with the teacher's interpretation of their strategy than in the classes of the other two teachers, who more strongly controlled the discourse with respect to the academic task structure. In those classes, however, it is important to ask whether attempts to rephrase or interpret students' explanations, even with attribution, constitute revoicing as envisioned by O'Connor and Michaels. This leads us to the bigger question of how the longer exchange sequences, in which revoicing served an important but limited role, potentially developed the participant structures that could ostensibly be created through revoicing.

Discussion

We reflect on how focusing on longer exchange sequences helps us to consider how revoicing and its proto-forms (i.e., those moves with some but not all of the features of revoicing described by O'Connor and Michaels) contribute to the development of social and academic task structures, especially structures in which students take on serious epistemic roles.

How Exchange Sequences Influenced Social Task Structure

Even though the range of accountable talk moves at times constituted a constrained form of positioning in that the teacher controlled how explanations were articulated and attributed, the moves still contributed to the portrayal of students as competent actors and thinkers. However, it should be noted, the lack of the third move limited student agency in terms of how their claims were taken up, with decreased roles especially in Pless's and Sadosky's classrooms.

Instances in which at least two of the three features were evident involved a continuum of control over responsibility for mathematical explanations. On the one end, teachers used the proto revoicing forms in ways that functioned as teacher explanation. In these cases, the teacher used an interpretation of a student's strategy as a beginning point to expand the mathematical claim but did not attempt to press the student or class to specifically focus on how the student to whom the claim was attributed may have interpreted the claim. That is, the teachers' interpretation became the focus of discussion as a tool to advance the academic task structure. This function of revoicing, as well as other functions that allow the teacher to control the content and flow of discussion, is seen by teachers as ‘muddying’ the ostensibly clear description of what revoicing is intended to accomplish (Herbel-Eisenmann, Drake, & Cirillo, 2009). In practice, revoicing, as seen by teachers, potentially describes a continuum of practices, which in part argues for looking at the characteristics and functionality of longer exchange sequences to see patterns in how the teacher positions students.

On the other end, the teachers, particularly Granville, used revoicing as a brief clarifying move to keep the discussion focused on the students’ explanation, including helping the student to elaborate her explanation more fully and helping other students to interpret that explanation for themselves. Granville seemed particularly skilled at using revoicing to coordinate the social and academic task structures. However, she did not explicitly scaffold the participant structure in the same way as the teacher in O’Connor and Michaels (1993) study; instead, her use of the extensive press for explanation made student thinking explicit features of classroom discourse and students took on the responsibility of aligning themselves in relation to the claims.

The regular presence of consecutive revoice and press moves in the exchange sequences was an interesting development. In these cases, the teacher used the revoice move not simply to attribute or to draw students into the discussion, but to establish common ground before continuing to press for explanation or for other students to interpret explanations.

How Exchange Sequences Influenced Academic Task Structure

Although it could be argued that the more teacher-focused forms exhibited by Pless and Sadosky allowed them to control the academic task structure and thus advance their didactical goals for the lesson, Granville’s skillful and persistent press for explanation and peer interpretation of strategies provided arguably the same or greater opportunities for students to make sense of the key mathematical ideas. That is, her use of accountable talk moves resulted in strongly coordinated social and academic task structures. She pressed students until the procedural and strategic features of the explanations were clear, which Granville supported by recording these features concisely on the same sheet as other strategies. This strategy allowed her not only to collectively press the class to interpret each strategy but also to compare strategies according to the primary concepts of the unit (e.g., the nature of comparison and nature of quantities being compared).

Revoicing as Situated Within Broader Structures

The revoicing moves used by the three teachers served a variety of purposes, not all of which were consistent with O’Connor and Michaels (1993) description of the move. In part, this was due to our interpretation of the move, which included proto forms that did not include all of the features listed by O’Connor and Michaels. However, our interpretations are consistent with those of other researchers and practitioners who have attempted to identify instances of revoicing in a wide range of classrooms. In part, the ambiguity stems from trying to isolate revoicing from broader discursive and activity structures and in part from trying to map messy data onto theoretically driven descriptions of discourse moves.

The broader exchange sequences, particularly those used by Granville, served many of the same functions as the revoicing moves described by O’Connor and Michaels (1993), suggesting that the broader set of accountable talk moves can create participant structures that position students as active contributors in ways that provide agency to the students. Much of the work in the longer exchange sequences was more implicit than in a more singular instance of revoicing, in terms of attributions and students’ opportunities to verify the interpretations of their claims. That is, there were extended opportunities for students to revise and clarify their explanations, notably during the revoice and press sequences.

It should be noted, however, that in many cases, especially in Sadosky’s class and occasionally in Pless’s class, that the proto forms of revoicing placed much of the work of interpreting and explaining on the teacher, with presses for verification and clarification often in the form of a known-answer questions. A question that arises from this research is how to help teachers develop awareness of the potential for transforming these proto forms into exchange patterns that provide greater opportunities for students to do the intellectual work in mathematics classrooms.

VISUAL REPRESENTATIONS IN MATHEMATICS PROBLEM-SOLVING: EFFECTS OF DIAGRAMS AND ILLUSTRATIONS

Jennifer L. Cooper
University of Wisconsin–Madison
jcooper4@wisc.edu

Martha W. Alibali
University of Wisconsin–Madison
mwalibali@wisc.edu

Many types of visual representations are used in math textbooks but not all of them contain mathematically relevant information. Little research directly addresses the effects of different types of representations on mathematics performance. Theories offer differing perspectives about how visual representations such as illustrations influence student learning. Here, we investigated the effects of diagrams and contextual illustrations on trigonometry problem solving. Diagrams helped all students, but the effect of contextual illustrations depended on students' backgrounds. Additionally, not all subgroups of students accurately assessed the effect of illustrations on their performance. We emphasize the need to consider how different types of visual representations interact with student characteristics and the problem-solving task.

Keywords: Problem Solving

Mathematics textbooks use a wide variety of visual representations, including diagrams, tables, graphs, decorative images, and photographs. Given students' frequent use of textbooks and the large number of visual representations in these textbooks, understanding how different types of visual representations affect problem solving and learning is critical.

Most research on the effects of visual representation has been conducted using scientific texts. It has focused primarily on diagrams and illustrations accompanying expository texts about causal phenomena. In such contexts, graphically integrating visual and verbal information is found to be beneficial, as is removing irrelevant information (e.g., Mayer, 2009). However, mathematical and scientific problem solving differ in many important ways, including different emphases on causality, spatial relationships, procedural and conceptual knowledge, and analytic methods. Thus, findings from research on science learning may not apply straightforwardly to math.

Existing research about the effects of visual representations in mathematics is based primarily on studies with elementary-age students, and it presents a complex and mixed picture. Some studies suggest that contextual illustrations hurt performance for particular subgroups of students (e.g., Berends & van Lieshout, 2009). Other studies suggest that decorative illustrations do not affect performance (e.g., Berends & van Lieshout), or that certain types of illustrations can benefit performance (e.g., Hegarty & Kozhevnikov, 1999; McNeil, Uttal, Jarvin, & Sternberg, 2009). Many studies also suggest that the usefulness of visual representations depends on students' ability levels (e.g., Booth & Koedinger, 2011; Berends & van Lieshout).

Theoretical Frameworks

In making sense of research on visual representations, two theoretical frameworks are particularly relevant: the Cognitive Theory of Multimedia Learning (e.g., Mayer, 2005, 2009) and Cognitive Load Theory (e.g., Sweller, 2004, 2005). Both theories address the processing and learning of information presented in different formats.

The Cognitive Theory of Multimedia Learning (e.g., Mayer, 2009) is based on three assumptions: (a) a limited capacity for processing information, (b) separate visual and verbal pathways through which information enters the cognitive system, and (c) meaningful learning arising from active processing. Cognitive Load Theory (e.g., Sweller, 2005) focuses on the cognitive load—the mental effort from the task itself, the processing required to integrate new and old material, and the processing required to work with a task's format. Overall, one idea is that the structure of the cognitive system imposes limits on how learners select, organize, and integrate information. These approaches have been used to guide instructional design.

Two principles derived from these theories are particularly relevant to the research reported here. The *multimedia effect* holds that words and pictures are better than just words (e.g., Butcher, 2006; Mayer & Anderson, 1992) based on the assumption of separate visual and verbal channels which can then be integrated for deeper learning. The *coherence effect* captures the performance benefits that occur when extraneous or seductive features of the material are eliminated (e.g., Harp & Mayer, 1997, 1998). Adding interesting but irrelevant material can overload the visual or verbal pathways or create too much extraneous load, thereby disrupting learning (Sweller, 2005). The coherence effect applies to both text and visual material.

Contextualization Perspective

Another theoretical perspective applicable to the current study focuses on how contextualizing or "grounding" math problems in real-world scenarios can help learners (Goldstone & Son, 2005; Koedinger & Nathan, 2004). Contextualization is thought to help students build a model of the situation underlying a problem. In addition, realistic content or greater familiarity with the content may promote generalization or facilitate reasoning because it fosters integrating the current problem with prior knowledge. Some studies have suggested that contextualization is more beneficial for simpler problems (Koedinger, Alibali, & Nathan, 2008), whereas other studies have suggested that it is more beneficial for difficult problems or lower ability students (Walkington, 2012). This body of research has typically involved contextualizing problems by adding verbal information to text, but contextualization can also be accomplished through accompanying visual representations.

Current Study

It remains an open question as to how the multimedia principle, the coherence principle, and the notion of contextualization apply to visual representations used in mathematics. The current research involves trigonometry problems accompanied by 4 types of visual representations: combining diagram presence (or not) with the presence of contextual illustrations (or not). The contextual illustration could add extraneous details through the graphics, but it also could ground the problem situation. We use the term *contextual illustration* since the illustrative features correspond to the spatial layout necessary to solve the problem. The perspectives discussed above vary in their predictions about which visual representations will be most helpful (see Table 1). We consider these effects in terms of student performance and evaluations of the problems.

Table 1: Predictions from Applicable Theoretical Frameworks

	Theoretical Prediction		
Multimedia Principle	Visual representations will help	→	Text by itself will be hardest
Coherence Principle	Extraneous information hurts performance	→	Problems with illustrations will be harder
Multimedia + Coherence Principles	Provide visuals but avoid extraneous information	→	Diagram by itself will be easiest.
Contextualization Perspective	Illustrations further ground problem solving	→	Problems with illustrations will be easier.

Method

Participants

Participants were 93 undergraduates, who received credit in introductory psychology for their participation. The majority (63%) had completed middle school math in the United States. Of those who had not, most (82%) had their earlier math education in an Asian country. Over two-thirds (69%) intended to major in a math or science field.

Participants were divided into subgroups based on their intended major (math/science field or not) and where their previous math education occurred (U.S. or non-U.S.). Students who were math/science majors were fairly evenly split into those who were previously educated in the U.S. (n = 34) and those who were previously educated outside the U.S. (n = 30). The vast majority of participants who were not math/science majors were educated in the U.S. (n = 25). Only 4 participants previously educated outside the U.S. were not math/science majors; this small group was excluded from the analyses reported here.

Design and Materials

Each participant received 4 problems based on a 2 (Diagram Presence) × 2 (Illustration Presence) within-subjects design, yielding 4 conditions: text alone, diagram alone, illustration alone, and illustration with diagram overlay (see Table 2). Condition order was counterbalanced across participants.

Table 2: First Background Story, Shown for Each Visual Condition

	No Diagram	**Diagram**
No Illustration	The parks department is putting a statue on a base. The statue is some distance away, and you are in a helicopter, eye level with its top. The angle of depression to the bottom of the statue (i.e., the top of the base) is 35 degrees. The height of the statue is 50 feet. If someone were to stretch a string from the bottom of the base directly to you, it would be 100 feet long. How tall is the base?	[text] + Illustration	[text] + 	[text] + 
Each of the 4 problems each participant received involved a different cover story. All required applying trigonometric relations to overlapping right triangles to solve for an unknown dimension. The different stories had varied combinations of sides and angles, such that the solution processes were not identical for any two problems. These types of problems were selected as they lend themselves well to concrete situations and are at an appropriate difficulty level for undergraduate participants. The order of the cover stories (and thus of the mathematical solutions) was held constant across participants. Each problem was on its own page, with the text and visual representation (if present) at the top of the page.

The illustration corresponded to the problem situation. As shown in Table 2, although it did have decorative features, it was also mathematically relevant because it indicated the spatial layout of the components of the story problem.

Procedure

Participants received a reference handout (with text and equations but no diagrams) of information about triangles and trigonometric formulas. The information was available throughout the study, and participants were told that not all of it would be needed. Participants worked through each of the four problems at their own paces. After completing the problems, they rated how difficult each problem was, how clear it was, and how willing they would be to do more problems like it. They assessed these characteristics on a 5-point Likert scale. While making these ratings, participants were permitted to look back over the problems but not to change any of their answers. Finally, participants completed a questionnaire about their attitudes towards mathematics, their math abilities, and their math background.

Results

A sizeable proportion of participants answered all or none of the problems correctly, and these rates depended on participant subgroup. For instance, 40% of the students who were not math/science majors answered *no* problems correctly and 30% of the math/science majors who received their previous education outside of the U.S. answered *all* the problems correctly. The results below include all participants; however, the patterns also hold for the subset of participants who did not perform at floor or ceiling (i.e., correctly answered 1–3 of the 4 problems).

Did Visual Condition Affect Accuracy?

We analyzed the dichotomous measure of accuracy on each problem using mixed models logistic regression (Bates & Maechler, 2009) in R. The best fitting model included the fixed factors of diagram presence, illustration presence, educational background / major (henceforth *participant subgroup*), and the interaction between illustration and participant subgroup. We also included participant and cover story as random factors; cover story significantly improved the model's fit ($p < .0001$). Coefficients and odds for the model are reported in Table 3.

Table 3: Coefficients from Regression Model for Accuracy Ratings

Fixed effects:	Estimate (logit)	SE	Odds	z value	Sig
Intercept	-0.53	0.68	0.59	-0.78	0.44
Diagram – no	Reference				
Diagram – yes	1.49	0.28	4.42	5.23	<.0001
Illustration – no	Reference				
Illustration – yes	0.996	0.47	2.71	2.1	0.04
Subgroup – outside US & math/science major	Reference				
Subgroup – US & math/science major	-0.39	0.64	0.68	-0.61	0.54
Subgroup – US & not math/science major	-1.15	0.70	0.32	-1.65	0.10
Illustration – yes x Subgroup – US & math/science major	-0.62	0.64	0.54	-0.96	0.34
Illustration – yes x Subgroup – US & not math/science major	-1.56	0.73	0.21	-2.13	0.03
Model: Accuracy ~ DiagramPresence + IllustrationPresence * Subgroup + (1 | CoverStory) + (1 | ID)					
Random effects (Intercepts): Variance of participant = 3.26 Variance of cover story = 0.91					

Participants performed significantly better on problems with diagrams than without, $p < .0001$ (see Figure 1; *SE* are corrected via procedure in Morey, 2008, to reflect within-subjects design). This effect existed for all three subgroups and did not interact with illustration presence.

However, the effect of illustration varied across participant subgroups. Participants who received their math education outside the U.S. (and were also math/science majors) performed significantly better with illustrations ($p < .04$) than without. This improvement differed significantly ($p = .03$) from the slightly negative effect of illustration on the US subgroup not majoring in math/science. The accuracy level of the subgroup who were not math/science majors was significantly lower than the accuracies the other two subgroups when there was an illustration (*p*s < .02), but this pattern did not reach significance when there was no illustration.

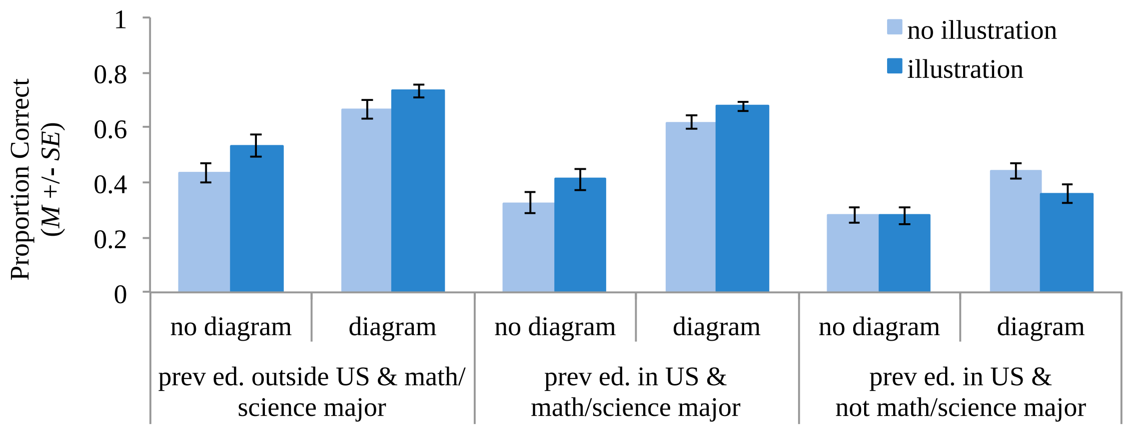

Figure 1: Average accuracy (+/– *SE*)

Did Visual Condition Affect Participants' Ratings of the Problems?

We combined participants' ratings of each problem's clarity and difficulty (reverse-coded) as well as their ratings of how willing they would be to do more problems similar to those completed. This composite measure offered an assessment of a participant's overall favorability towards a problem type. Correlations among the three measures ranged from .34 to .56, *p*s < .0001. The best fitting mixed effects model for participants' ratings included the fixed factors of diagram presence, illustration presence, and participant subgroup. We also included participant and cover story as random factors; cover story significantly improved the model's fit ($p < .001$).

As shown in Figure 2, participants viewed problems with diagrams significantly more favorably than those without, and they viewed problems with illustrations significantly more favorably than those without; respectively, each of these factors improved the fit of the model, $\chi^2(1) = 7.79$, $p = .005$ and $\chi^2(1) = 10.5$, $p = .001$. However, the magnitude of these effects was relatively small. Comparisons of the subgroups indicated that participants who were not math/science majors rated the problems significantly lower than participants with math/science majors (*t*s > 2.71), whose subgroups did not differ from one another ($t = 1.70$).

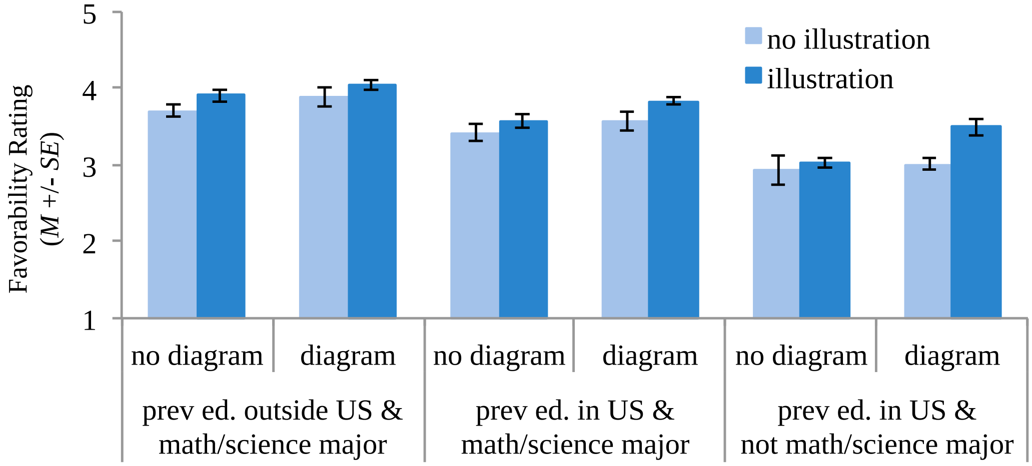

Figure 2: Average favorability (+/– *SE*)

Discussion

In this study, participants performed more accurately on trigonometry problems with diagrams. The effect of illustrations was mixed. Illustrations yielded a slight improvement in performance for students who intended a math/science major, but illustrations slightly hurt performance among students who were not intending to major in a math- or science-related field. These findings highlight that ability differences affect the use of visual representations.

The *multimedia principle* predicts that problems with visual representations would be solved more successfully than problems presented as text only. This was clearly the case for diagrams. The more mixed influence of contextual illustrations can be considered with respect to the *coherence principle* and the *contextualization perspective,* which make opposite predictions. Indeed, each prediction fit a subset of the participants. As predicted by the contextualization perspective, having an illustration benefited performance for participants who were math/science majors. In contrast, as was predicted by the coherence principle, illustrations hurt performance for those who were not math/science majors. Overall, though, the effects of illustration presence were relatively small.

These findings indicate that the coherence principle, which has been supported in multiple studies using science material (see Mayer, 2009), may not apply so straightforwardly in math. However, the coherence principle stresses the removal of extraneous details. Not all details are extraneous, and added visual details do not necessarily harm everyone's performance. This research used contextual illustrations that could have assisted students in mapping the problem content to the visual representation and thus does not necessarily contradict the coherence principle. It is also worth noting that the contextualized illustrations we used were more relevant to mathematics than the majority of illustrations that are found in American mathematics textbooks (Cooper et al., 2012; Mayer et al., 1995). Addressing the impact of purely decorative illustrations will be an important extension of this research.

Focusing on the cognitive load required by these problems offers a possible way to combine the two perspectives on the effect of illustrations and understand the dependence of the effect on subgroup. The cost of encoding and integrating the extraneous information (such as the design of the base of the statue) conveyed in illustrations may outweigh any possible benefits from contextualization if cognitive load surpasses the available cognitive resources. Illustrations might be more helpful for individuals with more math experience because such individuals can construct a contextualized mental representation of the problem scenario without exceeding their available cognitive resources. However, other research on contextualization has found grounding problems to offer greater benefits for students of lower math ability (see Walkington, 2012).

Diagram presence increased the favorability with which participants viewed the problems, as did illustration presence. Comparing this with performance data indicates that all participants' metacognitive beliefs about problems with diagrams matched their actual performance. However, only students intending a math/science major accurately perceived the effect of illustration presence. Participants who were not math/science majors performed the same or worse when an illustration was present, despite their more favorable view of these problems. This pattern of findings is particularly important to consider in light of the motivation-based argument that textbook visuals will help engage learners, particularly those with low math interest (see Durik & Harackiewicz, 2007, for related findings). However, it aligns with the research arising from the Cognitive Theory of Multimedia Learning and from Cognitive Load Theory, which hold that these extraneous but interesting details can be problematic for learning. As noted above, this may hold true especially when an individual's resources are taxed, which is more likely to occur for individuals with lower background knowledge.

The overall differences we observed in accuracy between students of different backgrounds are not surprising in light of the well-documented finding that students from many foreign countries outperform American students in math (Fleischman et al., 2010). What is more interesting is that students of different backgrounds were differentially affected by visual representations. The underlying constructs tapped by our measures of students' backgrounds need to be characterized with greater precision. We collected data on the intended majors and the country in which they received their middle school education. These measures may simply reduce to experience and interest in math; however, further research on students' backgrounds and how they affect performance is needed.

It is also worth noting that overall levels of performance in this study were not high, even in the highest performing subgroup. The problems we used were quite complex, and many components needed to be performed correctly in order to reach an accurate final answer. Students needed to know how to map information from the problem content to the visual representation and from the visual representation to their mental representation of the problem. Students also needed to identify what quantity to solve for, figure out the steps needed to reach the solution, and correctly apply the trigonometric formulas to reach a final answer. Understanding the differential effects of the type of visual representation on these different components of problem solving is an important arena for future research (see Butcher, 2006; McNeil et al., 2009).

In sum, this work highlights the need for a continued focus on the ways in which visual representations support learners' strategic problem solving and learning. Rather than asking simply which types of illustrations serve learners better, it is important to identify how learners with different backgrounds and skill levels utilize visual representations when solving problems.

Acknowledgments

The authors wish to thank the other members of the NCCMI Project team, Mitchell Nathan and Virginia Clinton, for their contributions. The research was supported in part by the Institute of Educational Science (IES) through R305B100007 and R305C100024. Any opinions, findings, and conclusions or recommendations expressed in this material are those of the authors and do not necessarily reflect the views of the IES.

GESTURES AS FACILITATORS TO PROFICIENT MENTAL MODELERS

Gestures are profoundly integrated into our communication. This study focuses on the impact that gestures have in a mathematical setting, specifically in an undergraduate calculus workshop. There was strong correlation between diagramming and the two types of gestures identified in this study (i.e., dynamic and static gestures). Dynamic and static gestures were part of the students' constructive thinking, whether it was related to the manner in which they viewed the problem or the construction of their diagrams. Nonetheless, gestures played a strong role in the students' problem solving and the manner in which the gestures were utilized provided insight into their constructive thinking.

Keywords: Classroom Discourse; Instructional Activities and Practices; Modeling; Problem Solving

Background

There have been numerous studies conducted on gestures and their presence in the educational environment especially in math and science related fields (Rasmussen, Stephan, & Allen, 2004; Chu & Kita, 2011; Goldin-Meadow, Cook, & Mitchell, 2009; Scherr, 2008). For example, Rasmussen, Stephan, and Allen (2004), studied gesturing in a differential equations class where they observed mathematical classroom practices become what they call taken as shared (TAS) ideas for the participants. Through their theoretical perspective they formed a gesture/argumentation dyad, which they used to analyze the gesturing that occurred among the classroom community. In short, their analysis was predicated upon students and teachers as opposed to just students.

Goldin-Meadow, Cook, and Mitchell (2009) explored the impact of teaching third and fourth graders how to gesture while solving a specific type of problem such as 3+4+6=__+6. In their study the participants were separated into three groups: the first was taught a correct gesture, the second group was taught a partially correct gesture, and the third group was not told to gesture at all. Although Goldin-Meadow, Cook, and Mitchell (2009) based their research on the manipulation of gesturing during a math lesson, their findings shed light on the idea that gestures act as an aid when it comes to problem solving for the children who gestured correctly or partially correctly as opposed to those who were not taught to gesture during the lesson.

Studies conducted by Engelke (2004, 2007), were based on understanding students' thought processes in related rates problems. She found that many students fail to understand these types of problems because there is a lack of transformational/covariational reasoning, which pinpoints students' deficiencies in geometry as well as being able to apply mathematical concepts to problems (i.e. similar triangles, substitution, and function composition). As revealed in Engelke (2007) function composition is a necessary tool when dealing with related rates problems. Engelke, Oehrtman, and Carlson's (2005) study highlighted the fact that not much research has been conducted in regard to student understanding of function composition. Other studies indicate that students tend to develop their notion of functions throughout their undergraduate years (Carlson, 1998).

Visualization and representation are dynamic in nature and are an important part of being able to solve word problems (Booth & Thomas, 2000; Carlson & Bloom, 2005; Cifarelli, 1998; Gravemeijer, 1997; Johnson-Laird, 1983; Lucangeli, Tressoldi, & Cendron, 1998; Simon, 1996). Johnson-Laird (1983) extensively discussed three types of mental representation of which two we considered "mental models which are structural analogues of the world, and images which are the perceptual correlates of models from a particular point of view" (p. 165). It has been theorized that in order to understand word problems, students benefit from drawing a diagram and trying to understand the relationships their diagrams represent of the given situation (Engelke, 2007). Visual and analytical skills are essential for students to understand mathematical concepts and construct mental models (Haciomeroglu, Aspinwall, & Presmeg, 2010). Hegarty and Kozhevnikov (1999) described visual-spatial representations as schematic or pictorial. The latter obstructs students from fully understanding the mathematics behind the problem, while the former encourages students to think about the problem in a more abstract manner. Gestures are a form of visual-spatial representation and we investigate how such representations facilitate the problem solving process. We seek to answer the question: How do students' gestures facilitate contextual problem solving in calculus? Through observing students' use of gestures while solving related rates and optimization problems, we will better understand the mental models and diagrams being created during the problem solving process.

Methods

In this study, we used open and axial open coding to observe three different supplemental instruction (SI) workshops, which consisted of undergraduate students taking first semester calculus. Pseudonyms were given to the participants for privacy purposes. The workshops were led by peer instructors. We focused on related rates problems as well as some optimization problems. We watched the videos specifically attending to students making hand gestures and the diagrams they drew during the problem solving process. The observed groups usually consisted of three students. The groups were given specific problems to complete as a team, although some students worked individually and then shared their ideas with their group members. Students often asked SI leaders for help. We took into account student-to-student and student-to-SI leader interactions.

Results

We identify diagramming as a visual tool, including drawing a picture, which is used during the problem solving process and is intrinsically linked to the construction of the mental model. The definition of gestures varies in the literature. For instance, Roth (2001) defined gestures as hand movements made with a specific form where "the hand(s) begin at rest, moves away from the position to create a movement, and then returns to rest"(as cited in Rasmussen, Stephan, & Allen, 2004). Although there are many definitions present today, we define gestures similarly to Roth: gestures are hand movement(s) where the hand(s) extends in an outward position, makes a movement or movements consisting of icons, symbols, and indices, and then returns to its normal position. Icons include gestures that demonstrate a thing, symbols are those that describe a thing, and indices are gestures indicating a thing (Clark, 1996 as cited in Rasmussen, Stephan, & Allen, 2004).

There are two types of gestures we identified: dynamic and static gestures. Dynamic gestures consist of moving the hands to describe the action that occurs in the problem or movements made to represent mathematical concepts. Within dynamic gestures there are two subcategories: dynamic gestures related to the problem (DRP) and gestures that are not related to the problem (DNRP). Static gestures are done to illustrate a fixed value (length, constant radius, etc.) or to illustrate a geometric object. Static gestures consist of static gestures related to a fixed value (SRF) and gestures related to the shape of an object (SRS).

Dynamic Gestures

We define DRP as hand gestures that consist of movements describing parts of the students' diagrams, whether it is the motion of an object or changing rates/values. DRP is further broken down into two subcategories. The first subcategory identifies hand gestures used to answer/clarify a concept/question to a classmate. A student may use a hand gesture to reason the problem out. For instance, a group of students, Jackie, Josh, and Cathy, were trying to solve the following related rates problem (the boat problem):

> A boat is pulled onto a dock by a rope attached to the bow of the boat and passing through a pulley on the dock that is 1 m higher than the bow of the boat. If the rope is pulled in at a rate of 1 m/s, how fast is the boat approaching the dock when it is 8m from the dock? (Stewart, 2009, p. 132)

Although the problem in the textbook has an image depicting the situation, students were not provided with the image. They had to construct the diagram and solve the problem.

Josh: You know what a pulley is right?
Jackie & Cathy: No
Josh: It's a little thingy [HG*: raises his right hand in the air, rotates his right index finger inward, then raises left hand to the same height as his right, puts both hands together, and pulls downward*] you pull…so it's gotta be on top.
Jackie & Cathy: Ohh….
Jackie: So it's going to be like that?
Josh: So… [*Drawing diagram*]
Cathy: I did it like that [*laughs a little*]
Jackie: See, how do they expect us to not know what a bow is
Cathy: Yeah…
Josh: You don't know what a boat is?
Jackie: I know what a boat is…
Cathy: But not a bow…or whatever

The gesture made in this clip is also characterized as a symbol because Josh describes a pulley with his hands. Although his peers, who did not know what a pulley was, prompted Josh's gesture, the gesture revealed his mental representation of the problem. After he makes the gesture, he begins drawing his diagram and concludes that the pulley must be on top. The gesture influenced Josh's perception of the problem (i.e. placement of the pulley), which also had a role in how he labeled his diagram. After this exchange, Jackie constructs an appropriate mental model of the situation as is evidenced by her subsequent exchange with Cathy.

The second subcategory deals with hand gestures done in order to understand and reason about the problem. For instance, Jackie is trying to solve the boat problem by first attempting to understand the dynamic element of the problem.

Jackie: [HG*: Jackie moves her hands in a circular inward motion (Figure 1)*] Is the…when its being pulled, it's being pulled from there?
Cathy: Yeah
Jackie: [HG*: Jackie points her left index finger towards Cathy's diagram (Figure 2)*] so then it's approaching on *x*, so okay we are looking for *dx/dt*, but then we're looking for this rate…

Figure 1: Jackie's gesture for boat

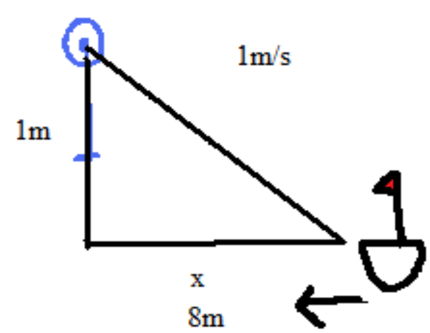

Figure 2: Cathy's drawn diagram for problem

Jackie's hand gesture is prompted because she is trying to understand the problem both conceptually and physically. In the first hand gesture, she is portraying the pulley with the use of her hands, which Clark (1996) classified as a symbol, because she is describing the pulley with her hands (as cited in Rasmussen, Stephan, & Allen, 2004). With the second hand gesture, she references Cathy's diagram (Figure 2) to understand what is happening to the boat. Here, Jackie is utilizing an index gesture, because she is indicating Cathy's diagram to observe the behavior of *x* as the pulley is pulled. Through the first and second hand gestures, she sees that as the rope is pulled, the boat moves closer to the dock. She recognizes that the change is occurring on *x*, and hence, she relates the change in *x* with *dx/dt*. The gesture made here, appropriated in part from Josh's earlier gesture, allows her to conceptualize the diagram described in the problem. The gesture acts alongside Jackie's constructive thinking as she tries to comprehend the situation at hand.

For DNRP, students and/or SI leaders use hand gestures to refer to mathematical concepts. The SI leader assisted Susan, Brian, and Cesar with the trough problem which states:

> A trough is 10 ft long and its ends have the shape of isosceles triangles that are 3 ft across at the top and have a height of 1 ft. If the trough is being filled with water at a rate of 12 ft^3/min, how fast is the water level rising when the water is 6 inches deep? (Stewart, 2009, p.132)

SI Leader: Now, what do you do to find what… cause you're trying to find *dh/dt* [HG*: He first moves his right hand right to left, with his fingers curved in the shape of a c, and then he changes the position of his hand and moves it up and down*] right?
Susan: Yeah. So we have to take the derivative of each side.
SI Leader: and that is when you plug in what your paused… Do you see it Cesar?

When the SI leader makes the hand gesture, his motion depicts the fractional aspect of the derivative (i.e., *dh* over *dt*). Additionally, Susan seems to associate finding *dh/dt* with implicit differentiation because she immediately thinks about taking the derivative of both sides when the SI leader mentions *dh/dt*. In another clip, Jackie explains to Cathy the difference between taking the derivative in a related rates problem, and taking the derivative of a (usual) function of *x*.

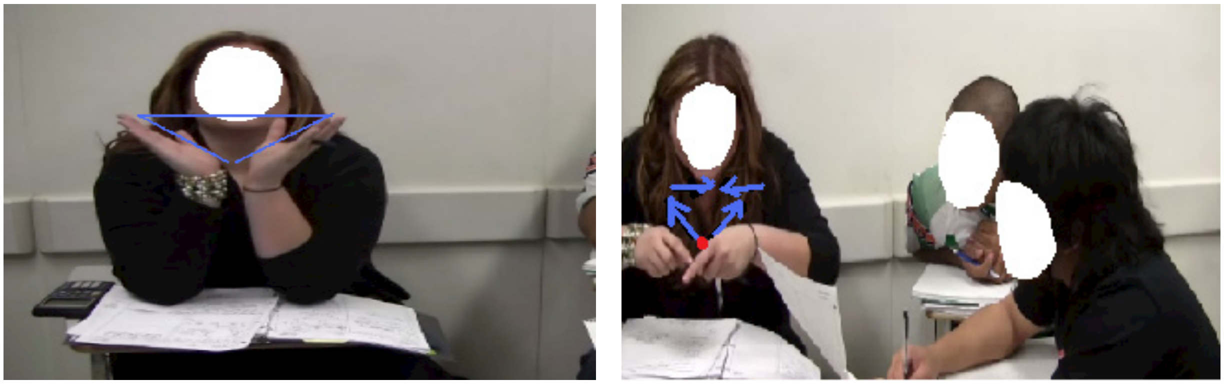
Cathy: Jackie I have a question [*laughs*]. Remember how last time you said we always keep *dy/dt*
Jackie: Mhmm.
Cathy: Do we also keep *dx/dt* cause it's not the same?
Jackie: Yeah…no, because we're not solving for uhmm… [HG*: lifts right hand up then moves it downward in a diagonal manner*] it's no longer like a just taking the straight out derivative of it, cause we have different properties that we need to relate together.

The hand gesture was a symbolic representation of a derivative. Along with her hand gesture and her explanation to Cathy, it can be seen that Jackie is able to discriminate between the derivatives in the context of a related rates problem and generally taking the derivative of some function of *x*. Although she does not explicitly state that the difference is based on taking the derivatives with respect to time, that underlying concept somehow triggered Jackie to separate the two. The gesture, in this case, did not act as part of Jackie's constructive thinking about the problem; rather the gesture was used as an explanatory aid.

Static Gestures

Apart from dynamic gestures, we identified static gestures, which consist primarily of gestures that illustrate a geometric object or refer to a fixed value (length of one the sides, constant radius, etc).We will distinguish them as static related to the shape of an object (SRS) and static related to a fixed value (SRF). SRS is focused on students or SI leaders utilizing their hands to depict the geometric shape of an object; we also consider referencing the general diagram as SRS. Here we see Susan trying to process the trough problem. Figure 3 shows Susan's initial image of the trough problem. She traces with her fingers the outline of tip up standard equilateral triangle. As seen in Figure 4, however, Susan changes the orientation of the triangle to a downward position as she reasons out the scenario in a realistic setting. Although not much is said, Susan's facial expression and gestures illustrate her thought process of trying to understand the general shape of the trough.

Susan: [HG*: elbows are bent and on top of desk, wrists are touching, hands are open diagonally, and pointing in opposite directions, flickers her left hand as she moves her pencil between her fingers, puts hands together, then pulls them apart in a diagonal direction Figure 4)*] so it's not the sides…it's the width [*SI Leader interjects and provides insight on the problem*]



Figures 3 & 4: Susan gestures to describe the trough

Her first gesture illustrates a cross-section of the ends of the trough; as she continues to think, she forms the length of the trough by pulling apart her two hands. Susan, along with many students, struggled to understand the geometric aspect of related rates problems. Engelke (2005, 2007) indicated that students tend to adopt a procedural way of thinking when they approach related rate problems. This may be why students have a hard time understanding problems such as the trough problem, which deal with a three-dimensional object, as well as applying the concept of similar triangles. For instance in the trough problem, Susan automatically drew an upright equilateral triangle (Figure 3) as opposed to visualizing the triangle upside down or oriented in a different way. Students with geometric misconceptions tend to construct incorrect diagrams, leading them to the wrong solution. If the SI leader had not intervened, the students would have attempted to solve the problem with an incorrect diagram, hence leading them to the wrong answer. That said, we consider SI leader intervention is necessary at times to provide students with guidance on challenging problems. The SI leader's help can start the students on the path to solving the problem correctly, without just giving them the answer. However, sometimes intervention by SI leaders, as also revealed in Scherr (2008), may actually interrupt a student's thinking.

The discussion below provides a glimpse as to how students think about a challenging problem.

Susan: Okay so like the square one is ten feet [HG: hands are both raised, fingers spread out flat, she then moves them down, putting hands in a diagonal position] like if you look at this from the top

Brian: It's like this right? [*HG*: *mimics Susan's gesture (Figure 5)*]

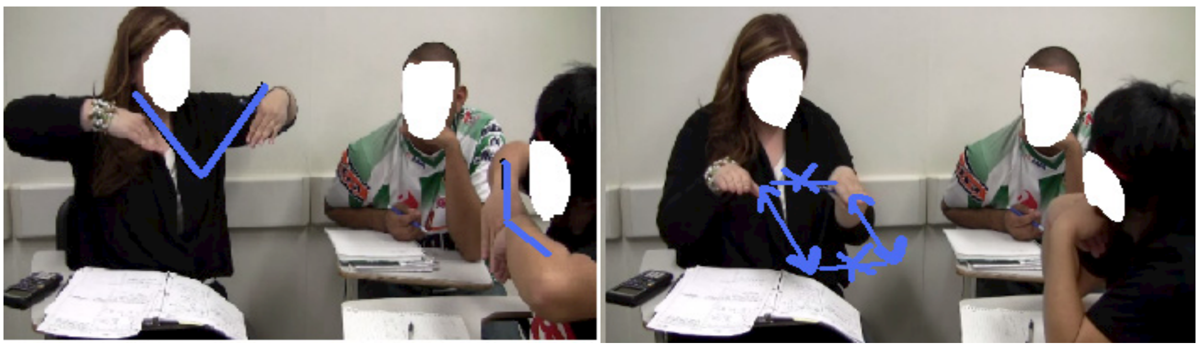
Susan: Yeah, the sides are cause you have the square part [*HG: hands are moved front to back then she brings them together, to denote the shape of a square (Figure 6)*] and that's the base [*HG: moves her left hand, which is extended and flat back and forth in a vigorous manner*], which is ten, but [*HG: she lifts her hands, elbows bent, hands in a diagonal manner, with hands in this position, she moves both index fingers back and forth*] then you have the three feet wide triangles that are coming down into it [*HG: moves hands that are elevated and in a diagonal position, down , closer to each other*], so [*HG: hands laid flat, palms facing the ground, she moves her hands left to right*] that's why it's not just a flat, it's not like a square box [*HG: moves both hands vertically*], it has that extra [*HG: elbows bent and tilted, hands are lifted up in a diagonal manner, then moves them a bit towards each other*] side coming in… so from if you look at it kind of from the top [*HG: hands are slightly up, moved up and down swiftly*] its coming down like that [*diagramming, then shows it to group members*] like that's what the inside looks like

Brian: Yeah

Van Zoest, L. R., Lo, J.-J., & Kratky, J. L. (Eds.). (2012). *Proceedings of the 34th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* Kalamazoo, MI: Western Michigan University.

Susan: …if you are looking at it and this is your bottom length, that right there, which is ten, [*HG: hands flat, lifted from desk, she moves them swiftly together and apart, then lifts them up*] so you can't just say its ten on the top and bottom, which is like what we were doing, on, in class…

Although Susan's mental picture of the diagram itself is not correct, her gestures show that she is engaged in constructively thinking about the solution to the problem. She gestured to describe the picture she was visualizing in her mind. She was able to transfer that mental image into a more realistic perspective with the use of gestures. Since she visualizes the diagram with a square bottom, she reasons that the top and bottom could not be the same because they have different lengths. She realized that the trough cannot be a square box, because the sides are diagonally positioned. She also seemed to recognize similarity between this problem and those discussed in class. The gesture that Susan made also prompted one of her group members to engage in the problem solving process. When she made the first gesture, Brian mimicked the same gesture (Figure 5), which showed that he was also thinking about the problem in an abstract manner.



Figures 5 & 6: Susan engages in describing the shape of the trough with her hands

For SRF we take into consideration the students' gestures done with respect to a fixed value, such as length or constant radius. These gestures are usually associated with students' diagrams. As mentioned above, SRF deals mostly with students referencing a fixed value. In this session, Brad and Mark work on a related rates problem that deals with the distance between two cars moving in different directions.

Brad: [*diagramming*] Specific, its saying, one is traveling south at 60 miles per hour
Mark: [*mumbles something*]
Brad: I don't know. So you times it, so 2 times 60 [*labels*], cause the two hours, [HG: *moves his left hand top to bottom*] that's the length, and 25 is the top.

Brad's gesture was done in order to describe a fixed value, in this case, length. Although his gesture was quick, it was done in an effort to explain to Mark the values corresponding to their specific diagram. This type of gesture shows how students associate given values to their diagrams.

Conclusion

A strong relationship between diagramming and the two types of gestures identified in the study is evident. Static and dynamic gestures were often used in regards to the students' diagrams, but static gestures seem to have a stronger relationship to diagramming as they deal with the diagram itself. In order for the student to even attempt solving the problem he or she began with drawing a diagram. It appears that when the students were stuck with their diagram or parts of their diagram, they gestured while trying to reason out the part about which they were confused. Several students gestured because they were trying to obtain a better understanding of how the diagram corresponded to geometric terms in the given problem. The more challenging the problems were, the more the students gestured. Some gestures were influenced by prior gestures and students quickly adopted and adapted gestures made by their peers. For instance, in the boat problem with Jackie, Josh, and Cathy, before Jackie made the gesture to describe how the boat was being pulled by the pulley, Josh's gesture, which described the pulley, had to occur first. Other times gestures arose because there was a lack of knowledge that was needed to even begin the problem. An example would be the trough problem that Susan's group was assigned. Her gestures were caused partly because neither she nor any of her peers knew what a trough was. In her mind she pictured an object with a square bottom and triangular sides. Since she did not know what a trough was, most of her gestures were done to figure out what the trough looked like. Most gestures have one thing in common; they were made to solve the problem by first understanding the problem abstractly. Although not much research has been done on the impact that gesturing has on undergraduate mathematics students, one must wonder whether or not the gesturing that occurs is beneficial to students. There is no denying that gesturing does influence the way students approach a problem, but to what extent?

CONCEPTUAL CONNECTIONS BETWEEN STUDENT NOTICING AND PRODUCTIVE CHANGES IN PRIOR KNOWLEDGE

Charles Hohensee
University of Delaware
hohensee@gmail.com

In this report, I examine what students noticed as they participated in an instructional unit on quadratic functions and how a shift in what they noticed was conceptually connected to productive changes in their prior knowledge about linear functions. My results show that, over the course of the instructional unit, students' attention shifted toward noticing changes in the quantities involved in quadratic functions. Furthermore, I identify two conceptual connections between the shift toward noticing changes in quantities in quadratic contexts and the productive changes in reasoning that students exhibited on post-interview linear function tasks.

Keywords: Algebra and Algebraic Thinking; Design Experiments; Mathematical Knowledge for Teaching

Purpose of the Study

Multiple studies in mathematics (and science) education have examined aspects of how prior knowledge changes as new knowledge is acquired (e.g., Hohensee, 2012; Smith, diSessa, & Roschelle, 1993; Vosniadou & Brewer, 1987). My study extends the research in this area by identifying explanations for why prior knowledge changes in productive ways as a consequence of new knowledge being acquired about a related but different topic. The purpose of the current research is to account for the role that features of the instructional environment played in bringing about the previously reported finding that five out of seven middle school students that participated in an instructional unit on quadratic functions exhibited productive changes in their prior understanding of linearity as a result of participating in the unit (Hohensee, 2012).

In the earlier research in which productive changes in prior knowledge were observed, students went from reasoning in non-proportional ways with the quantities from linear functions prior to participating in a quadratic functions instructional unit, to reasoning proportionally with the changes in linear function quantities after the unit. For example, in the pre-interview, when students were shown the graph of the linear relationship between the hours a cell phone was used and the cost of using the cell phone, Jenn,[1] one of the participants, reasoned *univariately* (i.e., she reasoned exclusively with the cost variable) and concluded incorrectly that the rate of the function was non-constant. However, on a post-interview task about the graph of a linear relationship between the number of employees in a business and the cost of running the business, Jenn reasoned proportionally with the changes in quantities (i.e., after finding a 4 employee change in the number of employees from 8 to 12 employees and a corresponding $2500 change in cost from $6000 to $8500, she multiplied the rate of $625 per employee by 4 employees to see if it produced the $2500 change in cost).

I considered various explanations for why students' prior knowledge about linear functions had changed as a result of participating in instruction on quadratic functions. Of the explanations I considered, *student noticing* offered the greatest promise as an underlying mechanism behind the productive changes. According to Lobato, Rhodehamel and Hohensee (2012), student noticing is defined as "selecting, interpreting, and working with particular mathematical features or regularities when multiple sources of information compete for students' attention" (p. 9). One important reason why student noticing recommended itself to my purposes was because research has already shown that student noticing possesses explanatory power for changes in how students think about novel tasks as a result of instruction (Lobato et al., 2012). Although what students notice and what students understand in a particular context is likely closely related, looking at what students notice offers a unique perspective on their thinking. In this paper, I examine what students noticed during an instructional unit on quadratics to see if it is conceptually connected to the productive changes in their prior knowledge about linear functions.

Theoretical Foundation: Noticing and the Focusing Framework

Much cognitive and psychological research has examined attention (e.g., McCandliss, Beck, Sandak, & Perfetti, 2003; Posner & Fan, 2008; Treisman & Gelade, 1980). However, only a small body of mathematics education research has examined attention from the perspective of what students notice in more realistic educational settings (e.g., Lobato et al., 2012; Radford, Bardini, & Sabena, 2007). Building on the limited prior work on student mathematical noticing, I used Lobato et al.'s definition of *noticing* as stated above. Furthermore, I used , et al.'s four-part *focusing framework*, which was specifically designed to characterize what students notice in mathematics instructional settings. The four parts are: (a) the centers of focus, which are the objects that students attend to within a given perceptual or conceptual domain; (b) the focusing interactions, which are the discursive practice that influence what students notice; (c) the features of the mathematical tasks, which are the attributes of the activities that students participate in that "afford and constrain" (Lobato et al., 2012, p. 12) what they notice; and (d) the nature of the mathematical activity, which is the participatory structure of the classroom environment (i.e., the norms that get established in the classroom). The center of focus represents the psychological aspect of noticing while the other three parts refer to the social structures of mathematics classrooms that influence what gets noticing. Thus, the focusing framework coordinates the psychological and the social, to develop a comprehensive picture of student noticing in realistic educational settings.

Methods

I employed a design-based research (DBR) methodology for this study (Design-Based Research Collective, 2003). Specifically, my quadratics instructional unit became the third iteration of the unit, the previous two iterations being part of a larger study conducted by the research team with which I was associated.[2] Thus, I continued the refinement of the activities that had been developed in the previous two iterations. My instructional unit was also similar in duration to the previous iterations (16 hours of instruction, spread over two weeks).

Seven students were recruited from an ethnically diverse urban middle school set in a middle class neighborhood. I, the author of this paper, served as the teacher. This is consistent with the principles of DBR in education, where the line between the teacher and researcher is often blurred to make in-the-moment refinements of the instructional design possible (Cobb, Confrey, diSessa, Lehrer, & Schauble, 2003).

Each class was recorded by two video cameras operated by graduate students and another researcher. The camera operators also served as external observers, presenting their observations to the teacher during debriefing sessions at the end of class. These observations further contributed to the refinement of the instructional unit. Incorporating observer feedback while the instructional unit is still being conducted is consistent with the principles of DBR (Steffe & Thompson, 2000).

I began data analysis by creating a descriptive account of the things that were said by students and the teacher with minimal interpretation (Miles & Huberman, 1994). I also identified episodes that seemed potentially rich with respect to student noticing during this pass through the data. To prevent data overload, the data was then reduced (Miles & Huberman, 1994) to these rich episodes. Next, multiple analytic passes were made through the reduced data, one pass for each part of the focusing framework. In the first pass, I identified the emergent *centers of focus* (i.e., what students appeared to be attending to mathematically). In the second pass, I used a priori codes to categorize the *focusing interactions* that occurred in and around the time in which each center of focus emerged. In the third analytic pass, I identified a connection between the features of the *mathematical tasks* that students engaged in and the centers of focus that emerged. In the fourth pass, I analyzed the *nature of the mathematical activity* that appeared to be related to the centers of focus that emerged in the instructional intervention.

Finally, I looked for conceptual connections between what students were noticing (their centers of focus) and productive changes that I had discovered in the students' prior knowledge about linearity during an earlier analysis of the post-interview (Hohensee, 2012). Looking for conceptual connections is consistent with the *realist view of causation* (Maxwell, 2004). Researchers who subscribe to a *realist view* assume that the actual causal mechanisms (processes) underlying regularities between events can be observed. In contrast, researchers who subscribe to the *regularity view of causation* assume that the causal mechanisms that underlie events are unobservable. The realist view aligns with taking a *process-oriented approach* to research (i.e., conducting qualitative research and creating causal explanations). Therefore, in looking for conceptual connections between noticing and productive changes in prior knowledge, I oriented my analysis toward noticing as a potential process underlying the productive changes in prior knowledge I had previously discovered.

Results

In this section, I present classroom evidence that shows there was a shift over the course of the quadratics instructional unit in what students noticed (see Table 1). Three types of evidence from the classroom data will be presented: (a) evidence of students' initial center of focus prior to the shift; (b) evidence of the new center of focus after the shift; and (c) evidence of the how the shift in center of focus was socially organized by particular kinds of focusing interactions, features of the mathematical tasks and nature of the mathematical activity (see Table 2).

Initial Centers of Focus

Students initially appeared to be focused on accumulated distances and accumulated times and in some cases on the changes in distance as well. Kendra,[3] Jenn, Armando, and Nicolas were initially focused on all three quantities. For example, on a Lesson 2 task, which involved a SimCalc Mathworlds™ computer simulation of a fish swimming according to a quadratic distance-time function, Kendra wrote, "From 0-2, it's 1 second. And then in the 2nd second it goes 6 feet, in the 3rd second it goes 18 feet, which is 10 feet. Then in the 4th second it goes 32 feet, which is 14 feet. In the 5th second it goes from 32 feet to 50, which is 18 feet." In this response, Kendra focused on the accumulated distances (i.e., 2, 18, 32 and 50 ft), the changes in distance (2, 6, 10, 14 and 18 ft) and the accumulated times (i.e., 1st, 2nd, 3rd, 4th and 5th second). To an adult, Kendra's talk about the 1st or 2nd second may seem like she was also attending to the 1-second changes in time. However, previous work in this area has shown that, unless middle school students explicitly refer to the 1-second changes in time (e.g., the fish went 6 ft in 1 second), they are likely not focused on those quantities (Lobato et al., 2012).

Other students like Peter, George, and Brady appeared to be initially focused on accumulated distances and accumulated times only. For example, on the same task described above, George and Brady recorded accumulated time/accumulated distance fractions (i.e., 1 s/2 ft, 2 s/8 ft, 3 s/18 ft, 4 s/32 ft, 5 s/50 ft, 6 s/72 ft, and 7 s/98 ft) and then reduced all to equivalent fractions with a 1 in the numerator (i.e., 1/2, 1/4, 1/6, 1/8, 1/10, 1/12 and 1/14). Despite George and Brady reducing their time/distance fractions to a numerator of 1, I did not count this as an instance of focusing on 1-second changes in time and the corresponding changes in distance because (a) they dropped the units for the reduced fractions; (b) they did not refer to the numerators as representing 1-second changes in time or to the denominators as changes in distance; and (c) they produced fractions that represented the set of *average distances* the fish travelled in the first 1, 2, 3, 4, 5, 6 and 7 seconds, rather than the changes in distance over each second.

Table 1: Summary of Shifts in Centers of Focus

Lesson when shift occurred	Student	Initial Center of Focus	New Center of Focus
Lesson 2	Jenn	Focus on accumulated distances and times and, in some cases, changes in distance	Focus on changes in distance and changes in time
Lesson 8	Armando		
Lesson 9	Nicholas		
Lesson 11	Kendra		
Lesson 8	Peter	Focus on accumulated distances and accumulated times	
Lesson 8	George		
Lesson 8	Brady		

Table 2: Summary of Social Organization of Individual Noticing

Individual component of shift in noticing	Social component of shift in noticing		
Center of focus after shift	Focusing interactions	Features of the mathematical tasks	Nature of the mathematical activity
• Focusing on changes in distance *and* changes in time	• Naming • Highlighting	• Specifically targeting an exploration of changes in quantities • Varying the relationships between changing quantities	• Presenting diagrams • Noticing features in others' diagrams • Asking *Can you explain why?* questions

New Center of Focus

As Table 1 shows, all students exhibited a shift in their center of focus with respect to the quantities they noticed in quadratic function distance-time data. Specifically, by Lesson 8, six students had converged on noticing the changes in distance and the changes in time. The other two students began consistently recording changes in distance and time in their diagrams for quadratic distance-time functions by lessons 9 and 10, respectively. One way that students exhibited this new center of focus was by recording changes in distance and time in their diagrams of quadratic distance-time data. For example, in Lesson 8, when students were presented with tabular quadratic distance-time data representing the motion of a remote-control (RC) car (i.e., [0 s, 0 yds], [4 s, 16 yds], [8 s, 64 yds]) and asked to produce a diagram showing speeds, George, Armando, Jenn, Brady, and Peter recorded changes in distance and the corresponding changes in time in their diagrams (see Figure 1 for Peter's diagram).

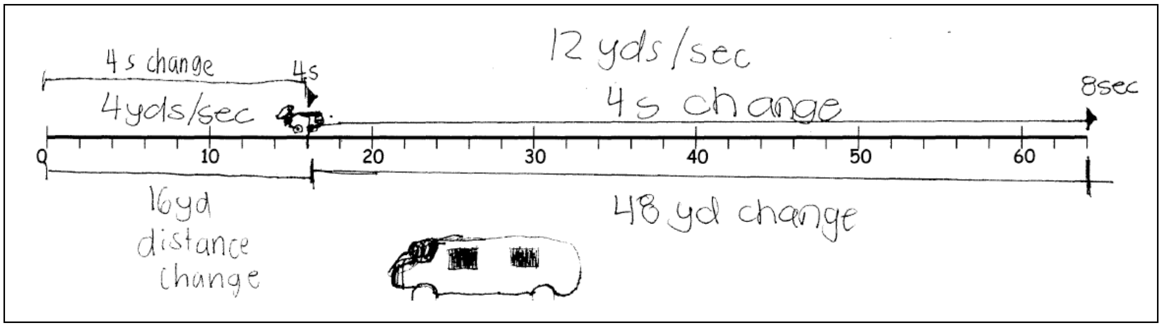

Figure 1: Peter's RC car diagram highlighting changes in distance and time

Students also verbally referred to changes in distance and time when explaining or reasoning about their own and other's diagrams. For example, when Kendra explained what she noticed in Brady's diagram, which had been projected for the class to see, she said, "Umm, he put the *change in time* like I think it's like the box thing and then the *change in distance* on the bottom where 0 to 16 yards. And then over here [points to another part of his diagram] he did the same." Jenn used similar language when describing her diagram:

> I have the *change in time* up here [points at change in time labels] 1 second for all of them, and *change in distance* [points at change in distance labels] and you can see like it's getting faster because the blocks are bigger [points from left to right].

Except for Armando, each student provided at least one example of similar dialogue.

After Lesson 8, there were only two instances in which students appeared to *not* focus on changes in distance and time. One instance occurred during Lesson 10, when Armando recorded changes in distance on his diagram, but not changes in time. The other instance occurred during Lesson 16, when Peter did not record changes in distance or time on his diagram. However, his diagram was not completed. It is possible that he would have added them had he had more time.

The new center of focus represents the psychological aspect of student noticing that emerged during the quadratics instruction. Next, I provide evidence of the interactions and educational structures that represent the social aspect of what students noticed. Later, I discuss how the new center of focus was conceptually connected to the productive changes in students' prior knowledge for which noticing is posited as an underlying process.

Focusing Interactions

Several kinds of focusing interactions appeared to influence what students noticed. In particular, analysis of the data revealed that *naming* and *highlighting* contributed to the shift in the center of focus.

Naming. The teacher used naming, which is defined as "the act of using a category of meaning from mathematical practice to classify and label some mathematical characteristic or property" (Lobato et al., 2012, p. 35), in introducing the new quantities *changes in distance* and *changes in time* (Lesson 3). In particular, the teacher said:

> So now I wanna ask you something . . . So if this is how clown or rabbit runs, could anybody see a place where the change in distance is 6 when the change in time is 1? . . . So maybe think about that just a second. I'll say it again. Can anybody see a place where the change in distance is 6 when the change in time is 1?

After introducing these new names and talking about them, the teacher encouraged students to use the new names:

> OK, so see if you can use the words that I'm using. I said what's the change in distance, or sorry, can you see a change in distance of 6 when there's a change in time of 1? So see if you can use the word "change" in how or what you're saying.

This kind of encouragement appeared to be effective because all students began using both names regularly in small- and whole-group discussions.

A hypothesis for why the names *changes in distance* and *changes in time* may have influenced what students noticed is that the names appeared to evoke for students a strong image of making comparisons. For example, the first time the teacher asked, "Can anybody see a place where the *change in distance* is 6 when the *change in time* is 1?" all but one student verbalized or gestured in a way that indicated they were making comparisons between two distances and/or two times (e.g., Peter and Jenn pointed from one distance to another on a number line; Armando said "The distance changes from 6 to 18 by 12 meters and 2 seconds"). This hypothesis is consistent with other findings that have shown that mathematical terms can create powerful images (e.g., Siebert & Gaskin, 2006).

Highlighting. The teacher and students used *highlighting*, which is defined as "methods used to divide a domain of scrutiny into a figure and a ground, so that events relevant to the activity of the moment stand out" (Goodwin, 1994, p. 610), to foreground changes in distance and changes in time on student-generated diagrams. An example of gestural highlighting occurred when Jenn, who was explaining to the other students her number-line diagram representing the distance and time for a swimming fish, swept her finger back and forth between positions of the fish to highlight particular changes in distance and time as she said, "I have the *change in distance* and the *change in time*, from each point [points to change in distance and change in time labels] that takes *one second*." An example of written highlighting occurred when the teacher annotated student work with arrows that highlighted the changes in distance and time and then projected the student work for the class to see and discuss.

In each of these examples, highlighting foregrounded the changes in distance and time and likely backgrounded accumulated quantities. In summary, highlighting and naming appeared to be focusing interactions that figured prominently in the emergence of the new center of focus on the changes in distance and changes in time.

Mathematical Tasks

There were at least two features of the mathematical tasks that likely contributed significantly to the emergence of the center of focus on changes in distance and changes in time. A common feature of tasks in Lesson 3 and Lesson 8 was that students were explicitly asked to find changes in distance and time. A common feature of tasks in Lessons 8, 9 and 10, was that they all involved students drawing diagrams of the same quadratic distance-time data, but with different equal partitions of the time variable (i.e., over 4 s, over 2 s and over 1 s intervals). Whereas the first feature explicitly directed attention to changes in distance and time, this second feature likely directed attention to changes in time. Interestingly, it was during Lessons 8, 9 and 10 that all students came to focus on changes in quantities. Thus, changes in distance and time appeared to become particularly salient for students during these tasks.

Nature of the Mathematical Activity

I characterized the nature of the mathematical activity that likely contributed to the shift in what students noticed as defining three related classroom norms (Cobb & Yackel, 1996): (a) presenting student work to the class, (b) noticing features of other students' diagrams, and (c) students asking each other *can you explain why?* The norm of presenting work provided students with examples of what others were noticing when creating their diagrams. In particular, students provided verbal evidence that they saw how others were recording changes in distance and time. Furthermore, the norm of noticing features of each other's diagrams meant that students publically identified the recorded changes in distance and time that they noticed on each other's diagrams. Finally, the norm of asking each other *explaining why* questions meant that students engaged in a close scrutinization of the quantities that were represented in each other's diagrams.

Discussion

In the results section, I provided evidence that all seven students in my study shifted their center of focus toward noticing changes in distance and time over the course of the instructional unit. Furthermore, I showed that particular focusing interactions, features of the mathematical tasks and the nature of the mathematical activity appeared to influence their shifts. However, an additional goal of my study was to determine if what students noticed in the instructional unit was linked to the productive changes I observed in five of the seven students' prior knowledge about linearity when I compared their understanding before and after the quadratics instructional unit. To achieve this goal, I compared what students noticed during instruction with the productive changes that five students exhibited when they reasoned proportionally with changes in quantities on linear function tasks during their post-interviews. This comparison led me to discover two important conceptual connections.

The first conceptual connection was that noticing changes in quantities in a quadratic context and reasoning proportionally with changes in quantities in linear function contexts both involve the same focus on changes in quantities. In other words, the new center of focus that emerged during instruction on quadratics persisted into the post-interviews, where students reasoned proportionally with changes in quantities in linear contexts. For example, on a post-interview linear function task about a water-pump, all but one student recorded both the changes in water volume and the corresponding changes in time. Thus, changes in quantities, which were established as a new center of focus in the instructional intervention, also appeared to be a center of focus during the post-interview.

Second, the students who appeared to most quickly establish a focus on both changes in distance and changes in time during quadratics instruction provided the greatest increase in proportional reasoning with changes in quantities on linear tasks in the post-interview. In the instructional intervention, Jenn and Nicholas were the first students to attend explicitly to the changes in distance and changes in time; George, Armando, Brady, and Peter required an extra lesson before they also began to focus on changes in distance and time; Kendra required three extra lessons. In the post-interview, Jenn, Nicholas, and Brady changed from reasoning non-proportionally to reasoning proportionally with changes in quantities, while Peter, George, and Armando's reasoning changed less, and Kendra provided no evidence of reasoning with changes in quantities. Therefore, the quicker the establishment of a focus on changes in distance and time, the greater the productive change in prior knowledge seemed to be. Brady was the exception because he exhibited similarly substantial changes in reasoning during the post-interview as Jenn and Nicholas did, despite not attending as quickly to changes in distance and time in the instructional intervention.

These conceptual connections suggest that noticing is an underlying mechanism for productive changes to prior knowledge that occur as a result of learning something new. Nevertheless, further investigation into the connection between student noticing and productive changes in prior knowledge, which has thus far been under-researched, is warranted.

MATHEMATICS, THE COMMON CORE STANDARDS, AND LANGUAGE: MATHEMATICS INSTRUCTION FOR ELS ALIGNED WITH THE COMMON CORE

Judit N. Moschkovich
University of California, Santa Cruz
jmoschko@ucsc.edu

This paper outlines research-based recommendations for mathematics instruction for English Learners (ELs) aligned with the Common Core Standards. The recommendations focus on improving mathematics learning and teaching through language for all students, and especially for ELs. These recommendations are intended to guide teachers and teacher educators in developing approaches to support mathematical reasoning and sense making for ELs.

Keywords: Classroom Discourse; Equity and Diversity; Standards

Introduction

This paper outlines recommendations for meeting the challenges in developing mathematics instruction for English Learners (ELs) that is aligned with the Common Core Standards. These recommendations for teaching practices are based on research that often runs counter to commonsense notions of language. The first issue is the term language. There are multiple uses of the term language: to refer to the language used in classrooms, in the home and community, by mathematicians, in textbooks, or in test items (Moschkovich, 2010). It is crucial to clarify how we use the term, what phenomena we are referring to, and which aspects of these phenomena we are focusing on. Many recommendations for teaching academic language in mathematics classrooms reduce the meaning of "language" to single words and the proper use of grammar (for an example, see Cavanagh, 2005). In contrast, work on the language of specific disciplines provides a more complex view of mathematical language (e.g., Pimm, 1987) as not only specialized vocabulary (new words or new meanings for familiar words) but also as extended discourse that includes syntax and organization (Crowhurst, 1994), the mathematics register (Halliday, 1978), and discourse practices (Moschkovich, 2007b). I use a socio-cultural and situated framework to frame these recommendations (Moschkovich, 2002). From this perspective, language is a socio-cultural-historical activity. I use the phrase "the language of mathematics" not to mean a list of vocabulary words with precise meanings but the communicative competence necessary and sufficient for competent participation in mathematical discourse practices.

It is difficult to make generalizations about the instructional needs of all students who are learning English. Information about students' previous instructional experiences in mathematics is crucial for understanding how ELs communicate in mathematics classrooms. Classroom instruction should be informed by knowledge of students' experiences with mathematics instruction, language history, and educational background (Moschkovich, 2010). In addition to knowing the details of students' experiences, research suggests that high-quality instruction for ELs that supports student achievement has two general characteristics: a view of language as a resource, rather than a deficiency, and an emphasis on academic achievement, not only on learning English (Gándara & Contreras 2009). Research provides general guidelines for instruction for this student population. Overall, students who are labeled as ELs are from non-dominant communities and they need access to curricula, instruction, and teachers proven to be effective in supporting the academic success of these students. The general characteristics of such environments are that curricula provide "abundant and diverse opportunities for speaking, listening, reading, and writing" and that instruction "encourage students to take risks, construct meaning, and seek reinterpretations of knowledge within compatible social contexts" (Garcia & Gonzalez, 1995, p. 424).

Research on language and mathematics education provides several guidelines for instructional practices for teaching ELs mathematics (Moschkovich, 2010). Mathematics instruction for ELs should (1) address much more than vocabulary; (2) support EL's participation in mathematical discussions as they learn English; and (3) draw on multiple resources available in classrooms (objects, drawings, graphs, and gestures) as well as home languages and experiences outside of school. Research shows that ELs, even as they are learning English, can participate in discussions where they grapple with important mathematical content. Instruction for this population should not emphasize low-level language skills over opportunities to actively communicate about mathematical ideas. One of the goals of mathematics instruction for ELs should be to support all students, regardless of their proficiency in English, in participating in discussions that focus on important mathematical concepts and reasoning, rather than on pronunciation, vocabulary, or low-level linguistic skills. By learning to recognize how ELs express their mathematical ideas as they are learning English, teachers can maintain a focus on mathematical reasoning as well as on language development.

Alignment with Common Core State Standards

The recommendations provided here describe teaching practices that simultaneously align with the Common Core State Standards (CCSS) for mathematics, support students in learning English, and support students in learning important mathematical content. Mathematics instruction for ELs should align with the CCSS, particularly in these four ways: (1) *Balance conceptual understanding and procedural fluency.* Instruction should balance student activities that address important conceptual and procedural knowledge and connect the two types of knowledge; (2) *Maintain high cognitive demand.* Instruction should use high cognitive demand math tasks and maintain the rigor of tasks throughout lessons and units; (3) *Develop beliefs.* Instruction should support students in developing beliefs that mathematics is sensible, worthwhile, and doable; (4) *Engage students in mathematical practices*. Instruction should provide opportunities for students to engage in mathematical practices such as solving problems, making connections, understanding multiple representations of mathematical concepts, communicating their thinking, justifying their reasoning, and critiquing arguments.

According to a review of the research (Hiebert & Grouws, 2007), mathematics teaching that makes a difference in student achievement and promotes conceptual development in mathematics has two central features: one is that teachers and students attend explicitly to concepts and the other is that teachers give students the time to wrestle with important mathematics. Mathematics instruction for ELs should follow these general recommendations for high quality mathematics instruction to focus on mathematical concepts and the connections among those concepts and to use and maintain high cognitive demand mathematical tasks, for example, by encouraging students to explain their problem-solving and reasoning (AERA, 2006; Stein, Grover, & Henningsen, 1996).

The CCSS and the NCTM Standards provide examples of how instruction can focus on important mathematical concepts (i.e. the meaning of equivalent fractions or the meaning of fraction multiplication, etc.) and how students can show their understanding of concepts (conceptual understanding) not by giving a definition or describing a procedure, but by using multiple representations, reasoning, and justification. For example, students can show conceptual understanding by using a picture of a rectangle as an area model to *show* that two fractions are equivalent or how multiplication by a fraction smaller than one makes the result smaller, and pictures can be accompanied by oral or written explanations.

The preceding examples point to several challenges in connecting *language* to content that students face in mathematics classrooms focused on conceptual understanding. Since conceptual understanding and mathematical practices are often made visible by showing a solution, describing reasoning, or explaining "why," instead of simply providing an answer, the CCSS implies an expectation that students will communicate their reasoning. Students are expected to (a) communicate their reasoning through multiple representations (including objects, pictures, words, symbols, tables, graphs, etc.); (b) engage in productive pictorial, symbolic, oral, and written group work with peers; (c) engage in effective pictorial, symbolic, oral, and written interactions with teachers; (d) explain and demonstrate their knowledge using emerging language; and (e) extract meaning from written mathematical texts. The main challenges teachers of ELs face are, first, to teach for understanding and then to support students in using multiple representations and emerging language to communicate about mathematical concepts. Since the CCSS documents already provide descriptions of how to teach mathematics for understanding, below I will focus on how to connect mathematical content to language, in particular through "Engaging students in mathematical practices" (Focus #4 above).

A Classroom Transcript

This transcript is intended to illustrate the recommendations and show how they play out in classroom interactions. The excerpt (Moschkovich, 1999) comes from a third-grade bilingual classroom in an urban California school with 33 students identified as Limited English Proficiency. In general, this teacher introduced students to topics in Spanish and then later conducted lessons in English. For several weeks the students had been working on a unit on two-dimensional geometric figures. Instruction had included using vocabulary such as "radius," "diameter," "congruent," "hypotenuse" and the names of quadrilaterals in both Spanish and English. Students had been talking about shapes and the teacher had asked them to point, touch, and identify different shapes. The teacher identified this lesson as an English as a Second Language mathematics lesson, where students would be using English in the context of describing and talking about geometric shapes.

1. *Teacher*: Today we are going to have a very special lesson in which you really gonna have to listen. You're going to put on your best, best listening ears because I'm only going to speak in English. Nothing else. Only English. Let's see how much we remembered from Monday. Hold up your rectangles . . . high as you can. (Students hold up rectangles) Good, now. Who can describe a rectangle? Eric, can you describe it [a rectangle]? Can you tell me about it?
2. *Eric*: A rectangle has . . . two . . . short sides, and two . . . long sides.
3. *Teacher*: Two short sides and two long sides. Can somebody tell me something else about this rectangle, if somebody didn't know what it looked like, what, what . . . how would you say it.
4. *Julian*: Paralela [holding up a rectangle, voice trails off].
5. *Teacher*: It's parallel. Very interesting word. Parallel. Wow! Pretty interesting word, isn't it? Parallel. Can you describe what that is?
6. *Julian*: Never get together. They never get together [runs his finger over the top side of the rectangle].
7. *Teacher*: What never gets together?
8. *Julian*: The parallela . . . they . . . when they go, they go higher [runs two fingers parallel to each other first along the top and base of the rectangle and then continues along those lines], they never get together.
9. *Antonio*: Yeah!
10. *Teacher*: Very interesting. The rectangle then has sides that will never meet. Those sides will be parallel. Good work. Excellent work.

The transcript shows that English language learners can participate in discussions where they grapple with important mathematical content. Students were grappling not only with definitions for quadrilaterals but also with the concept of parallelism. Student were also engaged in mathematical practices as they were making claims, generalizing, imagining, hypothesizing, and predicting what will happen to two lines segments if they are extended indefinitely. To communicate about these mathematical concepts students used words, objects, gestures, and other student's utterances as resources. This transcript illustrates several instructional strategies that can be useful in supporting student participation in mathematical discussions: asking for clarification, re-phrasing student statements, accepting and building on what students say, and probing what students mean. It is important to notice that this teacher did *not* focus directly on vocabulary development but instead on mathematical ideas and arguments as he interpreted, clarified, and rephrased what students were saying. This teacher provided opportunities for discussion by moving past student grammatical or vocabulary errors, listening to students, and trying to understand the mathematics in what students said. He kept the discussion mathematical by focusing on the mathematical content of what students said and did.

Recommendations for Connecting Mathematical Content to Language

Recommendation #1: Focus on students' mathematical reasoning, not accuracy in using language

Instruction should focus on uncovering and supporting students' mathematical reasoning, not on accuracy in using language (Moschkovich, 2010). Understanding the mathematical ideas in student's talk can be difficult. However, it is possible to take time after a discussion to reflect on the mathematical content of student contributions and design subsequent lessons to address these mathematical concepts. But, it is only possible to uncover the mathematical ideas in what students say if students have the opportunity to participate in a discussion and if this discussion is focused on mathematics. For teachers, understanding (and re-phrasing) student contributions can also be a challenge, perhaps especially when working with students who are learning English. It may not be easy (or even possible) to sort out which aspects of a student utterance are due to the student's conceptual understanding or the student's English language proficiency. However, if the goal is to support student participation in a mathematical discussion, determining the origin of an error is less important than listening to students to uncover the mathematics in what they are saying.

As we can see in the transcript, uncovering the mathematical content in Julian's contributions was certainly a complex endeavor. Julian's utterances in turns 4, 6, and 8 are difficult both to hear and interpret. He uttered the word "parallela" in a halting manner, sounding unsure of the choice of word or of its pronunciation. His voice trailed off, so it is difficult to tell whether he said "parallelo" or "parallela." His pronunciation could be interpreted as a mixture of English and Spanish; the "ll" sound being pronounced in English and the addition of the "o" or "a" being pronounced in Spanish. The grammatical structure of the utterance in line 8 is intriguing. The apparently singular "parallela" is preceded by the word "the" which can be either plural or singular and then followed with a plural "when they go higher." In any case, it is clear that Julian made several attempts to communicate a mathematical idea in his emerging second language. If we only focus on accuracy, we would miss his mathematical reasoning. Julian is, in fact, participating in mathematical practices and attempting to describe a property of parallel lines. This teacher moved past Julian's unclear utterance, he focused on uncovering the mathematical content in what Julian had said. He did not correct Julian's English, but instead asked questions to probe what the student meant.

Recommendation #2: Shift to a focus on mathematical discourse practices, move away from simplified views of language

In keeping with the CC focus on *mathematical practices* (Focus #4) and research in mathematics education, the focus of classroom activity should be on student participation in mathematical discourse practices (explaining, conjecturing, justifying, etc.). Instruction should move away from simplified views of language as lists of words, phrases, vocabulary, or definitions (Moschkovich, 2010). In particular, teaching practices need to move away from oversimplified views of *language as vocabulary*. An overemphasis on correct vocabulary and formal language limits the linguistic resources teachers and students can use in the classroom to learn mathematics with understanding. Work on the language of disciplines provides a complex view of mathematical language as not only specialized vocabulary (new words and new meanings for familiar words) but also as extended discourse that includes syntax, organization, the mathematics register, and discourse practices. Instruction needs to move beyond interpretations of the mathematics register as merely a set of words or phrases that are particular to mathematics. The mathematics register includes styles of meaning, modes of argument, and mathematical practices. Looking at the transcript, we can ask: What mathematical practices did Julian display? Julian was participating in three central mathematical practices, abstracting, generalizing, and imagining. He was describing an abstract property of parallel lines and making a generalization saying that parallel lines will never meet. He was also imagining what happens when the parallel sides of a rectangle are extended. If we only focused on vocabulary, we would miss Julian's participation in these important mathematical practices.

While vocabulary is necessary, it is not sufficient. Learning to communicate mathematically is not merely or primarily a matter of learning vocabulary. The question is not whether students who are ELs should learn vocabulary but, instead, how instruction can best support students as they learn both vocabulary and mathematics. Vocabulary drill and practice is not the most effective instructional practice for learning vocabulary. Instead, vocabulary and second-language acquisition experts describe vocabulary acquisition as occurring most successfully in instructional contexts that are language-rich, actively involve students in using language, require both receptive and expressive understanding, and require students to use words in multiple ways over extended periods of time (Blachowicz & Fisher, 2000). To develop written and oral communication skills students need to participate in negotiating meaning and in tasks that require output from students (Swain, 2001). In sum, instruction should provide opportunities for students to participate in mathematical practices, actively using mathematical language to communicate about and negotiate meaning for mathematical situations.

Recommendation #3: Recognize and support students to engage with the complexity of language in math classrooms

Language in mathematics classrooms is complex and involves multiple modes (oral, written, receptive, expressive, etc.), multiple representations (objects, pictures, words, symbols, tables, graphs, etc.), different types of written texts (textbooks, word problems, student explanations, teacher explanations, etc., different types of talk (exploratory and expository), and different audiences (presentations to the teacher, to peers, by the teacher, by peers, etc.). "Language" needs to expand beyond talk to consider the interaction of the three semiotic systems involved in mathematical discourse—natural language, mathematics symbol systems, and visual displays. Instruction should recognize and strategically support EL students' opportunity to engage with this linguistic complexity. Looking at the transcript, we can ask: What modes of expression did Julian and the teacher use? Julian used gestures and objects in his description, running his fingers along the parallel sides of a paper rectangle. The teacher also used gestures and visual displays of geometric figures on the blackboard. This example shows some of the complexity of language in the mathematics classroom.

Instruction needs to distinguish among multiple modalities (written and oral) as well as between receptive and productive skills. Other important distinctions are between listening and oral comprehension, comprehending and producing oral contributions, and comprehending and producing written text. Different mathematical domains, genres of mathematical texts, for example word problems and textbooks. Materials need to support and consider how artifacts serve as mediators. Instruction should support movement between and among different types of texts, spoken and written, among texts such as homework, blackboard diagrams, textbooks, interactions between teacher and students, and interactions among students.[1] Instruction should recognize the multimodal and multi-semiotic nature of mathematical communication, move from viewing language as autonomous and instead recognize language as a complex meaning-making system, and embrace the nature of mathematical activity as multimodal and multi-semiotic (Gutierrez et al., 2010; O'Halloran, 2005; Schleppegrell, 2010).

Recommendation #4: Treat everyday language and experiences as resources, not as obstacles

Everyday language and experiences are not necessarily obstacles to developing academic ways of communicating in mathematics (Moschkovich, 2002, 2007c). It is not useful to dichotomize everyday and academic language (Gutierrez et al., 2010; Moschkovich, 2010). Instead, instruction needs to consider how to support students in connecting the two ways of communicating, building on everyday communication, and contrasting the two when necessary. In looking for mathematical practices, we need to consider the spectrum of mathematical activity as a continuum rather than reifying the separation between practices in out-of-school settings and the practices in school (Gutierrez et al., 2010). Rather than debating whether an utterance, lesson, or discussion is or is not mathematical discourse, teachers should instead explore what practices, inscriptions, and talk mean to students and how they use these to accomplish their goals. Instruction needs to shift from monolithic views of mathematical discourse and dichotomized views of discourse practices and consider everyday and scientific discourses as interdependent, dialectical, and related rather than assume they are mutually exclusive. Looking at the transcript, we can ask: What language resources did Julian use to communicate his mathematical ideas? He used colloquial expressions such as “go higher” and “get together” rather than the formal terms “extended” or “meet.” These everyday expressions were not obstacles but resources.[2]

Recommendation #5: Uncover the mathematics in what students say and do

Looking at the transcript, we can ask several questions that illustrate this recommendation: How did the teacher respond to Julian’s contributions? The teacher moved past Julian’s confusing uses of the word “parallela” to focus on the mathematical content of Julian’s contribution. He did not correct Julian’s English, but instead asked questions to probe what the student meant. This is significant in that it represents a stance towards student contributions during mathematical discussion: listen to students and try to figure out what they are saying. When teaching English learners, this means moving beyond vocabulary, pronunciation, or grammatical errors to listen for the mathematical content in student contributions. (For a discussion of the tensions between these two, see Adler, 2001.) What instructional strategies did the teacher use? The teacher used gestures and objects, such as the cardboard geometric shapes, to clarify what he meant. For example, he pointed to vertices and sides when speaking about these parts of a figure. Although using objects to clarify meanings is an important ESL instructional strategy, it is crucial to understand that these objects do not have meaning that is *separate* from language. Objects acquire meaning as students talk about them and these meanings are negotiated through talk. Although the teacher and the students had the geometric figures in front of them, and it seemed helpful to use the objects and gestures for clarification, students still needed to sort out what “parallelogram” and “parallel” meant by using language and negotiating common meanings for these words.

Overall, the teacher did not focus on vocabulary instruction but instead supported students’ participation in mathematical arguments by using three instructional strategies that focus more on mathematical discourse: (1) Building on student responses: The teacher accepted and built on student responses. For example in turns 4–5, the teacher accepted Julian’s response and probed what he meant by “parallel.” (2) Asking for clarification: The teacher prompted the students for clarification. For example, in turn 7 the teacher asked Julian to clarify what he meant by “they.” (3) Re-phrasing: The teacher re-phrased (or re-voiced) student statements, by interpreting and rephrasing what students said. For example, in turn 10 the teacher rephrased what Julian had said in turn 8. Julian’s “the parallela, they” became the teacher’s “sides” and Julian’s “they never get together” became “will never meet.” The teacher thus built on Julian’s everyday language as he re-voiced Julian’s contributions using more academic language.

Researchers and practitioners alike need to recognize the emerging mathematical reasoning that English learners construct in, through, and with emerging language. To focus on the mathematical meanings English learners construct—rather than the mistakes they make or the obstacles they face—curriculum materials, professional development, and training for researchers needs to focus on recognizing emerging mathematical reasoning that expressed through emerging language. Professional development should support teachers in uncovering the mathematics in student contributions, when to move from everyday to more mathematical ways of communicating, and when and how to develop mathematical precision (Schleppegrell, 2010).

Acknowledgments

This work was supported by Grants #REC-9896129 and #ROLE-0096065 from NSF. The Math Discourse Project at Arizona State University videotaped this lesson with support by an NSF grant.

Endnotes

[1] Topics for further research include defining linguistic complexity for mathematical texts and providing examples of linguistic complexity that go beyond readability (such as the syntactic structure of sentences, underlying semantic structures, or frequency of technical vocabulary, verb phrases, conditional clauses, relative clauses, and so on).

[2] The question of whether mathematical ideas are as clear when expressed in colloquial terms as when expressed in more formal language is highly contested and not yet, by any means, settled.

FACTORS INFLUENCING MIDDLE SCHOOL STUDENTS' SPATIAL MATHEMATICS DEVELOPMENT WHILE PARTICIPATING IN AN INTEGRATED STEM UNIT

This study examined differences between two groups of students' spatial-scientific reasoning from pre to post implementation of an Earth/Space unit. Using a quasi-experimental design, researchers explored how instructional method and gender affected learning. Treatment teachers employed an integrated STEM curriculum while the control teacher implemented her regular Earth/Space unit. The Geometric Spatial Assessment (GSA), the Purdue-Spatial Visualization Rotation Test, and the Lunar Phases Concept Inventory (LPCI) were used to assess learning. Experimental groups made gains on periodicity LPCI domains while the control made gains on geometric spatial visualization LPCI domains. Only females made gains on GSA items. This is the first quasi-experimental study to examine students' spatial reasoning as they participate in Earth/Space units and to discover gender's role in this spatial development.

Keywords: Spatial Visualization; Sex Differences; Middle School; STEM Integrated Curriculum

Objective and Theory

Research studies have shown links between students' spatial reasoning ability and their understanding of scientific phenomena (Rudmann, 2002; Black, 2005). This is particularly true in the areas of Earth/Space phenomena. For example, Rudmann (2002) found that students' propensity to learn scientific explanations for phenomena such as the cause of the seasons was limited by their spatial aptitude. Similarly, Wellner (1995) reported that students were more likely to describe a correct cause of lunar phases when they had a strong spatial sense. Black (2005) claimed that "mental rotation is the most important in understanding Earth science concepts that are associated with common misconceptions … humans are handicapped by their single vantage point from Earth of the moving bodies in outer space" (p. 403).

We claim that one cannot understand many astronomical concepts without a developed understanding of four spatial mathematical domains defined as follows: (1) *Geometric Spatial Visualization*—Visualizing the geometric spatial features of a system as it appears above, below, and within the system's plane; (2) *Spatial Projection*—Mentally projecting to a different location on an object and visualizing from that global perspective; (3) *Cardinal Directions*—Distinguishing directions (N,S,E,W) in order to document an object's vector position in space as a function of time; and (4) *Periodic Patterns*—Recognizing occurrences at regular intervals of time and/or space.

The *Geometric Spatial Visualization* domain also involves *mental rotation* since as one visualizes a system, such as the Moon/Earth/Sun, one must consider and manipulate the motion of the system itself. *Spatial Projection* has a mental rotation derivative as well since one must mentally maneuver the sky throughout a day's viewing due to Earth's rotation.

Research on students' understanding of spatial concepts shows gender differences. Kerns and Berenbaum (1991) reported that males performed better than females on spatial tests and outcomes were significantly different in the area of 3D mental rotations (p. 391). Silverman, Choi, and Peters (2007) conducted a study that assessed the universality of sex related spatial competencies. They found that men scored significantly higher than women on a 3D mental rotations test in all ethnic groups with 40 countries participating in their research study.

Not only has literature shown gender differences on spatial assessments (in favor of males), but one study conducted by Rahman and Wilson (2003) also found significant main effects of gender and sexual orientation. Large differences were found on mental rotation spatial assessments between male groups in favor of heterosexual men while modest differences were found between female groups favoring homosexual women. Rahman and Wilson claimed “variations in the parietal cortex between homosexual and heterosexual persons” explained the results (p. 25).

Previous research on gender differences on spatial assessments were conducted by the first author. Wilhelm (2009) found that pre-teen female students scored significantly lower than pre-teen male students on spatial pre-tests. However, following an intervention that utilized integrated STEM curricula with many opportunities to experience 2D and 3D stimuli, females achieved significantly higher gain scores than their male counterparts. The study speculated that the initial sex differences (on pretests) could be explained by the faster maturation (during preteen years) of the male brain’s anatomical regions that handle spatial visual reasoning (Giedd et al., 1999). The implication of the study was that the 2D and 3D instructional intervention allowed females to develop their spatial skills resulting in significant achievement.

This study builds on earlier research conducted by Wilhelm (2009) and examines differences between two groups of sixth-grade students’ mathematical spatial reasoning and scientific knowledge from pre to post implementation of Earth/Space units. Using a quasi-experimental design, researchers evaluated how the curricular choice and instructional method affected learning outcomes. Treatment teachers employed an integrated STEM curriculum while the control teacher implemented her regular Earth/Space unit. Differences in understanding by gender groups were also investigated within and between control and experimental groups.

Participants

Research subjects were sixth-grade students from a south-central US school. The school’s demographic make-up was 84% White, 7% Black, 3% Hispanic, 3% Asian, and 3% Other; and 25% eligible for reduced-price lunches. One sixth-grade group ($N = 70$), taught by Ms. Glover (29 years experience), served as the control group. The experimental group ($N = 124$) was taught by two teachers (Ms. Stevens and Ms. Castle) with 3 and 8 years teaching experience, respectively. Both groups studied Earth/Space concepts related to the Solar System within their units. Treatment teachers employed an integrated NASA-based curriculum over a six-week period while the control teacher implemented her regular Earth/Space lessons for the same time duration. This was the first time that the NASA-based curriculum was being implemented by teachers in this state. Table 1 outlines the time spent on Earth/Space content by each (control/experimental) group, the content implemented, and the instructional format.

Table 1: Unit Timeline by Group with Lesson Content and Method of Implementation

Research Methods

This research focused on the development of students' mathematical spatial reasoning and scientific content knowledge from pre to post unit implementation. Students were assessed pre and post intervention via survey responses given to experimental and control science classes. Table 2 outlines each of the research questions pursued and data collection method.

Table 2: Research Questions and Methods of Data Collection and Instrumentation

Research Questions	Data Collection and Instrumentation
What science and spatial content knowledge and skills will students develop through Earth/Space unit experiences? *How will Earth/Space curricular choice and instructional method affect students' learning outcomes?* *What gender differences will be observed in learned science and spatial content knowledge and skills within and between the control and experimental groups?*	Pre and Post Content Surveys: – Lunar Phases Concept Inventory (LPCI) – Geometric Spatial Assessment (GSA) – Purdue Spatial Visualization-Rotation Test (PSVT-Rot)

This quasi-experimental study utilized quantitative measures to document students' understanding before and after project implementation. The quantitative data sources used to assess students' pre and post understandings were the Lunar Phases Concept Inventory (Lindell & Olsen, 2002), a multiple-choice survey which assessed eight science domains as well as four spatial domains (Table 3); the Geometric Spatial Assessment (Wilhelm, 2009), a multiple-choice survey which assessed the same four spatial domains (Table 3); and the Purdue Spatial Visualization-Rotation Test, which assisted with diagnosing the level of students' mental rotation reasoning (Bodner & Guay, 1997).

Table 3: Concept Domains: LPCI Science Domains and Corresponding GSA Math Domains

LPCI Scientific Domains			GSA Mathematics Domains
A - Period of Moon's orbit around Earth	B - Period of Moon's cycle of phases		Periodic Patterns (*occurring at regular intervals of time and/or space*)
C - Direction of the Moon's orbit around Earth	E - Phase due to Sun/Earth/Moon positions	G - Cause of lunar phases	Geometric Spatial Visualization (*visualizing the geometric spatial features of a given system as it appears in space above/below/within the system's plane)*
D - Moon Motion from Earthly Perspective	F - Phase-location in sky-time of observation		Cardinal Directions (*documenting an object's vector direction in space as a function of time from a given position*)
H - Effect of lunar phase with change in Earthly location			Spatial Projection (*projecting one's self to a different location and visualizing from that global perspective)*

A one-way analysis of variance (ANOVA) was conducted on pre-test scores to determine if there were significant differences between control and experimental groups and between gender groups. A repeated measures ANOVA (RMANOVA) was also conducted with the factor being gender and the dependent variables being pre/post scores, and again with the factor being control/experimental group with pre/post scores as dependent variables. This was conducted for each domain within each assessment as well as for the overall scores of each assessment.

Data and Analysis

Assessments

All quantitative assessments were given to both the experimental and control groups immediately prior to and at the conclusion of their Earth/Space unit implementation. Reliability was calculated using the Cronbach's alpha; this measures the instrument's internal consistency. The coefficient alpha was calculated for 0.72, 0.79, and 0.53 for the LPCI, the PSVT-Rot, and the GSA assessments, respectively. LPCI and PSVT-Rot values were high and acceptable; the GSA value was considered moderately acceptable. The control group scored significantly higher on all content pretests than the experimental group (Table 4). No significant differences between male and female groups were observed within the control group or the experimental group on the pre-tests for the LPCI, PSVT, or GSA.

LPCI Results

Control. The LPCI pre/post tests were given to 66 control students. A RMANOVA revealed a significant increase in the mean values from pre (26.6%) to post (38.5%) on overall test scores, $F(1, 65) = 48.1$, $p < 0.001$, partial $\eta^2 = 0.422$. The significant gain scores for control males and control females were 11.3% and 12.7%, respectively.

Experimental. The LPCI pre/post tests were given to 124 experimental students. A RMANOVA revealed a significant increase in the mean values from pre (21.2%) to post (33.7%) on overall test scores, $F(1, 123) = 72.7$, $p < 0.001$, partial $\eta^2 = 0.371$. The significant percentage gain scores for experimental males and control females were 12.1% and 13.0%, respectively. Table 5 illustrates gain scores by domain for each group.

To test for significant differences from pre to post on individual science domains, a RMANOVA was conducted for the control and experimental groups. Table 5 displays the percentage correct on each science domain. Results included experimental males achieving nearly triple the significant gains of the control males on Domain A (*orbital period*). Experimental females also made a significant gain on Domain A from pre to post whereas the control females did not. Domain B (*phase cycle period*) showed only experimental males with gain scores and Domain C (*orbital direction*) showed both control and experimental females and experimental males with significant gain scores. Only the control group made significant gains on Domain E (*phase and Sun/Earth/Moon positions*).

GSA Results

Control. The GSA pre/post tests were given to 58 control students. A RMANOVA revealed a significant increase in the mean values from pre (46.3%) to post (52.0%) on overall test scores, $F(1, 57) = 9.005$, $p = 0.004$, partial $\eta^2 = 0.136$. A RMANOVA also revealed a significant increase (7.5%) in the control female mean values from pre to post on overall test scores, $F(1, 30) = 10.7$, $p = 0.005$, partial $\eta^2 = 0.234$. Control males did not achieve a significant increase in scores.

Experimental. The GSA pre/post tests were given to 124 experimental students. A RMANOVA revealed a small significant increase in the mean values from pre (41.0%) to post (43.5%) on overall test scores, $F(1, 123) = 4.107$, $p = 0.045$, partial $\eta^2 = 0.032$. Like the control group, a RMANOVA revealed a significant increase (4.6%) in the experimental female mean values from pre to post on overall test scores, $F(1, 59) = 8.434$, $p = 0.005$, partial $\eta^2 = 0.125$. Experimental males showed no significant gains.

To test for significant differences from pre to post on individual spatial domains, a RMANOVA was conducted for the control and experimental groups (Table 6). Results show control females achieved significant gains on *Periodic Patterns* and *Geometric Spatial Visualization* whereas experimental females made a significant gain on *Cardinal Directions*. No male groups made significant gains on any GSA domain. Similar to Wilhelm's previous study, females in both control and experimental groups scored lower (not significantly) than their male counterparts on three of the four spatial domains on the pre-tests; and by the time of the post-tests, females ended with higher post-scores on three of the four spatial domains (see Table 6).

Table 6: Percentage Correct on Pre and Post Geometric Spatial Assessment by Domain for Control and Experimental Gender Groups

Spatial Domain	Con Male Pre (SD)	Con Male Post (SD)	Con Male Gain	Con Female Pre (SD)	Con Female Post (SD)	Con Female Gain	Exp Male Pre (SD)	Exp Male Post (SD)	Exp Male Gain	Exp Female Pre (SD)	Exp Female Post (SD)	Exp Female Gain

*$p < 0.01$

While the interaction effect between gender and time was not significant for either the control or experimental groups, one cannot help but notice the similarity in the plots shown in Figure 1 for both control and experimental groups where girls began with lower GSA scores and ended with higher scores than the boys.

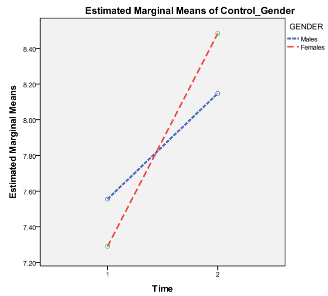

Figure1A: GSA control pre and post mean scores by gender

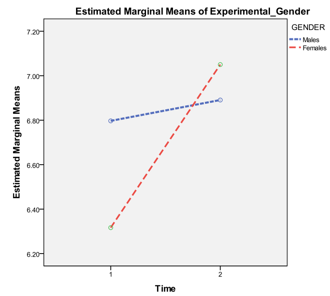

Figure1B: GSA experimental pre and post mean scores by gender

PSVT-Rot Results

The PSVT-Rot pre/post tests were given to 70 control and 111 experimental students. A RMANOVA revealed a significant increase in the mean values from pre to post for both control and experimental groups on overall test scores. Significant increases were also achieved by all gender groups except for experimental males (Table 7). These results indicate that *mental rotation* abilities are increased as a result of learning about Earth/Space science dealing with lunar phases no matter the curriculum or the instructional approach.

Table 7: Percent Scores on PSVT-Rot for Control and Experimental Groups

	n	Mean Pre % Correct (SD)	Mean Post % Correct (SD)	% Gain Score	F	p-value	Partial η^2
Control All	70	43.7 (20.2)	49.5 (21.6)	5.8	10.8	0.002*	0.135
Exp. All	111	35.6 (17.4)	40.1 (20.3)	4.5	7.035	0.009*	0.060
Control Males	35	45.9 (22.8)	52.9 (23.4)	7.0	6.26	0.017*	0.156
Exp. Males	61	38.4 (17.1)	42.9 (22.4)	4.5	3.04	0.086	0.048

*$p < 0.05$

Conclusion

The authors claimed that one must have well-developed spatial skills in order to understand astronomical phenomena having to do with the Moon and its phases. Students could come to the classroom already equipped with strong spatial reasoning, ready to understand complicated Earth/Space phenomena; *or* students will begin to develop the necessary spatial ways of thinking as they make sense of the patterns, geometries, and motions.

As we compared control and experimental groups' LPCI learning outcomes, we found the experimental group made significant gains on the periodicity of the Moon's orbit and phases. The authors attribute these gains to their five-weeks of lunar observations since students had the opportunity to notice patterns and lunar orbital direction. Control females also made significant gains with direction of the Moon's orbit, and both control males and females made significant gains on domain E (*phase and Sun/Earth/Moon positions*). This was not surprising since domain E was emphasized during instruction through worksheets, simulations, and modeling.

In analyzing the GSA results, other interesting features emerged. Only experimental females made significant gains from pre to post in the area of *cardinal directions*. The integrated STEM curriculum emphasized documentation of the Moon's position in terms of cardinal directions. Like the experimental group, only control females made significant GSA gains; however, theirs were on *periodic patterns* and *geometric spatial visualization*. The emphasis on Sun/Earth/Moon configurations for various phases could explain the *geometric spatial visualization* development.

The PSVT-Rot showed all groups (except experimental males) achieving small but significant gains from pre to post. This assessment tested students' mental rotation ability, which we claimed was linked to *geometric spatial visualization* and *spatial projection*. A correlation test was run on the post assessments to see how well the PSVT-Rot correlated to the GSA and the LPCI, and how well the LPCI correlated to the GSA. Table 8 displays significant correlations between these assessments with every group except for the control males with PSVT-Rot versus LPCI. This supports our original claim regarding the connection between students' spatial reasoning and lunar-related understanding.

Table 8: Correlations Between Post-LPCI, GSA, and PSVT-Rot Results by Group

	LPCI vs. GSA		PSVT-Rot vs. GSA		PSVT-Rot vs. LPCI	
	r	***p*-val**	***r***	***p*-val**	***r***	***p*-val**
Control All	0.543	0.000*	0.511	0.000*	0.431	0.000*
Control Males	0.437	0.024*	0.409	0.042*	0.305	0.075

Exp. Males	0.285	0.024*	0.495	0.000*	0.421	0.001*
Exp. Females	0.367	0.005*	0.413	0.004*	0.36	0.014*

Significance

This study is unique because it is the first quasi-experimental study that examines students' spatial reasoning as they participate in Earth/Space units. This study also extended previous research that examined the role gender plays in the development of spatial reasoning. Similar to Wilhelm's (2009) previous study, females scored lower and ended higher on three of four spatial domains (for both control and experimental groups). As noted earlier, brain developmental differences between gender groups during these preteen years could explain these results.

CONNECTIONS ACROSS REPRESENTATIONS IN STUDENTS' GROUP DISCUSSIONS OF A NON-ROUTINE PROBLEM

William Zahner
Boston University
wzahner@bu.edu

This research report examines how two groups of bilingual algebra students made connections among representations while solving a non-routine generalization problem. Using a socio-cultural orientation to mathematics learning, together with a semiotic lens on students' joint mathematical activity, this report details the type of connections among representations each group of students made as they solved the problem. Follow-up analysis shows that some connections afforded making more productive conclusions while other connections may have constrained the groups' solution processes. Finally, analysis of change across time reveals that the initial connections made by each group persisted across six weeks, despite intervening instruction that suggested other possible connections to solve the problem. The conclusion contains implications for researchers and practitioners.

Keywords: Generalizing; Connecting Representations; Collaborative Learning; Algebra and Algebraic Thinking

This paper reports on how two groups of bilingual algebra students made connections among multiple representations of an algebra problem (a story, diagrams, a table, equations, and a graph) while solving a non-routine problem about generalizing a linear relationship. This analysis addresses the continuum of student learning in school mathematics. Making connections—whether across presentations, among mathematical concepts, and/or between situations and mathematical representations—is a critical component of mathematical understanding (Hiebert & Carpenter, 1992; National Council of Teachers of Mathematics, 2000; National Research Council, 2001; Presmeg, 2006). Given the centrality of connections in students' conceptual understanding (Hiebert & Carpenter, 1992), prior research on how students learn about and reason with linear functions has examined the ways that students connect or coordinate representations (e.g., Brenner et al., 1987; Lobato, Ellis, & Muñoz, 2003; Moschkovich, Schoenfeld, & Arcavi, 1993; Presmeg, 2006; Radford, Bardini, & Sabena, 2007).

This paper extends prior research on mathematical connections by examining the affordances of different connections made by two groups of students as they solved a non-routine generalization task. The data for this empirical report are from a study that investigated how bilingual students learned to reason about the rate of change of linear functions through engaging in peer discussions. This research report focuses on findings related to the question, How did each group of students use and connect multi-semiotic tools to solve generalization questions during peer discussions of a non-routine algebra problem? Initial answers to this question led to a follow up analysis of the affordances of the different mathematical connections each group made and the relative persistence of the connections made by each group.

The primary finding, which is outlined in more detail below, is that each group connected two or more representations as they reasoned through the given task, but there were important differences in the combination of connections that each group relied upon. The connections each group made afforded (and at times constrained) making accurate generalizations. Moreover, the combination of connections each group discussed remained mostly stable over a time period of six weeks.

Framework and Prior Research

This study is grounded in a sociocultural approach to thinking and learning (Vygotsky, 1978; Wertch, 1998). Under this approach, learning mathematics may be examined as a process of appropriating culturally shared tools for engaging in mathematical activities (Forman, 1996; Moschkovich, 2004; Rogoff, 1990). For example, in the domain of school algebra, learning is evidenced by the increasingly skillful use of tools for algebraic problem solving—where tools include things such as mathematical inscriptions, standard algorithms, and mathematical discourse practices. This framework acknowledges that the meaning of these tools for thinking is not static. For this reason, many researchers in this tradition often refer to *inscriptions* rather than *representations* (Sfard & McClain, 2002). This report uses the term representations to align with prior research and with standards documents in mathematics education, while retaining the notion that the meaning of representations is constantly under negotiation.

When examining whether and how students make connections, a critical question that arises is, *what* do students connect? This analysis focuses on the connections that these students made between the multiple semiotic resources available in the problem (a story, diagrams, a table, a graph, and questions) as well as representations constructed by the students (equations, numerical answers, alterations to the diagrams, et cetera). Evidence of connections is visible when students use or coordinate multiple representations (Hiebert & Carpenter, 1992) and this can be observed in their talk, gestures, and writing (Moschkovich, 2008; Radford, Bardini, & Sabena, 2007). For example, at one point in this study, one student referred to the problem story while pointing at a diagram as his group debated which numbers to fill in to a table of values. In this case, I argue that the students connected the story, the diagrams, and the table.

The content focus of this study is how students generalize linear relationships and reason about the slope of linear functions as a rate of change. While understanding the relationship between slope and rate of change is a critical topic in school mathematics, prior research suggests that many students struggle with this concept, and that the origin of these difficulties may lie in how students and their teachers use representations and computational procedures to reason about the slope of linear functions (Leinhardt, Zaslavsky, & Stein, 1990; Lobato, Ellis, & Muñoz, 2003).

In a review of the literature on student learning of mathematical functions, "making connections" was identified as a key component of fluent reasoning with mathematical functions (Wlimot, Schoenfeld, Wilson, Champney, & Zahner, 2011). The centrality of connections is also highlighted in the descriptions of mathematical discourses as multi-semiotic (O'Hallaran, 2003; Radford, Bardini, & Sabena, 2007). From a semiotic perspective, generalizing from particular cases requires seeing the particular (e.g., the first three terms of a geometric pattern) as representative of more than the particular (e.g., the *n*th term of the pattern). Therefore generalizing is intimately related to making connections (Radford, Bardini, & Sabena, 2007). This work extends prior work reported in Wilmot et al. (2011) by examining (a) how connections developed across time during group discussions, and (b) how the quality of connections mediated each group's success in generalizing a linear relationship during a group discussion.

Methods

Setting and Participants

This study examined the mathematical reasoning of two groups of ninth grade students enrolled in a bilingual algebra class at a comprehensive high school in an agricultural region of California. Over 90% of the students at the school were Latino/a and 35% of the students were classified as English Learners. Seventy-seven percent of the school population was eligible for a free or reduced price lunch. The two groups were enrolled in a bilingual algebra class taught by an experienced teacher who has been recognized for her excellent teaching and for her skillful use of group work. Thirty percent of the students in the class spoke primarily Spanish, and the remaining students spoke both Spanish and English. The bilingual setting was chosen intentionally because it is a site where attention to language and meaning in mathematics was likely (Sierpinska, 2005).

The algebra curriculum focused on reasoning and problem solving in real-life contexts, and this data collection coincided with a unit focused on interpreting data and reasoning with linear functions (Fendel, Resek, & Alper, 1996). In consultation with the researcher, the teacher selected two focal groups of four students each. The groups were chosen to be representative of the class and each group had students with a broad range of prior mathematics achievement.

Group 1 consisted of two boys and two girls who all reported speaking Spanish at home, but who primarily spoke English in class. Two of the students in Group 1 moved to the U.S. from Latin America as children, but they were classified as “Fully English Proficient” by their school at the time of the study. Group 2 included four students who were all recent immigrants from Latin America. All members of Group 2 were classified as English Learners. The members of Group 2 spoke mostly Spanish in class, and the teacher provided them with copies of the curricular materials in Spanish. Two members of Group 2 left the school halfway through the data collection, and two other Spanish-dominant students in the class replaced them in the group.

Data Collection

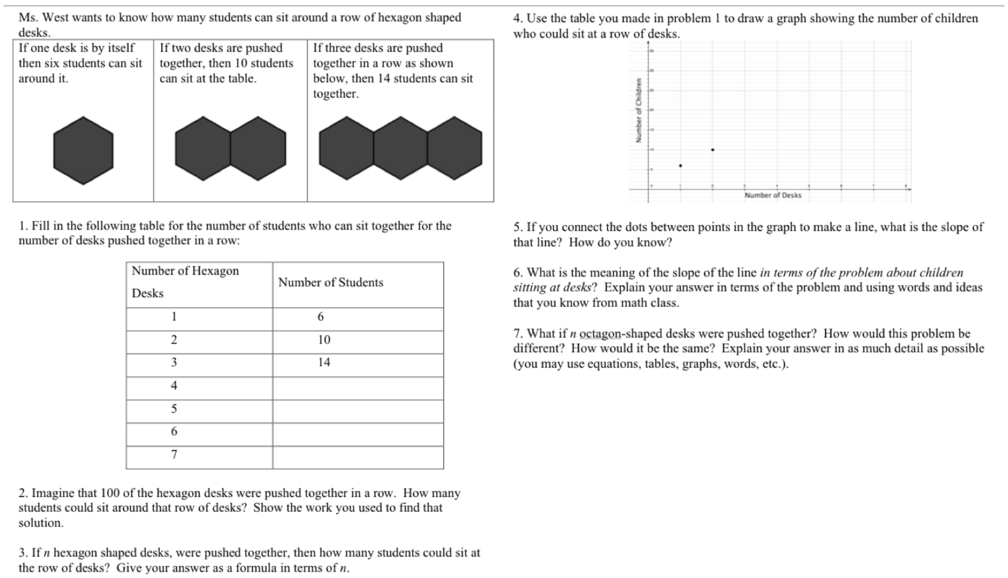
The principles for data collection were derived from Moschkovich and Brenner’s (2000) naturalistic paradigm for research on mathematical thinking, as well as the microgenetic method for examining learning across time (Chinn, 2006). Following these principles, the data collection included six weeks of in-class observations as well as a series of three out-of-class group problem solving discussions. The out-of-class group discussions were designed to systematically document change across time in the students’ reasoning on non-routine problems that required using important concepts related to rate, slope and reasoning with linear functions. The in-class observations are regarded as naturalistic observations that reveal how the students’ mathematical reasoning developed in relation to ongoing activity (Moschkovich & Brenner, 2000). Due to length restrictions, this report focuses on the out-of-class group discussions.

Each group participated in three out-of-class discussion sessions: one near the start of the unit, one near the middle, and one a week after the unit was finished. The problems that the students solved during these discussions were adapted from previous research and piloted before the data collection. Each group worked on the same problem multiple times across the six weeks, allowing for direct comparisons of changes and similarities in the groups’ reasoning across time (Chinn, 2006). In the protocol for these discussions, the students were instructed to discuss each problem as a group, come to agreement, and write one agreed-upon answer on the group’s paper. These discussions were video recorded, and copies of the students’ final answers and scratch work were collected. The videos were transcribed with a focus on capturing the propositional content of the students’ talk, and gestures were included in the transcript when students made deictic statements. This analysis focuses on the groups’ discussions of one task, Hexagon Desks. This task was chosen because (a) each group discussed it thoroughly during each discussion session, (b) both groups appeared to come to consensus on their answers to this question, and (c) this question invited the most “real life” connections for the students.

Hexagon Desks asked the groups to construct a generalized linear relationship describing how many people could sit around a row of 1, 2, 3, and more Hexagon Desks arranged in a row. Figure 1 contains a copy of the problem in English (Group 2 received the problem in Spanish). Variations of this task have appeared on the National Assessment of Educational Progress, among many other venues. The type of questions and the order of the questions in Hexagon Desks were written to parallel questions from mathematics problems that the students completed in class (e.g., observe a numerical pattern, make a table, and then generalize).

The first question on Hexagon Desks asked students to complete a table showing the number of people who could sit at a row of 4, 5, 6, and 7 desks. Question 2 required the students to find how many people could sit at a row of 100 desks. Question 3 required generalizing the pattern for *n* desks. In Question 4, the students graphed points from the table on a given graph. Question 5 asked the students to imagine connecting the points with a linear function and to compute the slope of the liner function (the question was worded to sidestep the issue of discrete and continuous functions since that was not a topic of discussion in the students’ class). Question 6 asked the students to explain how the slope of the linear model related to the story about desks. Finally, Question 7 was an open ended question asking the students to explain how their answers would change if the desks were octagons rather than hexagons.

Some questions on Hexagon Desks demanded making at least one connection, while other questions invited, but did not require, making multiple connections. For example, Question 6 asked the students to explicitly connect the slope of the linear model back to the story about pushing desks together (e.g., “the slope is 4 because each new desk adds four new places at the row of desks”). This question required making a connection between two representations. In contrast, Question 1 invited, but did not require, making connections because it could be solved without connecting representations by noticing the numerical pattern within the table.



Ms. West wants to know how many students can sit around a row of hexagon shaped desks.

If one desk is by itself then six students can sit around it.	If two desks are pushed together, then 10 students can sit at the table.	If three desks are pushed together in a row as shown below, then 14 students can sit together.

1. Fill in the following table for the number of students who can sit together for the number of desks pushed together in a row:

Number of Hexagon Desks	Number of Students
1	6
2	10
3	14
4	
5	
6	
7	

2. Imagine that 100 of the hexagon desks were pushed together in a row. How many students could sit around that row of desks? Show the work you used to find that solution.

3. If *n* hexagon shaped desks, were pushed together, then how many students could sit at the row of desks? Give your answer as a formula in terms of *n*.

4. Use the table you made in problem 1 to draw a graph showing the number of children who could sit at a row of desks.

5. If you connect the dots between points in the graph to make a line, what is the slope of that line? How do you know?

6. What is the meaning of the slope of the line *in terms of the problem about children sitting at desks*? Explain your answer in terms of the problem and using words and ideas that you know from math class.

7. What if *n* octagon-shaped desks were pushed together? How would this problem be different? How would it be the same? Explain your answer in as much detail as possible (you may use equations, tables, graphs, words, etc.).

Figure 1: The task the students discussed

Analysis

This analysis relied primarily on the transcripts of the group discussions and the copies of the students' written work. However, the video recordings were used throughout the analysis process to clarify ambiguities in the students' talk and to document the students' gestures. The transcripts were divided into segments corresponding with each group's work on a particular problem in Hexagon Desks. For example, each group's talk about Question 2 was one segment in each transcript. Some segments were divided into sub-segments when the group discussed subparts of a question separately. For example, as Group 1 discussed Question 1of Hexagon Desks, they engaged in several sub-discussions to decide which values to add in each cell in the table.

The first stage of analysis required documenting the connections among representations made by each group. Connections were coded by noting when each group made verbal, gestural, or written references to more than one representation during a particular segment in the transcript. For example, when completing the table of values on Question 1, Mateo in Group 1 explained why the net result of adding a new hexagon is adding four new spaces: "you add another one [hexagon] and nobody's gonna be sitting on that one." As he said "sitting on that one," he pointed to a vertical line at the intersection of two hexagons on Krystal's paper. With this utterance the group was coded as making a connection between the numerical table, the diagram, and the story about seating students at desks.

In addition to documenting connections, each group's final written answers were analyzed to examine whether the final result of the group's discussion was a correct response to each question. This analysis led to claims about the relative affordances of different connections made by each group. Finally, the connections made by each group and each group's agreed-upon final answers were compared across the three discussion sessions to analyze whether and how the groups' connections developed across time.

Results

Each group made multiple connections as the students worked through the questions on Hexagon Desks. In general, Group 1 had longer discussions and they made connections among multiple semiotic resources as they solved each question, while Group 2 tended to be focus on pair-wise connections. For example, in the quotation from Mateo in Group 1 above, Mateo connected the table, the given diagrams, and the story about seating students at desks. In contrast, when Group 2 discussed the same question on Hexagon Desks, they focused exclusively on the numerical pattern within the table. This is illustrated in the following excerpt from their first discussion of Hexagon Desks. (Note: in the transcript, comments are in double parentheses, while translations are in double parentheses and quotation marks).

1.	Hector	Son seis catorce, son seria ((“it’s six, fourteen, they are a series”))
2.	Iris	Yo puse xxx de cuatro ((“I put xxx by four”))
3.	Hector	Dieciocho ((looks at Iris and points at Graciela's paper)) Dieciocho ((“eighteen eighteen”))
4.	Graciela	Por qué? ((“why?”))
5.	Hector	Dieciocho, son cuatro-- cada uno tiene cuat- ((“Eighteen it is four, each one has four”)) Este tiene seis, este tiene diez, y este tiene catorce ((pointing at the table on Graciela’s paper)). Cuánto es la diferencia? ((“This one has six this one has ten, and this one has fourteen. How much is the difference?”))
6.	Graciela	Cuatro. ((“four”))
7.	Hector	Son cuatro ((lifts up four fingers)) ((“They are four”))
8.	Graciela	Um
9.	Hector	Entonces son dieciocho ((“Then they are eighteen”))
10.	Iris	Son dieciocho ((”they are eighteen”))
11.	Hector	Son veintidos(.) Son vientiseis(.) Son treinta(.) ((“They are twenty two, they are twenty six, they are thirty”))
12.	Graciela	Ah hum ((nods her head up and down))

This trend in the way each group made connections held across all three discussions. Group 1 repeatedly made multiple connections among three representations for the problem: they referred to the given diagram, the story, and the table as they solved Questions 2, 3, and 7, and they discussed how these representations were related. Group 2 adopted a narrower focus, they consistently connected each question back to the numerical patterns from the table. For example, when Group 1 generalized the pattern for 100 hexagons (Question 2), they focused on the contributions of the top, bottom, and sides of the diagram of a chain of hexagons to calculate the answer of $200 + 200 + 2 = 402$. In contrast, each time Group 2 attempted Question 2, they attempted to generalize the numerical pattern using only the table. Their answers across all three discussions were $100 \times 4 = 400$, 150, and $42 \times 10 = 420$ respectively, showing that they were not able to use this numerical pattern to successfully generalize to the hundredth case.

A first follow up analysis compared the connections across representations that the groups made with each group’s agreed upon final answers. While both groups made some connections, not all connections proved equally useful for solving the problem or reaching a generalization. Group 2’s responses to Question 2 show that their ways of focusing on the numerical pattern in the table was not useful for developing a generalization about how many students could sit at a row of 100 desks. By the third discussion both groups were able to use the graph to successfully compute the slope in question 5. Group 2 was able to correctly answer Question 6 (interpret the meaning of the slope) by noting that the slope of the linear model was 4, and they also used a connection between the linear function and the story to describe the meaning for the slope, saying that this slope was the same as the “add four” that results from adding an additional desk to the row of desks. Meanwhile, although Group 1 was able to calculate the slope using the graph, they did not describe the meaning of the slope in relation to the problem, thus there was no evidence that they were connecting representations to justify their response to the slope interpretation question. One possible explanation for Group 1’s difficulties interpreting the slope is that the net change of “add four” was not as readily apparent when focusing on the “adding and subtracting” action of adding a new hexagon on the end of the diagram. Thus, the different connections made by each group provided different affordances for justification and for generalization.

Finally, the second round of follow-up analysis examined how the connections made by each group shifted as they solved Hexagon Desks on three distinct occasions across the six-week data collection timeline. In general, each group consistently drew upon a similar set of connections each time they discussed the problem. For example, during Discussion 1, Group 1 repeatedly made connections between the table, the diagrams of hexagons, and the story as they completed the table in Question 1. During Discussions 2 and 3 Group 1 again referred to the table, the diagrams, and the story as they reasoned through which values to put in each line of the table. Likewise, Group 2 consistently used the connection to the numerical "add four" pattern in the table all three times they solved Question 1. While there were some changes in the groups' responses across time, the relative consistency in the connections made by each group indicates that once a group makes connections among representations, these may remain consistent for a particular problem.

Discussion

This study has illustrated the connections across representations made by two groups of students as they solved a non-routine generalization problem, explored the affordances of making different connections, and illustrated that each group's initial connections remained fairly stable across six weeks.

Implications for Research

These findings indicate that *making connections* may be a necessary, but not sufficient, characteristic for describing how students develop conceptual understanding in mathematics. Just as Wertsch (1998) noted that some number systems afford calculation by hand using standard algorithms, some connections may afford more mathematical insight than others, especially for developing generalizations. One connection, such as the recursive rule of "add four" in the table is common, but it is not necessarily the most useful connection for making generalizations about linear models (see also Kaput 1992 on the particular issue of recursive rules). Moreover, this study indicates that the connections that students initially made were relatively robust across time. For mathematics educators, this study invites a more systematic examination of which connections among which representations, and for which purposes or goals, have the most affordances for students' mathematical reasoning.

Two possible follow up studies might investigate (a) what sequences of instructional activities promote productive shifts in the connections that students make while generalizing about linear functions, and (b) whether the affordances of different connections can be incorporated in assessments to better understand students' emergent mathematical understandings.

Connections to Practice

The data collection for this study coincided with a classroom unit on interpreting data, graphing, and reasoning with linear functions. While this analysis focused on the groups' out of class discussions, the stability of the connections made by each group across time was surprising to both the researcher and teacher because, to us, the students' in-class work appeared related to the goal of generalizing linear functions from data. For teachers and instructional designers, this study illustrates the well-known fact that student thinking can be oriented toward different goals than those intended by curriculum designers (Newman, Griffin, & Cole, 1989). Student thinking may also remain consistent from the learners' own perspectives and thus appear to teachers as resistant to change through instruction. In this study, although the students did reason with linear functions, make sense of slope, and solve real life problems in the classroom, they did not seem to draw upon those classroom experiences while solving Hexagon Desks. While this study does not necessarily show how to help students draw on their classroom experiences, it does indicate that there is a continuing need to address this issue in both research and practice.

The difference in how each group made connections (and the affordances of those connections) is not suitable evidence to make generalizations about all bilingual students learning math in Spanish or English. First, these groups were chosen to illuminate two particular cases of students using social and linguistic tools, but not to represent of all bilingual students. Second, the data show that both groups were successful in different ways. For example, Group 1 was able to solve Question 2 by connecting the diagrams and story, but they were not able to solve Question 6. Conversely, Group 2 used a connection to the "add four" pattern in the table solve Question 6 but that did not work for solving Question 3.

Conclusion

This analysis of the connections among representations made by two groups of students illustrates a critical issue faced by students as they navigate transitions along the learning continuum of school algebra. The connections that students make between representations are primary mediators of students' learning and understanding (National Council of Teachers of Mathematics, 2000; National Research Council, 2001). The findings of this study suggest that simply making connections across representations is not enough. Researchers and teachers need a better understanding of which connections students make, for which purposes, and how connections develop across time. An improved understanding of these issues can affect students' success navigating the continuum of school mathematics.

Portfolio assessment amongst general populations in mathematics and other disciplines has been suggested to be a useful tool for tracking emergent student understanding and, thus, has been proposed to also be a useful tool for English language learners (ELLs). In this research, 10 teachers implemented an "ePortfolio" with 30 primary (grades one to three) ELLs. Results suggest that while conceptually an ePortfolio is a promising tool, user-interface challenges limited effective pedagogy and these challenges were not seen as unique to the tool used in the research. Additionally, parent-level factors that were unanticipated also emerged that were influential in the overall research.

Keywords: Assessment and Evaluation; English Language Learner; Elementary School Education; ePortfolio

As global mobility continues to increases over the next decade, the percentages of English language learners (ELLs) can be expected to grow (Cummins, 2007). ELLs are defined as "students in . . . English language schools whose first language is a language other than English, or is a variety of English that is significantly different from the variety used for instruction . . . , and who may require focused educational supports to assist them in attaining proficiency in English" (Ministry of Education, 2007, p. 8). Robinson (2010) points out that many current strategies used to support and assess ELLs have historically been appropriated from other student populations (i.e., special education), and do not address the barriers that linguistic challenges present. Also, traditional assessment practices in schools have been found to be more advantageous for some students over others (Gutiérrez, Bay-Williams, & Kanold, 2008).

This research explored the implementation of an "ePortfolio" in mathematics for primary ELLs in grades one to three. The objectives of this research were to: (a) work with teams of teachers to implement ePortfolios for identified ELLs in grades one to three, and (b) evaluate the extent to which ePortfolios potentially increased the "reliability and validity of the evaluation of student learning" (Ontario Ministry of Education, 2010, p. 39) both empirically and holistically.

Literature Review

As numerous researchers suggest, ELLs should be able to demonstrate what they know with limited or no English (Ministry of Education, 2007). Rivera and colleagues (2006) call for "ELL-responsive" approaches and sensitive assessment strategies that allow ELLs to effectively demonstrate their knowledge using a variety of methods. ELLs require more time and frequent assessment over time. Opportunities for assessment should occur in ELLs first language, and use of translation where possible is recommended (Rabinowitz, Ananda, & Bell, 2005; Robinson, 2010). Portfolios are often identified as a useful tool for assessment of ELLs that facilitate both collection and creation of artifacts where progress over time can be tracked and documented (Stiggins & Chappuis, 2011). Although portfolios are strongly recommended throughout the literature for ELL their efficacy has not been well evaluated. However, promising results about the usefulness of portfolio assessment amongst general school populations have been found in mathematics education and other disciplines (Fukawa-Connelly & Buck, 2010).

Theoretical Frameworks

Culturally responsive pedagogy has been suggested to be effective at improving outcomes of marginalized groups or populations in schools such as Hispanic, African-American, linguistically diverse, and so forth (Gay, 2000; Torres-Velasquez & Lobo, 2004). According to Howard and Terry (2011), culturally responsive pedagogy

> embodies a set of professional, political, cultural, ethical, and ideological disposition that supersedes mundane teaching acts, but is centered in fundamental beliefs about teaching, learning, students, their families, their communities, and an unyielding commitment to see student success become less rhetorical and more of a reality. (p. 347)

In the case of the present research, our particular interest is directed towards shifting classroom practices in assessment, which have been historically shown to be particularly under privileging to ELLs in two ways. Cummins (1984), for example, says that IQ assessment tools have shown to be a highly unreliable indication of intelligence for ELLs in that the tests consistently show lower than normal intelligence. Cummins shows that these results are reflective of language proficiency as opposed to intelligence. Alternatively, there is also the risk that some forms of assessment may suggest students know more than they do because there may be an illusion of competency based upon perceived levels of language proficiency.

Methods

Participants

Participants for this research were from an urban school known for its high levels of diversity and immigrant populations. The research was implemented for one school term during the second half of the year. The school had up to 50 languages spoken at the school. There were 47 ELLs invited to participate of which 30 agreed to participate. There were 15 males and 15 females. In total there were 10 teachers (all teachers teaching grades one to three), three English as a Second Language Teachers (ESL), one principal, two university researchers, and one teacher/research assistant that participated.

Data Sources/Instruments

All parents completed a demographic questionnaire. School-based data of the ELLs' language proficiency were also obtained. To obtain a measure of the students' mathematical ability, a non-verbal arithmetic problem solving task using manipulatives was administered by a trained teacher/research assistant to assess students' mathematics knowledge without relying solely on their language competence. It was initially proposed that standardized tests (i.e., Woodcock-Johnson III Tests of Achievement battery (WJ III ACH)) would also be collected at the beginning and the end of the research; however, this was not completed due to some of the early findings related to parents and to the user-interface challenges which we explain in our results shortly.

Student generated artifacts (e.g., drawings and mathematical work done on the computer or scanned into the computer through a document camera and scanning device), audio, and video recordings were collected through the ePortfolio. Teacher collaborations/professional development took place in person, informally day-to-day, and electronically. Field notes were collected by research assistants during face-to-face meetings.

For this research, we partnered with *Desire2Learn* (D2L) who provided the web-based Learning Environment (LE) and ePortfolios proposed by them to be suitable for K-12 student populations. The LE provided common space for students and teachers to post to discussion rooms, access articles or other artifacts (e.g., video links), engage in assessment, and gather assessment data. The ePortfolios were predominantly student-driven. The ePortfolio also was available in Canadian English, Canadian French, U.S. English, UK English, Spanish, Arabic, Simplified Chinese, Indonesian. This provided an important opportunity for some of our ELLs to benefit use of their first language (Torres-Velasquez & Lobo, 2004).

Each classroom involved in the research was provided with a laptop computer, a document camera, and set of headphones which included microphones. Students could access these tools during class time when appropriate. Support for the students, when needed was provided by the classroom teacher, an ESL teacher, or the teacher/research assistant. The ePortfolio was used for a ten-week period.

Procedures

A parent information session was hosted at the school where the research was introduced to parents. Translators were present to answer any questions that arose. Parents were also informed that anonymity could not be assured as a result of their participation given that video data and audio data would be used as part of the analysis, for dissemination, and for future knowledge mobilization efforts emerging from the research. Those parents who did not attend had information letter and consents translated to the home language where possible sent home with their child. Follow-up phone calls were conducted by classroom and ESL teachers to secure consent and answer questions.

Teachers gathered face-to-face to plan on eight-half days, and three-full days over the course of the entire two years with two half days and one full day occurring prior to the ePortfolio being implemented with students. These opportunities for interaction involved planning curriculum and assessment tasks, videotaping virtual asynchronous “conversation” starters for students, engaging in assessment, some professional development related to mathematics learning (e.g., problem solving, generating multiple solutions, error analysis, conversation starters, etc.), and ELL (e.g., assessment challenges, role of first language communication, culturally sensitive pedagogy, etc.). These sessions were jointly led by teachers and researchers in the project.

Students were introduced to the ePortfolios in small groups by their ESL teacher and additional training was provided, as needed. Students were trained on how to customize their screens, upload documents using document cameras purchased for the research, record voice and audio files, and record small video clips to be used for the asynchronous virtual conversations with their teachers , and as we explain shortly, sometimes with each other.

Results and Discussion

Two main results emerged. First, our potential participant group was reduced from 47 to 30 because parents were reluctant to allow their child to be involved because their child was “Canadian” and not an ELL. These concerns were voiced during the information session and to teachers following the session. Despite these children being identified as an ELL and receiving school-based ESL resources and support, many parents at the information session and even after to their teachers were very adamant that their child was not “ESL.” Parents’ identity, both their own and that of their child’s, prevented our intentions for culturally sensitive pedagogies to advance to the extent that we had planned. Second, and most critically, while the LE and the ePortfolio were proposed by D2L to have been used effectively in a primary setting, the overly complex work-flow challenges proved to be unmanageable for teachers and often were contrary to effective pedagogy and assessment practices. Moreover, students required support each time they tried to engage with their ePortfolios because of the extensive navigation required within the tool. The product did not match good pedagogy and was primarily reduced to a presentation tool. It is very important to note that as a result of the challenges we were experiencing, we reviewed other available “ePortfolio” products. While some were perhaps easier to use, they all had similar pedagogical deficiencies that reduced their overall potential to support teaching and learning.

Conclusions

Culturally sensitive pedagogy discourse must be extended to include parents—currently a perspective that is absent from the scholarship in this area. Parents are important pedagogical resources and thus must be considered for all students. Many of the ePortfolios available appeared to be further behind the “Web 2.0-ready” students in classrooms today, and lacked pedagogical grounding. Product developers are encouraged to work closely with teachers and to partner with universities to develop ePortfolios. While the notion of ePortfolios is promising, still there is little empirical research in their efficacy in classrooms and should be introduced with caution about the proposed added value. Even our own attempts in this research were thwarted while attempting to navigate product developers' views of pedagogy and those from within the discipline.

STRONGER ARGUMENTS WITHIN INDUCTIVE GENERALIZATION IN MIDDLE SCHOOL MATHEMATICS

Using examples as a means of justification is a common strategy in mathematical and non-mathematical domains. However, in domains such as biology, significant research has explored the justification of generalizations through strategic reasoning about examples. We suggest that while example-based inductive reasoning cannot generate conclusive proof in mathematics, middle school students do engage in strategic inductive reasoning in math. We find that children have preferences for the use of particular example-based arguments in mathematics, much as they do in other domains. These strategies are also influenced by their knowledge about examples. Having a better understanding about how students employ example-based inductive reasoning in mathematics could ultimately help students' deductive proof development.

Keywords: Reasoning and Proof; Middle School Education

Curricular standards emphasize constructing and evaluating conjectures and proofs as central to mathematical understanding across grade levels (Common Core State Standards Initiative, 2010). However, it is well documented that students frequently use examples to justify the truth of conjectures, treating empirical evidence as sufficient proof (e.g., Bieda, 2001; Healy & Hoyles, 2000). We suggest that students' inductive strategies, by which we mean the use of examples to "prove" conjectures, actually reflect fairly sophisticated mathematical reasoning.

Inductive reasoning, or generalizing from examples in order to justify a conjecture, is also widespread in domains such as biology (e.g., Hayes et al., 2010; Osherson et al., 1990). Induction is a powerful form of reasoning, and considerable research has focused on strategies used in intuitive inductive reasoning. From this body of research, we know that having more examples, using a diverse set of examples, and using highly typical examples all increase children's and adults' judgments of the strength of an inductive argument. Inductive reasoning in these domains is strategic; some types of arguments are viewed as stronger evidence.

In mathematics, however, students' example-based justifications are viewed as erroneous and tangential to the desire to help students construct deductive proofs (e.g., Harel & Sowder, 1998). However, inductive approaches could also be viewed as a starting point to better understand conjectures and to provide possible insights for proofs (e.g., Simon & Blume, 1996). While inductive strategies do play an important role in mathematics, particularly in helping students develop generalizations (e.g., Ellis, 2007), much remains to be understood about how to effectively help students leverage their inductive strategies into insights that can support deductive arguments (Bieda, 2011; Stylianides & Stylianides, 2009).

Thus, our approach considers strategic inductive reasoning in mathematics as a topic worthy of investigation in its own right, in addition to its role in the transition to deductive reasoning. In this research, we examine middle school students' differentiation of example-based arguments and relevant strategic reasoning. This will inform researchers and educators about how students' knowledge and beliefs guide their current approaches to generalizations. As a starting point, we ask if principles of inductive inference in mathematics are similar to those from other domains.

Methods

Participants

Middle-school students in 6th to 8th grade (n = 433, 49% Female) from a school in a midsize Midwestern city participated in this study. All classrooms, aside from one class of Algebra I students, used a reform-oriented curriculum, CMP 2 (Lappan et al., 2006).

Materials and Procedure

Participants received a survey consisting of 24 problems. Each problem presented participants with a conjecture and two narratives, each with a fictional student who tested example(s) related to a particular characteristic to figure out if the conjecture was always true. The participant was asked to evaluate the relative strength of each fictional student's argument.

Participants received problems from two of three **domains** (numbers, shapes, and birds). Half of the students received specific conjectures (e.g., "If you add any number to four times itself, you always get a multiple of 5"), and half received conjectures that only referred generically to a mathematical property.

After each conjecture, participants read two narratives, each with an example-based reasoning strategy tried by a fictional student in order to justify the truth of the conjecture. Each narrative was based on the level of the relevant **characteristic** manipulated through the fictional students' example choices. Table 1 gives the assessed characteristics (here we focus on 4 of the 6 used in the study), along with the levels that were used by each of the fictional students. These characteristics were chosen based on both their applicability to inductive reasoning outside mathematics and students' reported explanations for example choice.

Table 1: Levels Used for Each Characteristic (Within–Subjects), Number Domain

Characteristic	1st Level	2nd Level
Quantity of Examples	two numbers	five numbers
Diversity of Examples	really similar numbers	really different numbers
Commonness of Examples	a really common number, one you see every day	a really unusual number, one you do not see every day
Sampling Method	picked a number at random	picked a number that was really, really big [or small]

The narratives by the fictional students were presented in three different **labeling formats** (manipulated between-subjects). The examples each fictional student used as part of their argument were described by a label, as shown in Table 1, (e.g., "I tried this with a really common number"), the item (e.g., "I tried this with **9**"), or both the label and item. The items selected for the levels of each characteristic were based on previous studies (Williams et al., 2011). Reported analyses compare the two formats with a label to the format without a label.

Each fictional student's narrative ended with the statement, "It worked for [this number] so I think this means the property is always true." Participants selected which fictional student made them more likely to think the property is true for all cases in that domain. Then, participants rated how convincing each person's demonstration was on a 1–7 Likert scale. Here, due to space, we only address their numerical ratings of the demonstrations.

Design and analyses. Putting the different variables together, the 24 problems each student received (2 domains $\times$ 6 characteristics $\times$ 2 instances of each characteristic per domain) were presented in different randomized orders. Demographic information and math attitudes were gathered but not reported here. Linear mixed-effects regression (Bates & Maechler, 2009) was used in R to model student preference for each characteristic; MCMC sampling was used to determine significance levels (see Baayen, 2008).

Problem domain, conjecture type, labeling format, and their possible interactions were treated as fixed factors.

Results

Quantity of Examples

Arguments with five examples were preferred over arguments with two examples, $p = .0001$. This was true for problems across domain, labeling format, and conjecture generality. Also of note, narratives testing five examples were rated as the most convincing among all characteristics ($M = 5.32$, $SE = 0.045$), whereas narratives with two examples were rated as the least convincing ($M = 3.87$, $SE = 0.046$).

Diversity of Examples

Unlike the characteristic of quantity, students' differentiation of arguments based on example diversity depended on labeling format. In all domains, students preferred diverse examples over similar examples only when a label was present ($p = .01$).

Commonness of Examples

Like diversity, students preferred an uncommon example over a common example only when a label was present ($p = .02$). This overall preference for uncommon examples was stronger when reasoning about numbers ($p < .05$), even without labels.

Sampling Method

As with diversity and commonness, student preference for one level of a characteristic over the other depended on labeling format. When a label was present, students preferred a random example over an example chosen because it was an extreme size, $p < .001$.

Reasoning When No Label Was Presented

We saw above that students' preferences for particular levels of characteristics were clearly established when a label was present. In a few instances, they applied similar types of reasoning to cases without labels. In order for the item only condition to affect performance, students needed to infer characteristics of the items and then make judgments about the relative argument strength. This was easily accomplished with *quantity*, as that is a visible feature of the example sets. With *diversity* and *commonness*, preferences for particular levels extended to the item condition only for the number domain.

Discussion

The middle school students we studied recognized different qualities of example-based arguments in mathematical and scientific domains. That is, they strategically applied principles to distinguish stronger and weaker inductive arguments. Testing more examples was broadly recognized as increasing the strength of an argument. In addition, arguments based on dissimilar sets of examples, uncommon examples, and randomly selected examples were stronger than their complements when labels were present.

However, without the labels of the characteristics, students' preferences for stronger inductive arguments were often limited to the number domain. It is possible that these were cases in which students could infer, to some degree, the features of relevant characteristics. Thus, students recognized the significance of the characteristics but did not spontaneously consider examples outside of the number domain. Our selection of examples could have influenced this or students may not have been familiar enough with the features of the examples in order to infer the relevant dimensions. Learning how examples relate or differ is a key factor in inductive reasoning (Christou & Papageorgiou, 2007).

While example-based justifications cannot conclusively prove a conjecture's truth, previous research has shown that students often use these approaches. Thus, this study informs educators and researchers about how children think about these example-based approaches—we see that they think strategically about their justifications. In general, students applied the same principles of evidence, distinguishing between more and less convincing empirical arguments, across domains. These principles match those identified as reliable and effective in the psychological literature on inductive reasoning (e.g., Osherson et al., 1990). Knowing that the same principled strategies are being employed during inductive reasoning in mathematics and science is a good starting point. These strategic judgments about different types of example-based arguments may form the basis for introducing formal deductive arguments. Students might be able to harness their strategic inductive reasoning to appreciate the limits of even the strongest empirical argument. Building on that these existing strategies and knowledge may result in deeper connections as students become fluent with both inductive and deductive reasoning strategies.

This paper explores the construct of mathematics identity by testing a hypothesized framework based upon students' beliefs and experiences related to mathematics. This study examined data drawn from the Factors Influencing College Success in Mathematics (FICSMath) project, a national survey study of college students enrolled in single-variable calculus at 2- and 4- year institutions across the United States. Structural equation modeling was used to confirm the salience of the mathematics identity framework, indicating that students' mathematics interest, their being recognized by others in mathematics, and beliefs about their ability to perform and understand mathematics were directly related to their mathematics identity.

Keywords: Beliefs; Modeling

Purpose

The purpose of this study is to test an explanatory model for mathematics identity by examining responses to a survey of college students enrolled in single-variable calculus across the United States. Mathematics identity is a construct that has the potential to improve our understanding of complex mathematics classroom environments, the broader context of mathematics education, and what it means to be a mathematics learner (Lester, 2007). This is because it simultaneously accounts for the individual's perspective, the influence of the communities with which the individual identifies, and the social context in which the learning occurs. Although the concept of mathematics identity promises to aid in examining these complex connections and in better understanding students' experiences and persistence in mathematics, Cobb (2004) stated that mathematics identity is underdeveloped as an explanatory construct in research. Research on the construct of identity in relation to mathematics has begun to develop an explanatory framework (Holland & Lave, 2001; Sfard & Prusak, 2005; Solomon, 2007), but these research efforts have been mostly confined to a micro-identity approach (moment-to-moment), as opposed to a macro-identity approach (global view). This study will develop an explanatory model for mathematic identity in a macro-level approach using structural equation modeling (SEM) on national survey data.

Theoretical Framework

This study defines mathematics identity as how students see themselves in relation to mathematics based upon their perceptions and navigation of everyday experiences with mathematics (Cass, Hazari, Cribbs, Sadler, & Sonnert, 2011). This definition focuses on students' views about themselves in relation to mathematics and how their experiences with mathematics have influenced their perceptions. The framework in this study takes into account the sociocultural link that Sfard and Prusak (2005) state to be an important component to identity research as well as the perspective that a person has multiple identities that overlap and influence one another (Gee, 2001). Further, mathematics identity is seen as being comprised of multiple sub-constructs. Using results from previous research on science identity (Carlone & Johnson, 2007; Hazari, Sonnert, Sadler, & Shanahan, 2010), this study hypothesizes a framework for mathematics identity that is comprised of the sub-constructs interest, recognition, competence, and performance. The sub-constructs of competence and performance have been combined, based on results from a prior study (Cass et al., 2011), as seen in Figure 1.

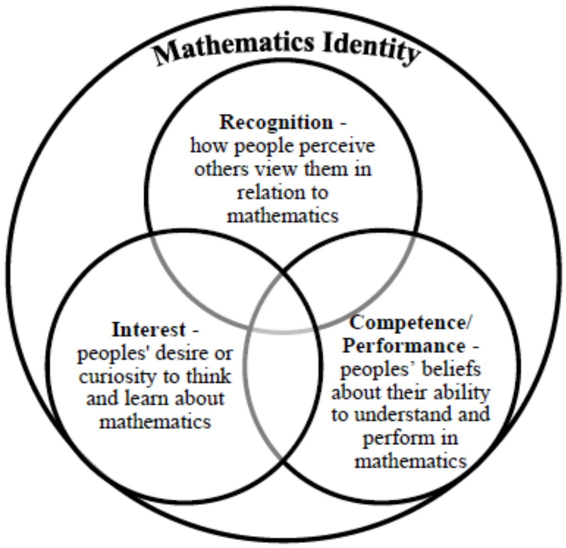

Figure 1: Mathematics identity framework

The research question guiding this study is: to what extent do the data map onto the sub-constructs of interest, recognition, competence/performance, and how these sub-constructs relate to the construct of mathematics identity?

Methods

This study is part of the Factors Influencing College Success in Mathematics (FICSMath) project, a national survey study of 10,437 students enrolled in 336 single-variable calculus classes at 134 colleges and universities across the United States. The survey included items on students' experiences in high school mathematics, students' background information, students' attitudes and career goals, as well as performance in their college calculus classes.

Validity of the survey was established through pilot testing of the survey with 45 students and a focus group with experts in science and mathematics education. Further, a test re-test study with 148 students was conducted to examine the stability (a form of reliability) of the survey. Results indicated an overall reliability coefficient of 0.71 for linear variables and 94 percent agreement for binary and categorical variables.

SEM was used to investigate the construct of mathematics identity. Nine items from the FICSMath survey were used in the measurement model as detailed in Table 1. All the indicator variables for interest and competence/performance were dichotomous variables (0 = disagree, 1 = agree), while the indicator variables for recognition were on a Likert-scale (1 = No, not at all, 6 = Yes, very much).

Table 1: Items from FICSMath Survey

Latent Variable	Indicator Variable	Survey Item
Interest		*Do you agree or disagree with the following statements?*
	Q44enjoy	I enjoy learning math.
	Q44interest	Math is interesting.
	Q44lookforward	I look forward to taking math.
Recognition		*Do the following people see you as a mathematics person?*
	Q45mathpersonp	Parents/Relatives/Friends
	Q45mathpersont	Mathematics teacher
Competence/ Performance		*Do you agree or disagree with the following statements?*
	Q44understand	I understand the math I have studied.
	Q44nervous	Math makes me nervous.
	Q44persist	Setbacks do not discourage me.
	Q44exam	I can do well on math exams.

The variable Q45mathpersons was used as a scaling variable for the latent variable mathematics identity. This variable asked participants to rate themselves to what degree they see themselves as a mathematics person (1 = No, not at all, 6 = Yes, very much).

Results

The goal in SEM is to achieve the best model fit without compromising the theory being represented. Figure 2 details the final structural model along with the corresponding fit indices.

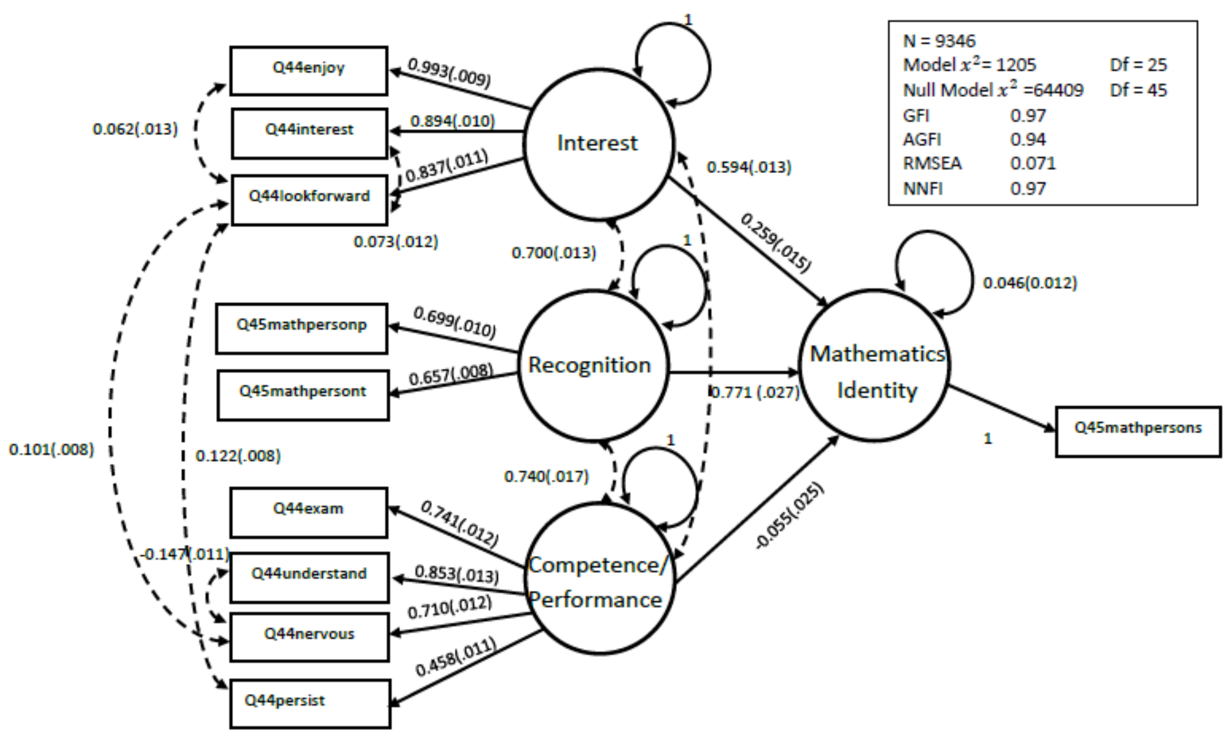

Figure 2: Final model and fit indices

By looking at the fit indices, it can be seen that the final model is a good model with fit indices falling within recommended levels. Furthermore, all pathways in Figure 2 were highly significant ($p < 0.001$).

Discussion and Conclusions

The mathematics identity framework was strongly supported by the data given that the sub-constructs of interest, recognition, and competence/performance had a significant direct effect on mathematics identity, though the negative effect of competence/performance was unexpected. The effect is strongest for the sub-construct of recognition, which indicates that students who believe that their parents, peers, relatives or teachers see them as a mathematics person are more likely to develop a mathematics identity. Interest also has a significantly positive effect on mathematics identity indicating that students who have an interest in mathematics have a higher mathematics identity. Competence/performance has a negative effect on mathematics identity, which is so tiny (–0.055), however, as to be practically negligible. This result may be a consequence of the lack of variability in this specific sample with respect to competence/performance beliefs, i.e. college calculus students may have very similar levels of such beliefs when they enroll in these courses. It is also important to note that competence/performance also had strong indirect effects through both the sub-constructs of interest and recognition. Another study is currently being conducted with a different population of students. This study will test the theoretical framework again and unravel whether the current choice of sample explains the competence/performance finding in this study.

Because mathematics identity is associated with student persistence in STEM (Cass et al., 2011; Cribbs, 2012), it is important to consider the beliefs of students related to mathematics identity, and how exactly these beliefs could positively or negatively influence student choices. These results have broader implications for mathematics researchers and educators. In terms of the classroom, educators can incorporate practices that help to draw student interest, as has been advocated by the National Council of Teachers of Mathematics (2000). Being recognized as a mathematics person plays an even more vital role for students' mathematics identity. However, how students come to feel recognized needs to be further explored. More broadly using the mathematics identity framework established in this paper, future research can investigate the impact of teacher practices on mathematics identity.

AN EXAMINATION OF NON-MATHEMATICAL ACTIVITIES IN THE MATHEMATICS CLASSROOM

Zandra de Araujo
University of Missouri
dearaujoz@missouri.edu

Stein and Smith (1998) classified mathematics tasks by their cognitive demand. In this paper, I examine tasks in which the cognitive demand falls outside of the classifications proposed by Stein and Smith into what they refer to as non-mathematical activity. I explored instances of non-mathematical activity in three secondary mathematics courses. This examination led to three classifications of non-mathematical activity—word activities, transcription activities, and motivation activities. I discuss each of these activity types in detail and suggest strategies to bring a mathematical focus back to these activities. I close with a discussion of implications for mathematics educators involved in the training of preservice and inservice teachers.

Keywords: Curriculum; High School Education; Instructional Activities and Practices

A large portion of teachers' jobs entails selecting and enacting curriculum materials for their students. Ben-Peretz (1990) is one of several researchers who have asserted, "The ways in which teachers handle the curriculum determine, to a large extent, the learning processes in their classrooms" (p. 23). For this study I have chosen to examine one aspect of mathematics curricula, mathematics tasks. I have adopted Stein and Smith's (1998) definition of a task as "a segment of classroom activity that is devoted to the development of a particular mathematical idea" (p. 269). Tasks are the activities teachers select for students to enact. Doyle and Carter (1984) wrote, "The study of tasks, then, provides a way to examine how students' thinking about subject matter is ordered by classroom events" (p. 130).

A number of researchers have created classifications to describe mathematics tasks. Stein, Smith, Henningsen, and Silver (2009) classified mathematical tasks into four different categories. Each of the four categories related to the type and depth of mathematical thinking required of students as they solve mathematics tasks, what Stein et al. referred to as cognitive demand. Stein et al. also briefly discussed instances where tasks seemed to fall outside of these categorizations due to their non-mathematical nature.

I define non-mathematical activities as tasks where the mathematical goal of the lesson is lost or misaligned. I was able to identify such tasks by attending to the tasks' cognitive demand. The non-mathematical tasks were those tasks that fell outside of the cognitive demand classifications proposed by Stein et al. (2009). Rather than examining only those tasks that support meaningful mathematics instruction, I suggest that there is value in examining those activities that fail to create meaning. Although several studies have examined teachers' uses of mathematics tasks (e.g., Stein et al.), a review of the literature found no studies specifically examining tasks Stein et al. refer to as falling into the non-mathematical classification. For this paper I examined tasks of this type. In particular, I examined characteristics of these activities and the ways in which teachers might bring mathematics back to the forefront.

Methods

This study is part of a larger study in which I examined teachers' selection and enactment of curriculum materials for English language learners. I employed a qualitative, multiple case study methodology. The participants—Ms. Thomas, Ms. Hunter, and Mr. Dubois—were secondary mathematics teachers who taught a ninth grade, mathematics class. Each of the teachers was in their sixth year of teaching. The primary data sources for this study are surveys, interviews, observations, and classroom artifacts. I administered a survey to each teacher prior to conducting interviews or observations. I observed each teacher's ninth grade mathematics course daily for two weeks. Each observation was video recorded and partially transcribed. I conducted daily interviews with each teacher prior to observing their teaching and conducted two extended interviews after the two weeks of observations. Each interview was audio recorded and transcribed verbatim. The classroom artifacts consisted of student work and the tasks selected by the teachers.

I analyzed the data using the constant comparison method decoupled from grounded theory. This involved many rounds of inductive coding. I first analyzed each teacher individually and identified emerging themes using analytic memos. I then collapsed these themes into codes as I analyzed each of the different data sources for each teacher. I then performed a cross case analysis looking across the three teachers to identify those codes which were relevant to all the teachers. I consulted with my major professor in developing and verifying the codes. In the following section I discuss findings related to the teachers' task modifications.

Findings

The cognitive demand of the tasks I observed in this study frequently devolved into non-mathematical activity. The transfer of cognitive demand from mathematics to something other than mathematics is a phenomenon Stein et al. (2009) briefly addressed in their book, although they did not describe how this transfer occurs or what it looks like as it is happening. In this section I describe the different types of non-mathematical activities I observed.

Word Activities

During my time in the teachers' classrooms, I witnessed three categories of non-mathematical activities. The first of these categories is word activities. During the interviews, each of the teachers stated the need to build their students' mathematical vocabularies. Although the stated teachers' goals for many tasks were to build academic vocabulary, the tasks they selected seldom achieved this goal. The activities chosen by the teachers were frequently solitary exercises requiring no mathematical understanding. The teachers' failure to use the terms in context and allowance for resources that reduced many of the tasks to transcription activities led to my classification of these tasks as non-mathematical activities. I have termed tasks of this type *word activities*. This terminology highlights the difference between a focus on words without meaning versus activities that help build academic language (Coggins, Kravin, Coates, & Carroll, 2007).

Each of the teachers in this study presented his or her students with word activities. Guy Dubois' lengthy list of terms required students only to copy the definitions out of the textbook's glossary. Similarly, both Natalie Hunter and Meg Thomas asked their students to create flashcards for important mathematical terms. In order to create the flashcards, the teachers expected the students to find definitions for the terms in their notes or textbook and copy them onto note cards. This transfer of words from one source to another is something I term a transcription activity, an idea discussed in the following section. The teachers frequently coupled word activities with transcription activities.

Transcription Activities

The second category of non-mathematical activity I witnessed is what I have termed transcription activities. Perhaps the best description of this category is through the example of a court stenographer. Stenographers create written records of court proceedings. Stenographers sit in on a multitude of different cases and listen to testimony that witnesses provide in technical language. Though a stenographer witnesses and records the courtroom proceedings, it is unlikely he or she understands the details of all of the recordings. This is understandable as the goal of the stenographer is to create a written record in real time, not to understand what he or she writes.

In the mathematics classroom, a similar situation exists in transcription activities. The teachers often attached a mathematical learning goal to these lessons, but the mathematics tended to get lost in implementation. The purpose of many of these transcription activities was for students to explain or understand a mathematical concept. There were different ways in which these activities appeared in the mathematics classrooms. One such way, which I frequently encountered in the teachers' classrooms, was the copying down of teacher work. In such scenarios, the teacher was frequently at the board working out a problem. As the teacher worked out the problem, he or she expected the students to copy down the solution. In addition to copying down the teacher's solution, transcription activities include those tasks in which teachers ask students to restate an idea in their own words. In this case, the student is simply recanting an experience but does not have to have an understanding of the experience. Each of the teachers had instances of tasks that devolved into transcription type activities as they were implemented. The classroom norm seemed to be that when students struggled, the teachers would take over the mathematical thinking, thus transforming tasks into transcription activities.

Motivation Activities

Motivation activities are the third category of non-mathematical activity I encountered and involved activities where students were engaged in crafting or other hands on activities that did not have a mathematical goal. I chose the term motivation activities because the teachers selected these activities in order to engage and motivate students to learn mathematics. In many cases these motivation activities, on the surface, appeared to be mathematical in nature due to their enactment in a mathematics classroom and the inclusion of mathematical words. Upon closer examination, however, it was clear that these activities lost the mathematical focus leading to their categorization as non-mathematical activities.

One such activity was the creation of the quadrilateral mobiles in Ms. Thomas' classroom. Though the students were required to write down the properties from the board to their mobile pieces, this was simply a transcription activity. The students spent the vast majority of this time cutting the pieces into the appropriate shape and decorating the mobile with markers.

Classroom games can also fall into the gimmicky activities category. Ms. Thomas played "trashketball" with her students. This game, meant to serve as a review, required students to answer questions in small groups. If a group's answer was correct, they received the opportunity to throw the trashketball from one of three lines into a waste bin. Clearly, throwing a trashketball into a waste bin does not engage students in mathematical activity, though it did motivate the students to participate. This was not the only non-mathematical portion of the game. The questions Ms. Thomas had students answer were from the prior night's homework assignment. Therefore, students had only to write down a response from a paper.

Discussion

Teachers can learn to avoid non-mathematical activities if provided the proper resources and support. Non-mathematical activity stems from the absence or misalignment of mathematical goals. In order to bring the mathematics back to non-mathematical tasks, teachers should first clearly identify mathematical learning goals on which they would like their lesson to focus. The task must then be selected to support the development of the mathematical goal. Throughout the implementation of the task, the teacher must remain carefully attuned to the mathematics to avoid the transfer to non-mathematical activity, a process that frequently occurred in the teachers' classrooms in this study.

In the case of the word activities, teachers must commit to helping students attach meaning to the mathematical terms. The challenge is to create vocabulary activities that attach meaning to terms rather than simply creating word activities. Building students' academic language is an especially important and challenging aspect of teaching mathematics. Academic language means more than learning words; it suggests the meaningful use of words in mathematical contexts. Barnett-Clarke and Ramirez (2004) explicated, "not only do students need explicit instruction to read and write mathematical symbols and words, they also need to learn how to express mathematical ideas orally and with written symbols" (p. 57). Understanding the importance and meaning of academic language may help teachers develop activities that go beyond the learning of words and help students to learn the language of mathematics.

Teachers should avoid activities that require students to simply transcribe material rather than engage in mathematical thinking. Teachers should select tasks that allow students to extend and evaluate thinking rather than to simply restate what the teacher has already stated. Teachers should avoid transferring tasks to transcription activities by eliminating the productive struggle and taking on the mathematical thinking for students because productive struggle is a necessary part of engaging with higher cognitive demand tasks (National Council of Teachers of Mathematics, 2010).

Many of the motivation activities could be rethought to retain the "fun" while bringing in rigorous mathematics. Teachers may find that students can find motivation in solving tasks focused on real world phenomena related to their interests. In terms of games such as Ms. Thomas' "trashketball," teachers could include new tasks for the teams of students. These tasks could include high cognitive demand problems requiring students to work together toward a solution.

Defining types of non-mathematical tasks provides researchers and teachers with a common vocabulary when discussing these tasks. Understanding the aspects of the tasks that fail to support students' mathematical engagement provides a starting point for discussions related to strategies that add the mathematics back into such tasks. Teachers may be able to use the categorizations I have presented in order to critically examine their own activities to ensure the tasks they implement support students' interactions in mathematical thinking.

STUDENTS' OF COLOR MATHEMATICAL IDENTITY IN AN INTENSIVE SUMMER PROGRAM

Lateefah Id-Deen
Michigan State University
iddeenla@msu.edu

Additional opportunities are available for students of color who have historically been marginalized by the system of schooling in summer programs that can support them to be successful in mathematics. Yet, we know little about students' experiences in these opportunities. In this empirical study, the author employed a case study approach to better understand African American students' developing mathematical identity in an intensive summer program. Data was collected through audio journals, interviews, and student written work to gauge students' beliefs about their mathematical identity. Preliminary results suggest students' conceptual understanding, confidence, and peer interaction in the summer program positively affected their mathematical identity.

Keywords: Equity and Diversity; Informal Education

It is commonly known that many students of color underperform in mathematics (Secada, 1992; Ladson-Billings, 1997), and they rarely enter mathematics-related fields (Bailey, 1990), in comparison to their white counterparts. Those who demonstrate competence in mathematics are better positioned to be economically independent (Secada, 1992). Some research has shown that in some of the most successful schools for these students (Kitchen, DePree, Celedon-Pattichis, & Brinkerhoff, 2007), teachers are working extraordinarily long hours to provide experiences that level the playing field. As Apple (1992) pointed out, however, the intensification of teaching makes it difficult to put additional demands on teachers. Although much research in mathematics education focuses on these students' in-school experiences, we cannot rely solely on K–12 schools. There is a dearth of empirical studies concerning out-of-school and summer programs, especially programs designed for students who have historically been marginalized in school mathematics.

In this report, I focus on students' developing mathematical identity in the context of a summer program designed to support students who have been historically under-represented in higher education and in STEM fields. Following the work of Martin (2006), I define mathematical identity as the "participants beliefs about: (a) their ability to perform in mathematical contexts, (b) the importance of mathematical knowledge, (c) the constraints and opportunities to enter mathematics fields, (d) the motivation and strategies used to obtain mathematics knowledge" (p. 19). The research questions are: In what ways does an intensive summer program shape four African American students' mathematical identities? What impact do the students think this intensive summer program will have on their schooling experiences in relation to their mathematical identity?

Relevant Literature

Identity

Mathematics education researchers have a growing interest in student identity because the identities that students construct have an impact on their learning (Nasir & Cobb, 2007). "[Identity] is also important with respect to equity in students' access to significant mathematical ideas. Mathematics is typically framed in terms of students' cognitive abilities (or the assumed lack thereof), mathematics as it is realized in the classroom also appears to function as a powerful filter in terms of identity" (Cobb, 2004, p. 333).

Mathematical Identity

To understand how African American students' mathematical experiences were internalized at a psychological level, Martin (2000) analytic framework focuses on the construction of mathematics identities. He examines sociocultural factors and how they relate to in-school mathematics experiences. He found that sociohistorical factors (historical discrimination regarding policies and practices among African Americans), community factors (parent and guardian beliefs about the importance of mathematics), school factors (influence of teachers and institutional beliefs), and individual agency (students' personal beliefs about their abilities to do mathematics, motivation to learn, and the importance of learning mathematics) are important in developing mathematical identity (Martin, 2000). For the scope of my study, I focus specifically on the students' individual agency because this study is of smaller scale than Martin's work. The research on mathematical identity and identity in mathematics education has been conducted in the context of *school* mathematics. Out-of-school experiences designed for students who are typically under-represented in mathematics, however, can also have an impact on students' mathematical identities.

The Promise of Summer Programs

Shapiro, Gatson, Hebert, and Guillot (1986), for example, found that after only two hours of mathematics and two hours of literacy per day, low socio-economic status (SES) students of color improved in computation and conceptual understanding. This study shows that summer programs have the potential to improve a student's ability to do mathematics, which provides evidence that at least one aspect of mathematical identity (i.e., ability to perform mathematics) can be influenced by out-of-school experiences. Yet, it remains unclear whether additional aspects of math identity might also be impacted.

Some empirical studies of summer literacy programs allow me to speculate further about out-of-school learning experiences. For example, in a program focused on reading skills, Chaplin and Capizzano (2006) found improvements in test scores and increases in the amount of time students spent reading books. These findings lead me to speculate that a summer program might increase interest in doing mathematics or the desire to take more mathematics courses. Shapiro et al. (1986) showed their summer program helped reduce the rate of reading comprehension that is typically lost in the summer. These types of impacts could help develop students' motivation and strategies related to literacy. The same kind of benefits might occur in mathematics-based summer programs, but no research seems to have focused on this area.

Methods

This study comprises qualitative case studies (Yin, 1984) of four rising 10th grade African American students. Although case studies are not generalizable to make decisive claims, they do provide an in-depth examination of the phenomena being studied (Yin, 2003).

Context

This summer program offers Latino/a and African American students an intensive four-week summer program. One goal of the program is to improve students' math readiness by teaching Algebra, Geometry and Pre-Calculus to rising ninth, tenth, and eleventh graders. In the past seven years, the program has had 98% of its students attend college, with 80% attending a four-year university and 63% of university-attending students majoring in a STEM field (Hargrave, 2011). This program provides a successful out-of-school context for mathematics education researchers to examine summer programs and their specific benefits for students of color.

Data Collection

In consultation with the program director, I selected the four focus students and contacted each student to collect some background information. During the program, I conducted interviews and collected audio journals and student written work. During each of the four weeks, the students were asked to record an audio journal Monday through Wednesday to talk about their experiences. On each Thursday, I listened to each journal and generated a set of interview prompts, clarified questions, and probed with respect to the four components of mathematical identity. On each Friday, I conducted 45-minute interview with each student using a semi-structured format. The final interview took place four weeks into fall semester to help me understand the impact on their schooling experience. Additionally, I collected students' written work to gauge their mathematical progress in course requirements.

Data Analysis

Using Martin's framework, I focused on understanding and unpacking students' individual agency. Since Martin did not elaborate his codes, I articulated codes for the interview and audio journals to accompany each of the four dimensions of mathematics identity. For example, I drew on Jansen's (2006) analysis framework that used modal verbs, expressions of affect, and repetition to understand which aspects of an experience are seen as important to students. The data collected from the audio journals will provide personal narratives of students' strategies and motivation, and their beliefs about the significance of the mathematics as it pertains to the development of their mathematical identity. As part of the analytic process, I wrote weekly memos, based on information gained from the audio journals and interviews, which were the basis of a case report for each student at the end of the four weeks. The student work was analyzed by comparing the weekly tests to the pre- and post-tests. When possible, I conducted member checks (Glesne, 2006) to make sure the students' perspectives were accurately portrayed in this study, and I looked for discrepant events within the data, allowing me to have trustworthy results with the codes that were derived from the interview data.

Results and Discussion

The analysis for this paper is currently ongoing, but I share some tentative results here, which will be expanded upon in the presentation. I will focus what ways does an intensive summer program shape two African American students' mathematical identity. In the program, students were able to focus on conceptual understanding in mathematics. Students' confidence to do mathematics also improved when they returned to school by their successes experienced in the program. Such programs are intense, so in order for students to be successful, they must persist through the difficulties of learning a large amount of mathematics in a short time frame. An emphasis is placed on learning about careers in the STEM fields was stressed, so students were able to learn about careers they had no idea existed. Students worked with so many other students of color who also wanted to be successful in school, which helps them be more motivated, which is something they say they did not witness when they were back in their home schools. Although I have observed these changes in students, little empirical research in this area has been done to date.

Mathematical identities afford and constrain different opportunities for learning and participation in wider contexts (Anderson & Gold, 2006), which could exist in out-of-school contexts. Given that almost every university offers such programs for students of color, this work will help to understand better the role an intensive summer experience in developing underrepresented students' mathematical identity. Such work can inform the design of related programs and policies, as well as help the public school system better understand the kinds of experiences they might develop or encourage students of color to be involved in.

STUDENTS' EXPERIENCES OF SEEKING INJUSTICE-INDUCED HELP IN A MATHEMATICS CLASSROOM

Simon Karuku
University of Alberta
karuku@ualberta.ca

Elaine Simmt
University of Alberta
esimmt@ualberta.ca

In this paper, we describe the phenomenon of a need for help that comes about as a result of problematic classroom practices, as re-lived and described by Tanzanian high school mathematics students. Through the students' experiences, we demonstrate how unequal power relations in the classroom can suppress students' voices, rendering their attempts at seeking justice futile. The students' experiences were characterized by pain and resignation.

Keywords: Equity and Diversity; High School Education; Affect, Emotion, Beliefs, and Attitudes

Introduction

In maths classrooms the world over, students seek help with their maths learning when they experience a lack in their knowledge or understanding. Seeking help in maths may be considered unique in its own way for at least two reasons. First, most maths concepts are abstract by nature, and thus many students experience difficulties not only in relating the concepts to their own prior knowledge and experiences, but also in establishing the connections between the concepts. Even in maths "word" problems, which may be argued to closely resemble problems in other academic disciplines, the language used is different from the one used in ordinary speech, and so many students inevitably encounter ambiguities and difficulties when solving such problems. Secondly, maths often serves as a gatekeeper to many careers and fields of study. This privileged status of maths over other academic disciplines serves well to perpetuate the popular myth of maths as a difficult subject. Seeking help is thus ascribed to persistence in the face of a challenging task, as well as the ability to recognize when help is needed, to decide to seek help, and to secure the needed help from others (Ryan & Pintrich, 1997). By seeking help, students increase their chances of understanding the content, thereby achieving the learning outcomes. Unfortunately, some students are reluctant to seek help even when help is needed and available, because they do not want to appear "dumb" in the eyes of others (Butler, 2006; Ryan & Pintrich, 1997), or out of a desire for independence, or even out of a concern about the competence or utility of available help (Butler, 2006). Although these and other research findings reveal a great deal about students' behaviour when seeking help, they do not offer us a deep appreciation of the student's experience of seeking help. The purpose of the study from where this paper is drawn was to explore and understand the essence and meaning of help in the context of maths learning from high school students' perspective.

Background

The Tanzanian education system has a 2-7-4-2-3+ structure; that is, 2 years of pre-primary education, 7 years of primary education, 4 years of ordinary level secondary education (also known as "O-level"), 2 years of advanced level secondary education (also known as "A-level"), and at least 3 years of university education (United Republic of Tanzania, 2011). The participants reported in this paper were A-level maths students. Only a small proportion of O-level students go on to A-level. In 2009, for example, only 15.4% of the candidates who sat for the final O-level examination proceeded to A-level (p. 55). Thus, these participants may rightfully be described as very resilient, hardworking and very much interested in succeeding. However, as shall be demonstrated in this paper, the phenomenon of seeking help is normally manifested in the complexity of the contexts within which the students learn.

Methodology

This study was informed by the research methodology of hermeneutic phenomenology, whose aim is to deepen our understanding of what it is like "from the inside" to live through an experience, by describing the "lived-through quality" of the experience (van Manen, 1997, p. 25). Data consist of concrete descriptions of lived events provided by those who have lived through the experience of the phenomenon. These raw data are commonly obtained through open-ended interviews with individual participants, as well as through participants' own written accounts of their lived experiences. The transcriptions of the interview data and participants' own written accounts are then transformed into short concrete anecdotes that are aimed at reawakening the reader's basic experience of the phenomenon being described (p. 122).

Seeking Help or Seeking Justice?

What is it like for students to ask for help in maths? What meanings do students ascribe to their lived experiences of seeking help in maths? And what is the pedagogical significance of understanding these meanings? These were some of the questions we set out to examine in the study from where this paper is drawn. We expected to learn about the diversity of frustrations, concerns, successes and strategies attendant to seeking help in maths. But instead of, or in addition to, describing a moment they sought help with a mathematical task, some students described experiences of injustice and inequity in their maths classrooms. And so in this paper, we explore the domains of social justice and lived human experience.

Orienting Oneself Toward Injustice: Re-orienting One's Way of Being with the Other

In the middle of his first year in A-level, Phineas transferred to a new school, and was shocked to find that the maths teacher was charging additional tuition fee for some of the mandated lessons. The teacher was teaching two topics simultaneously, one of which was to be paid for. Phineas describes his experience of being required to leave the class for lack of money:

> *It pained me to see him kick me out of class for lack of money when he was being paid by the government to teach me. But even more painful was the fact that he would not be repeating this topic during the regular class time.*

The phenomenon of seeking help begins with a sense of dissatisfaction with an aspect of our life-world's condition, emanating from a realization that we lack what we consider vital or important for our life-worldly existence. Only in the midst of a felt need or want do we seek help. A need may draw our attention to the fact that we do or do not have a right, something we may have all along taken for granted. Phineas' inability to pay for the extra tuition fee being levied by the teacher appears to have drawn Phineas' attention to his entitlement. Because he does not have full access to the prescribed maths curriculum, Phineas feels that he has been unjustly treated, and so he stands in need of justice. He is aware that his teacher is legally and socially restrained from acting unjustly towards the students. In other words, Phineas knows that his teacher is legally and morally obligated to follow the terms of the contract between the teacher and the government, in which the teacher, in exchange for his salary, is to teach maths to students in accordance with the approved curriculum documents, and to address students' learning difficulties in an equitable, fair and impartial manner.

The awareness of our right to something that is brought about by a need may alter our way of being with the other. We may, for instance, begin to question the other's indifference to his/her moral obligations as they affect our rights. Our response to perceptions of injustice may include feelings of pain. Phineas says that it pained him to see the teacher kick him out of the class. Pain—from the Latin *poena*, meaning punishment or penalty (Harper, 2001)—is unpleasant and hurtful. Phineas is being punished in spite of his innocence. He is thus being subjected to the injustice of an undeserved and unjustifiable punishment.

Injustice Demands to Be Heard

Students may react to perceptions of injustice in the classroom by seeking help from the school administration. But what the conversations with some of the students in this study revealed is that unless one appeals to one's moral conscience, any external imposition of ethical responsibility cannot guarantee the authenticity of a pedagogical enterprise. When Kalunda observed that her maths teacher was frequently missing his teaching duties, she reported the matter to the headmaster. She describes the outcome of the headmaster's intervention:

> *Now the class monitor has an attendance register. When a lesson is taught, the monitor remarks: "Taught" and appends his signature against the remark. If the teacher assigns someone to copy some notes for the class, the monitor remarks: "Notes Written" and appends his signature. The teacher is then expected to countersign against each of the monitor's signature. But I have several experiences where the teacher comes to class, gives you questions, hangs around for a few minutes, and then leaves. The questions will not be graded nor discussed. Of course the teacher will not agree to sign if the monitor remarks: "Untaught" And so when the headmaster or his deputy delves through the attendance register, he will find that the teacher's signature is there, almost everywhere. And the game is over. But it is we the students who really know what goes on inside the class.*

Although the attendance register was meant to enforce justice in the teacher, he is somehow managing to get around it. A scenario is eventually established where a masquerade of adherence to one's ethical obligation goes unchallenged by the other. Who, then, is to blame for the injustice in Kalunda's classroom? The headmaster, to whom Kalunda's teacher is subordinate, may have done his job by warning or reprimanding Kalunda's teacher. In fact the headmaster may be thinking that Kalunda's classroom is running smoothly. The ball, as it were, is in the students' court. But then there is a problem: The playing ground may not be levelled for a fair play. If the power relations between oneself and the subjects over whom one is ethically responsible are skewed in one's favour, then any pedagogy based on other-rather-than-self-monitoring is bound to break down even under the other's keen and watchful eye.

In another interview we learned Jacinta's teacher would regularly miss his lessons. At times he would come to class and appoint one of those students who had attended private tuition to teach some topics to the class. Jacinta recounts her experience when she responded to these unjust practices:

> *It reached a point where everyone was dissatisfied with how we were learning maths. One day, the Deputy Headmaster came to our class and, in a very friendly manner, asked: "What problems are you facing in this class?" Now I just said to myself: "This is our administrator. If we don't tell him what we are going through, whom shall we tell?" So I decided to be honest. And it was as if everyone else was waiting for someone to initiate. So we said we had this and that problem in maths. The Deputy promised to look into the matter. But then I don't know how he presented the issue to the maths teacher, because the next time the teacher came to class, he was very angry with us. Thereafter, we became the marked group. Anytime you went to the staff room, a teacher would always find something to punish you for—your blouse, tie, shoes, socks, finger nails. And there was enmity between us, the "bad" class, and the teachers. From that incident, I learnt to persevere, whatever the case. Now if someone comes and asks how we are doing, I'll just look at them. And so people are just dying like that, each one on her own, quietly but surely.*

To speak is to be a person, to be unique, to be recognized. But the act of speaking is relational; it is something between oneself and an other. When we speak, we are voicing a desire to be listened to, to be heard, to be understood. But what happens when our speaking turns out to be merely an act of losing our ideas? What is it like to have our right to be heard violated? Jacinta knows that she is capable of learning much more maths than she is learning at present. She believes that she is not learning as much maths as are required to meet the intellectual demands of modern life and work. She knows that at the end of A-level, her demonstrated competencies in maths will determine her prospects for job opportunities and/or her admissibility to various programs in institutions of higher education. The main cause of Jacinta's dissatisfaction with her progress in maths is the indifference of her maths teacher to his ethical obligations.

The teacher is not adhering to the recommended instructional time guidelines for the maths curriculum. He is not monitoring the progress of the students and the course as required by the ministry. And contrary to his professional ethics, he is sanctioning an unqualified person to perform the duties of a maths teacher, and without compensating this person accordingly. Jacinta's act of seeking help from the Deputy headmaster produces in Jacinta's teacher a disinterest in Jacinta's welfare. Jacinta's teacher manages to mobilize his colleagues in the maths departmental office and together, they wittingly adopt a hostile "we-against-them" attitude towards the students. To whom can Jacinta now turn for justice? Or has she been officially consigned to silence? Has her need for help been rendered a taboo, something not to be spoken of?

Pedagogical Implications

When we think of students seeking help in maths, we most often imagine the object of their need for help being specific to a particular mathematical task. Yet students in this study raised a much more nuanced notion of help than has been written about in the literature. We knew that issues of self-confidence and esteem might be woven into the students' experiences of seeking help, but we didn't expect to hear about students' experiences of seeking justice in their search for help. What these students' experiences do is, on the one hand, to remind us that the "text" of the phenomenon of help cannot be isolated from its larger context and, on the other, to highlight some of the challenges that hinder students' realization of their full learning capacities. The onus, then, is on educational leaders to be more pedagogically sensitive to the challenges that students encounter in their classrooms. One sure way of guaranteeing authentic and meaningful learning experiences for the students is ensuring that the classroom is an arena for justice and voice.

MATHEMATICAL LISTENING: SELF-REPORTS OF HOW STUDENTS LISTEN AND ITS RELATION TO HOW THEY ENGAGE IN MATHEMATICAL DISCUSSION

Karl W. Kosko
Kent State University

Mathematical listening is an important aspect of mathematical discussion. Yet, relatively few examinations of this phenomenon. Further, existing studies of students' mathematical listening come from observational data, lacking the student perspective. The present study examined student replies to an open-response question regarding what happens to their thinking about mathematics when they listen to their peers' mathematical talk. Results suggest varying ways of listening that range from more passive to more active forms. Additionally, relationships were observed between ways of listening and perceived forms of engaging in mathematical discussion.

Keywords: Affect, Emotion, Beliefs, and Attitudes; Classroom Discourse

Overview and Purpose

The literature focusing on mathematical discussion has suggested student engagement in discussion allows them to reflect more deeply about mathematical concepts and improve their understanding of the content (e.g., Hiebert & Wearne, 1993; Kazemi & Stipek, 2001; Mercer & Sams, 2006). Yet, simple participation in discussions does not necessarily transfer to a deeper understanding of mathematics (Kosko & Miyazaki, 2012; Manouchehri & St. John, 2006). Students' active listening has been posited as a defining characteristic of productive engagement in mathematical discussions (Hufferd-Ackles, Fuson, & Sherin, 2004; Otten et al., 2011). Researchers examining student listening have suggested that as students transition from a more passive to a more active form of listening, they are observed to engage more interactively with their peers during mathematical discussions (Hufferd-Ackles et al., 2004; McCrone, 2005). This transition can be scaffolded by the teacher, such that they have students revoice (restating or rephrasing another student's statements) their peers (Otten et al., 2011).

The various studies on students' mathematical listening have a common theme in that they all examine students' interaction to determine degrees or forms of mathematical listening. While these studies describe active listening as being inherently connected to student interaction in discussion, with specific focus on the ability to revoice, they pose the risk of observer-related bias. Specifically, listening is not a directly observable act, and an additional perspective is necessary to confirm or disconfirm findings from prior studies. I suggest that this additional perspective should be that of the student. In order to assess the student perspective, I used high school students' written responses to an open-response survey question asking how they listened to their peers and what happened to their thinking. I also gathered closed-response data regarding the manner and frequency that these students perceived they engaged in mathematical discussions. Comparison of students' responses to the open-response item regarding mathematical listening with closed-responses to the manner and frequency students participate in mathematical discussions was meant to address several gaps in the literature, as well as confirm or disconfirm findings of observational studies thus described. First, I sought to examine how students listened by assessing their own perspectives of what listening did to their mathematical thinking. This examination provides the student perspective, which I hypothesized would deepen our understanding of mathematical listening. Next, I examined how these perceived ways of listening related to the manner in which students reportedly engaged in class discussions. This examination was meant to uncover the degree to which passive participants in discussion were passive or active listeners (i.e., does a student have to talk frequently in a discussion in order to listen reflectively). Finally, the examinations of this data were meant to extend those of previous studies, by providing an additional perspective of the phenomenon.

Methods

Data were collected from 62 high school geometry students in five classes taught by the same teacher. Students were enrolled in a rural high school in the Southeastern United States. At the end of the year, students completed a set of open-ended questions, of which I examined responses to the question: *When you listen to other students talk about math in class, what happens to your own thinking about math? Please explain your answer*. Students also completed a closed-response which included items assessing students' perceived engagement in mathematical discussion (e.g., "When talking about math in class, I explain what I mean in detail"). Responses for items were on a 6-point Likert scale (*1= Strongly Disagree* to *6 = Strongly Agree*), and demonstrated sufficient internal reliability (M = 3.93, SD = 1.08, α = .73).

A main aim in studying students' perceptions about mathematical listening is to better understand how mathematical listening relates to mathematical thinking. To investigate this relationship, I examined the grammatical processes students used in their responses to the prompt, and the participant references associated with those processes. Processes are part of the grammatical system of transitivity (Halliday & Matthiessen, 2004), whose basic function is to convey meaning, or to describe "a particular domain of experience" (Halliday & Matthiessen, 2004, p. 170). Since the item prompt specifically asked about students' thinking, I also examined responses for references to such thinking. Five categories emerged based on similar meanings conveyed. The analysis and emergence of these categories is described below, by category.

Doesn't Listen emerged from two responses where students explicitly stated that they did not listen to their peers' mathematical discussions. *Nothing Happens* was the classification used to organize 15 responses where students conveyed that their thinking remained the same. For example, one student stated that: *I can't really say hearing others talk about math <u>warps</u> **my opinion of it***. The process <u>*warps*</u> conveys change, or lack thereof, to the participant ***my opinion***, which sits in as a reference for thinking. Several other students made the explicit statement, ***it** <u>stays</u> the same*, or a variation of such statement. Both classifications *Doesn't Listen* and *Nothing Happens* suggest, at most, limited engagement on the part of the student. While 29.1% of students conveyed that their thinking does not change when engaged in listening to others' during mathematical discussions, the remainder of responses suggested that students were engaged, in some degree.

The classification *Learning Happens* was used to classify 30.9% of student responses where students indicated that they did engage in some form of cognition, but provided little detail beyond such description. One such statement in this classification was: ***My own thinking** <u>is changed</u> and it <u>teaches</u> me different **things that I didn't understand** at first.* In describing their thinking, the student conveyed that it changes, but also by listening, the student suggests they are taught ***things that*** [they] ***didn't understand***. Another student stated: *It <u>can help show</u> me **what I don't know***. The student conveys some sense of learning from the process <u>*show*</u>. In both statements, some form of learning is conveyed, but the details of the learning is loosely structured. While it is tempting to suggest the lack of specificity is due to poor communication on the part of the student, I suggest that students are signaling a particular type of engagement with mathematics. Specifically, mathematics is treated as an entity that can be right or wrong, possessed or not. In short, it is treated in a simplistic manner that may value answers and products over processes and concepts.

Math Happens represented 10.9% of student responses and included responses where students described their thinking as changing in such a way that they discovered or learned new mathematical information. In the student response, *I try to <u>**understand**</u> what they are saying and try their way of solving the problem*, represents a subtle departure from the conveyed meaning in statements classified as *Learning Happens*. The student uses the process and reference to student thinking <u>***understand***</u> to describe their learning of mathematics. However, mathematics is treated as a set of processes or procedures, rather than a product or answer, as is the case in *Learning Happens*. Another student response, *It <u>opens</u> **my mind** to how to do other kinds of math*, conveys that the student's ***mind*** is opened to do math. Doing math conveys a process rather than a product. While seemingly subtle, this difference between the *Learning Happens* and *Math Happens* categories is crucial. Statements categorized as *Math Happens* describe changed thinking in regards to methods and strategies while statements categorized as *Learning Happens* describe changed thinking in regards to products or solutions.

Another feature of statements in *Math Happens* is that the references to thinking were more often conveyed as processes than in *Learning Happens*. Specifically, variations of the process "understand" were more consistently used in *Math Happens* statements. However, to "understand" is quite different from other mental processes one might engage. In distinguishing reflection from thinking, Dewey (1910) noted that "reflection thus implies that something is believed in (or disbelieved in), not on its own direct account, but through something else which stands as witness, evidence, proof, voucher, warrant; that is, *as grounds of belief*" (p. 8). Such a distinction characterized the classification of *Reflection Happens*, which represented 29.1% of student statements. *Reflection Happens* classified statements that used processes such as *compare*, *reflect*, *contrast*, etc. Such mental processes reflected the distinction made by Dewey, in that they conveyed meaning associated with cognition that represented some form of comparison in search of "grounds of belief." Following are two examples of statements classified in this manner: (1) *I **compare** [my thinking] to their* **thinking, (**2) *I listen to what they're saying, **consider** it and **compare** it to how I would solve it.*

Noticeably, in the first statement, "thinking" is present both as a process, in the form of ***compare***, and participant, in the form of ***thinking***. This particular example illustrates how the processes identified based on Dewey's conceptions relate to the notion of reflection as a form of metacognition. The student conveys the sense that they are manipulating the abstracted object of "my thinking" through the mental process of comparison. The second statement uses the same type of mental process but incorporates a procedural statement about the mathematics (i.e., *how I would solve it*). When examining how mathematics itself is described for the *Reflection Happens* category, there appears to be little observable difference with how it is described in the *Math Happens* category. Specifically, mathematics is referred to generally with procedures. Therefore, the defining distinction between these categories is not how mathematics is treated or referred to, but in how students conveyed they thought about the mathematics (e.g., "comparing" rather than "understanding").

The classifications presented in the previous section represented not only categorical, but ordinal data (1 = *Doesn't Listen*; 2 = *Nothing Happens*; 3 = *Learning Happens*; 4 = *Math Happens*; 5 = *Reflection Happens*). Specifically, statements in higher ordered classifications conveyed more active forms of cognition on the part of the student. Using the classification schemes as ordinal data, I correlated this student data with students' composite scores for *discussion*. The calculated Spearman Rho coefficient was found to be statistically significant with a moderate effect size (ρ = .38, p < .01). This result suggests that the more active form of listening students reported they engaged, the more they reported explaining and justifying their mathematics when they participated in discussions.

Discussion

Throughout the present study, I sought to examine what students reported happened to their own thinking while listening to other students talk about mathematics. Results suggested several different ways students reported their thinking was affected. Additionally, these different ways of thinking represented a transition from less to more active forms of thinking. The highest point on this continuum involved students in reflection, which included comparing and contrasting their own mathematical thinking to their peers'. This action is similar to the observable act of revoicing identifed by others (e.g., Hufferd-Ackles et al., 2004; Otten et al., 2011). Given the corresponding results presented in such previous work with the findings described in the current study, it seems that an important, practical implication of the present study is for teachers to facilitate active listening by having students rephrase and summarize their peers' mathematical contributions in class.

The findings presented here suggest that students' mathematical listening comes in many forms. Yet some forms appear more desirable than others. Therefore, the findings of the present study suggest a complicated picture of how students engage in mathematical listening, and what researchers and teachers may observe of this phenomenon when watching students talk about mathematics.

IDENTITY AND EQUITY AMONG LATINA/O[1] UNDERGRADUATES IN AN EMERGING SCHOLARS MATH WORKSHOP

Sarah Oppland-Cordell
Northeastern Illinois University
s-cordell@neiu.edu

This study uses an identity lens to explore how equity processes evolve for two Latina/o undergraduate students in a culturally diverse Emerging Scholars Program (ESP) Calculus I workshop at a predominantly White urban Midwestern university. Drawing on Gutiérrez's (2007, 2008) definition of equity, findings indicate that equity processes became strengthened for the participants through four dimensions (access, achievement, identity, and power) over time. Drawing on critical race theory and Latina/o critical theory, findings reveal that participants' participation through their racial identities—co-constructed with their gender, class, and math identities—aided in strengthening all four dimensions. Findings support that understanding how race, gender, and class function in Latina/o students' math experiences and identities, including in math classroom contexts, expands knowledge about how to develop equitable math practices.

Keywords: Equity and Diversity; Post-Secondary Education; Instructional Activities and Practices

Purpose and Background

In math education research and policy documents, equity issues have become more complex and received heightened attention in recent years (Allexsaht-Snider & Hart, 2001; Hodge, 2006; NCTM, 2000). Studies that investigate equity issues in math communities of practice often draw on sociocultural theories of learning (Lave & Wenger, 1991; Wenger, 1998). However, emerging equity math education research advocates for using a broader sociopolitical theoretical lens that addresses, for instance, contextual factors, identity, power, race, gender, and class (Gutiérrez, 2007; Martin, 2007; Nasir & Cobb, 2002). At a time when math achievement disparities among different racial, ethnic, and socioeconomic groups subsist, broader conceptualizations of equity would allow for a deeper understanding of the complex and often concealed mechanisms that support and impede students from experiencing equity in their math trajectories.

While equity definitions often discuss the importance of providing students with access, learning opportunities, and outcomes in relation to mathematics (Allexsaht-Snider & Hart, 2001), rarely do they include a dimension that addresses the mathematical empowerment of students and communities (Martin, 2003). However, Gutièrrez (2007, 2008) provides a definition of equity consisting of four dimensions that address access, learning opportunities, outcomes, and empowerment. Drawing on this definition, this study conceives equity in relation to the ESP Calculus I workshop community as:

(a) *access* – participants express satisfaction with how they are able to access the resources and opportunities that enable them to interact with quality mathematics;
(b) *achievement* – participants express satisfaction with the Calculus I grades they earn, they exhibit high participation rates, and they persist in mathematics;
(c) *identity* – participants develop stronger self-perceptions as math learners and positively co-construct this perception with other identities they possess; and
(d) *power* – participants exhibit agency related behaviors that contribute to transforming school or society (2008, p. 360).

Each dimension develops over time and is dependent upon each student's unique experiences, interactions, goals, and identifications as they engage in the ESP workshop's practices.

Too often math education equity research essentializes Latina/o students' experiences (Boaler, 2002) and fails to differentiate equity from enlightened self interest purposes (Secada, 1989). In contrast, this research adds to math education scholarship expanding meanings for equity among Latina/o students by acknowledging how their identities, agency, and sociopolitical constructs, such as race, gender, and class, function in their math trajectories. This is one of a few studies to adopt broader equity definitions to investigate how equity processes and equitable math practices develop for Latina/o students (Boaler, 2008; Gutièrrez, 2002).

Method

This project is part of a larger study that employed multi-case study and cross-case analysis (Yin, 2009) to explore undergraduate Latina/o students' identity constructions and participation in ESP (Oppland, 2010). In the larger study, multiple data sources, including interviews, reflections, and direct classroom observations, were analyzed to construct an in-depth case study for each participant that described how they co-constructed their math and racial identities, how their workshop participatory trajectories developed over time, and how their racial identities fortified their participation. This study expands upon prior findings by investigating how two Latina/o students' participation through their racial identities (and its co-construction with other identities) contributes to strengthening four dimensions of equity. Participants include Vanessa, an 18-year old, second-generation Mexican American immigrant, and Immanuel, a 19-year-old, first-generation Mexican American immigrant.

This study views both *narrative identity* (Sfard & Prusak, 2005) and *participative identity* (Wenger, 1998) as critical for interpreting how participants' racial identities inform equity processes. While narrative identities refer to stories that are generated as individuals contemplate and share their experiences (Sfard & Prusak, 2005), participative identities refer to the identities of participation and non-participation individuals construct as they engage in communities of practice (Wenger, 1998). Drawing on Wenger's (1998) social ecology of identity framework, participative identity in this study refers to how participants construct identities as ESP workshop members and how they negotiate and claim ownership of mathematical meanings through three modes of belonging (engagement, imagination, and alignment).

The ESP research site is located in Hall University, a large four-year research university in Chicago, Illinois. The ESP workshops were modeled after Uri Treisman's doctoral dissertation work, which aimed to discover explanations for why African American students were struggling to learn calculus at the University of California, Berkeley in the mid-1970s. Drawing on this model, optional ESP math workshops at Hall run parallel to students' standard math courses and encourage culturally diverse peer groups to collaboratively solve challenging problems. The ESP workshop in which this study occurred consisted of 27 students. Class demographics were roughly 41% Latina/o (4 females and 7 males), 30% Asian (5 females and 3 males), 22% White (2 female and 4 males), 7% African American (1 female and 1 male), and 44% female.

Data analysis consisted of four phases. Phases 1 and 2 involved coding interview data, constructing thematic memos, and writing narrative summaries that described how participants negotiated math and racial identity co-constructions (Phase 1) and constructed participative identities (Phase 2). Phase 2 also involved analyzing the remaining data sources and comparing that evidence to the narrative findings. Phase 3 involved identifying emergent themes related to how participants' racial identities strengthened their workshop participatory trajectories. Phase 4 involved identifying how participants' participation through their racial identities contributed to strengthening the four equity dimensions. When attempting to understand these connections, in addition to drawing on CRT and LatCrit theory, I used a grounded theoretical approach in terms of allowing relevant themes to emerge in the data.

Results

Results indicate that participants' participation through their racial identities—co-constructed with their gender, class, and math identities—powerfully contributed to strengthening the equity processes they experienced in relation to the ESP workshop context through all four dimensions.

Access refers to participants expressing satisfaction with how they are able to access the resources and opportunities that enable them to interact with quality mathematics. This study perceived the ways in which participants' racial identities contributed to positively shifting their participative identities as strengthening their access to mathematics. In a previous study (Oppland, 2010), results show that participants' racial identities (and their intersection with their gender, class, and math identities in some instances) contributed to optimistically shifting their participation in the ESP context by: (1) strengthening comfort levels with peers, (2) positively altering perceptions of their and peers' math abilities, and (3) allowing them to challenge racialized math experiences. For instance, in the ESP context, both participants challenged prior racialized secondary math experiences they managed while interacting with math teachers.

Achievement refers to participants expressing satisfaction with the Calculus I grades they earn, exhibiting high participation rates, and persisting in mathematics. Participants revealed that the ESP context aided them in earning higher Calculus I grades, that their workshop participation increased over time, and that peer interactions powerfully assisted in strengthening their participation and math appropriation. Participating through their racial identities contributed to optimistically shaping how participants interacted with peers in terms of positively altering their perceptions of their and peers' math abilities and strengthening their comfort levels with peers. For instance, sharing cultural backgrounds with Latina/o students contributed to both participants convergence towards practicing math with Latina/o students in the ESP context.

Identity refers to participants developing stronger self-perceptions as math learners and positively co-constructing this perception with their other identities. Both participants indicated that they positively co-constructed math and racial identities in the ESP classroom setting:

> It's good to see how other Hispanic people are so good at doing math. It's not what people usually think of. I think it makes me proud that there's a chunk of us…I'll put myself in that group that are willing to do whatever to be good at math… (Vanessa)

> I never met Hispanic or Latino people that are this high up like me. I was expecting to come to [Hall] and not be similar to people in that cultural background…I don't feel alone…when you get to this class you and I are breaking stereotypes. (Immanuel)

Power refers to participants exhibiting agency related behaviors that contribute to transforming school or society. Participants indicated that their ESP experience contributed to fortifying aspects of their identities that they perceived as important for creating positive change in their Latina/o families and communities. This included strengthening Immanuel's ability to tutor a younger sibling in math and Vanessa's ability to function as an academic role model for Latinas within her community.

The Latina/o participants' stories reveal the complex psychological and sociopolitical mechanisms underlying their math learning processes within a collaborative ESP Calculus I workshop that contributed to their mathematical success. Such knowledge can be applied to create equitable math learning environments that aid undergraduate students in effectively transitioning through gateway courses, that mathematically empower students in K–16 contexts, and that support underrepresented students in persisting through the K–16 math pipeline.

Endnote

[1] Latina/o is a political term produced by American culture that is used to describe people who have origins in the Hispanic countries of Latin America or Spain and people who self-identify as Latina/o (Ferdman & Gallegos, 2001).

EXPLORING COGNITIVE DEMAND, STUDENT PARTICIPATION AND LEARNING IN MIDDLE SCHOOL ALGEBRA[1]

Samuel Otten
University of Missouri
ottensa@missouri.edu

This brief report analyzes mathematical task enactments in 12 middle school algebra classrooms using the complementary lenses of cognitive demand and participatory demand. Whereas cognitive demand is well known in the field as a conceptualization of the thought processes entailed in solving a mathematical task, participatory demand is a new construct that captures student involvement in mathematical discourse during enactment. Correlational analysis revealed a significant relationship between participatory demand and average student gain scores on a pre- and post-test, but not between cognitive demand and gain scores.

Mathematical tasks are the essential building blocks of much of mathematics instruction. Yet, enacting tasks in mathematics classrooms in ways that promote deep mathematical thinking and spur rich mathematical communication is a challenging endeavor (Henningsen & Stein, 1997; NCES, 2003). To illuminate aspects of this challenge, researchers from the QUASAR project analyzed *cognitive demand*—the kinds of thinking processes entailed in solving a task (Stein, Grover, & Henningsen, 1996). In particular, they traced shifts in cognitive demand throughout the phases of task enactments, such as a teacher focusing on correct answers, which can lower cognitive demand, or a press for justification, which can maintain a high level of cognitive demand. Such maintenance or declination of cognitive demand is important because high levels of cognitive demand have been linked to positive student outcomes (e.g., Stein & Lane, 1996).

This body of research focused on student thinking has had a widespread impact, informing pre-service and in-service teacher education as well as subsequent research in mathematics education. More recently, however, there has been a new and growing body of research focusing on classroom discourse (Ryve, 2011) and students' participation in a mathematics community as inseparable from their learning of mathematics. In this article, the construct of *participatory demand*—the extent and nature of student interactions during the enactment of a mathematical task—is used as a complement to cognitive demand, with both together providing a fuller picture of mathematical task enactments than either would provide separately. Using these complementary constructs, enactments of various mathematical tasks designed with the same learning goal were analyzed and investigated in relation to students' attainment of that learning goal as measured by gain scores between a pre- and post-test.

The research question guiding this analysis was as follows: *How does the cognitive demand and participatory demand of mathematical task enactments relate to students' learning of the content of those tasks?* This work is situated within an ongoing investigation of a larger set of questions that will not be reported here.

Theoretical Perspective

From a sociocultural perspective, learning is viewed not as the accumulation of knowledge in an individual's mind but as a collaborative process through which a learner comes to participate in particular discourse communities (Lave & Wenger, 1991). Cobb, Yackel, and Wood (1992) recognized the importance of collective processes but argued for striking a balance between the collective and the individual when considering learning in mathematics. Echoing Cobb, Yackel, and Wood, this study is an attempt to view students as both individual thinkers and collective participants in the mathematics classroom. In particular, the construct of cognitive demand is used to attend to potential thought processes during mathematical task enactments and the construct of participatory demand is used to attend to student interactions.

To structure the observations of task enactments in mathematics classrooms, a modified version of the Mathematical Tasks Framework (Stein, Grover, & Henningsen, 1996) is used. As Figure 1 depicts, a written mathematical task typically proceeds through several phases of enactment: the teacher sets up the task, students work on the task (individually, in small groups or as a whole class), and then the teacher and students look back at their work (perhaps to share solution strategies, summarize key ideas, or draw connections). The final portion of the framework highlights the fact that the written task and its enactment shape what students learn from the experience.[2] This study, in particular, is investigating the relationship that cognitive demand and participatory demand of mathematical task enactments have on one conceptualization of student learning, namely, their gain scores on a written pre- and post-test.

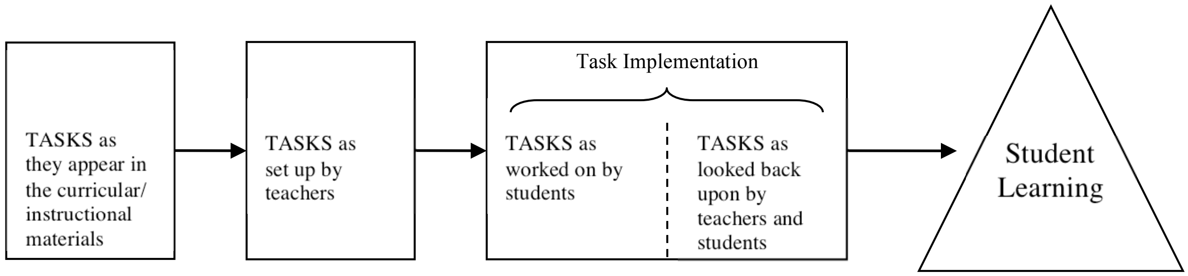

Figure 1. A modified version of the Mathematical Tasks Framework (MTF)

Method

Twelve sets of video recordings of lessons from nine middle school teachers in two states comprised the classroom data for this study (see Table 1). The analyzed lessons (n = 52) were those dealing with the learning goal of using variables to represent co-varying quantities. Although the learning goal of the analyzed lessons was constant, other characteristics varied, such as the geographical region, teacher's years of experience and educational background, and the curriculum materials being used. This variation provided a range of task enactments.

Table 1: Participating Teachers and the Data Collected for This Study

Teacher	State	College Major	Yrs. Exp.	Grade	Textbook	Students

Note: [a] indicates a Master's degree at time of observation. [b] indicates observations during multiple academic years.

Main instructional tasks (i.e., excluding warm-up activities and homework review) were identified and parsed according to the modified MTF (see Figure 1). Each of the four phases were then coded for level of cognitive demand, using methods from past research (Stein, Grover, & Henningsen, 1996), and nature of participatory demand. Participatory demand codes focused only on verbal participation and consisted of two sub-codes: *level of student participation* and *focus of student participation*. The level of participation was high, medium, or low depending on the extent to which students were speaking full sentences (as opposed to single-phrase turns). The focus of participation was mathematical, semi-mathematical, or non-mathematical and used a technique called thematic analysis (Lemke, 1990; Herbel-Eisenmann & Otten, 2011) to determine the extent to which students were verbalizing semantic relations between mathematical terms (as opposed to stating mathematical terms in isolation or non-mathematical terms and relations). These aspects of participation are important because, as Lemke (1990) argued, coming to participate in a discourse community means being able to combine terms in ways that make sense in that context. Double coding was conducted on a sample of the videos and inter-rater agreement was greater than 80% on each dimension.

Student learning was operationalized as gain scores between a pre- and post-test measuring students' aptitude with respect to using variables to represent co-varying quantities. The tests consisted of 7 multiple-choice items, 8 constructed-response items, and 1 multi-part item and were piloted prior to this study. Inter-rater agreement was 94–99% on pre- and post-test scoring. The twelve sets of data were ranked separately by standardized average gain score, prevalence of high cognitive demand, and prevalence of high-mathematical participatory demand. Spearman's rank correlation coefficient (ϱ) was used to test the pairwise relationship between these variables.

Results

First, based on past research (e.g., Stein & Lane, 1996), one would expect cognitive demand to be positively correlated with average gain score. However, these two variables were weakly ($\varrho = 0.273$) and insignificantly ($p = 0.196$) correlated in this study, though this lack of evidence for a relationship is not necessarily evidence of a lack of relationship. For instance, the instruments used here may have been insufficiently sensitive to detect the association. Second, based on arguments for the importance of student discourse in mathematics classrooms (e.g., Ryve, 2011), one might also expect participatory demand to be positively correlated with average gain score. Indeed, a positive relationship was found ($\varrho = 0.406$), significant at the 10% level ($p = 0.095$). It is somewhat surprising that this relationship was detected with only 12 classes involved in the analysis and with verbal participation being coded in the enactments but a paper-and-pencil assessment of student learning.

Interestingly, nearly 30% of the squared deviations between participatory demand ranking and gain score ranking come from a single teacher, Ms. Cesky, who was ranked second to last with respect to participatory demand but had the fourth highest standardized gain score. The fact that the correlation between participatory demand and gain scores approached significance even with the inclusion of Ms. Cesky suggests that the other 11 sets of lessons exhibited an exceedingly strong link between these two variables. Indeed, calculating ϱ based on the rankings of the other 11 classes yields $\varrho = 0.664$ ($p = 0.0102$), which is highly significant.

Looking Ahead

What is the relationship between cognitive demand and participatory demand during task enactments? Conventional wisdom states that it is easier to get students talking about mathematics if they have something interesting to talk about, namely, a high-level task. In the present study, no significant relationship was found between cognitive demand and participatory demand, that is, there were numerous instances of high student participation around low cognitive demand processes and low student participation around high cognitive demand processes. This does not imply, however, that students working on high-level tasks did not have mathematical ideas to share verbally—it may just be that these ideas were not elicited during enactment. Perhaps coming to better understand these relationships between cognitive demand and participatory demand will allow us to better understand the broader relationship between enactment and student learning.

A correlation was found between participatory demand, operationalized as verbal utterances by students of mathematical semantic relations, and gain scores on a pre- and post-test of a middle school algebra learning goal. Although not necessarily a causal link, this finding does support claims about the importance of student participation in mathematics classroom discourse.

Endnotes

[1] This work was completed as part of the dissertation requirement for a doctoral degree at Michigan State University, with financial support from the College of Natural Science. The author thanks Beth Herbel-Eisenmann, his dissertation committee, the *Project 2061* group, and the teachers and students who made the study possible.

[2] Although the arrow points unidirectionally toward learning, learning also occurs during the phases of enactment and students' learning also shapes the enactment itself.

SECONDARY PRE-SERVICE MATHEMATICS TEACHERS' CONCEPTIONS OF EQUITY

Sarah A. Roberts

Alejandra Salinas
Boston University
salinas@bu.edu

This study examines secondary pre-service teachers' (PSTs) conceptions of equity in the teaching of mathematics as part of a preliminary research investigation. Teachers' conceptions around equity in the mathematics classroom affect their classroom practices. Therefore, it is important to know what PSTs' conceptions around these issues are in order for teacher educators to help address any gaps or misunderstandings. We used three tasks during methods courses across three universities to elicit PSTs' conceptions. We found that unless specifically prompted, most students do not consider issues of race, power, ethnicity, SES, or language when they envision their future mathematics teaching.

Keywords: Equity and Diversity

The majority of pre-service teachers (PSTs) are educated to teach students from a White, Eurocentric middle-class culture (Kyles & Olafson, 2008). As a result, PSTs often hold a set of values that differ from the shared values of the student populations they will teach; these differences are referred to as a cultural discontinuity. The cultural discontinuity often leads to lower expectations for students from minority or low SES backgrounds (Gay, 2000; Ladson-Billings, 1994). Given that all mathematics students need high expectations and strong support (NCTM, 2000), we see it as the responsibility of mathematics teacher educators to prepare secondary mathematics teachers to provide these expectations and supports for their students.

Moreover, Barlow and Cates (2006) suggest, "beliefs affect how teachers see their students…thereby impacting [their] instructional practices" (p. 64). In other words, teachers' beliefs, or conceptions, act as a filter and shape how a teacher structures his/her classroom environment. Researchers suggest there is a strong relationship among teachers' beliefs, personal experiences, and how they teach (Levitt, 2001; Stuart & Thurlow, 2000). Therefore, understanding PSTs' conceptions of equity in the teaching of mathematics enables mathematics teacher educators to provide PSTs appropriate learning experiences, pedagogical tools, and knowledge of others' experiences and backgrounds in order to help minimize the cultural discontinuity and raise expectations. Consequently, the purpose of this study is to understand secondary mathematics PSTs' conceptions of equity.

Theoretical Perspectives

Cultural discontinuity can be described as the cultural mismatch between a teacher's and her students' cultural norms and values (Gay, 2000; Oakes, 1985). Cultural discontinuity is a problem for teachers and students, particularly for teachers with students from minority and low-income backgrounds (Gay, 2000; Lasdon-Billings, 1994). Discontinuity is often evident in teachers' differential treatment and expectations of students based on student demographics. Because many teachers view mathematics as a universal, culture-free subject (Rousseau & Tate, 2003), they do not connect their mathematics instruction with students' culture and background, therefore contributing to this discontinuity. According to Irvine (2003), "Students fail in school not because their teachers do not know their content, but because their teachers cannot make connections between subject-area content and their students' existing mental schemes, prior knowledge, and cultural perspectives" (p. 47).

Methods

This preliminary research took place during a single semester in three different secondary mathematics methods courses at three universities. Each class had 10–12 students enrolled, for a total of 33 participants, with 18 females, 15 males, and over 90% of the students being Caucasian. The participants were a mixture of undergraduate, post-baccalaureate, and master's students.

The authors developed and implemented three tasks that were designed to elicit secondary mathematics PSTs' attitudes, thoughts, and beliefs about issues of equity in teaching mathematics. The first task asked students to respond to the following prompt in 2–3 pages: "'All students can learn mathematics.' Do you agree or disagree with this statement? How do/don't you foresee this playing out in your future classroom? Be specific." The second task required students to respond to quotes related to equity and mathematics. Some examples include: (a) *The way teachers teach mathematics does not send any messages; mathematics is free of context*; and (b) *Teachers have different expectations of their students based off of the students' ethnic and socio-economic background*. The instructor at one university placed the quotes around the classroom, and students recorded their reactions on post-it notes. After responses were recorded, the PSTs summarized the class' reactions, discussed the meaning of each quote, and answered additional questions from the class. The other instructors assigned two quotes per student and asked them: (1) to write their interpretation of each quote in 1–2 paragraphs and (2) to write their reaction to the quote in 1–2 paragraphs. The final task required our PSTs to (1) design an equitable mathematics classroom environment, (2) explain the role of the teacher and the role of the student, and (3) describe why this mathematics classroom is equitable. This was a written assignment at two of the universities and a class discussion activity at the third university.

We individually analyzed the data during and after data collection, which allowed us "to focus and shape the study as it proceed[ed]" (Glesne, 1999, p. 130). Our initial analysis has focused on identifying if and how our students were thinking about race, socioeconomic status, home culture, English learners, and issues of power. Additionally, we looked for how students discussed how they might use race, socioeconomic status, home culture, English learners, and issues of power as resources to support student learning in the mathematics classroom, as well as the role of mathematics in changing or affecting cultural, civic, and social change. We individually wrote analytic memos (Maxwell, 2005) to identify themes within and among each task. We then discussed the themes that seemed most prevalent across the three contexts and tasks.

Results

As stated above, it is important that PSTs are thoughtful about issues related to equity in mathematics. As these three tasks were given to our students, we were hopeful each would elicit our students' thoughts, attitudes, and knowledge about equity and its role in teaching and learning mathematics. The following describes student responses to each task:

All Students Can Learn Task

Students' disabilities, motivation, learning styles, and ability are factors to students learning mathematics

Although the majority of PSTs agreed that all students could learn mathematics, the extent of students' learning is dependent on their disabilities (e.g., dyslexia and dyscalculia), motivation, or innate ability. PSTs responded that these students have the ability and capability of learning mathematics, but instruction must be differentiated to help them learn. PSTs contend, "Some people are math people and other people aren't," therefore "all students can learn math, just not the same math", and "students can learn math if they want to." The PSTs also stated it was the teacher's responsibility to differentiate his/her teaching, consider students' learning styles and strengths, and "make math fun" so students are motivated.

Equity Quote Museum Task

Quote 1: Minority and linguistically diverse students have not been construed as visible players within mathematical discourses either in or out of schools.

PSTs generally interpreted this quote to mean that minority and linguistically diverse students are not active participants in the mathematics classes. Some reasons PSTs mentioned included: (1) a teaching force is mostly Caucasian, which disadvantages minority; (2) these students do not participate because they "struggle asking question, discussing mathematical ideas, and working together;" and (3) "linguistically diverse students often fall behind due to their inability to communicate using the language of the teacher and other students."

Quote 2: The way teachers teach mathematics does not send any messages; mathematics is free of context.

Many PSTs disagreed with this quote because they contend a teacher's enthusiasm sets the tone to learn mathematics, which can either be "math is fun" or "math is boring." Other PSTs disagreed because mathematics should relate to students' lives and involve real world contexts. Real world contexts ranged from general (e.g., different jobs) to specific (e.g., calculating a tip). Lastly, some PSTs agreed with this quote because many textbooks present mathematics as a series of formulas and procedures without and context, and that's how teachers teach it.

Quote 3: "I thought math was just a subject they implanted on us because they felt like it, but now I realize that you could use math to defend your rights and realize the injustices around you… now I think math is truly necessary and, I have to admit, kinda cool. It's sort of like a pass you could use to try and make the world a better place" (a 9th grade student).

When reacting to this quote, PSTs focused on the usefulness of mathematics and how disconnected this student felt in the past. Some PSTs were attuned to the social justice elements mentioned in the quote (e.g., defend your rights and make the world a better place) and discussed the national budget, the impact of war, and the meaning of the national debt in their responses. Yet, other PSTs emphasized the teachers' role is to get students excited about mathematics.

Quote 4: Teachers have different expectations of their students based off of the students' ethnic and socio-economic background.

Many PSTs stated this quote represented an unfortunate truth. They contended that teachers are negatively biased towards students' capabilities based on their ethnic and socio-economic background, and teachers need to look past these stereotypes. Some PSTs also mentioned that these expectations are not necessarily negative and reference that the stereotype of Asian students might lead to unfounded high expectations. Other PSTs responded teachers should have different expectations for their students, but not just base it on ethnicity or SES.

Create an Equitable Classroom Task

PSTs' equitable classrooms included three themes. First, PSTs portrayed the role of the teacher as having high expectations for all students, being a facilitator, and creating a safe environment where students are respected and fully participate. Second, students would likely be sitting in groups, where students could help and learn from each other. Third, although minimal, some PSTs made some comments about gender, race, culture, and English language learners. For example, PSTs mentioned students need to be respectful of each others' race and culture and teachers need to plan lessons that allows all students access regardless of a student's cultural background and/or language strengths.

Discussion

Our study supported that PSTs generally have issues of cultural discontinuity when they consider their own mathematics teaching. In general, our PSTs discussed learning disabilities, inherent ability, learning styles, and motivation. They also discussed that a teacher's role is to be enthusiastic, make mathematics fun, care, foster a safe learning environment, and make mathematics applicable and engaging through context. We learned that, unless explicitly prompted, students do not readily connect phrases such as "all students" or "equitable" to issues of race, gender, culture, language, or socio-economic status. However, our PSTs responses to the quotes indicate some students are thinking deeply and thoughtfully about these topics. However, these ideas of equity in their mathematics classroom do not seem to be deeply embedded into their daily thoughts about teaching and learning.

This study was designed to give us initial insight of our PSTs conceptions of equity in mathematics. This preliminary analysis has confirmed that PSTs need guidance and support in developing these ideas and having them ingrained into their thoughts about the teaching and learning of mathematics.

UNIFYING CURRICULUM INITIATIVES: TWO CAN BECOME ONE

Gale L. Russell
University of Saskatchewan
gale.russell@usask.ca

Egan J. Chernoff
University of Saskatchewan
ejchernoff@usask.ca

In Saskatchewan (a western Canadian province), teachers of mathematics face two major challenges with the implementation of a renewed curricula: the use of teaching and learning approaches based upon constructivist learning theory (CLT), and the infusion of First Nations and Métis (FNM) content, perspectives, and ways of knowing (CPW) into their enactment of the curricula. The teachers are not only being asked to think about the teaching and learning of mathematics differently, but to also find ways to infuse culturally relevant experiences that for most teachers in the province are foreign to their own culture. In this paper, we explore these two challenges facing the province's teachers by analyzing them through the theoretical lenses of two different worldviews, the traditional Western worldview and an Indigenous worldview, leading us to a proposal for how these two challenges might be addressed through one solution.

Keywords: Curriculum; Equity and Diversity; Teacher Beliefs; Learning Theory

In 2006, Saskatchewan began renewing its mathematics curricula. During the renewal process, two initiatives emerged as primary foci: the use of teaching and learning strategies based upon constructivist learning theory (CLT), and the infusion of First Nations and Métis (FNM) content, perspectives and ways of knowing (CPW) into the mathematics classroom. As the renewed curricula started to move from development to implementation, concerns were expressed about the magnitude of the challenge presented by these two initiatives for the province's mathematics teachers. At the same time, many people working on this project expressed the unsubstantiated "gut feeling" that if teachers embrace one of the two initiatives, the second could naturally occur. In this paper, we present a theoretical analysis that has led us to a justification for this "gut feeling" and to the identification of such a connection.

Literature Review

Infusing FNM Content, Perspectives and Ways of Knowing

For more than two decades, policies and action plans have been implemented with the aim to make the educational system more accessible and more responsive to FNM students and communities. One of the factors driving to these actions was the under representation of FNM students in high school science and mathematics classes which "leads to economic, resource management and sovereignty problems for First Nations, Inuit, Métis communities…; and this under representation defines an ethical problem of equity and social justice for the rest of Canada" (Aikenhead, 2006, p. 387). The under representation of FNM students in high school mathematics courses continues to be a concern within Saskatchewan as the percent of FNM students attaining Math 20 (giving them the grade 11 mathematics credit required for graduation) is well below that of their non-Aboriginal counterparts (Saskatchewan Ministry of Education, 2009b). Moreover, the final grades attained by the FNM students who do take Math 20 are consistently and significantly lower than their non-FNM counterparts (Saskatchewan Ministry of Education, 2010). These statistics significantly contributed to the move to infuse all new curricula with FNM CPW, ultimately bringing the renewal of the mathematics curricula into the arenas of ethnomathematics and culturally responsive mathematics education research.

Ethnomathematics research is concerned with the mathematical thinking and doing (including the teaching and learning of it) within cultures, the history and politics of the mathematics used and taught in schools around the world, and the interplay between the two. Researchers in the field of ethnomathematics, such as M. Ascher, U. D'Ambrosio, M. Frankenstein, and A. B. Powell, have demonstrated repeatedly that mathematics is a culturally defined artifact of human life, and that the mathematics taught in schools today is culturally biased. Non-ethnomathematicians who encounter different ways of thinking and doing mathematics, argue that the people and cultures performing these "acts" are not doing "real" mathematics (D'Ambrosio, 1997; Powell & Frankenstein, 1997). Emerging from ethnomathematic's rejection of this deficiency model of viewing other mathematics has led to research into culturally responsive mathematics education in which the findings of the ethnomathematics community are brought to bear within mathematics classrooms.

Constructivist Learning Theory

Within Saskatchewan's renewed curricula, the following statements form the basis of the expectations for the strategies used in the teaching and learning of mathematics: "Any learning in mathematics that is a result of the logical structure of mathematics can and should be constructed by students" (Saskatchewan Ministry of Education, 2009a, p. 15), and the inquiry approach, which is to be foundational in the teaching and learning of all subjects, "is a philosophical approach to teaching and learning, grounded in constructivist research and methods" (p. 23). The notion of students constructing their own mathematical understandings, and the research about teaching and learning strategies and approaches to achieving such construction, fall within the field of constructivist learning theory.

Constructivist learning theory emerged from the work of two researchers: Jean Piaget and Lev Vygotsky. Although the two researchers varied in how they believed children moved from one stage of learning to another, both based their work on the idea that, as humans, we generate our own knowledge through the interaction of our experiences and ideas. Out of Vygotsky's social and Piaget's cognitive constructivist learning theories, CLT strategies for supporting learners in the gaining of new knowledge have been emerging within research. These strategies vary from broad approaches to learning, such as inquiry and teaching through problem solving, to more specific methods, such as the use of children's literature, multiple representations, group discussions and the creating of open learning environments and experiences that allow students to enter into a dialogue and learn in ways that honour their past experiences and knowledges.

Theoretical Lenses

One's worldview, the overall schema through which one views and lives in the world, informs how one approaches all aspects of life, including mathematics and the teaching and learning of mathematics. We now consider two significantly different worldviews, or lenses: the traditional Western worldview and an Indigenous worldview.

The Traditional Western Worldview

The traditional Western worldview (TWW) is the foundation of Western society's knowledge, systems, and ways of being. Within this worldview, what knowledge and ways of knowing are of value corresponds to the following characteristics: knowledge is linear, singular, static and objective in nature, resulting in one correct answer and one right way of achieving it; specialization is an indication of greater knowledge; knowledge is gained through the Scientific method; measurability is essential to ascertain the truth; knowledge relates to physical objects and processes that are external to the individual; compartmentalization, isolation and categorization of knowledge is necessary for true understanding; and knowledge must be captured in written form in order for the truth of it to be maintained (Kovach, 2009; Little Bear, 2000).

An Indigenous Worldview

Although there is no one Indigenous worldview (IW), as each Indigenous group has fundamental differences from each other (Kovach, 2009; Little Bear, 2000), there are common characteristics across Indigenous groups that allow for the presentation of an overarching and broad Indigenous worldview. An Indigenous worldview holds that: knowledge is meaningful in terms of the place in which and for which it is attained; knowledge emerges through relationships (physical, social, emotional, and intellectual)—to people and to the physical and spiritual world (and beyond); knowledge is subjective (as well as objective) in nature; diversity in ways of knowing and of knowledge are valued and the individual is valued for what they contribute to the group; observation, personal experience and intuition are valid sources of knowledge; knowledge should be sought and gained in order to give back to the greater whole; and, truth can be captured and kept within oral language (Kovach, 2009; Little Bear, 2000).

Analysis

Infusion of FNM CPW Through the "Eyes" of the TWW and an IW

The infusion of FNM CPW into the teaching and learning of mathematics would necessarily imply that there are alternative approaches, even alternative answers, to mathematical questions and inclusion of contexts. Such an attempt would necessarily come in conflict with the notions of the singularity, objectivity, abstract and static nature of knowledge, which are valued characteristics of knowledge within the TWW. For a teacher grounded in TWW, the infusion of FNM CPW would at best seem a waste of time, and at worst a corruption of mathematics.

Inherent within an IW is the acceptance of diversity in the ways of knowing and in knowledge, the valuing of the place of the knowledge, and the direct connection between knowledge and relationships. In these ways, among others, a teacher grounded within an IW would not only see the importance of the infusion of FNM CPW, but would naturally seek the inclusion of any CPW that would honour the diversity of their students' cultures, experiences, and individuality.

CLT Strategies Through the "Eyes" of the TWW and an IW

For a teacher grounded in the TWW, alternate approaches to the teaching and learning of mathematics, such as CLT strategies, would seem frivolous, even contradictory, to how they know knowledge is and how it can be attained. Within the TWW, having children attempt to construct knowledge would be a waste of time, since knowledge is imparted from those who are already specialists. Thus, the very foundation of CLT strategies (students constructing knowledge rather than receiving it) cannot be fit into the TWW. As a result, teachers grounded in this worldview would not readily engage in the use of CLT strategies.

Being based in the belief in an individual's ability to construct knowledge, the CLT strategies endorse the IW valuing of the diversity of knowledge and ways of knowing. In addition, the CLT strategies focus on starting where the student is, the place of their knowledge, another parallel to an IW. Although an IW does not explicitly seek abstract knowledge, it also does not deny the possibility of such knowledge, moreover, it supports the connection of such knowledge to the place and relationships used in creating it.

Discussion

Based upon our (albeit brief) analysis, we now draw two conclusions: that there is a connection between the two curricular initiatives challenging teachers of mathematics in Saskatchewan and that the two initiatives become one through a change in worldview. Through the lens of an IW, the infusion of FNM CPW and the use of CLT strategies are intrinsically connected. From this perspective, one can see that the foundational beliefs for both initiatives are, in fact, the same. In both cases, the teaching and learning of mathematics is based upon the knowledge and ways of knowing that the students bring to the classroom and not upon pre-described steps and procedures. As well, both initiatives value the differences brought to the table by all individuals in the learning process. Finally, both approaches to the teaching and learning of mathematics are based upon context, place, and meaning for the learner.

On the other hand, both the use of CLT strategies and the infusion of FNM CPW are in contradiction to, or, at best, irrelevant within the TWW. The foundational beliefs of the TWW, in particular that knowledge of value is linear, static, objective, abstract, compartmentalized, and singular, all conflict with both of the curricular initiatives.

It would not be a far leap for one to conclude that when grounded in an IW, the teaching and learning of mathematics would be open to the use of CLT strategies as well as the infusion of FNM CPW. Alternatively, one can easily conclude that when grounded in the TWW, neither initiative is likely to be successfully engaged in. As a result, we contend that by grounding the teaching and learning of mathematics within an IW, the two curricular initiatives become one—that of embracing a different worldview. Moreover, we refer to this approach to the teaching and learning of mathematics as the *transreform approach*—an approach that not only reforms how mathematics is taught, but what is valued and acknowledged within a mathematics classroom. Finally, the transreform approach to the teaching and learning of mathematics is not just possible and desirable for FNM students and their teachers, rather such an approach would be supportive of all students, regardless of their ethnic, cultural, or experiential backgrounds.

Acknowledgments

Although we present these ideas for the first time in written (academic) form, there are unrecognized giants whose shoulders have given us the vantage point we have used—the ancestors of the Indigenous peoples, who over the millennia have created, refined, and shared openly their Indigenous worldviews. We hope that in doing this research and writing, we might begin to give back and contribute to the ongoing efforts of decolonization.

TEXT RELEVANCE AND LEARNING FROM UNDERGRADUATE MATHEMATICS TEXTBOOKS

Annie Selden
New Mexico State University
aselden@math.nmsu.edu

Mary Shepherd
Northwest Missouri State University
msheprd@nwmissouri.edu

We consider the role of text relevance in formulating an explanation for why undergraduate students do not read large parts of their beginning mathematics textbooks. In a previous paper (Shepherd, Selden, & Selden, in press), we asked why it is that good readers, who were also good at mathematics, did not read large parts of their beginning mathematics textbooks ***effectively****, that is, why they could not work straightforward tasks based directly on that reading. Here, we reanalyze that data in terms of text relevance to consider the role that students' personal implicit or explicit goals may play.*

Keywords: Post-Secondary Education; Instructional Activities and Practices; Curriculum

Introduction

The concept of text relevance has been proposed by reading researchers because readers "need literacy skills beyond those required for the comprehension of simple texts; they need to be able to identify, understand, and integrate ideas within and across documents." *Text relevance* refers to "the instrumental value of text information for enabling a reader to meet a reading goal" (McCrudden, Magliano, & Schraw, 2011, p. 2).

Only a little research seems to have been done on how students read their mathematics textbooks, but having to read one's mathematics textbook is an important and difficult transition to learning mathematics independently in college. Osterholm (2008) surveyed 199 articles on the reading of word problems, but found little about reading comprehension of more general mathematical text and did not consider text relevance. Weinberg and Weisner (2010) have introduced a framework for examining students' reading of their mathematics textbooks. While we see this framework as proving a useful perspective, in our previous research (Shepherd, Selden, & Selden, in press) we took a different perspective and considered whether, and how, students construct meanings very close to those of the author and mathematical community.

Research Question

A consideration of text relevance and individual goals rather naturally brings up the question: What are the reading goals of typical undergraduate students when reading their beginning mathematics textbooks? We considered this question somewhat indirectly in a previous study (Shepherd, Selden, & Selden, in press). In that paper, we asked why it was that good readers, who were also good mathematics students, did not read large parts of their mathematics textbooks *effectively*, that is, why they could not work straightforward tasks based on that reading. We now reconsider our data in terms of text relevance. In particular, we ask: What does the concept of text relevance have to offer in terms of explanatory power when analyzing why university students do not read their beginning mathematics textbooks effectively?

Our Previous Research on Students' Reading

Eleven volunteer precalculus and calculus students, who attended a U.S. Midwestern comprehensive state university, were interviewed. According to their ACT reading comprehension and mathematics scores, as well as according to their mathematics instructor, they were good at both reading and mathematics.

The interviewees each read aloud a new section of their respective textbooks, one selected by their instructor. These passages were selected because the students would be familiar with the notations and prior definitions used and because the students were judged to have the necessary prerequisites for reading them. The precalculus students read about "The Wrapping Function" from Barnett, Ziegler, and Byleen

(2000, pp. 336–343). The calculus students read about “Extrema on an Interval” in Larson, Hostetler, and Edwards (2002, pp. 160–164). Along with definitions, theorems, examples, figures, and discussions, the precalculus book had “Explore/Discuss” tasks and the calculus book had “Exploration” tasks to encourage students to become active as they read.

The interviewees were stopped at intervals during their reading and asked to try a task based on what they had just read, or asked to try to work a textbook example (task) without first looking at the provided solution. These were the places that the textbook authors would probably have assumed readers would independently pause for such activities. The tasks were straightforward ones based directly on the reading and required very little in the way of problem-solving skills. They were what might be called “routine exercises.” After the entire section had been read and a few final tasks were attempted, the students were questioned about how reading during the interview differed from their normal reading of their mathematics textbooks. For further details, see Shepherd, Selden, and Selden (in press).

All of the students in our study had considerable difficulty correctly completing some of the straightforward tasks based on their reading. The percent of tasks done correctly by individual students ranged from 13% to 76%. The students had trouble reading and understanding definitions and using theorems. All read the expository parts of the textbook since that was part of the interview, but upon questioning at the end, some students viewed exposition as of minor importance—something often to be skipped or skimmed. The students stated that they normally wanted to concentrate on exercises (tasks) and find similar worked examples in their textbook.

In our previous paper, we drew on the psychology literature on “zoning out” during reading (e.g., Smallwood, Fishman, & Schooler, 2007) to suggest that *cognitive gaps*, that is, periods of lapsed or diminished focus, during reading may explain some of our students’ ineffective reading. In this paper, we reexamine our data in terms of text relevance to consider whether our students’ reading behavior, may have been greatly influenced by their personal implicit or explicit goals.

Concepts of Text Relevance

There are a number of concepts that text relevance researchers have considered: goals, working memory capacity, standards of coherence, and academic purpose. We will consider these, in turn, to see how they might apply to our data on undergraduates’ reading of their precalculus and calculus textbooks in an interview setting.

Goals

Reading in instructional settings is often task-induced, and readers’ goals may affect their inferential processes while reading. Tasks can impact “how people judge information’s relevance to their goals and the strategies that they enact to meet their goals.” Readers’ goals can also affect their online processing (e.g., their strategy use and their attention allocation) as well as their offline products (e.g., their learning from, and memory of, the text) (McCrudden, Magliano, & Schraw, 2011, pp. 3 -4).

In addition, reading goals are the outcome of a complex interaction between external intentions and personal intentions. “Specific relevance instructions [can] prompt readers to focus on discrete text segments … whereas general relevance instructions [can] prompt readers to read for a general purpose (e.g., to read for study).” Also, because people have limited working memory capacity, they will devote more resources to relevant stimuli and fewer resources to less relevant stimuli. Skilled readers “can achieve optimal cognitive efficiency by formulating reading goals and developing criteria for determining information’s relevance to those goals.”

The above ideas naturally bring up the following potential research question: In reading their mathematics textbooks, do students attempt to achieve optimal cognitive efficiency by looking for sample worked problems to mimic, rather than by first reading the entire section? We do not have an answer to this question, but one of our students’ proffered comments is suggestive. Zoe said, “Usually I will read in between if it looks like it’s important, but if it just looks like it’s fluff, or explaining it, and I already understood it—like, I understood the definition pretty well [referring to her reading during the interview] so maybe I wouldn’t have read. ...”

This comment, and similar ones, seem to indicate that our students did not consider it worthwhile to read the entire section before attempting their homework exercises, especially the exposition at the beginning, if having them complete the exercises correctly was the instructor's goal (as perceived by the students), and they wanted to complete their homework assignments as quickly and completely as possible in order to get good grades.

Working Memory Capacity

It has been shown that "a reader's working memory capacity (WMC) affects online processing when they read for different purposes. …" Furthermore, working memory resources are important because they also allow the reader to integrate ideas across sentences, a process that involves the maintenance of previously translated [i.e., comprehended] text as attention is focused on new information that must be processed" (Linderholm, Kwon, & Wang, 2011, p. 201). Although we had information on our students' ACT reading comprehension and mathematics scores, we did not have information on their working memory capacities as measured by the reading span task (RST) (Daneman & Hannon, 2007), so it is possible that knowledge of their working memory capacities might have given us some additional insights.

Standards of Coherence

Standards of coherence refers to the types and strength of coherence that an individual reader aims to maintain during reading. These can be implicit or explicit and reflect that individual's desired level of understanding for a particular reading situation, and influence "the dynamic pattern of automatic and strategic cognitive processes that take place during reading. They [standards of coherence] are influenced by various aspects of the reader, the text, and the task" (van den Bock, Bohn-Goettler, Kenedou, Carlson, & White, 2011, p. 125).

Characteristics of the text include the "specific content of the text, the order in which the content is presented, gaps in the semantic flow, layout, [and] the presence of text signals such as titles and italics" (van den Bock et al., 2011, p. 125). We did not question our students about why they normally read their textbooks as they did, but one calculus student volunteered that the textbook was not "clear" and another referred to parts of the calculus textbook as "jibberish."

Characteristics of the reader include working memory capacity (discussed briefly above), and inadequate or insufficient prior knowledge (discussed in our previous paper). Readers can adopt standards of coherence that are incomplete, but adequate (in the eyes of the reader). They "at times may pursue less-than-maximal coherence. … Such 'good-enough' processing is not necessarily a matter of laziness but may be a matter of efficiency" (van den Bock et al., 2011, pp. 128–129).

Because they were asked to do so, our students read parts of the textbook, such as the exposition, that they said they would not normally have read. Winnie, one of the calculus students, commented in her final debrief, "I don't think it's [the textbook/author] clear a lot of times like, I don't know. It helps me if I see an actual [worked] example [like the homework exercise] that we're actually going to be working on."

We conjecture that our students did not have adequate standards of coherence, as their goal in the course was, very likely, to complete the homework exercises as quickly as possible.

Academic Purpose

Some reading researchers consider both academic purpose and goals, and view purpose as overall goals for reading, such as the one that our students probably had, namely to fulfill a requirement and to get a good grade, whereas specific reading goals are seen as being more relevant to the task at hand. For our students, that seems to have been to complete the assigned homework exercises as quickly and efficiently as possible. As Tara said in her final debrief interview, "I don't usually get the reading done before class, because I'm trying to do homework from the day before." In general, "Given the clear impact of reading purpose on reading process, reading purpose instruction should be included in the curriculum of those reading for academic purposes" (Linderholm, Kwon, & Wang, 2011, p. 219). However, given that the instructor of our precalculus and calculus students had provided our students some carefully considered instruction in the reading of their textbooks (Shepherd, 2005), this is no straightforward task.

Concluding Remarks

The ineffective reading we observed in our students had to do with *not* being able to consistently correctly work straightforward tasks, immediately after reading how to work them. It could be that our students were simply not accustomed to reading their textbooks in order to find out how to work tasks, but rather depended greatly on their instructor to illustrate such methods during class. Or perhaps a lack of self-efficacy led them to believe reworking tasks would not produce new results.

WHAT'S THE DIFFERENCE BETWEEN DOUBLING AND SQUARING?: INVESTIGATING STUDENTS' DEVELOPMENT OF POWER MEANINGS OF MULTIPLICATION

Erik S. Tillema
Indiana University Purdue University Indianapolis
etillema@iupui.edu

This paper reports on a clinical interview study conducted with 14 sixth grade students. During the study students were presented with Cartesian product, arrangement, and combination problems. The purpose of using these combinatorics problems was to investigate in what ways such problems could support students' development of a meaning for raising a quantity to a whole number power—a power meaning of multiplication. Two results of the study were: (1) a framework for investigating students' multiplicative reasoning in contexts that can potentially support their development of a power meaning of multiplication; and (2) a comparison of explanatory constructs necessary to explain students' multiplicative reasoning in contexts that can potentially support a linear operator meaning of multiplication and contexts that can potentially support a power meaning of multiplication.

Keywords: Cognition; Middle School Education; Number Concepts and Operation

Students commonly confuse a linear operator meaning of multiplication (i.e., doubling, tripling, etc.) and a meaning for multiplication that involves raising a quantity to a whole number power (i.e., squaring, cubing, etc.)—a power meaning of multiplication (Van Dooren, De Bock, Janssens, & Verschaffel, 2008). This confusion has been expressed in researchers' findings in a range of ways: as students "errors" when working with algebraic symbols like overusing squaring in notation to express doubling or tripling (MacGregor & Stacey, 1997) and concluding that "$(x + y)^2 = 2x + 2y$" or that "$(x + y)^2 = x^2 + y^2$" (Matz, 1982); and as students difficulty in differentiating linear and square units like confusing perimeter and area (Simon & Blume, 1994).

Despite the well documented difficulties that students experience with a power meaning of multiplication, K–8 curricula overwhelmingly contain problems that are aimed at supporting students' development of a linear operator meaning of multiplication (Confrey, 1994; Van Dooren, De Bock, Janssens, & Verschaffel, 2008); often one of the first times students experience problems that have the potential to involve a power meaning of multiplication is when they take their first algebra course where curricula include solving quadratic equations and reasoning about quadratic functions. This trend in curricula along with the findings outlined above raise the following questions:

(1) What is the relationship between students' development of a linear operator meaning of multiplication and a power meaning of multiplication?
(2) Does helping students develop a strong linear operator meaning of multiplication support their subsequent development of a power meaning of multiplication? If so, how?
(3) Do students need problems or experiences that are not emphasized in current curricula to develop a power meaning of multiplication?

Responding to these questions has the potential to profoundly impact the way that K–8 curricula are structured (Confrey, 1994), and to inform current discussions among researchers about what kinds of experiences students need prior to taking algebra courses in order to be successful in them (e.g., Kaput, Blanton, & Moreno, 2008). The purpose of this paper is to respond to these questions by outlining a framework that establishes how students' multiplicative reasoning differs in contexts that have the potential to support their development of a linear operator meaning of multiplication and contexts that have the potential to support their development of a power meaning of multiplication.

Two Meanings of Multiplication

One common problem that K–8 curricula use to help students' develop a linear operator meaning of multiplication—a meaning where one quantity acts or operates on the other—are equal groups problems like the Donut Problem.

> *The Donut Problem:* There are 4 packages of donuts. Each package has 6 donuts. How many donuts are there total?

The reason these problems have the potential to support students' development of a linear operator meaning of multiplication is because they can involve students in creating composite units and repeating these composite units to determine the total number of donuts (Steffe, 1992, 1994). In doing so, a student treats the quantities in the problem asymmetrically—one quantity acts or operates on the other.

In contrast to equal groups problems, researchers have identified that combinatorics problems like the Outfits Problem have the potential to support students' development of a power meaning of multiplication (Behr, Harel, Post, & Lesh, 1994; Confrey, 1994; Vergnaud, 1983).

> *The Outfits Problem:* There are 4 shirts and 3 pants. An outfit is 1 shirt and 1 pants. How many possible outfits can you make?

One reason that problems like the Outfits Problem can support students' development of a power meaning of multiplication is that in the statement of the problem the two quantities (shirts and pants) are symmetric—one quantity is not explicitly identified as the quantity that acts or operates on the other. A second reason that problems like the Outfits Problem can support students' development of a power meaning of multiplication is the outfits can be created from pairing one shirt with one pants. Pairing one shirt with one pants to create an outfit means that the outfits are a unit that contains two units, but they are counted as a single unit (Vergnaud, 1983). The formation of this type of unit contrasts with the units, donuts, which are counted as one in a problem like the Donut Problem. In fact, the formation of outfits can be symbolized as $1 \times 1 = 1$ (i.e., one squared equals one).

In order to investigate the difference between students' linear operator meanings of multiplication and power meanings of multiplication, I conducted an interview study with 14 sixth grade students. The interview study consisted of three interviews. The first interview was a selection interview whose purpose was to identify which of three multiplicative concepts students used to solve problems that I deemed were likely to support their understanding of a linear operator meaning of multiplication. The goal of the second and third interviews was to make models of the students' multiplicative reasoning in combinatorial contexts in order to identify whether and how the students created different units in these contexts. In the next section I outline the framework that I used to identify the multiplicative concepts that the students were using in the selection interview.

Conceptual Framework

Schemes

A *scheme* has three parts—an assimilatory mechanism, an activity, and a result (von Glasersfeld, 1995). The assimilatory mechanism involves a person in making an interpretation of a problem. The assimilatory mechanism triggers the activity of a scheme, in which a person carries out mental operations on physical or mental material or both. The activity, then, produces a result. When a person can use the result of a scheme in assimilation of a future problem without carrying out the activity that produces it, the person has *interiorized* the scheme and constructed a *concept* (von Glasersfeld, 1995).

Framework for multiplicative reasoning. Steffe (1992, 1994) has identified two mental operations—iteration and units coordination—that are central to the schemes that students' construct in their solutions of equal groups multiplication problems. *Iteration* involves the repetition of a unit and *units coordination* involves the insertion of units within units. He has used differences in how students use these two mental operations to identify three qualitatively distinct multiplicative concepts that students construct.

Students who use the first multiplicative concept (MC1) to solve equal groups problems like the Donut Problem by iterating a unit of one six times and inserting these six units into a containing unit to create a unit of six units in activity (i.e., one package of six donuts). They would continue with this activity, iterating six more units of one and inserting these six units into a containing unit to create another unit of six units in activity, as they continue to solve the problem. One behavioral indicator that a student is engaged in this activity is that they coordinate two counts as part of their solution of an equal groups problem. So a student could count: one, two, three, four, five, six that is one package; seven, eight, nine, ten, eleven, twelve that is two packages, etc.

Students who use the second multiplicative concept (MC2) to solve equal groups problems have interiorized the activity just described. Therefore, they can assimilate equal groups problems using a unit of units structure and operate on this structure as part of their solution of a problem. This means that to solve a problem like the Donut Problem they are likely to iterate a unit of six units four times, and as they iterate a unit of units structure they are likely to use strategic reasoning to combine the sixes together. For example, these students can reason that six and six is twelve because six and four is ten and two more is twelve. In doing so, they reasoned that the second unit of six units was composed of a unit of four units and a unit of two units, and used this to strategically combine it with the first unit of six units. To finish solving this problem, they are likely to continue this type of strategic reasoning to determine that the result of the problem is twenty-four. At this point, these students can insert the four units of six units into a containing unit to create a unit of four units of six units in activity.

Students who use the third multiplicative concept (MC3) to solve equal groups problem have interiorized the activity just described. Therefore, they can assimilate equal groups problems using a unit of units of units structure and they can operate on this structure as part of their solution of a problem. Because these students have interiorized a unit of units of units structure, they no longer have to engage in iteration or units coordination to solve equal groups problems. Instead they can solve an extension of the Donut Problem that involves twelve packages of six donuts by reasoning that ten packages of six donuts is sixty donuts and two packages of six donuts is twelve donuts so there are a total of seventy two donuts. In solving the problem in this way, they reasoned that a unit of 12 units of 6 units is composed of a unit of 10 units of 6 units and a unit of 2 units of 6 units, evaluated each of these structures using multiplication, and combined the result of each multiplication problem to get 72 donuts.

Methods and Methodology

The study was conducted at an urban middle school in partnership with a sixth grade teacher. The research team, which consisted of three researchers, spent the first three months of the school year observing and co-teaching with the sixth grade teacher in her regular classroom. The purpose of these activities was twofold: (1) to make an initial determination about which of the three multiplicative concepts students were using; and (2) to build trust between the research team and the students who were potential subjects of the interview study. At the end of the three-month period 14 students agreed to participate in the interview study. 11 of these students were African American, 2 were Hispanic, and 1 was Caucasian, 5 were boys, and 9 were girls. This demographic breakdown was representative of the demographic breakdown of the entire sixth grade population as well as the population of the school.

The interview study consisted of a sequence of three interviews. Students were interviewed individually in order "to collect and analyze data on mental processes at the level of a subject's authentic ideas and meanings" (Clement, 2000, p. 547). The first interview was a 45-minute non-video recorded selection interview, which was used to identify which of the three multiplicative concepts the students were using; 3 students were identified as using the first multiplicative concept, 6 were identified as using the second multiplicative concept, and 5 were identified as using the third multiplicative concept.

The second and third interviews were 45-minute video recorded interviews. The second and third interview protocols consisted of a sequence of increasingly difficult combinatorics problems, which included Cartesian product, arrangement, and combination problems. The initial findings from the study will be discussed as part of the presentation.

ALGEBRAIC REASONING THROUGH COMBINATIONS AND PATTERNS: BILINGUAL LATINAS "EXPERIENCING" MATHEMATICS

Zayoni N. Torres
University of Illinois at Chicago
ztorre4@uic.edu

Research on gender and mathematics has often compared female and male students' attitudes, performance, achievement, and confidence levels. Although more recent research has moved beyond this dichotomy to explore how female students experience mathematics, it often places race, class, and nationality as secondary to gender subordination. This paper sets out to explore how group interactions, within the context of an afterschool mathematics club, mediate the way bilingual Latinas engage in and experience mathematics. Qualitative analysis of transcripts reveal, in same gendered groups (a) equal participation status when multiple languages and strategies are privileged; (b) exclusion of particular students when one language resource and certain strategies are privileged; and (c) the facilitators key role in shaping these interactions.

Keywords: Equity and Diversity; Gender; Algebra and Algebraic Thinking

Gender and Mathematics

Much of feminist analysis places race, class, and [nationality] as secondary to gender subordination (Wolf, 1996). Within the U.S., few studies explore the power relations of gender with race, class, and language around mathematical meaning making. Much of what we do know about gender and mathematics results from research comparing female and male students' overt behaviors such as answers on a mathematics test, items on a confidence scale, student-teacher interactions, or students' career decisions (Fennema, 1996). Although providing rich information, this approach is limited. Highlighting differences can be taken to be concluding that females are less able in mathematics (Fennema and Hart, 1994), mark males as "the standard" against which females are measured, can lead to programs seeking to fix perceived "deficits" (Kaiser & Rogers, 1995), and fail to recognize existing disparities within these gendered groups. More recent research investigates how females construct mathematical knowledge and experience mathematics (Fennema, 1996). This is consistent with a feminist perspective in mathematics education, which entails the question "how do women experience mathematics?" be addressed (Damarin, 1995); where the mathematics content itself takes a peripheral role. Viewing mathematics learning as a socially constructed process and recognizing that students tend to voluntarily work in same gendered groups, this paper sets out to explore how group interactions, in an afterschool context, around activities developing algebraic thinking through combinations and patterns, mediate the way bilingual Latina's experience mathematics.

Theoretical Framework

Through a sociocultural framework and perspectives from feminist standpoint theory and the politics and epistemology of location, this study examines combining sociopolitical factors influencing students' 'experiencing' of mathematics. Sociocultural theory suggests that development is mediated through social interaction, where language and dialogue are central to ones overall development (Vygotsky, 1986). This was an important aspect of the afterschool program, as participants collectively engaged in meaningful activities while learning higher-level mathematics (Khisty, 2004). Feminist standpoint theory suggests the existence of subjectivity through agency and authorship (the 'who' and 'what' of mathematical learning) (Burton, 1999), where females' voices, mathematical and nonmathematical experiences, and unique perspectives are valued (Fennema, 1996). My, as researcher, "locationality (historical, national, generational)" and "positionality (race, gender, class, nationality)" and the acknowledgment of how "the dynamics of where we are always affects our viewpoint and the production of knowledge" (Wolf, 1996,

p. 14), is informed through the "politics and epistemology of location" (Haraway, 1991). These perspectives inform my viewpoint on teaching and learning, informed by various positionalities and the process of reflexivity.

Los Rayos de CEMELA

An afterschool mathematics club, Los Rayos, was developed as part of the Center for the Mathematics Education of Latinos/as (CEMELA) at the University of Illinois at Chicago and in partnership with a Chicago public elementary school located in a working class and predominantly Mexican/Mexican-American neighborhood (Khisty, 2004). Los Rayos, an adaptation of The Fifth Dimension (Cole, 2006) and La Clase Mágica (Vásquez, 2003), took a dual-language (Spanish-English) approach to its non-remedial curriculum (e.g., pre-algebra, probability, and proportional reasoning). Over a three-year period, mainly one volunteer cohort of Latina/o students participated from 3rd to 6th grade. Approximately 14–20 Latina/o students participated, with a fairly equal number of females and males. Sessions ran twice a week for ninety minutes each session, where students had the autonomy to choose a group to work with, a mathematical task to work on, and the language(s) to work in.

Methods and Data Analysis

I focus on groups of female students (9 females total) and facilitators, ranging from combinations of 2 students and 1 facilitator to 4 students and 1 facilitator. All identify as bilingual (Spanish-English). Primary data consist of videotapes of individual interviews and student participation. Secondary data consist of student work and facilitator's field notes. The research methodology of critical ethnography, an in-depth study of a cultural group, where education is seen as political in nature (Trueba, 1999), supports the investigation of multiple aspects of student identity, including language use, in generating mathematical understanding. Focus is placed on dialogue and language use since in feminist research, language, as competing ways of giving meaning, is the place where subjectivity is constructed (Richardson, 2000). This resulted in 5 episodes of group interactions around tasks developing algebraic thinking using combinations and patterns ranging in time of 33 minutes to 94 minutes. These were informed by student interviews and student work (valuing these students' voices), and facilitator's field notes. Transcripts were coded for shifts in student participation, language use (Spanish, English, or both), and under what conditions (when, how, and how often) allowed for optimal student participation and use of multiple language resources.

Findings

Qualitative analysis of transcripts reveal (a) equal participation status in same gendered groups when multiple languages and strategies are privileged; (b) exclusion of particular students in same gendered groups when only one language resource and certain strategies are privileged; and (c) the facilitator's key role in shaping these interactions.

Equal Participation Status

The dynamic of same gendered groups often led to rich interactions and the equal participation of all group members. Here the facilitator acknowledged, valued, and built off of students' language resources and mathematical strategies. An example is when Cara, Miriam, Karmen, and Neyreda were working on a task: I know that you want to give your mother a floral gift (for Mother's Day) and you have $20 to spend. What flowers would you buy? [Priced: roses $2.50; margaritas $0.29; tulips $0.45; and basket $1.29] How many different combinations can you make with $20? Students' positionalities (gendered practices, class, and nationality) were key and allowed for familiarity with Mother's Day, flower arrangements, and $20 as a suitable price for an arrangement at the local floral store.

Cara: I already have five dollars.
Facilitator: Okay put more.

Karmen: Okay I want three of these…no, five of these, seven of these.
Facilitator: Good. [As she watches what Karmen is jotting down]…
Neyreda: Can I just spend this much?
Facilitator: No you have to do more…. *How much more do you need Neyreda?*
Neyreda: I don't know.
Facilitator: Let me see. [Picks up her paper to see strategy used]
Miriam: I have fifty-seven dollars and three cents!
Facilitator: How much?
Miriam: Fifty-seven dollars and three cents! *I bought three of each one…*
Facilitator: Look Karmen this is what you have right now: nineteen with nine.
Miriam: You can buy, you can buy one of each: nineteen zero nine plus each one.

Cara, Karmen, Neyreda, and Miriam devised individual and shared strategies (starting with a combination of flowers (using addition and multiplication); adding flowers to the combination; and applying subtraction strategies as needed [see English, 2003])—while using both Spanish (as shown italicized) and English. The facilitator drew on each student's strategy by asking for an explanation, clarification, or to see each student's work. The facilitator then valued and capitalized on individual strategies through appraisal words (Good) and on each student's language resource by using a similar language as students addressed her. This resulted in socially constructed algebraic reasoning where students' different combination outcomes were within cents of the $20 limit (Cara: $19.80; Karmen: $19.99; Neyreda: $19.94; and Miriam: $19.60).

Exclusion of Students

When the facilitator did not capitalize on all students' language resources and problem solving strategies, it led to the partial or full exclusion of certain students. An example is when Yolanda, Cara, Karmen, and Neyreda were working on a task: Juanita has pennies, nickels, and dimes in her purse. She has eight coins altogether, including more dimes than nickels, more nickels than pennies, and fewer pennies than nickels. What are the two different amounts of money she could have? Students' positionalities (gender, race, and national) were key and allowed for connecting with Juanita (in task) and being able to identify U.S. coins.

Yolanda: So it looks like she has more dimes than anything.
Facilitator: Yeah she has more dimes and she has eight all together.
Cara: Eight, five plus…
Facilitator: No eight coins, not eight cents. *Eight coins, she has eight coins*. Yes she has eight, so we have to figure out how many dimes…*How many coins of 5 are there, how many coins of 10 are there, so that there are 8 in total and that there are more of 10 than 5 and more of 5 than 1*. More dimes than nickels, more nickels than pennies.
Cara: [Places a number of coins down and then counts] ten, twenty, thirty, forty, forty-five, fifty, fifty-five, fifty-six.
Nadia: What are we doing?
Facilitator: Do you want to read it in Spanish? [looks at Neyreda and Karmen] *Let's read it in Spanish*. Do you need help Yolanda?
Yolanda: No I'm okay I got it.

In this example, Yolanda and Cara quickly got involved with the task. The facilitator solely used English at the beginning of the task, which excluded Karmen (who identifies as a more dominant Spanish speaker). And although, Yolanda was at first engaged, the facilitator was more focused on Cara (acknowledging her strategy and shifting to using mainly Spanish (as shown italicized)). Yolanda (identifying as a more dominant English speaker) became excluded. What resulted was that Yolanda and Karmen, although listening attentively, did not fully participate until another facilitator intervened. By failing to recognize the language resources each student felt most comfortable with and failing to acknowledge these students' strategies, led to the exclusion of students, no collective meaning-making, and loss of valuable student input.

Discussion

The afterschool program promoted bilingualism, higher-level mathematical thinking, and student autonomy through meaningful activities. As students tended to work in same gendered groups, this seemed to have a dual-effect. First, students engaged in rich mathematical meaning making where they collectively constructed mathematical knowledge around the decided tasks. This rich dialogue occurred particularly when the facilitator capitalized on students' language resources and problem solving strategies. On the other hand, even within same gendered groups where females had much to talk about and much in common, particularly with shared gender, race, and class, the differences became evident in terms of language and abilities. When the facilitator failed to use, acknowledge, and capitalize on students' language resources and problem solving strategies, this led to the exclusion from full participation of certain students. This study points to the importance of moving beyond the female-male dichotomy; beyond race, class, and nationality as secondary to gender; and beyond individual students as learners devoid of context. Further research is needed addressing approaches to investigating the complexities involved in gendered groups experiencing mathematics.

Acknowledgments

The preparation of this paper was supported in part by a grant from the National Science Foundation to CEMELA (No. ESI-0424983). The findings and opinions expressed are the authors and do not necessarily reflect the views of the funding agency.

I am grateful to Dr. Lena Licón Khisty for her comments on an earlier draft of this paper and to the reviewers for their suggestions in improving the final paper.

A FRAMEWORK FOR ANALYZING MATHEMATICS LECTURES

Aaron Weinberg
Ithaca College
aweinberg@ithaca.edu

Emilie Wiesner
Ithaca College
ewiesner@ithaca.edu

Timothy Fukawa-Connelly
University of New Hampshire
Tim.FC@unh.edu

Despite efforts to make college classrooms more inquiry-based, typical college students still spend approximately 80% of their time in class listening to lectures (Armbruster, 2000). Consequently, it is important for us to develop an understanding of the opportunities students have for making sense of lectures in upper-level mathematics courses, where the focus is on definitions, proofs and examples. To do this, we propose to view the lecture as a "text" and describe both the aspects of the text and the students' beliefs that affect this sense-making process. This brief research report describes previous work in this area and outlines a framework for analyzing lectures.

Keywords: Instructional Activities and Practices; Post-Secondary Education

Introduction and Research Goals

Despite efforts to make college classrooms more inquiry-based, typical college students still spend approximately 80% of their time in class listening to lectures (Armbruster, 2000). Lecture listening is a difficult cognitive task for college students (Ryan, 2001), but it is important, since what students take away from lectures is closely linked to what they learn (e.g., Titsworth & Kiewra, 1998). In upper-level mathematics classes, where the focus is on definitions, proofs and examples, it is particularly important for us to develop an understanding of the aspects of lectures that shape the ways students are able to make sense of—and learn from—lectures.

The goal of our research is to develop and use a collection of frameworks to describe the various factors that influence and constrain students' opportunities for making sense of mathematics lectures. Specifically, our research questions are to identify:

1. The components of a lecture and how these relate to the instructional goals of the lecture.
2. Students' *observing models*: their beliefs about observing, taking notes during, and learning from lectures
3. The components of the *implied observer* of a lecture, how these components affect students' opportunity to learn, and how they relate to students' own lecture notes

Lecture Components

Lectures contain numerous components that students must attend to and interpret. These components can be broadly distinguished by their mode of presentation: written, spoken, and gestural; following Shein (2012), we further classify gestures as *pointing* (drawing attention to an aspect of the lecture) and *representing* (representing an object, process, or relationship). Beyond these modes, we divide lecture components into *communicational* and *mathematical* aspects.

Communicational aspects of a lecture include organizational cues, immediacy, and temporal-spatial components. Titsworth and Kiewra (1998) defined *organizational cues* as "detailed transition statements and signposts indicating macro- and microelements of lecture organization." We can separate these cues by their *temporal focus*: whether they are organizing transitions from moment-to-moment, from day-to-day, and from unit-to-unit or class-to-class. *Immediacy* refers to instructors' attempts to reduce the social distance between themselves and their students through the use of gesture and tone, use of the first-person plural (e.g., "*we* have noticed…"), and conveying a sense of care and well-being. In addition, instructors may write notes in a non-linear fashion, structuring their board-work to make connections to previous ideas, adding a *temporal-spatial* component to the lecture.

Mathematical aspects of a lecture include facts, procedures/algorithms, and processes. *Facts* include definitions, examples, and results of mathematical theorems. *Procedures and algorithms* include step-by-step methods that students are expected to know or follow. Mathematical *processes* include *problem-solving* (e.g. creating definitions, using definitions, using particular types of proof structures), mathematical *communication*, *representation* (e.g., using diagrams or formal symbols), and *justification* (e.g., conjecture or formal proof structures, such as direct, contradiction, induction, contrapositive, or counting).

Observing Models

We base our framework for observing models on an analogous idea from the literature on reading comprehension. Schraw and Bruning (1999) describe *reading models* as "set[s] of systematic beliefs readers bring to the act of reading that guide their goals and strategies" (p. 283); Weinberg and Wiesner (2011) described how students' reading models can impact the ways they read mathematics textbooks, and Schraw and Bruning (1999) found that particular reading models help students read more productively.

We define *observing models* analogously to the reading models identified by Weinberg and Wiesner (2011): The set of systematic beliefs that students bring to the act of observing a lecture that guides the ways they engage with the lecture. Students who have a *lecturer-centered* observing model believe that the lecture consists of a collection of idea units that they should record and internalize. In contrast, students with an *observer-centered* model believe that they generate a personal meaning through a transaction with the various lecture components (even if this transaction does not involve physical involvement in the lecture).

Many students believe that the only way they can learn from lectures is to take verbatim notes (e.g., Kiewra & Fletcher, 1984; Peper & Mayer, 1986), suggesting the prevalence of lecturer-centered observing models. However, research has suggested taking notes selectively, paraphrasing, and adding personal information—indicators of observer-centered models—leads to improved performance on exams (e.g., Van Meter, Yokoi & Pressley, 1994).

Implied Observers

In contrast to the static nature of a textbook, the temporal nature of mathematics lectures and the myriad components that they incorporate places significant demands on the observer. Weinberg and Wiesner (2011) described the *implied reader* of a mathematics text as the set of behaviors, codes, and competencies needed to engage with the text in a meaningful and accurate way. We build on their definition to define the *implied observer* of a mathematics lecture analogously and construct a framework for describing their behaviors, codes, and competencies.

Behaviors are actions that the implied observer takes. Some of these actions are *physical*, such as paying attention to the instructor and the board-work, or recording enough in notes to learn ideas or reflect on them later. Other actions are *mental*. These include: (a) monitoring your own understanding; (b) identifying "ideas" and "concepts" so they can be reified; (c) recalling examples, proofs, definitions, theorems, or proof structures; (d) noticing abstract structures in exemplars and connecting them to definitions and theorems; (e) recognizing and keeping track of the macro- and micro-structure of the lecture; (f) engaging with ideas in the order they are presented; (g) committing definitions (and other facts) to memory; and (h) being critical and skeptical of claims, as well as making conjectures along with the instructor.

Codes are systems of signification, or ways of ascribing meaning to components of the lecture. Implied observers of lectures use particular codes to interpret various aspects of the lecture. These codes can be classified as *formatting* (e.g. the layout of the board, temporal sequencing, fonts and colors), *symbol use* (e.g., commonly-used mathematical symbols, such as G representing a group), *diagrams* (i.e., understanding the ideas conveyed by various collections of symbols), *vocabulary* (both technical words, such as "abelian," and delimiters that signal the beginning or end of a section or idea), *verbal* codes (e.g., pauses and forms of emphasis), *mathematical grammar* (e.g., use of "we" or "recall"), and interpreting various *gestures*.

Competencies are the knowledge, skills, and understandings that enable the observer to understand and work within the established context. These may be mathematical, such as knowing particular definitions or theorems, or being able to perform specific procedures. These competencies may also relate to physically participating in the lecture, such as being able to write quickly and legibly, summarizing verbal presentations into written form, and instantly recalling the relevant facts, definitions, procedures (etc.) that the lecturer is addressing.

In addition to the more general mathematical and procedural competencies, the implied observer also has specific competencies related to mathematical proofs and their presentations, which play a central role in upper-level mathematics classes. There is relatively little research describing how proofs are actually presented in undergraduate mathematics classes or how students understood these presentations (Mejia-Ramos & Inglis, 2009). To address this, we adapt Mejia-Ramos et al.'s (2010) framework for describing proof comprehension. Their framework includes five main dimensions: (a) the meaning of terms and statements (including the meaning of theorems, of the individual statements, and the meaning of terms); (b) the justification of individual claims; (c) the logical structure; (d) higher-level ideas that provide form and direction; and (e) the general method used by the proofs.

Data Collection and Analytical Methods

We have begun collecting and analyzing data in a pilot study. The data corpus consists of videotaped classroom observations that expert observers have transcribed, notes from student volunteers (which Castello and Monero (2005) describe as "a symbolic mediator between the content taught by the teacher and the knowledge constructed by students" [p. 268]), and interviews with the students. Our analytical focus is on identifying opportunities for learning, which we hypothesize is affected by the degree to which the actual and implied observers coincide as well as the relationship between the structure and components of the lesson and students' observing models.

The classroom observations are designed to capture as much of the "text" of the lecture as possible. This enables us to identify the components and the implied observer of the lecture. We also collect students' notes. The notes, along with the interviews, help us identify observing models. In addition, incongruities between the notes and lecture components help us identify aspects of the implied observer.

For example, the course instructor may rely on various proof heuristics—such as an "onto proof"—and we will describe whether these heuristics are part of the implied reader, whether the students' notes are guided by this heuristic, and whether the students' notes and their interview responses indicate that they possess the underlying codes. In the interviews, students are asked to describe their beliefs about their role in a lecture-based classroom and how they use their notes as learning tools. Before each interview, we identify key excerpts from the lecture (where the instructor attempts to convey a difficult idea, where the board work isn't developed linearly, or where an aspect of the lecture didn't appear in the student's notes), present the corresponding video clips to the student, and ask them how they thought about these components of the lecture.

Summary

In order to understand undergraduate mathematics students' opportunities to learn class material, it is important for us to describe and better understand the constraints and affordances inherent in mathematics lectures and the ways students' beliefs might affect the way they construct meaning from mathematics lectures. In particular, we view students' opportunity to learn mathematics from a lecture as the interface between the implied observer and the actual observer—a student's own behaviors, codes, and competencies, along with the ways they comprehend proofs. Although the framework described here has not yet been subjected to revision based on data analysis, we hope that it provides a valuable theoretical lens for beginning to describe the difficulties students may have making sense of lectures and, by doing so, enable educators find ways to help students engage with and learn from mathematics lectures.

THE RECRUITMENT AND RETENTION OF MATHEMATICS AND COMPUTER SCIENCE MAJORS

Tara Banks
Arkansas State University
tara.banks@smail.astate.edu

Amanda Lambertus
Arkansas State University
alambertus@astate.edu

Statistical data and current surveys show that the number of undergraduates interested and completing degrees in the Science, Technology, Engineering and Mathematics (STEM) fields is rising (National Research Council, 2006). Mathematics courses have been and continue to be gatekeepers to higher education and therefore to achieving STEM degrees (Blickenstaff, 2005). In addition to possibly being underprepared for mathematics and computer science majors, students often portray negative attitudes related to these fields (NRC, 2006). The focus of this study is to explore undergraduate Mathematics and Computer Science departments and the factors that influence the students to choose and complete degrees in these fields. By examining the recruiting and educational practices within these departments and linking those practices to students' perceptions and experiences, this ongoing study reveals successful practices for producing mathematics and computer science majors.

Ten comparable universities were selected to participate, within each university STEM department chairs were contacted through written and electronic communications. Only one university opted to participate, and within that university only 44 mathematics and computer science majors responded. Through the utilization of an online survey, demographic and qualitative data on students' experiences and perceptions were collected. Responses to open ended questions were coded using characteristics based on the Community of Practice framework (Wenger, McDermott, & Snyder, 2002). These characteristics were developed during a study on graduate mathematics departments (Lambertus, 2010). Additional characteristics were developed through open coding and development of content themes (Creswell, 2007).

Students interested in Mathematics and Computer Science highlighted five characteristics of their departments: (1) the University Departments (UDs) provide welcoming and diverse environments for undergraduate student success; (2) UDs provide a variety of structures to support students throughout their academic careers; (3) UDs facilitate opportunities for interaction among members; (4) alumni create opportunities for interaction among students, faculty, and alumni; (5) faculty members create opportunities for interaction among themselves and students and value resulting relationships. As a result UDs should: foster relationships among its members, encourage advisors to be mentors, provide support for success, and involve students in research early in their academic careers.

UNDERSTANDING TEACHING AS ENACTMENTS OF CARE: CASE STUDIES OF AFRICAN-AMERICAN MATHEMATICS TEACHERS OF STUDENTS OF COLOR

Ann R. Edwards
University of Maryland
aedwards@umd.edu

Nancy Tseng
University of Maryland
ntseng@umd.edu

Hollie Young
University of Maryland
hyoung1@umd.edu

This study examines how teachers of color in urban schools socialize their students into being doers and learners of mathematics and how they support students' mathematics identity formation (Martin, 2000). It is a commonly held notion that "knowing" and "connecting with" one's students is critical for supporting their transition into being learners of mathematics. However, the ways mathematics teachers establish strong relationships with their students (particularly for diverse learners) remains less clear. Recent theoretical work by Bartell (2011), integrating theories of care with culturally relevant pedagogy, provides insight in this area. She argues that teachers who *care with awareness* "know their students well mathematically, racially, culturally, and politically" (p. 65) and leverage this knowledge to create substantive learning opportunities. Taking up the theoretical lens of care (Bartell, 2011; Hackenberg, 2010; Noddings, 1984), we build off this work and provide a fine-grained analysis of the practices of two African American high school Algebra teachers, April Lincoln and Floyd Lee, to demonstrate how they supported and engaged their students as mathematical learners.

Data from each teacher include 25 audio/video-recorded teaching observations and 9 interviews. Analysis of interview data focused on: views of students; descriptions of teaching practice; rationales for practices; and views of mathematics. Analysis of classroom observations attends to the presentation of mathematics; patterns of classroom discourse; and explicit references to students' personal experiences, beliefs, and identities. The case of Floyd Lee illustrates how one teacher builds relationships with his students that attend to issues of access and equity. Drawing on his ties to the local area (an urban, primarily African-American community), he connects his own racialized and class-based experiences with the lives of his students. Specifically, he discusses how he "knows" the kinds of students in his classes and what it takes for them to "make it." Floyd leverages this knowledge and explicitly communicates the importance of mathematics and how it bears directly on students' potential to achieve future success. The case of April Lincoln illustrates how one teacher, who identifies herself and is seen by others as having particular aptitude for working with students characterized as low-performing or with IEPs, establishes nurturing relationships by attending to students' affective and individual needs. She works to make the content accessible, positions students as capable and competent learners, and attempts to create a safe and respectful environment to learn.

This work seeks to develop an understanding of the heterogeneous ways two African American teachers conceptualize and enact caring in practice. Knowing more about how teachers develop and maintain relationships with their students can provide insight into how to better prepare teachers to support students' math identity formation and their mathematics learning.

A STUDENT'S REACH SHOULD EXCEED HER GRASP, OR WHAT'S TECHNOLOGY FOR?

Thomas G. Edwards
Wayne State University
t.g.edwards@wayne.edu

S. Aslı Özgün-Koca
Wayne State University
aokoca@wayne.edu

The negative effect of poverty on student achievement in mathematics is well documented. So, too, is the positive effect of instruction focused on higher-order thinking, meaning, reasoning and understanding on the mathematics achievement of children of poverty. We delivered a lesson activity that uses TI-Nspire to support middle school students' interpretation of boxplots to 115 students in a high-poverty middle school. Preliminary data analysis indicates that the use of the technology provided helpful scaffolding for these students as they applied higher-order thinking and reasoning to understand the meaning behind these statistical representations of data.

Keywords: Data Analysis and Statistics; Equity and Diversity; Instructional Activities and Practices; Technology

One way in which the mathematics achievement of students in high poverty areas has been addressed is by providing instruction focused on higher-order thinking skills (Balfanz & Byrnes, 2006). However, McKinney and Frazier (2008), in a study of 64 mathematics teachers working in high-poverty middle schools, found that the vast majority of their sample reported frequently using lecture, drill and practice, and teacher-led lessons. Despite the influx of technology into U.S. mathematics classrooms over the last twenty years, Usiskin's (1990) vision of technology as an equalizer has not fully come to fruition, particularly not in high-poverty schools. Synthesizing these ideas we envisioned mathematics pedagogy for use in high poverty schools by focusing on higher-order thinking, reasoning, and understanding with technology to support teaching.

The 115 eighth-grade students in a high-poverty school whose work is reported in this paper were chosen by convenience sampling. Participating students took a pretest on day 1, engaged in the lesson activity on day 2, and took a posttest on day 3. The students working in pairs used TI-Nspire calculators and completed a worksheet that was designed to help them make sense of and interpret box-plots and make connections between two statistical plots. All of the responses to the two questions on both the pretest and posttest were analyzed quantitatively and qualitatively.

According to the quantitative results, there was a statistically significant effect on the test scores on three short-answer items, with students scoring higher on the posttest. Qualitative analysis revealed that even following a brief intervention, students were able to learn technical features of box-plots. Some students wrote longer answers that were much more mathematically mature on the posttest than on the pretest. We believe that technology by itself is not responsible creating these results, but valuing and focusing on the meaning of a box-plot via powerful, multiple-linked representations might be. In this way, perhaps the promise of Usiskin's (1990) vision of technology as a great equalizer can one day be fully realized.

MATHEMATICAL LITERACY ASSESSMENT DESIGN: A MULTIVARIATE ANALYSIS OF PISA 2003 MATHEMATICS ITEMS IN THE U.S.

Adem Ekmekci
The University of Texas at Austin
ekmekci@utexas.edu

Guadalupe Carmona
The University of Texas at Austin
lcarmona@utexas.edu

Keywords: Assessment and Evaluation

This study draws on National Research Council's (NRC) assessment design framework that proposes the assessment triangle, where each corner represents: cognition, or model of student learning in the domain; observation, or evidence of this knowledge; and interpretation, or making sense of this evidence (Pellegrino, Chudowsky, & Glaser, 2001). The triangle representation signifies the idea of interconnectedness of the three elements as opposed to having them as isolated from each other, which is problematic and often times found in most of assessment designs. Of the five important recommendations for research outlined in NRC's assessment report, one urges for in-depth analyses of these three elements and their coordination. Thus, this study sheds light on these elements and their interconnectedness by analyzing data from a widely used international assessment design: Programme for International Student Assessment (PISA).

PISA assesses mathematical literacy in a multidimensional structure: content, processes, and situations (or context). The first, "content," is divided into 4 dimensions (overarching ideas): quantity, space and shape, change and relationships, and uncertainty. "Processes" consist of 3 competency clusters: reproduction, connection, and reflection. Lastly, "situations" are defined in terms of 4 dimensions: personal, educational/occupational, public, and scientific (OECD, 2009).

The purpose of this study is to investigate the validity of an international mathematics assessment (PISA) and its relationship with mathematical literacy based on following research questions: (1) *What content dimensions* do PISA *2003 mathematics items reflect?* (2) *To what extent do U.S. students' responses to mathematics items match the original assessment framework?*

A factor analysis (FA) was conducted for PISA 2003-US. The results could be summarized in 3 parts. First, results suggest that only one construct explains the most of the variance in students' responses to mathematics items. This result does not confirm the original multidimensional design of assessment items and implies weak connection between *cognition-observation* elements of assessment triangle. Secondly, the *space of individuals* shows no significant differences between males and females but some math items seem more correlated to low achievers. Lastly, the *space of variables* shows that few items were less correlated to the rest of items. Overall, the results show a rather low consistency among the three components of PISA's assessment design. More interpretations and deeper discussions will be presented in the poster. However, some causes for this weak interconnectedness are yet to be explored through further multivariate analyses (Carmona, Krause, Monroy, Lima, Ávila, & Ekmekci, 2011).

FOREGROUND: TRANSITIONING STUDENT MOTIVATION FOR LEARNING MATHEMATICS

Denival Biotto Filho
State University of Sao Paulo – Unesp, Rio Claro – SP, Brazil
denivaldenival@gmail.com

Keywords: Affect, Emotion, Beliefs, and Attitudes; Equity and Diversity; Informal Education

This poster presentation results from a doctoral study in progress that aims to investigate possible changes in students' perspective of their future. This is important since it can provide them with reasons for learning. This subject has been treated from different perspectives for over 30 years, but in this study I emphasize the sociological concept of foreground (Skovsmose 2007). Foreground refers to how individuals see their social, economic, and political opportunities, that is, their perception of their future possibilities in life given its sociopolitical context. Foreground also includes how one interprets and reacts to these opportunities and to their expectations. The mathematics education research literature has several studies involving the concept of foreground (Skovsmose, Scandiuzzi, Alrø, & Valero, 2008; Alrø, Skovsmose, & Valero, 2009). An important outcome of this research literature is that hopeful foregrounds provide reasons for learning, or the opposite, in the case of broken foregrounds, that is, the case of ruined perspectives, which are common among students in unfavorable social situations. Since students' foregrounds motivate or discourage the learning of mathematics, it is vital to consider this question: How can mathematics education create mechanisms for the "reconstruction" of broken foregrounds? To better understand this problem, I will develop mathematical activities that involve social, political and cultural realities. I will conduct my investigation in two different environments: a Brazilian social institution that shelters economically poor children and adolescents in an after-school center, and a virtual learning environment in a school in the United States that serves immigrant students. The work at this virtual environment will occur in the context of a project directed by Arthur B. Powell which develops his investigation using a multi-user version of the GeoGebra, through the online environment, called Virtual Math Teams (Powell & Dicker, 2011). I believe that this comparative study—face-to-face, out-of-school environment in Brazil and virtual, in-school environment in the U.S.—contributes to debates about learning environments that provide opportunities for students to "reconstruct" their broken foregrounds.

STUDENTS' CONCEPTIONS OF MATHEMATICS AS SENSIBLE AND RELATED INSTRUCTIONAL PRACTICES

Maureen M. Grady
The Pennsylvania State University
mmg250@psu.edu

Students' conceptions about the nature of mathematics play a critical part in the development of mathematical proficiency. The productive disposition strand of mathematical proficiency is described as a "habitual inclination to see mathematics as sensible, useful, and worthwhile, couple with a belief in diligence and one's own efficacy" (National Research Council, 2001, p. 5). Despite the importance of students seeing mathematics as sensible, research on students' conceptions about mathematics indicates that the majority of students do not have a conception of mathematics as connected and coherent (Crawford, Gordon, Nicholas, & Prosser, 1994; Petocz et al., 2007). There is very little research about student actions that might signal that students see mathematics as sensible or about the instructional practices that might be effective for the development of such a conception in high school students.

Description of this Study

This study examines action-oriented indicators of students' conception of mathematics as sensible and the instructional practices that influence the development of this conception of mathematics as students transition into high school. In particular, this study examines action-oriented indicators that students in one purposefully-chosen 9th grade mathematics classroom conceive of mathematics as sensible and systematically examines the instructional practices within that classroom that may be associated with the students developing such a conception of mathematics. The first phase of this study was to adapt questionnaire and interview questions from research on conceptions of mathematics to create a list of action-oriented indicators that students conceive of mathematics as sensible. The list was then tested for usefulness and completeness by using it to code student actions in several classroom observations. The next phase of the study will be to examine one mathematics classroom for indicators that students conceive of mathematics as sensible, study the instructional practices in that classroom, and seek links between instructional practices and students' conceptions of mathematics as sensible.

Findings

I found that the list of action-oriented indicators is a useful tool for extracting from a classroom setting incidents in which students' actions indicate a conception of mathematics as sensible. I have also identified several instructional practices that appear to be associated with the development of a conception of mathematics as sensible as students make the transition from middle school to high school mathematics.

ELEMENTARY TEACHERS' VIEWS OF AND EXPERIENCES WITH MATHEMATICS, MATHEMATICIANS, AND MEDIA

Jennifer Hall
University of Ottawa
jennifer.e.hall@uottawa.ca

Keywords: Teacher Beliefs; Affect, Emotion, Beliefs, and Attitudes; Elementary School Education

In North America, mathematics tends to have an image problem: People often dislike or fear the subject area (Boaler, 2008), and mathematicians are portrayed in stereotyped ways in the media (Applebaum, 1999). Negative attitudes toward mathematics are linked to decreased participation and achievement (Ma, 1999), but it is unclear how these attitudes form.

With these concerns in mind, I sought to understand how children may be impacted by growing up in a culture that is rife with negative views surrounding mathematics and mathematicians. My overarching goal in conducting this research project is to provide a better understanding of the complex interplay between outside sources (i.e., parents, teachers, and the popular media) and children's views of mathematics and mathematicians.

My study is framed by a social constructivist and feminist epistemological stance, wherein I understand the discipline of mathematics and views of mathematics and mathematicians to be socially constructed and gendered in nature. Following, my conceptual framework positions the actors in the study (i.e., students, parents, teachers, and media) as being both producers and (active) consumers of ideas about mathematics and mathematicians.

My study investigates elementary students' views of mathematics and mathematicians and the ways that parents' views, teachers' views, and popular media representations may impact students' views. Data collection consisted of online questionnaires, drawings of mathematicians, and focus group interviews (with media prompts) with Grade 4 and 8 students; interviews with parents; interviews with teachers; and document analysis of children's media.

For this presentation, I focus on the teacher interviews, in order to fully examine the ways in which teachers, a key socializing agent in children's lives, act as producers of ideas about mathematics and mathematicians. Additionally, the teacher interviews provide an understanding of the ideas about mathematics and mathematicians that teachers consume.

Teacher interviews took place in the 2010–2011 school year with 10 Grade 4 and 8 teachers from Ontario. The interviews (average duration: 1.5 hours) investigated the teachers' experiences with mathematics throughout their lives, their teaching philosophies, and their views of mathematics, mathematicians, and the media more broadly.

The interviews were transcribed verbatim, which resulted in more than 400 pages of data, and analyzed using Atlas software. Emergent coding was completed for each participant separately, and then comparisons were drawn across participants. Results will be discussed with regard to the conceptual framework of producers and consumers.

WHAT COMMUNITY COLLEGE STUDENTS OF DEVELOPMENTAL MATHEMATICS THINK ABOUT LEARNING MATHEMATICS

Jessica J. Harnly
Syracuse University
jjharnly@syr.edu

America has a growing need to address high school graduates' preparedness for the study of college-level mathematics. One-third of first-year college students in America need to take at least one remedial course, because they lack skills needed to succeed in college-level courses (Taylor, 2008). According to Stigler, Givvin, and Thompson (2010), community colleges have implemented various systemic reforms such as learning assistance centers or redesigned curricula, but community colleges have not instituted significant pedagogical changes. "Substantive improvements in mathematics learning will not occur unless we can succeed in transforming the way mathematics is taught" (Stigler et al., 2010, p. 5). To make such pedagogical shifts in the teaching of students of developmental mathematics, we need to examine the perspectives and needs of these students and the mathematical pitfalls experienced by them in their current courses (Stigler et al., 2010). In this study I investigated the perspectives of community college students of developmental mathematics on their current experiences in mathematics class and on what they think mathematics class *should* look like.

Eight community college students enrolled in intermediate algebra courses participated in semi-structured interviews. Participants recently graduated from high school and were at least 18 years of age. My sample was randomly selected from forty volunteers who indicated a willingness to participate in an interview. I asked the students to describe their current experiences in a developmental mathematics class.

Three main themes arose from the eight interviews: the classroom environment, views of learning math, and the purpose of math. Participants viewed the classroom environment as unengaging and unmotivating. Classes were characterized by inattentiveness and poor attendance. Students were expected to take notes on lectures and practice mathematical procedures. No group work or peer collaboration occurred in any classes, although several students indicated they would enjoy this. Students' responses conveyed various views of learning mathematics. Several students considered repetition crucial for learning; however, repetition in a lesson is "boring" or "tedious." Students wanted to be shown procedures, but several students expressed a desire for a deeper level of understanding of concepts. Consistently students saw no purpose for taking intermediate algebra, beyond satisfying a graduation requirement. All students wanted a patient teacher who explains things well and jokes around with them.

In analyzing students' perspectives, I gained insights about what students want and need from a mathematics class as they transition from high school to college. In addition to sharing these findings, I will also illustrate students' experiences with problem solving tasks that I conducted and will discuss how these influenced the students' perspectives.

PROBLEM SOLVING THINKING CO-CONSTRUCTION OF LATINA/O ENGLISH LANGUAGE LEARNERS IN AN AFTER-SCHOOL MATHEMATICS ENRICHMENT COURSE

Candace Joswick
The Ohio State University
joswick.1@osu.edu

Sarah Gilchrist
The Ohio State University
gilchrist.42@osu.edu

This study aimed to trace and explain how problem solving, as one form of mathematical practice, is co-constructed in a classroom, using interactional analysis and drawing from in-depth case studies of two students, one Latino and one Latina English Language Learner (ELL) enrolled in an after-school program for urban students. Latina/o students in the United States perform consistently lower on average than their White peers on national and international mathematics assessments (e.g., NAEP, NCES, 2011). This underperformance of Latina/o ELL students in mathematics is discouraging, given that not only will the particular population continue to grow, but also the clear social and economic inequities created by such underachievement (cf. Gutstein & Peterson, 2005; Moses & Cobb, 2001). Attempts at improving the mathematics achievement of this population remain futile in the absence of a deep understanding of how classroom environment, instruction, and curriculum might provide space for their growth and development. Research in this area is currently lacking in mathematics education; this study was designed to address this gap. More specifically, the data collection and analysis was guided to address: How do Latina/o ELL students co-construct problem solving thinking through interaction with their teacher and peers in a mathematics enrichment course?

Our study supports that exploring the co-construction of mathematical problem solving thinking reveals multiple dimensions of students' thinking. For example, capturing what is happening (e.g., prosodically, physically, socially, materially, structurally, verbally, etc.), provides a picture of: the influences on a student's thinking, a student's use of verbal and non-verbal language, and the existence of power and influence of language and cultural hegemony. These aspects of classroom interactions contribute to what knowledge is honored, considered, taken-up, and further developed—greatly impacting students' growth in mathematical understanding. The use of discourse analysis revealed how the students' interactions with their teacher and peers, through language and related semiotic systems, influenced their mathematical thinking and knowledge building. Multiple layers of analysis (cf. Fairclough, 1995) uncovered that influences such as power, interaction structure, prosodics, and materials, play a significant role in both participants' mathematical work and in institutional sociomathematical norms (Yackel & Cobb, 1996) as depicted in the student/teacher interactions. The complete case studies of each participant reveal how their participation and that of their teacher and peers, in small and whole class discussions, shapes their mathematical thinking during problem solving.

BUILDING MATHEMATICAL MODELS: IDENTIFYING COMMON ERRORS IN ENGINEERING STUDENTS' WORK WITH LINEAR PROGRAMMING PROBLEMS

Rachael Kenney
Purdue University
rhkenney@purdue.edu

Tuyin An
Purdue University
ant@purdue.edu

Sung-Hee Kim
Purdue University
kim731@purdue.edu

JiSoo Yi
Purdue University
yij@purdue.edu

Nelson Uhan
Purdue University
nuhan@purdue.edu

Keywords: Modeling; Post-Secondary Education

In this study, we aim to answer the following question: What difficulties to engineering students encounter as they build symbolic models of typical linear programming modeling tasks?

Linear programming problems are more complex than typical algebra word problems. The increased number of variables and level of complexity can contribute to learners' difficulties (Jonassen, 2000; dos Santos & Brodlie, 2004). Students often struggle with deciding what to include in a mathematical model (Wang & Brooks, 2007) as well as with deciding how to represent the chosen items. To better understand how students develop deeper conceptual understandings of LP modeling, it is important to understand the existing characteristics of different student errors across LP problems.

We collected data from students enrolled in an undergraduate engineering course in optimization who were learning LP problems for the first time. We collected responses for five quizzes focused on linear programming and analyzed them to understand the types of errors that students made while building mathematical models. Three coders worked together to identify and describe each individual error in a sample of ten randomly selected quizzes in order to build an initial coding scheme, which was further revised and applied to all quizzes.

Our analysis resulted in a taxonomy of errors that contains four primary categories. *Decision Variable Errors* include instances where students introduced their own new variables that were either disruptive or not clearly connected to the given variables. *Variable Relationship Errors* involve ways that students developed incorrect relationships among the variables and coefficients given. This category of errors was identified more often than any others. *Notation Errors* refer to mistakes specifically linked to a mathematical symbol such as summations, subscripts, inequality and equal signs. *Form Errors* involve the omission of the non-negativity constraints. Many of these errors do not seem context specific, but instead represent a conceptual difficulty where students may understand the problem, but cannot translate to a correct mathematical solution. As our work in this area continues, our goal is to develop a visualization tool that could help students better understand the complexity of LP problems, organize the given information, and check the validity of the models they create.

AFFECTIVE COMPETENCE IN MATHEMATICAL LEARNING

Virginia Rivera Lara
Universidad Veracruzana
vrivera@uv.mx

Javier Lezama
Instituto Politécnico Nacional
jlezamaipn@gmail.com

Keywords: Affect, Beliefs, Attitudes

Categories present in affective domain in mathematical learning are analyzed (Gómez-Chacón, 2000; Maab & Schlöglmann, 2009; Reeve, 2003; Rivera, 2006, 2011). The relationships found among them are showed to provide an overview of the affective domain and to point out the aspects that allow the approach to emotional competency in the mathematical learning.

The leading elements: teacher, student, knowledge and people around them and the links that they have with the psychological and some socio-cultural aspect are displayed.

It is emphasized that to learn and to use mathematics, the affective aspect that goes implicitly in students' learning has an equal importance that the cognitive and skills aspects.

Theory of Social Representations (TSR) is applied (Moscovici, 1979), employing the technique of focus groups as dynamics form of collective in-depth interviews applied in several groups of Mexican teachers from primary education level until higher education level.

Categories of beliefs, emotions, attitudes, attributions and ethics and morals are considered for the implementation of the dynamics of focus groups, taking focus of attention in the epistemological, cognitive, didactic and social aspects (Rivera, 2006, 2011).

The representations obtained in this way are then presented schematically in relationship to the categories of the affective domain analyzed. This allows showing photography of the reality and it validates the structured conceptual frame that has been glimpsed by the investigators who have investigated in this aspect and that have been validated in this work.

The Social Representation founded indicate four weak points, left of side by the teachers: the emotional category, the ethics and morals aspect; to give a permanent emphasis to the indissoluble link that is present between epistemological and the cognitive beliefs, and finally cultural partner considers the environment where the learning is effected, with the complex and unpredictable implications that this have inside, in the affective and into the cognitive aspects and skills that the mathematical learning have inside too.

It can be foreseen how far teachers are from having in them and propitiating in their pupils an affective competency and a competency in mathematical learning, which involves also to the cognitive and skills aspects.

TOWARD SUCCESSFUL TRANSITIONS FOR ALL: UNPACKING IDENTITY THREATS AMID AFRICAN AMERICAN STUDENTS' MATHEMATICS LEARNING EXPERIENCES

Gregory V. Larnell
University of Illinois at Chicago
glarnell@uic.edu

As part of a broader "social turn" in mathematics education research (e.g., Lerman, 2000)—and, perhaps more recently, a sociopolitical turn (Gutiérrez, 2010)—there has been growing attention to the role of identity construction as a social element of mathematical thinking and learning (Martin, 2000; Sfard & Prusak, 2005). Although many conceptualizations of identity have emerged or been incorporated from other areas of inquiry (e.g., psychology, philosophy, sociology, anthropology), mathematics education researchers have recast and re-operationalized identity in mathematics-specific terms and contexts (cf. Bishop, 2012; Martin, 2000). Despite the increased attention within the field, however, there is still a need to deepen analytical perspectives on identity and to empirically explore the ways in which mathematics-specific identities may shift and respond to other social factors in certain situations and/or over time.

This poster presentation has three central aims: (a) to advance a framework for analyzing mathematics identities as narrative performances; (b) to present a study in which this framework was used to explore African American students' mathematics learning experiences in a university-level remedial course; and (c) to unpack the narrative version of a social-psychological phenomenon, stereotype threat (Steele, 2010) and discuss the various ways in which (and factors by which) students respond to identity threats (cf. Lindemann Nelson, 2001).

The poster draws on two study participants' narratives about their transitions from high school- to college-level mathematics courses, particularly as the transition includes a remedial mathematics course. Across series of semi-structured interviews, Cedric and Vanessa—two high-achieving, African-American, high-school graduates who upon matriculation to college were placed in a mandatory, non-credit-bearing, basic-skills algebra course—discussed the influence of socialization factors on their mathematics learning experiences over the course of several months (cf. Martin, 2000). These interviews were supplemented with recurrent observations during the same period. The findings of the study center on four responses to threat that emerged from the students' narratives: identity satisficing, contingency detection, masternarrative threats, and counternarrative "repair."

ATTENDING TO IMPLICIT KNOWING IN THE MATHEMATICS CLASSROOM

Martina Metz
University of Alberta
martina17@shaw.ca

Elaine Simmt
University of Alberta
esimmt@ualberta.ca

Keywords: Affect, Emotion, Beliefs and Attitudes; Metacognition

We sat with a small group of mathematics teachers working on a problem: "In a warehouse you obtain a 20% discount but you must pay a 15% sales tax. Which would you prefer to have calculated first, discount or tax?" (Mason, Burton, & Stacey, 1982, p. 1). All concluded that order does not matter (unless you're the seller or tax-collector). Although in agreement, one person commented: "It feels wrong that the solutions should come out the same." I (Martina), too, was unsatisfied and located my discomfort in an association with adding then subtracting a particular percentage to the cost of an item and not coming back to the starting point. I realized that a general notion of "coming back to where I started" was interfering–not with my (already strong) confidence in my solution to the warehouse problem, but by creating an uncomfortable feeling of non-resolution. This experience helped motivate this study: How might learners deepen their awareness of partially conscious feelings associated with doubt and certainty and use them as gateways to deeper mathematical understanding?

We conceptualized the study within an enactivist view of cognition, emphasizing autonomous, co-emergent, and embodied knowing (Thompson, 2007), and we used these principles to design the research classroom. Attending to aspects of understanding that dwelled beneath full awareness–even after stated problems were solved–was of particular interest. Varela's (Varela & Scharmer, 2000) notion of researcher as an empathic coach and Gendlin's notions of "felt sense" (1978) and "implicit intricacy" (1991) were helpful in bringing more of such understanding to awareness.

By attending to external indicators of felt meaning, learners interacted with each others' implicit understanding in ways that helped bring it closer to consciousness and into conversation. Here, the importance of directly referring to emerging understanding in ways that were broad enough to allow it to evolve became clear. Conversely, prematurely insisting on clarity and logic precluded awareness of the implicit.

Acknowledgments

This research was supported by the Social Sciences and Humanities Research Council and by the University of Alberta.

Researchers have begun to understand the ways in which students' developing identities as knowers and doers of mathematics shape their understanding of the discipline of mathematics and their place within it (Cobb & Hodge, 2007; Martin, 2000). As such, mathematics education researchers have recently employed the construct of *identity* to gain insight into how students' beliefs, attitudes, and motivations are negotiated within the mathematics classroom context. Current empirical studies have primarily focused on younger students in the K–12 setting and have taken into consideration the relationship between students' identities and classroom norms.

The purpose of this study was to contribute to the ongoing conversation about the ways in which students' mathematical identities are studied and interpreted. Specifically, I was interested in exploring the mathematical identities of college students. Having recently transitioned to the university setting, I hypothesized that early college students would be in a unique position to articulate their observations, interpretations, and evaluations of classroom norms in ways that younger students in other settings may not. Through a multi-layered qualitative case study of Malik—an African American male student enrolled in a college Algebra course at a large, Midwestern university—I sought to answer the following questions: (a) How does Malik enact his own mathematical identity through language? and (b) How does Malik use language to frame his relationship to other students in his class?

In the initial phase of analysis, I interpreted the interview data collected from four classroom participants through the lens of *normative identity*, or the "identity that students would have to develop in order to affiliate with mathematical activity as it is realized in the classroom" (Cobb & Hodge, 2007, p. 166). Out of all of the participants, Malik stood out as having an interesting and unique perspective on classroom norms. Malik's descriptions were distinctly different from the others' in that he consistently defined himself in opposition to his peers, describing himself as fulfilling a unique role in the classroom. For example, he described the ways in which speaking up in class can be scary—"'cause everyone looks at you with that blazing stare"—but that he overcame this fear to ask questions on behalf of his peers. He felt that he was a role model for other students. After reading and re-reading the data that I collected, I began to notice a connection between this identity and his language use, prompting me to do further investigations into his language. A subsequent discourse analysis, which focused on his use of "I-statements" (Gee, 2011) and pronouns, revealed the ways in which his identity was enacted through language. Taken together, these results provide unique insights into Malik's identity as a college Algebra student, which have implications for future work on identity.

USING VIDEOS OF HOW CHILDREN LEARN MATHEMATICS WITH PARENTS

David Pratt
Purdue University North Central
dpratt@pnc.edu

David Feikes
Purdue University North Central
dfeikes@pnc.edu

Keywords: Elementary School Education; Informal Education

Parents are often overlooked and could be one of the missing links in the continuum to help all children better understand mathematics. Videos of children learning math (along with associated commentary) can also be a useful resource for parents. This study reports the results of an online survey completed by parents after they viewed videos of children engaged in mathematical activity.

Videos have been shown to be a powerful tool in helping preservice teachers expand their content knowledge and in developing beliefs that promote developing mathematical understanding (Philips et al., 2007). One of the key features of using videos is in helping viewers of the videos *notice* (Jacobs et al., 2010) what is important in children's learning of mathematics. The videos and especially the expert commentary included at the beginning and end of these videos is designed to help viewers make sense of the video in a new way.

Our research looks at how we can help parents help their children with their mathematical homework. One of our goals is to encourage parents to focus on the way children think about the mathematics. Rather than providing parents with a multitude of resources to help their children learn mathematics, the primary hypothesis of our research is that children's understanding of mathematics can be improved by empowering parents with knowledge of how children learn mathematics.

We sent a letter home to all second and fifth grade parents in two small-town Midwestern elementary schools. In the letter we asked parents to view multiple students solving the same math problem in the grade respective to their own child's. At the conclusion of the videos, they were asked to complete an online survey.

The results of the survey indicate that: (1) many parents are actively involved in helping children with mathematics homework, (2) parents' confidence in helping their children with mathematics varies, (3) these videos were helpful to parents, (4) the videos reinforce the idea that children think about mathematics differently than adults, (5) for some of the parents, the videos helped them better understand how their own children think about mathematics, and for some parents, the videos helped them think about ways of helping their children learn mathematics.

NCTM's *Curriculum and Evaluation Standards* (1989) tied mathematical power to mathematical literacy and emphasized the central roles of reading, writing, and discussion. Although the Common Core State Standards for Mathematics (CCSSM) (CCSSI, 2010) do not mention reading and writing in the mathematics classroom directly, the standards for mathematical practices require, implicitly, fluency with the language of mathematics. We suggest that reading and writing in mathematics will be critical to the successful attainment of the mathematical practices proposed by the CCSSM. Although the mathematics education community has discussed the importance of and provided recommendations for incorporating reading and writing into mathematics classrooms (e.g., Barton & Heidema, 2002; Thompson et al., 2008), there remains a need for empirical research on the effects of reading and writing about mathematics, particularly in middle school (Bangert-Downs, Hurley, & Wilkinson, 2004).

Our research questions were as follows: (1) To what extent does the self-reported value that teachers place on reading and writing about mathematics influence the value that their students place on those same activities? (2) To what extent do the classroom pedagogical decisions regarding reading and writing about mathematics affect student attitudes toward those activities?

Data were collected over one year as part of the third edition evaluation studies of two textbooks developed by the University of Chicago School Mathematics Project (UCSMP), *Transition Mathematics* and *Algebra*. Analyses are based on data from mathematics teachers (n = 41) and their students (n = 931) in grades 6–9 from 12 schools (n = 10 public and n = 2 private) in nine states. Including the curricula used as comparisons to UCSMP, nine different curricula are represented in the study. Teachers provided intended plans for reading and writing on initial questionnaires and documented enacted decisions on final questionnaires; students completed an end-of-the-year questionnaire about their attitudes toward reading and writing mathematics.

Data analysis used multi-level logistic modeling. Results show that classroom time spent reading and writing were the predictors that most positively influenced the likelihood that students valued reading and writing about mathematics. These results have practical implications that can guide teachers to improved pedagogical practices that can maximize student transitions toward increased participation in the mathematical practices of the Common Core.

THE MATHEMATICS PHILOSOPHY OF A PRESCHOOLER: EXPLORING MATHEMATICAL ACTIVITY AND BELIEFS

Jamie Wernet
Michigan State University
wernet@msu.edu

There is a growing view in the mathematics education community that mathematical knowing is a cultural activity (Bishop, 1988; Burton, 1994; Millroy, 1992; Nasir, Hand, & Taylor, 2008). Bishop (1988) wrote that because mathematics is a cultural activity, children bring their own mathematical meanings to the classroom and thus play an active role in the cultural practice of mathematics education. So it is important that teachers—as well as families and children themselves—recognize how children might experience mathematics outside of school to help navigate the transition into school mathematics.

The purpose of this study was to investigate the mathematical activity children engage in and beliefs they have about mathematics before entering school. Through a qualitative case study of three-year-old Olivia, who had no formal school experience including daycare and preschool, I sought to answer the following questions:

- What is the nature of Olivia's mathematical activity according to Bishop's (1988) framework?
- What seems to be Olivia's philosophy of mathematics?

More specifically, I used Bishop's six types of mathematical activity—counting, measuring, playing, explaining, designing, and locating—as a framework for activity, and the what, who, where, when, and why of mathematics to gain insight into her mathematics philosophy.

Using two full weeks of home-based observation and two semi-structured interviews, I found that Olivia's mathematical activity was plentiful and widely varied, with multiple events in each of the six categories of activity. To her, however, mathematics is a far more limited activity in terms of what it is and where and when we engage in it. Namely, she believed mathematics is something "smart" people do "at schools" involving "writing numbers and letters," though science can be used to investigate and solve problems. The incongruence between her activity and beliefs could be problematic, and suggests some implications for instruction. For example, professional development for existing teachers and courses for future early elementary teachers could emphasize the nature of students' mathematical activity at home and how to recognize and mathematize those experiences in the classroom.

IMPROVING MULTIPLICATION STRATEGIC DEVELOPMENT IN CHILDREN WITH MATH DIFFICULTIES

Dake Zhang	**Yan Ping Xin**	**Karleah Harris**	**Yi Ding**
Clemson University	Purdue University	Lane College	Fordham University
dakez@clemson.edu	yxin@purdue.edu	kharris@lanecollege.edu	yding4@fordham.edu

Keywords: Assessment; Elementary School Education

The purpose of the present study was to test the effectiveness of a constructive Strategic Training (ST) program for improving students' performance in solving multiplication problems. Multiplication is a foundational skill that children are expected to master through third to fifth grade (National Council of Teachers of Mathematics [NCTM], 2000). However, students with mathematics learning disabilities often fail to achieve these academic standards (No Child Left Behind [NCLB], 2000). The participant was a third grader with math difficulties (Carl) who was recruited from a Midwestern elementary school in the United States. Carl had average or above average IQs but scored lower than the 35th percentile in the Math Fluency Subtest of the Woodcock Johnson Test of Achievement (Woodcock, McGrew, & Mather, 2001). First, we gave a baseline assessment to the participant, including a 1 × 1-digit multiplication calculation test and a 1 × 2-digit multiplication calculation. We found that Carl's accuracy in solving 1 × 1-digit problems was low (medium = 50% correct) and his accuracy in solving 1 × 2-digit problems was even lower (0%). Carl responded to more than half of problems with incorrect operations or replied with "I don't know." Therefore, the researchers designed an ST program for Carl to gradually transition from Level 1 (incorrect operations and don't know) to Level 2 (unitary counting) and then to Level 3 (repeated addition) and Level 4 (direct retrieval and algorithm). Wave A was designed to help Carl master unitary counting strategies by introducing small-number problems that allowed him to count by ones; When Carl had established consistent use of the unitary counting strategy, he was introduced to Wave B which was aimed to transition him to increased use of double counting and/or repeated addition. Results showed that Carl rapidly increased his use of double counting and repeated addition and took only one session to begin using repeated addition for 50% of all trials of the session. Correspondingly, Carl increased his accuracy in Wave B probes to 100% by the third session. Then Wave C intervention aimed to help Carl transition to greater use of higher order strategies such as algorithm and decomposition. With Carl's quick acceptance of using algorithm strategy, he improved his accuracy of solving Wave C problems up to 70% correct. In short, results showed that Carl began the intervention on the lowest strategic developmental levels and were consequently given individualized tasks to promote this strategic development during differential waves.

PHOTO-ELICITATION/PHOTOVOICE INTERVIEWS TO STUDY MATHEMATICS TEACHER IDENTITY

Theodore Chao
Harvard University
tchao@utexas.edu

How do mathematics teachers think of themselves? The construct of identity—how teachers see themselves—is an important and understudied construct in understanding mathematics teaching. This study investigates the use of Photo-Elicitation/Photovoice Interviews with six high school Algebra I teachers. Each teacher captured or chose photographs of their "world," then presented them during a formal interview. Through stories elicited in this process, mathematics teacher revealed personal/private identities they often covered up with their professional identity. These mathematics teacher identities fell along a professional learning continuum with a conservative identity on one end and radical multiculturalist identity on the other end.

Keywords: Teacher Education–Inservice/Professional Development; Teacher Knowledge; Teacher Beliefs Equity and Diversity

Objective of the Research Study

Over the last several decades, mathematics educational researchers built a substantial body of work exploring how to support mathematics teachers. Spurred by Shulman (1987), researchers have focused on teacher's professional knowledge of mathematics (Hill et al., 2007), their beliefs about how mathematics is learned (Philipp, 2007), and their dispositions towards mathematics (National Research Council, 2001), among other things. However, Shulman also warned that taking this professionalization too far risks losing sight of the human element inherent to what makes teachers teach. Shulman wrote, "We must achieve standards without standardization. We must be careful that the knowledge-base approach does not produce an overly technical image of teaching, a scientific enterprise that has lost its soul" (Shulman, 1987, p. 20).

Many mathematics teachers might feel successful in their professional responsibilities of mathematics teaching, yet still feel disconnected, unfulfilled, and even powerless in connecting their personal identity with who they are in the classroom (de Freitas, 2008; Drake, Empson, & Dominguez, 2003; Van Zoest & Bohl, 2005). Most educational research focuses only on the person that exists in this professional role–the teacher in the classroom. By uncovering the personal story that lies beneath the professional story and allowing mathematics teachers to confront and reflect upon these aspects of their identity, we might begin to know the "soul" or identity of a mathematics teacher.

This study investigated teachers' conceptions, notions, and stories of themselves through the construct of *mathematics teacher identity*. In particular, the following research questions guided the investigation: What kinds of things does a photo-elicitation/photovoice interview capture about mathematics teachers in regards to identity? What does the photo-elicitation/photovoice interview reveal about mathematics teachers that may not be captured through other research methods?

Theoretical Framework

Many scholars have looked at the construct of the identity as a lens for research in education (Bishop, 2012; Boaler & Greeno, 2000; Cobb, Gresalfi, & Hodge, 2009; de Freitas, 2008; Drake, Spillane, & Hufferd-Ackles, 2001; Gee, 2000; Holland, Lachicotte, Skinner, & Cain, 1998; Van Zoest & Bohl, 2005). This extensive work on identity in education centers on the constructs of *dilemma, relationships, narrative, agency,* and the *photo-elicitation/photovoice interview* to understand the identity of teachers or students.

Dilemma

The work on teacher identity historically centers on the construct of "dilemma" (Connelly & Clandinin, 1995; Lampert, 1985; Lyons, 1990; Shulman, 1988). Lampert (1985), one of the first researchers to write about her teaching as scholarly work, framed her journey into connecting her teaching practice to her personal beliefs through the dilemmas she encountered in her classroom. Lyons (1990) also examined teachers' dilemmas, particularly analyzing how teachers resolved or dealt with moral dilemmas that came up in their relationship to students, finding that when teachers responded to dilemmas, they were forced to examine themselves, which led to growth—to change.

Clandinin and Connelly (1996, 1995) use the idea of dilemma as central to their construct of Teachers' Professional Knowledge Landscapes, finding that the *big* dilemma teachers face is between theory and practice. To navigate this dilemma, teachers tell both *Cover stories* and *Secret stories*. *Cover stories* are the stories, "In which they portray themselves as characters who are certain, expert people. These cover stories are a way of managing their dilemmas" (Clandinin & Connelly, 1996, p. 15). *Secret stories* takes place behind closed doors, often revealed only in private spaces (i.e., happy hours or parking lot chats), among like-minded colleagues.

Palmer (2007) uses the term *Divided Life* to mean the same thing—the separation of external from their internal, causing a psychic rift between teacher-selves and the way teacher actually perceive themselves. de Freitas's (2008) work exploring mathematics teacher identity through classroom discourse found the same warring elements, referred to as procedural registers versus personal narrative registers.

Relationships

Relationships and formed with other teachers is another construct researchers use in exploring teacher identity (Grier & Johnston, 2009; Holland et al., 1998; Van Zoest & Bohl, 2005; Wenger, 1998). Wenger (1998) uses the construct of *Communities of Practice* to look at identity formation, particularly within socially-constructed spaces. In this definition, a teacher creates his or her identity through learning how to be a member of a particular community of practice, in this case, the community of teaching. Van Zoest and Bohl (2005) build their definition of mathematics teacher identity through this idea of the various communities of practice that a person inhabits as they become a mathematics teacher. Holland, Lachicotte, Skinner, and Cain (1998) study identity within the aspect of creation; identity as enacted in the building, forging, and authorship of *Figured Worlds*. Grier and Johnston (2009), in looking at the identities of STEM career changers, found that socialization into the teaching culture was crucial to creating a teacher identity.

Narrative

Hiebert, Gallimore, and Stigler (2002) pushed forward the idea of using narratives as a way to understand teaching. This idea echoes Bruner's (1986, 1996) ideas about the need for a narrative construal as necessary for studying teachers and teaching. Doyle (1997) also showed that narrative-based research on teaching was just as valid and measurable as any other forms of research, especially quantitative endeavors. Drake and Drake, Empson, and Dominguez (2001, 2006) found that mathematics teacher identity was best elicited through the *Math Stories*, which were teacher narratives about prior and current experiences with mathematics. Sfard and Prusak even go so far to claim that identity and narrative are one and the same, "No, no mistake here: We did not say that identities were *finding their expression* in stories—we said they *were* stories" (Sfard & Prusak, 2005, p. 14).

Agency

Agency and power are other constructs used to understand mathematics teacher identity (Crockett, 2008; de Freitas, 2008; Gee, 2000; Gutstein, 2006). Gee (2000) defines a teacher *Discourse identity* as the individual traits of a teacher that are recognized through discourse/dialogue of/with the teacher. When a teacher's *Discourse identity* is legitimized/seen by others, the teacher moves away from a socially defined professional identity, and is thereby open to understand the hegemony of the system they live within.

Palmer (2007) similarly says that the choice to live "divided no more" by rectifying the dilemma of warring identities, is the first step towards true teacher social revolution.

Crockett (2008) outlines a culturally-based continuum to categorize mathematics teacher identity. Teachers often start with a *Conservative* identity, characterized by practice and beliefs that mimic the "traditional" mathematics education they encountered as a student. Then, teachers move to a *Liberal* identity, characterized by inquiry-based, "reform" teaching practices mirroring the ideas promoted by NCTM (National Council of Teachers of Mathematics, 2000). Finally, an identity that teachers rarely ascend to is the *Radical Multicultural* identity, which involves teachers empowering students to act independently, make free choices, and use mathematics to not just see, but also do something about the injustice in their own communities and worlds (Freire, 1970; Gutstein, 2003).

The Photo-Elicitation/Photovoice Interview

The Photo-Elicitation/Photovoice Interview is a research method that anchors an exploration into identity by adding a visual structure to teachers' narratives. Researchers introduce photographs, either selected by the participant or the researcher, into the interview context (Clark-Ibanez, 2004; Gauntlett & Holzwarth, 2006; Harper, 2002). The method successfully elicits identity for a number of reasons. First, visual and creative methods like this are especially useful for studying identities (Brown, Wiggins, & Secord, 2009; Clark-Ibanez, 2004; Gauntlett & Holzwarth, 2006). Second, visual and creative research methods open up imaginative spaces in a non-invasive way that honors teachers' busy schedules and responsibilities (Clark-Ibanez, 2004; Gauntlett & Holzwarth, 2006; Harper, 2002). Third, this method has a strong history of studying identity within other social sciences, such as nursing and anthropology research (Hansen-Ketchum & Myrick, 2008). It is only recently being used within education research (Clark-Ibanez, 2004). Fourth, the PEI excels in generating a narrative structure authored by the research participants themselves (Brown et al., 2009; Clark-Ibanez, 2004; Gauntlett & Holzwarth, 2006). Finally, photovoice techniques elicit teachers prior knowledge by focusing on what they know rather than what they do not know; this empowering reflection leads to social action and critical consciousness (Freire, 1970; Wang & Burris, 1997).

Methods and Procedures

The six teachers who participated in this study taught Algebra I at six different high schools located in large, urban cities in a large Southwestern state. I had previously interacted with all six teachers through research, professional development workshops, and classroom observations for a previous research project. I chose teachers who expressed interests in exploring and talking about their identities as it connected to their mathematics teaching and whom I felt would tell "good" stories.

The Process

I first visited each teacher to give them digital cameras and a loose prompt to "capture your world as a mathematics teacher" in at least twenty photographs. We then set up a time and date to sit individually for a formal Photo-Elicitation/Photovoice Interview two weeks in the future. During these two weeks, I observed at least one Algebra I class period for each teacher to get a feel for their teaching practice and style, to get to know their classroom and school culture, and to be available to answer any questions each teacher might have about the study, the research method, or what types of photographs they should capture. A day or two before the scheduled interview, I sent an email to each teacher reminding them about the interview and also prompting them to choose the ten most important photographs out of original twenty in order them by importance. This forced editing of the photograph pool right before the interview provides a space for each teacher to reflect upon each photograph.

I then sat with each teacher for the actual Photo-Elicitation/Photovoice Interview, each one taking place after school in the teacher's classroom and lasting at least 90 minutes. In the interview, each teacher shared one photograph at a time in order of self-selected importance. I used a minimal interview structure, using non-judgmental and non-evaluative language such as, "Tell me more about that," or, "How does that connect to you as a mathematics teacher?" (Johnston, 2004). I also used clinical interview strategies to get teachers to elaborate more on how each image connected to their identity (Ginsburg, 1997).

Data Sources

Audio data from each interview was captured with digital recorder and then transcribed for analysis using a grounded theory coding structure. I coded for emerging themes of mathematics teacher identity centering on the overlap of professional and personal identities (Corbin & Strauss, 2007; Merriam, 2009). The main data source was the interview of each teacher, which I transcribed in InqScribe to build an emerging coding scheme. Each interview consisted of at least 90-minutes of transcribed audio. While the actual photographs that teachers shared and the notes I took during classroom observations added tremendous depth to the interview, I did not consider them as primary data and did not thoroughly analyze them.

Analysis Approach

Analysis began during transcription. InqScribe allowed the inclusion of time codes for every line of interview data, as well the tagging of thematic codes in order to start build a general grounded theory (Corbin & Strauss, 2008). These first-pass codes formed the initial stages of a categorical scheme to organize the data, (Corbin & Strauss, 2007). Then, using a textual conversion script I wrote in Perl, I imported the transcripts from InqScribe into Transana.

I then built a theoretical sample by analyzing the two longest interviews, listening to the audio and reading the transcripts in order to create individual audio clips that seemed important (Corbin & Strauss, 2008). Each clip captured something that eluded to mathematics teacher identity, which allowed me to create a deeper, more robust code set grounded in a more general understanding of the data now that I had transcribed all the interviews. For the first interview, I created 103 clips. For the second interview, I created 69 clips. Both of these clips generated a total of 446 codes within 35 categories.

At this point, I started to see the need to combine similar categories or drop categories to make the analysis more manageable. I went through the code set with a specific lens of looking at the how teachers were telling *Cover* or *Secret stories* (Clandinin & Connelly, 1996; Connelly & Clandinin, 1995) in order to collapse the categories. I then used the second-pass code set to analyze the remaining four interviews, adding codes and categories as necessary. This allowed me to focus specifically on the construct of mathematics teacher identity in a way that was not specific to any one teacher. It also allowed me to see initial conclusions from the data as we noticed how certain codes or categories were used again and again. This third-pass (and final) code set contained 206 codes within 14 categories.

I then went back and wrote up a four-page summary of the main categories and keywords I found for each teacher. I emailed each teacher their summary, asking them to add to, edit, or clarify anything in the summary they wanted in order to create a form of member-check validity (Corbin & Strauss, 2007). I specifically asked each teacher to ensure that what I was finding was true to his or her "voice" and to check that I was being "real." I also asked each teacher to choose a pseudonym that was both personal and unique. Feedback from each teacher was incorporated back into the analysis.

Results

This paper looked specifically at the usage of the Photo-Eliciation/Photovoice interview in eliciting teacher identity. Specifically, I examined what was revealed through the interviews and what this method captured that other research methods might miss. Deeper analysis into the actual construction of mathematics teacher identities and formation of agency will be forthcoming in further papers.

Cover Stories Initially

In each interview, the first few photographs usually involved the teacher talking about something in their past that was important to them in terms of their mathematics identity. Usually it was a picture of their family, which elicited a narrative of a parent who was "good" at mathematics and therefore taught them that they could be too. This led to a narrative where teachers revealed they chose to be a mathematics teacher because of this prior experience, because they liked math.

In fact, this "I like math" was the most dominant *Cover story*. The following transcript shows how one teacher, Mr. Ginobili, initially creates a story that his sister and him became mathematics teachers because they inherited a "math gene" from their accountant father. All of this comes from a photograph Mr. Ginobili shares of his sister.

Mr. Ginobili: Just the fact that, for both of us [Self and Sister], math is our passion.
Interviewer: For her as well?
Mr. Ginobili: Yeah. I mean, she became the math lead, and they told her, like, what would you want to do and stuff like that. And she was like, math was definitely her thing. And I mean, I see that coming from my father because of the accounting. And the fact that number sense really came, is an easy trait for us to attain.
Interviewer: So tell me about that, then. So you feel like you were instilled with a high sense of number sense?
Mr. Ginobili: Yeah, I think so. I mean, and it's probably, you know, a gene that we developed, that we got from our dad or anything like that.

Photographs Reveal Secret Stories

A traditional interview or belief survey might end here, taking up this teachers' cover story as valid and concluding that this particular teacher holds an entity-based view of mathematics as genetically predestined—the belief in a "math gene." This might lead to conclusions of his teaching practice as "traditional." Yet, through the anchoring structure of the Photo-Elicitation/Photovoice interview, teachers were forced to stare at the photograph and continue to reflect on what the image meant to them. This opened up space to go beyond the *Cover story* and reveal the *Secret story* that connected to their personal/private identity.

For instance, minutes after talking about this "math gene," Mr. Ginobili reveals a *Secret story* about his competitive, yet supportive, teaching relationship with his sister. Mr. Ginobili reveals his passion for working with struggling students.

Interviewer: What do you see in yourself in your sister?
Mr. Ginobili: I think we really have the same passion for the kids. You know, I'll go over to her house every once in a while and she'll be thinking about, "Oh, well this kid is really struggling with this and I need to have an activity for them." And she's really passionate for each one of her kids. And I, I don't want to say that I have that same passion, because she really goes far beyond what's necessary of her. But you know, and like, I still, I do have a little bit of passion for my kids, you know. If I see one of them struggling, you know, you always want to talk to them and figure out what's wrong and stuff like that.

A few minutes later, another *Secret story* further reveals that, through Mr. Ginobili's relationship with his sister, he understands the importance of listening to his students. He reflects upon a teaching belief of valuing listening to students' prior knowledge.

Mr. Ginobili: I think the skills that are really helped me as a teacher and more as a mentor to the kids, is something that she sees in me and she likes and that's why she comes to me more than she does my brother, right? Because she's told me before, she's like, well, if I need somebody that I can talk to and will listen to me, I'm going to call you because, you know, you have that in you. And it's one of the things that makes me want to be a teacher, is the fact that I can listen to kids and I like listening to people, the stories and really try to help them out whenever possible. And so she sees that in me.

Through these Photo-eliciting/Photovoice interviews, teachers revealed the *Secret stories* that described their mathematics teaching practice, weaving narratives that reflected how they saw themselves as a mathematics teacher rather than the usual *Cover stories* they are used to living with.

Discussion and Conclusion

This study fills a current gap in the research on understanding mathematics teacher through the lens of identity. This research extends previous research on teacher identity by incorporating the structure of the Photo-Elicitation/Photovoice Interview to ground the teacher's space for authorship. I successfully explored a research tool that captured teachers' voices without hovering, disrupting their practice, or looking for only what I wanted to see. I attempted to answer Shulman's (1988) call that the best forms of teacher support must involve meeting teachers where they are. This study introduces a professional development tool that gets teachers to reflect on themselves in a minimally invasive and easily implementable way. Mathematics teacher identities are unique and varied; so getting teachers to reflect on their own identity as mathematics teachers helps them become more aware of their own teaching practice.

With more time and resources to do follow up interviews or observations, I might have been better able connect the results with actual teacher practice or student reports. I could also have incorporated multiple narratives into building a mathematics teacher identity, a limitation of singular interview structure.

In the end, this experience allowed teachers to get past their *Cover* stories, remove the "mask" (as one teachers put it), and reveal how they really see themselves. Perhaps if there were more developed constructs to understand these identities, we as a research community can better show the value in knowing what makes each mathematics teacher human, unique and special.

An evaluation of the impact of a professional development experience on participants' ability to explore student voices as input for improving the teaching of mathematics evolved into a self-study of our growth as non-evaluative listeners. This paper specifically describes our emergent awareness of the evaluative stance implicit within our attempt to examine teachers' writing samples with the goal of developing a framework, denying teachers agency and identity. This presented us with a living contradiction since this stance conflicted with our belief that learners deserve both.

Keywords: Equity and Diversity; Teacher Education–Inservice/Professional Development; Instructional Activities and Practices

Introduction

This paper exemplifies transition; it is the story of our journey along a continuum of professional growth. It is told in three parts, parts that defy the typical organization of a research report. We begin at our genesis: an evaluation of the impact of a professional development experience on participants' ability to explore student voices as input for improving the teaching of mathematics. We then describe the transition of our work from an evaluation project to a self-study of our growth as non-evaluative listeners. Our self-study resulted in an awareness of the evaluative stance implicit within our attempt to develop a framework by which to classify teachers' writing samples, thus denying teachers agency and identity. We end the paper with a discussion of the theoretical stance that grounds our work as we consider future teaching and research activity and the "living contradictions" (Whitehead, 1989) that have emerged creating new dissonances in our practices.

Genesis

We, the authors of this paper, were involved in the planning and implementation of a large scale Mathematics and Science Partnership for professional development. Our goals, identified in concert with district faculty and administrators, were to support teachers in becoming better listeners and in understanding the importance of listening to students as a major component of their practice. In conducting the workshops for teachers we were operating under norms for best practices for professional development as defined by the larger mathematics education community. Lesson study (Yoshida, 1999), using student interviews (Schifter & Fosnot, 1993), and Thinker-Doers (Hart, Najee-ullah, & Schultz, 2004; Hart, Schultz, & Najee-ullah, 2004) were all integral components of our program that are defensible with tomes of literature.

We began this project in an effort to evaluate one cycle of this professional development. Our research question was: "How effective had we been in supporting teachers to become better listeners and to understand the importance of listening to students as a major component of their practice?" Participants in our professional development had conducted clinical interviews with their students and had written a reflection paper summarizing their interpretations of students' mathematical understanding and the implications for their teaching. Therefore, we decided to use these data to explore our research question.

At this stage we were framing our work according to the norms of action research (Lewin, 1946) with an emphasis on a qualitative analysis of the teacher reflections. As action researchers we were looking for indicators of how our cycle of PD practices had impacted our teachers' listening strategies. We thought that our analysis would provide insights as to how teachers used the voices of students to make sense of students' mathematical understanding.

Early in our work we found ourselves positioning the teachers on two dimensions, as to whether they seemed teacher-centered or student-centered and whether they were analytic or descriptive in their reflections. In this positioning, we attempted to keep individual reflections intact and carried through the individual contexts in which those teachers were working. As our work progressed we found that some of the data allowed us to make clear decisions as to these two dimensions. However, some cases were much more difficult to categorize. Keeping the analysis at the level of the teacher became unwieldy and in our second attempt we agreed to work with excerpts or "chunks" from the papers. By reducing the grain size to passages rather than entire papers, we tried to keep the focus on abstract ideas rather than individuals. In Figure 1 we present two iterations of our framework. The early stage of analysis resulted in sorting the data according to a framework with two dimensions and multiple levels of nuance. As our analysis of the data evolved, we recognized the need for more encompassing and detailed categories leading from the framework on the left to that on the right.

Figure 1: Evolving framework

As our work progressed we sensed personal disappointment in the work of the teachers. We had inadvertently understood the diagonal (from lower left to upper right) of our new extended framework to indicate growth along a listening continuum. We had hoped that more of our teachers' chunks would have been placed in the student-centered inference cell. To us this would indicate a teacher who listened and reflected on the child's understanding of mathematics. How could a professional development program grounded in best practices have had so little impact on teachers' listening strategies? We began to conclude that we had failed in the mission and goals of our program.

During a professional conference we received positive feedback from members of the mathematics education community about the framework and the way we were analyzing our data. The exercise of discussing and negotiating with colleagues regarding where to place teachers' work on the framework proved to be stimulating and educational for us. It wasn't until colleagues suggested that this framework could be used to create vectors that characterized teacher growth over time that we started to sense a discomfort in the goals of our actions. This interpretation of our work, both in the moment and in its future retelling within our group, reflected to us like a mirror the true nature of our work. Juxtaposed with teaching teachers to listen non-evaluatively was our own story as teachers, listening in judgment of our students.

In hindsight, having someone challenge our framework could have caused us to realize the nature of our evaluative posture and pushed us further along the continuum of our professional growth. It wasn't until we started writing our findings and results that we became increasingly aware of our living contradictions. In theory we believed in (and taught project participants about) listening non-evaluatively to students in order to gain insights into their mathematical understanding. Yet, we were unable to enact the same non-evaluative listening practice with our own students (participants in our PD). We were listening non-evaluatively to our teachers' sharing of conceptual understanding during their mathematical activities, but were unable to suspend doubt (Harkness, 2009) and judgment when they shared genuine reflections about their practice.

In looking back now it is interesting to note that nearly a year went by during which we were naïve about the contradictions in our beliefs about teaching and our practices. Throughout that year we had engaged in activities that we believed would push us toward deeper understanding of our practice. We collaboratively reflected on our program, participated in a reading group on postmodern and critical theories, and attended professional conferences as a venue for vetting new ideas and receiving challenging feedback. However, to become more aware of our evaluative nature and the contradiction we were living, it would take three key catalysts: A personal reflection from a colleague, a revisiting of postmodern thinking, and efforts to situate our research within a shifting paradigm.

Major Transitions

Three Key Catalysts

A personal reflection, told in first-person narrative. A group of mathematics educators attending an international conference were invited to observe and experience local mathematics classrooms. The purpose was to understand the local context and culture of mathematics teaching, a context and culture unfamiliar to attendees. I traveled with a small group of mathematics educators to observe a day at a government-funded elementary school. We were given a warm welcome by children dressed in their best uniforms, wearing fresh flowers in their braided hair, performing traditional songs and dances. The lesson I observed was in a classroom studying 3-D geometry. There were interesting artifacts on display including local containers used to measure milk along with tins and boxes presumably used to talk about the volume of prisms. The teacher appeared proud of the lesson and artifacts used and eager to give students a stage on which to demonstrate what they knew. We witnessed many recitations and demonstrations by eager students who waived their hands wildly to signal to the teacher that they were ready to shine. Both the teacher and the children had worked hard to impress the visitors. At the end of the lesson, we were given the opportunity to ask the teacher questions about the lesson and about the school. Few questions were asked, and those few were along the lines of "How long has this lesson been going on?"

The next morning, the group of mathematics educators reconvened outside of the context of the school. Immediately, the conversation turned to a discussion of what we had seen. We had not been there in the capacity of evaluation, yet we automatically assumed this role. The criticisms flew around the table indicting not only the actions and decisions made by the teacher, but also the skill of the students. *"The lesson was taught by rote. The students were memorizing and not reasoning. There was too much focus on multiplication facts and too little on measurement concepts or problem solving. If the lesson had been rehearsed (it must have been), then who knows if the students even understood what they had been asked to recite and demonstrate?"* I, like others in the group, was comfortable dissecting the lesson and took license in judging what we had seen without any further context or background.

Once this story was shared within our current community, our group began to reflect on the act of observing and studying teaching and learning. This particular story evoked concerns about the evaluative stance that is so natural to this work. As we discussed the story together as a group, we discovered empathy for the teacher and the students and regretted the missed opportunity to understand the complexity of a specific act of teaching. The opportunity had been given to uncover that complexity and truly understand the dynamics of the lesson; the teacher had invited questions and discussion, yet no one had thought to ask about the specific needs of the teacher, students and community and why this particular lesson could help fulfill those needs. The group had denied the teacher and students reason. Who gives mathematics educators the right to judge teachers and their enactments? Are we such experts that we can, on first sight and without economic, political or cultural context, determine the value of an instructional episode? How quickly we strip teachers of agency (Valero, 2004) and identity (Brown, Jones, & Bibby, 2004).

Revisiting postmodern thinking. Concurrently with our evaluation project, we were all involved in a book study of *Mathematics Education Within the Postmodern* (Walshaw, 2004). Each week we met to discuss a different chapter, each of us taking turns facilitating that discussion. Some chapters we discussed for multiple weeks, arriving at insights we valued and took personally. These discussions were humbling for many of us as we began to see similarities in our thinking about our "students" and the structures in our educational system that oppress students and teachers. The constructs of power, agency, privilege, identity and oppression were particularly central to our discussions and seemed relevant to our work with students and teachers.

This was all in a general abstract sense. It was not until we began considering these issues in our research practice and the reflection above was shared that our thinking on these matters became concrete and available for application. It was as if the pieces of a jigsaw were flying about in the ether, but had finally begun to arrange themselves in a way to create a picture of our research practice. It was very much like the experience shared by Valero (2004), "my postmodern attitude did not result from a conscious paradigm selection; rather, it was constructed as I met school leaders, teachers and students in different schools in the world whose lives shook me in significant ways" (p. 36).

Our colleague's personal reflection was an obvious example in which we could apply these new principles and identify the power structures that existed. Much more challenging was the application of these principles to our practice. As we continued to revise and reconsider our work in framing the work of teacher listening, we faced this challenge head on. Revisiting our previous discussions and readings from the study group caused us to question the act of characterizing individuals within any framework, and particularly the one we had developed. We expected our teachers to gain respect for the whole student and not parcel their perceptions into evaluative boxes like "mathematically correct." Yet, we were doing this for them. We were being evaluative listeners and positioning them according to our critical lens, denying them voice and reason in their own practice. At this point, our conversation and the purpose of our project shifted in substantive ways. As one member stated, "*As I analyzed reflections, I felt more aware of the difficulty of what we were asking them to do and the vulnerability it required giving me more empathy for the teachers.*"

Acknowledging living contradictions in our work. According to Whitehead (2009), the practitioner addressing the question "How do I improve what I am doing?" will engage in a reflection that will illuminate their living contradictions. As he explains: "I am thinking here of 'I' existing as a contradiction in the sense of holding together a commitment to live certain values with the recognition of the denial of these values in practice" (p. 87). We frame this discussion of our living contradictions as it relates to our practice as researchers and teachers.

We chose a qualitative research design to best address our research purpose. The qualitative research design that we adhered to denied us our values—to respect and honor teachers' voices—the very values that we wanted our teachers to accept as a critical component of good teaching. In our quest to be scientific and methodical in our research process, we identified a data set, i.e., teachers' written reflections, that we analyzed and interpreted using the tools of qualitative inquiry. As warranted by the norms of academic research involving human subjects, we were concerned about preserving anonymity and remaining unbiased in our interpretations of data. This led us to devise coding mechanisms that masked teachers' identities. Also, in an effort to make more of their statements fit our framework, we cut up entire reflection papers into smaller chunks. All of this manipulation of data fragmented the teachers' work and thus created an abyss between the teachers' reflections and the context in which they had been operating. In concealing the teachers' identities we were no longer able to honor their voices and engage in non-evaluative listening. We realized that our chosen research paradigm denied us the opportunity to listen. We had interpreted teachers' writing without considering the social, political and cultural realities of teaching.

Just as we denied our values of respecting and honoring teacher voices in our research, we realized that the same could be said in relation to our teaching. What began as a study of our teacher's writing samples became this story about the development of a faulty framework – one that revealed to us the limitations of our thinking and the contradiction between assuming an evaluative stance (that gave teachers neither agency nor identity) and preaching that learners deserve both. As constructivist teachers, when teaching mathematics, we have, for the most part, learned how to give reason (Duckworth, 1996) to our students as we listen to their mathematical voices. We have learned how to embrace the mathematics of students in shaping our knowledge of mathematics. We are effective in suspending doubt (Harkness, 2009) as our students describe their mathematical thinking. For the most part, we honor and respect the mathematical voices of our students. For this reason we create a learning environment where we are co-constructors of mathematics with our students. However, our analysis of our work with teachers revealed to us another glaring contradiction—Why were we able to give reason to learners when dealing with mathematics, but so unable to give reason to the learner when dealing with teaching? We seemed to have a pre-conceived vision of what constitutes good teaching and were unable to hear the voices of teachers with alternative perspectives—perspectives that grew out of living within a social, political and cultural reality to which we were strangers.

Moving Forward on the Continuum of Professional Growth

How do we live with our living contradictions? We face the personal challenge of positioning ourselves as mathematics education researchers within a new research paradigm that is more aligned with our values. The pressures of our discipline require adherence to a strict code of long standing expectations regarding what counts as valued research. In fact, these constraints sometimes feel oppressive as we work to align our values to our practice. Still the awareness of the living contradiction in our research will guide our future projects.

The living contradiction in our teaching has caused us to question many of our typical practices as mathematics educators, especially in the role of professional development providers or math consultants to districts and schools. We have often engaged in practices such as:

- Accepting the challenge of helping a teacher "improve" her practice based on just a few observations;
- Watching short video-clips of teachers at professional conferences and drawing inferences about their practice as a whole;
- Making judgments about teacher practices from knowing the textbooks adopted by their districts;
- Consulting with schools or districts and accept the administrator's assessment of their staff; and
- Designing professional development experiences based upon our expert analysis of student performance data.

In hindsight, we realize that in each of these instances we have positioned ourselves as experts and denied our teachers agency and identity. The challenge that remains for us is to find a way to enact our new perspective on our role in professional development. What does it mean to engage in professional development with teachers without assuming an evaluative stance; to go into our work together with teachers without a preconceived notion of what is to be learned or taught? We want to do work that respects and maintains the dignity of our teachers and gives them autonomy in crafting a picture of ideal practice. We have begun to acknowledge the value of co-constructing meaning alongside teachers, but need to explore models for how this can be accomplished. We want to move from being imparters of teaching knowledge to being co-conspirators in the act of defining good practice. Perhaps the best next step we can take is to talk about our own learning and to continue to document a living theory (Whitehead, 2009).

"WRONG, BUT STILL RIGHT" – TEACHERS REFLECTING ON MKT ITEMS

Janne Fauskanger
University of Stavanger, Norway
janne.fauskanger@uis.no

Reidar Mosvold
University of Stavanger, Norway
reidar.mosvold@uis.no

The mathematical knowledge for teaching (MKT) measures have become widely used among researchers both within and outside the U.S. Despite the apparent success, the MKT measures and underlying framework have been subject to criticism. The multiple-choice format of the items has been criticized, and some critics have suggested that opening up the items might be an option. One way of opening up the items is to include commentary boxes that allow teachers to explain their thinking. This paper reports on a Norwegian study where commentary boxes were added to MKT items in order to investigate the connection between teachers' responses to the items and their written reflections. The results indicate that there is a mismatch between the answers given by the teachers on the MKT items and their written reflections. Teachers' written reflections do not always support their responses to the MKT items.

Keywords: Mathematical Knowledge for Teaching; Teacher Knowledge; Teacher Reflections

Introduction

Knowledge about mathematical topics and teaching tasks with which teachers struggle is useful when preparing professional development (PD) programs (Hill, 2010). Various methods have been used to study and assess different aspects of teachers' knowledge (e.g., Hill, Sleep, Lewis, & Ball, 2007). The work by Ball and colleagues at the University of Michigan (e.g., Ball, Thames, & Phelps, 2008) is well known, and they have developed the concept of "mathematical knowledge for teaching" (MKT). MKT is defined as "the mathematical knowledge used to carry out the work of teaching mathematics" (Hill, Rowan, & Ball, 2005, p. 373). They have also developed sets of multiple-choice (MC) items to measure MKT. These MKT measures were designed from studies of the work of teaching mathematics in the U.S. (e.g., Hill, 2010). The results from these researchers' efforts are encouraging. MKT appears to make a difference to the mathematical quality of instruction (Hill et al., 2008), as well as to students' achievements in mathematics (Hill, et al., 2005). Morris et al. (2009, p. 492) have described MKT as: "the most promising current answer to the longstanding question of what kind of content knowledge is needed to teach mathematics well."

Many researchers have built upon the efforts of Ball and colleagues, and the MKT measures have been widely used both within and outside the U.S. (e.g., Ng, 2012). Despite the apparent success of this research, there have also been critics (e.g., Schoenfeld, 2007). It is suggested, for example, that the knowledge required for teaching may be more culturally based than simply pertaining to mathematical knowledge (Stiegler & Hiebert, 1999; Stylianides & Delaney, 2011), and that cultural aspects have not been taken into consideration in the development and application of the MKT measures. There have been efforts to study the challenges of translating and adapting the items into a different cultural context (e.g., Fauskanger, Jakobsen, Mosvold, & Bjuland, in press; Ng, 2012) and to compare some of these challenges (Ng, Mosvold, & Fauskanger, 2012). Substantial additional investigation is needed to learn more about the cultural issues related to the translation, adaptation and use of MKT items in different cultural contexts. Another criticism relates to the MC format of the items. Schoenfeld (2007) claimed that the MC format has the potential to complicate the items for test-takers. This claim was supported by findings from a Norwegian study (Fauskanger, Mosvold, Bjuland, & Jakobsen, 2011). In the Norwegian study, teachers suggested that the items include commentary boxes to enable the teachers to explain their thinking, which has been proposed as one way to open up the items. Thus, an extended discussion of the validity of the items appears to be necessary.

The present paper contains a discussion of the criticism as addressed by adding commentary boxes to enable the inclusion of teachers' written reflections to the MKT items. One expectation would be that teachers responding correctly to an item would also provide reflections that support their responses, but to our knowledge no previous attempts have been made to investigate opening up of MKT items in this way. We address herein the following research question:

> What is the connection between teachers' responses to MKT items and their written reflections concerning the content of the items?

Given the importance of developing students' fluency in multi-digit arithmetic as a foundation on which to build a proper understanding of the decimal number system (e.g., Verschaffel, Greer, & De Corte, 2007), we have chosen to analyze data from a MKT testlet, including four items where different methods of decomposing a three-digit number are presented.

Methods

The research reported in this paper is part of a larger project focusing on teachers' MKT and their corresponding beliefs about MKT (e.g., Fauskanger, 2012). For the purpose of this paper, data from 30 teachers' responses to MKT items and their written reflections will be analyzed, taken from one testlet including four MC items. This testlet has not been released for publication,[1] therefore we are only able to provide a description of it. The stem presents a context dealing with groups of students who have decomposed a three-digit number (e.g., 456) into hundreds, tens, ones and tenths in different ways. The question posed is which answer the teacher should accept as correct. In the first item (1a), the students have answered incorrectly (e.g., 456 decomposed into 4 hundreds, 50 tens and 6 ones). The remaining three items represent correct decompositions including hundreds, tens and ones (1b), hundreds, tens and tenths (1c) and tens and ones (1d). The decomposition that strictly follows the positions (e.g., 456 divided into 4 hundreds, 5 tens and 6 ones) is not present in any of the items.

Although MKT items are normally used in a testing situation, other alternative uses have been applied. In our study, the teachers responded to the items at home. It is important to consider the advantages as well as disadvantages of allowing teachers to work with the MKT items at home (see e.g., Hill, 2011). One obvious consequence is that the teachers in our study had the opportunity to discuss the items with others. Their written reflections, however, were individual. They were asked to reflect on the following questions in the commentary boxes: (1) What do the students responding as in items (a) to (d) know? (2) What, if anything, do they need to learn more about? (3) Do the items in this testlet reflect a content that is relevant for the grade(s) you teach? (Why?/Why not? Please provide an illustrating example from your classroom). The reflections were provided for the entire testlet, not for each individual item.

The 30 teachers (8 men and 22 women) were participating in a one and one-half year PD course, and the written work reported on was given as an assignment after their first day in this PD. Sixteen of these teachers worked in grades 1–4, nine in grades 5–7 and five in grades 8–10. Their working experience as teachers varied from less than 5 years to more than 20 years, and their formal education in mathematics (education) varied from 0 to 60 ECTS.[2]

The analysis was conducted with the aid of the computer software NVivo9 (QSR International). The teachers' written reflections were first divided into two groups. One group contained reflections from teachers who had identified the correct key for all four items in the testlet (main group 1, table 1), whereas the second group contained reflections from teachers who had responded incorrectly to one or more of the items (main group 2, Table 1). In the next phase of the analysis, a grounded theory approach (Strauss & Corbin, 1998) was applied in order to analyze the reflections from these two groups of teachers according to how they had commented on the items. Based on several cycles of reading and re-reading the data, the teachers' reflections were refined into codes that were revised several times to establish consistency. The codes were based on well-established findings from the literature concerning place value (e.g., Jones, Thornton, Putt, et al., 1996; Verschaffel, Greer, & DeCorte, 2007). Two sub-categories (a and b in table 1) were discovered for each of the two main groups as a result of this analysis.

Results

In this section, we present the results from our analysis of data regarding the connection between teachers' responses to the four MKT items and their written reflections on the content of the items. Item 1a presents a context where a group of students had given an incorrect response to the MKT item. All 30 teachers in our study identified the key in this item, but 10 teachers had incorrect responses to at least one of the other items in the testlet. If the teachers selected the alternative "I am not sure," their answer would then be coded as incorrect (see Table 1).

Table 1: Teachers' Reflections Regarding Multiple Decompositions

	Think multiple decompositions are correct (1)	Think multiple decompositions are incorrect (2)
All correct (a)	7	13
At least one incorrect (b)	1	9

It is important to notice that it was not always evident in which groups the teachers should be placed; when placing the teachers in groups we allowed them the benefit of doubt if their reflections were ambiguous (e.g. Gerd's reflection below). Two among the seven teachers in the first group could have been placed in the second group, but were placed in the first group although some thoughts in their written reflections were incomplete.

Correct Responses with Supporting Reflections (Group 1a, Table 1)

Although 20 teachers identified all four correct keys in this testlet, only seven displayed supporting thinking in their written reflections. Oda[3] was one of the seven teachers who gave the correct answer to all four items, and she wrote this in her reflections on item 1c:

> I think we have before us an advanced solution in relation to the place value system (in this item). This student has a well-developed number concept and is able to use his fantasy when replacing the one with tenths. In this way, his knowledge about tenths is displayed.

Two of the seven teachers indicate that the students display a very good understanding when they make a decomposition of numbers that differs from the standard decomposition. Tor writes:

> They could have given a more simple solution by using 4 hundreds, 5 tens and 6 ones, but we can say that some (students) are clever in the way they don't necessarily use the correct decomposition but still get the right answer.

The reflections of some teachers were less clear, and as a result it was difficult to evaluate whether or not they displayed a correct manner of thinking. In relation to item 1b, Gerd writes:

> This is, consciously or unconsciously, written in a more advanced way. It might be that he wants to show that he has complete mastery of this, or it might just be a coincident.

These reflections indicate that Gerd believes that the students might have a more advanced understanding, but she is not certain about whether or not their responses are conscious. Later in her reflections, however, she writes that: "none of these solutions are perfect according to the place value system." This last assertion is not explained further.

Correct Responses with Non-Supporting Reflections (Group 2a, Table 1)

Of the 20 teachers who had correct responses to all four MC items in this testlet, 13 provided reflections that did not entirely support their responses. Dina writes:

> The students need to learn about the standard place value system and the proper exchange between digits.

Brit writes:

> The students need to learn more about exchange, learn to fill up the ones, tens, hundreds, etc. Know that each position has its (distinct) value. When the value exceeds 9, they should shift position.

In relation to item 1d, Frida writes that the students:

> ... lack an understanding of the place value system, and the student only understands the tens place and ones place in the place value system. The total sum is still 456, so the student obviously understands decomposition and the value of the number (...) All students are on their way towards an understanding of how a number can be written in extended form. They have to learn more about the place value system. They need to reach an understanding of which number belongs where, one number in each position.

The suggested solutions in items (b) through (d) are all mathematically correct, and these teachers have identified the correct solutions in the MC items. In their reflections, however, they seem to insist on the mathematical convention: “When the value exceeds 9, they should shift position.” Although they recognize that the students’ solutions were mathematically correct, they do not regard them as “the answer the teacher is seeking,” and, therefore, their reflections do not support their responses to the MC items. The written reflections of these teachers are in line with those given by the nine teachers in the last group (2b in Table 1), which consists of teachers who have identified one or more incorrect keys and who have written reflections supporting their responses to the MC items. For example, Erna identified three correct keys and writes this in her reflections:

> Student b) is wrong, but still right. Incorrect decomposition, but the correct total (amount). The student has understood how to decompose the number so that it doesn’t increase or decrease in value, but still hasn’t placed it correctly according to the place value system.

Eli identified the correct key for item 1a only, and she writes this in connection with items 1b-d:

> b) This student manages to decompose the number 456, but apparently hasn’t completely understood the value of the digits in the place value system. It is indeed correct that you can decompose 456 into 3 hundreds, 15 tens and 6 ones, but this is not the answer the teacher is seeking.
>
> c) This student has understood the value of the numbers 4 and 5, but is mixing up the ones. It is a little bit funny to see that the student makes it so hard on himself. This student knows that there are 10 tenths in 1 one.
>
> d) This student knows how many tens there are in 456, but hasn’t understood the value of the digits.
>
> Which of these answers you should approve as correct depends on how long the students have been working on this topic. If the students have been working with this for an extended period of time, I wouldn’t have approved any of the answers. If, however, this is the introduction to decomposition of numbers, I would have approved b) through d).

In their reflections, the teachers in the fourth group appear to insist on the same mathematical convention as the teachers in the second group do.

Incorrect Responses but “Correct” Reflections (Group 1b, Table 1)

Out of the ten teachers who gave incorrect responses to one, two or three items, or who gave the response “I am not sure” to some of these items, one teacher showed an understanding of the MKT being measured in her reflections. Laura marked all three items with “I am not sure” (which is coded as an incorrect response), but she argued in her reflections that the testlet stem could be interpreted in different ways and that the key for each item would be dependent on how the stem was understood. The following is an excerpt from Laura’s reflections:

> Item a) is wrong by all means. Items b), c) and d) are wrong if it (the problem presented in the stem) is a closed problem, but they are correct if it is an open problem.

By “closed problem” this teacher means using the positions given (e.g., 456 = 4 hundreds, 5 tens and 6 ones) and by “open problem” the teacher means open to other ways of decomposing three-digit numbers. This teacher’s written reflections are in line with some of those from the seven teachers in the first group.

Discussion and Conclusions

Four groups (as presented in Table 1) emerged in our analysis, and the results from our study indicate that there is not always a clear connection between the teachers’ responses to the MKT items and their written reflections. Researchers who use the MKT items would probably expect, or at least hope, that teachers who answer the MC items in the measures correctly also have an appropriate understanding of the content, and the other way around. In our study, there are some teachers who follow this pattern. We have, however, identified an apparent mismatch between the responses to the MC items and the written reflections of several teachers. We have seen an example of one teacher (group 1b) who provided incorrect responses to the MC items but who displayed a high level of understanding in her written reflections. She appears to know the mathematics but she is still unable to determine for what answer the test-makers are looking. Another group of teachers (group 2a), were interesting as they were able to select the correct answer, but appeared to still believe that there is a particular name for the number that is better. These teachers are able to see that “4 hundreds, 5 tens and 6 ones” is the same value as “4 hundreds, 15 tens and 6 ones,” but still believe that the name that matches the place values is better. If we consider the example of using the standard Norwegian algorithm for calculating 456 minus 37 (Figure 1), we have an example where the “place value name” is clearly not the best name for the number. As a result, teachers who hold such beliefs could be seen as in transition along a continuum. First, we have the teachers who are not able to understand non-standard decompositions of numbers. Second, there are teachers who can understand multiple decompositions of numbers, but who still believe that the standard decomposition is best. Third, there are teachers who understand and value multiple decompositions of numbers. Fourth and finally, there is a possibility that some teachers understand, value and can explain the use of alternate decompositions.

$$\begin{array}{r} {}^{10} \\ 4\cancel{5}6 \\ -\ \ 37 \\ \hline 419 \end{array}$$

Figure 1: Standard Norwegian algorithm for subtracting 37 from 456

The findings may be explained in a variety of ways. We present four possible explanations as follows.

1. The findings are incidental. This might be connected with our study being limited by the number of participants as well as the limited focus of the items. More research is necessary in order to investigate whether or not the same tendencies can be found in a larger number of participating teachers.
2. This apparent mismatch is specific to this particular topic. It would be pertinent to also investigate whether or not, or if the same pattern can be found for all sets of MKT items.

3. There are cultural differences involved in how teachers reflect upon these items. One such difference might be related to how the decimal number system is taught. If such cultural differences are involved, it would be of great interest to conduct additional research to investigate this further. Researchers have already adapted and used MKT items in different countries (e.g., Ng, 2012), and if there are cultural differences related to the connection between teachers' responses to items and their reflections, great care should be taken when it comes to how the results from such studies are interpreted. We suggest that efforts should be made to investigate these issues both inside and across cultures to learn more about the connection between teachers' MKT, their corresponding beliefs and the educational culture(s).
4. A final possible explanation of the differences between these Norwegian teachers' responses to the MKT items and their written reflections is that there are indeed, as Schoenfeld (2007) argued, constraints resulting from the MC format of the items. Such possible difficulties with this format might be specific to culture, as Fauskanger and colleagues (2011) suggest. From the results of the present study, however, it does not appear that the MC format itself makes it more difficult for the teachers. The complicating connection between the teachers' responses to the MKT items and their written reflections only indicates that the MC items are harder to interpret than they might appear. The inclusion of commentary boxes along with the items, or other ways of opening up the items, should be investigated further. It would also be relevant to include interviews with teachers to further investigate teachers' reflections as well as the connection between these reflections and their MKT as measured by their responses to the items.

Our study indicates that researchers have to be careful concerning the conclusions they draw when measuring teachers' MKT. Particular care should be taken when using these measures in other cultural settings and more research is needed in this area. We argue that it is important to include the teachers' reflections in order to learn more about their MKT, and more research is needed to investigating teachers' epistemic beliefs (Fives & Buehl, 2008) related to the different aspects of MKT. Analyses of teachers' reflections concerning MKT items can be particularly useful in this regard. Follow-up interviews with teachers in groups 1b and 2a would also be relevant for future studies.

Endnotes

[1] The numbers have been changed in our descriptions of the item in order not to reveal the entire item, and these details in the teachers' reflections have been changed accordingly.

[2] ECTS stands for European Credit Transfer and Accumulation System. One year of full-time studies in Norway gives 60 ECTS.

[3] The teachers' names have been changed to ensure anonymity.

This study examines the connection between mathematical knowledge (described as a teacher's engagement in mathematical processes and actions on the products of those processes) used by a beginning secondary mathematics teacher (Fiona) in her personal mathematical problem solving and the mathematics in which she engaged her students in her classroom instruction. This Process and Action approach involved analysis of Fiona's use of four mathematical process/product pairs (justifying/ justification, generalizing/generalization, defining/definition, and representing/representation). Two themes arose in the analysis of interview and classroom observation data: (a) Although able to do so, Fiona did not regularly engage in processes in her personal mathematics or classroom mathematics, and (b) Fiona focused on selected features of a product or mathematical object rather than attending to all relevant features.

Keywords: Teacher Knowledge; Mathematical Knowledge for Teaching

Purposes or Objectives of the Study

Research interest has recently burgeoned regarding the relationship between teachers' mathematical knowledge and the ways that that knowledge impacts what happens in the classroom. Of particular interest is how teachers' knowledge affects both what teachers do and what students learn. Over the years, researchers (e.g., Eisenberg, 1977; Hill, Rowan, & Ball, 2005; Monk, 1994) have investigated the relationship between teacher knowledge and student achievement, typically using proxies for teachers' mathematical knowledge. These studies have often found that teacher knowledge is related to student achievement, but they have not shed light on how teacher knowledge affects what is happening in classrooms. This question has received much less attention from researchers, and many of the studies of that relationship do not separate content knowledge and pedagogical content knowledge (e.g., Hill, Ball, Blunk, Goffney, & Rowan, 2007; Lehrer & Franke, 1992; Swafford, Jones, & Thornton, 1997), leaving one to wonder about the effects of content knowledge itself on instructional practice. Studies that examined the relationship between content knowledge and classroom practice (e.g., Baumert et al., 2010; Rowland, Martyn, Barber, & Heal, 2000; Tchoshanov, 2011; Wilkins, 2008) have found relationships, but these studies focused on narrowly defined aspects of classroom practice (e.g., cognitive demand of tests and homework, students' opinions about instruction, teachers' self-reports of reform practices) and used written tests of predetermined categories of teacher knowledge (e.g., high and low content knowledge, cognitive type of content knowledge). Although the studies identified relationships, they did little to explain why these relationships might have occurred. The study reported here used extensive sets of interviews and observations focused on teachers' mathematical knowledge and its use in the classroom to characterize and explain the relationship between a teacher's mathematical knowledge and classroom practice. This study addressed the question of what characterizes a beginning secondary mathematics teacher's engagement in personal mathematics and classroom mathematics and the relationship between them.

Perspective

We describe mathematical knowledge in terms of four mathematical processes and their respective products: defining, justifying, generalizing, and representing, and actions on (or uses of) definitions, justifications, generalizations, and representations (Zbiek, Peters, & Conner, 2008). Using the processes and products to characterize a teacher's mathematical knowledge allows us to examine the mathematics demonstrated in his/her problem solving (*personal mathematics*), the mathematics in which the teacher engaged his or her students (*classroom mathematics*), and the relationship between the teacher's personal and classroom mathematics. A second affordance of using mathematical processes is that it transcends both mathematical content areas and grade levels, since the use of these processes and products is not dependent on either of these factors. Examining mathematical knowledge as knowledge evidenced by engagement in mathematical processes allowed us to examine mathematical knowledge over a period of three and a half years across three different content areas.

Methods

Our data consist of five task-based interviews and 16 teaching observation cycles of a secondary mathematics teacher, Fiona (a pseudonym). At the beginning of data collection, Fiona was enrolled in a secondary mathematics teacher certification program at a large Mid-Atlantic university. She was one of several in the program who volunteered to participate in the study. The task-based interviews (*Area*, *Count*, *Cube*, *Wrap*, and *Defining*) were conducted during Fiona's teacher preparation program for the purpose of understanding her use of mathematical processes and products in her personal mathematics. To understand Fiona's use of processes and products in her classroom teaching, teaching observation cycles were conducted during her student teaching (pre-calculus), first-year teaching (algebra), and second-year teaching (geometry). An observation cycle consists of a pre-observation interview, an observation, and a post-observation interview.

All the task-based interviews were videorecorded and audiorecorded, transcribed, and annotated. Teaching observation cycles were audio-recorded, transcribed, and annotated. Still photos from the teaching observation cycles were also collected. The task-based interviews were coded line-by-line for Fiona's use of processes and/or products by the research team. The coded instances were elaborated, categorized into the four process/product categories, and analyzed for emerging themes. Any disagreements were resolved by review of the data by the entire team. This procedure was repeated for the teaching transcripts, but included the coding and analysis of mathematical activity and pedagogical choices. After the initial coding and analyses, the team then compared Fiona's use of process and/or products in her personal mathematics with their use in her classroom mathematics.

Figure 1 illustrates parts of the Cube and Area tasks. In Cube, Fiona was asked to describe the pattern and determine the surface area and volume of the model shown in the left panel of Figure 1. In Area, Fiona was asked to describe the mathematical relationship between the sum of the area of the circles and the area of the equilateral triangle shown in the right panel of Figure 1 as the number of circles on the base increased. [One side of each equilateral triangle passes through the centers of the circles on that side and the endpoints of the same side lie on circle(s).]

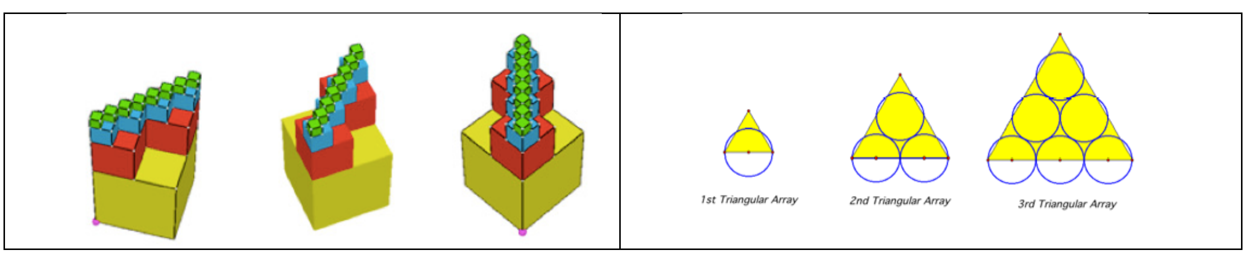

Figure 1: Some of the illustrations accompanying the cube and area tasks

Results

Representing

Fiona tends to notice and pay attention to only select features of representations rather than accounting for the representation's complete set of relevant characteristics. In Area, when Fiona was given the graph of the function defined as the difference between the area of the triangle and the sum of the areas of the circles, she focused on the x-value of the minimum point of the function as invariant and interpreted it as the point at which the area of the triangle exceeds the sum of the area of the circles. She seemed to recognize that the graph of the differences required a change from negative to positive without recognizing that the negative-to-positive change captured by the minimum was a change in slope rather than a change in the output value of the function. She did not attend to the x-intercepts, the feature of the graph most relevant to the question she was asked, until she was specifically asked about them.

In her classroom mathematics, Fiona missed opportunities that might have engaged her students in linking different representations. For example, in student teaching, she purposefully did not interpret for students a graphical representation of derivative that appeared on an activity sheet. During the post-observation interview, Fiona ably linked this graphical representation to a symbolic representation of derivative but she stated that "they don't know that, and if I would explain it to them I would have confused them, I think endless amounts" as the reason for not discussing the graphical representation. She seemed to have made a conscious choice not to include this in her lesson. This might have been because her goal was only for students to be able to apply the limit definition of derivative in order to complete exercises and she thought that trying to develop further understanding of the limit definition was not worth confusing students.

In both her personal and classroom mathematics, Fiona often focuses on local features of representations and seems not to grasp the entire representation. This tendency of localization and inattention to connections is frequently observed in her personal and classroom mathematics and suggests that mathematics as an integrated system is not central to her conception of mathematics.

Justifying

In her personal mathematics, Fiona regularly makes initial mathematical claims for which she provides no or limited mathematical rationale. Fiona offers mathematical justification unprompted only when she recognizes an error and engages in correcting the error. Otherwise, Fiona justifies her mathematical claims only after she is prompted by the interviewer with questions such as, "How might you convince someone of your claim?" Moreover, when Fiona justifies by referencing properties of mathematical objects, she often fails to complete a valid mathematical argument. In these instances, Fiona often attends to one property of the mathematical object, but fails to attend to other relevant and necessary properties. In the Area interview, for example, Fiona engaged in justifying that the sum of the areas of the circles in an array is larger than the area of the triangle in the same array. She identified two differences in the symbolic representations of the two areas, but based this argument on one difference in the formulas (one area formula involved multiplying by π and the other involved dividing by the square root of three) without accounting for the other difference (($x + (x - 1) + (x - 2) + \ldots + 0$) versus x^2) (see Figure 2).

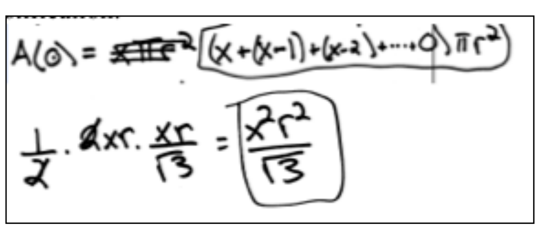

Figure 2: Fiona's representations of the sum of areas of the circles and the triangle area

In the context of Fiona's classroom mathematics, Fiona seldom engages in mathematical justification or asks students to justify. Across all three years of teaching, Fiona regularly misses opportunities to engage students in justifying. One of these instances occurred as Fiona taught rules for derivatives in student teaching. Fiona followed her presentation of the product rule with a presentation of the quotient rule. Even when a student pointed out the similarity between the product rule and the quotient rule, Fiona did not use the comment as a segue to recognizing and justifying that the quotient rule can be viewed as an instance of the product rule.

When Fiona engages in justifying or asks students to justify she often accepts superficial rationales. These superficial rationales were often rules or step-by-step procedures Fiona taught the students to use for a set of homework exercises. In first year teaching, for example, Fiona asked the students to justify the claim that 156 is the y-intercept of the equation $y = 78x + 156$. Fiona accepted a student response of "Because I know the equation is y equals $mx + b$ and then b is the y-intercept," echoing a fact that Fiona had taught during the previous class.

Instances of justifying in Fiona's personal mathematics and teaching seem to indicate that Fiona sees the role of justifying as verifying an assertion rather than as a critical process in her mathematics. Although Fiona ably demonstrates her ability to justify in her personal mathematics, she rarely does so without prompting. Often her justifications are invalid, because she attends to only some of the relevant features or properties of a mathematical object. In Fiona's classroom mathematics, she justifies or has students justify in the context of reviewing homework exercises or in-class examples. These justifications are usually superficial rationales or rules that do not provide mathematical connections.

Generalizing

In Fiona's personal mathematics, she generalizes but rarely uses generalizations. Although she generalizes, she does not tend to generalize without being prompted even when it seems reasonable to do so. For example, in Cube, Fiona was asked to find the volume and surface area of a stack of cubes. Fiona recognized that the volume of a cube in one particular layer was one-eighth the volume of a cube in the previous layer, but was hesitant to conclude that this was true for all layers and did not do so until she was prompted. Fiona's generalizations are not always correct, and these incorrect generalizations are often due to her focusing on a limited domain or set of examples and not accounting for all possibilities. For example, in Count when asked about a three-dimensional analogue of the circles situation shown in the right panel of Figure 1, Fiona generalized that no matter the size of a pyramid constructed of spheres, there are no interior spheres. She based this incorrect generalization on having examined only a single case.

In Fiona's classroom mathematics, there were many more instances of generalizations than generalizing. Similar to her personal mathematics, Fiona does not engage in generalizing when it seems that it would be appropriate to do so. For example, rather than giving students a single equation that can be used in various exercises, Fiona directed students to use three different equations for three different, but clearly related, cases: the equation $y/x = k$ to find the value of k, the equation $y = kx$ to find the value of x, and the equation $f = kd$ to find the value of k in an exercise involving Hooke's Law. Fiona discusses and implements activities that potentially provide students the opportunity to engage in generalizing. However, when she implements activities aimed at generalizing, she usually leads students to reach a generalization that she has predetermined rather than allowing for generalizations she has not anticipated. The theme in her teaching seems to be that generalizations are finished products, suggesting that she may consider the universe of possible generalizations as fixed and known. Also, Fiona states generalizations that are false, often based on a limited domain or set of examples. For example, when introducing a lesson on graphing lines, Fiona states the incorrect generalization, "There is a y-intercept and an x-intercept for every single line," not accounting for horizontal or vertical lines.

Although Fiona's personal mathematics did not make use of generalizations and her classroom mathematics contained almost no generalizing, Fiona's personal mathematics and her classroom mathematics have two main commonalities. First, Fiona often does not generalize when it seems as if it would be appropriate to do so. Second, Fiona often incorrectly generalizes or states incorrect generalizations because she is focusing on a limited domain or examples and is not accounting for all possibilities. The absence of further commonalities in Fiona's generalizing and use of generalizations may be attributed to the lack of the use of generalizations in her personal mathematics and the lack of generalizing in her classroom mathematics.

Defining

As with other processes, the process of defining does not seem to play a central role in either Fiona's personal mathematics or her classroom mathematics. We hardly ever observed her engaging in defining and most often we saw her engaged with the product of defining, namely definitions. In her personal mathematics and teaching, she tends to focus on elements of definitions rather than thinking about the definition as a whole. She seems to compartmentalize definitions and not to coordinate them in her teaching or in her personal mathematics. In the task-based interviews, she was presented with six ways in which people may talk about a parallelepiped (see Figure 3). She was asked which of the six descriptions are most similar to each other. If Fiona were to be thinking of these six statements as defining six separate objects, we would expect her to consider the mathematical entity each statement defines and to compare those entities. However, she chose to examine parts of each statement and to compare them to parts of other statements. For example, she stated that descriptions B and F are similar to each other because they both describe a six-sided polyhedron. However, she never endeavored to examine each description as a whole.

a. **A parallelepiped is a box with a lid.**
b. **A parallelepiped is a polyhedron with six faces that are parallelograms, which could be rectangles, squares or rhombuses but not trapezoids.**
c. **A parallelepiped is a cube whose sides are rectangles.**
d. **A parallelepiped is a prism the base of which is a parallelogram.**
e. **A parallelepiped is a hexahedron each face of which is a parallelogram.**
f. **A parallelepiped is a hexahedron with three pairs or parallel faces.**

Figure 3: Six ways people may talk about a parallelepiped

This tendency to focus on parts of a definition, rather than on the whole definition, is also reflected in her teaching. For instance, Fiona presented a definition of a vertex as "a point at which three or more faces meet." However, later on during the same lesson, Fiona introduced the phrase, "a vertex of a cone," offering a description: for a cone, "a curved surface connects the base to the vertex." One of her students pointed out that what she has labeled as a vertex is not actually a vertex, given the original definition of a vertex. Fiona agreed with the student without offering an explanation for her agreement. In the post-observation interview, Fiona explained that the student who asked the question is "very smart" and answering his question would just confuse the other students in the class.

The previous example involving the vertex also highlights how Fiona seems to view mathematics as a static and fixed body of knowledge, rather than something that can be discovered using the processes. If Fiona were to privilege a perspective of mathematics that encourages involvement in mathematical processes such as defining, we would have expected her to engage the student in a discussion of the mathematical properties of the two definitions of a vertex. This view is further illustrated in her first year of teaching when she presented her students with a definition of a y-intercept of a line. Fiona asked one of her students to read the textbook definition of a y-intercept, "The y-value of the point where the line crosses the y-axis." However, when Fiona repeated this definition and subsequently used it, she re-worded it as, "The y-intercept is the point where our line crosses the y-axis." Fiona seemed unaware of the change she made to the definition of a y-intercept, or she may not have seen a difference in the two definitions presented. Either possibility points to her seeing mathematics as comprised of static and disconnected pieces of information, and thus, if these pieces of information conflict with each other, she does not seem perturbed by it.

Conclusions

Two themes characterize Fiona's use of processes and actions on the products of those processes. These themes cut across several processes and are evidenced both in her personal mathematics and in her classroom mathematics.

Themes

The first theme is that, although Fiona has demonstrated competence in engaging in all four of the mathematical processes studied, the processes of generalizing, justifying, and defining are not central to how she engages in mathematics or how she engages students in mathematics. In her task-based interviews, Fiona generally engages in these processes only when prompted. Similarly, while teaching, she seldom engages in processes or requires that students do so even though we observed several occasions (e.g., students asking Fiona for justification or Fiona providing students with activities designed to lead to generalizing) in which it would have seemed reasonable to engage in processes. Fiona is far more likely to engage in actions on the products of processes than to engage in processes or to engage her students in those processes. The possible exception to this is the process of representing. In her personal mathematics, Fiona seems to use representing to help her in problem solving, often using one type of representation to create another and connecting representations to provide justifications. In her classroom, although Fiona occasionally directs students to use different representations in problem solving (e.g., directing students to draw a graph if they are struggling with writing an equation of a line or having them use geometric figures to generate tables of values in order to look for a generalization) she often misses opportunities to have students examine multiple representations even when it would seem to make sense to do so (e.g., not showing students a graph to explain a limit definition of derivative).

A second theme is that Fiona has a tendency, when working with processes and actions on the products of those processes, to focus on some features of a product or mathematical object and not attend to other relevant features. In her personal mathematics, many of Fiona's justifications are incorrect because she has not attended to all of the relevant characteristics of the object in question. In the Defining interview, Fiona incorrectly defines a particular set of polyhedra as having exactly one pair of parallel faces without recognizing that some of the polyhedra in the set have more than one pair of parallel faces. In her classroom mathematics, she uses the term vertex as having universal applicability and fails to distinguish between definitions of a vertex of a polyhedron and a vertex of a cone.

Conceptions of Mathematics

Much of the work to date on teachers' and students' conceptions of mathematics has been focused on describing and categorizing these conceptions. For example, Ernest (1988) categorized conceptions of mathematics into three broad categories: an instrumentalist view of mathematics as a set of unrelated but utilitarian rules and facts, a Platonist view of mathematics as a static body of knowledge, and a problem solving view of mathematics as dynamic and continually expanding. Lerman (as cited in Thompson, 1992) identified two different prevailing conceptions of mathematics: the absolutist perspective, that is, the perspective that "mathematics is based on universal, absolutist foundations" and the fallibilist perspective that "mathematics develops through conjectures, proofs, and refutations and is accepted as inherent in the discipline" (Thompson, 1992, p. 132).

There is growing evidence that teachers' conceptions of subject matter have an influence on their classroom instruction and there have been a few studies that provide evidence of the link between teachers' conceptions about mathematics and their instruction (e.g., Cross, 2009; Raymond, 1997; Thompson, 1984). It is evident that this influence is not direct or simple and results are inconsistent about how strong that influence may be.

Although Fiona did not speak directly about it, it is conceivable that Fiona's conception of mathematics could explain her approach to processes and actions on the products of those processes in both her personal mathematics and her classroom mathematics. The pervasiveness and consistency of the two themes we identified across the four processes and in both Fiona's personal and classroom mathematics seem to indicate that Fiona has a conception of the nature of mathematics that is not centered on the use of mathematical processes and does not require attention to connections and consistency. It seems likely that Fiona views mathematics as a fixed body of facts, ideas, and rules that are not necessarily or easily connected. Within such a concept of mathematics many of Fiona's actions make sense. For example, if mathematics is a fixed set of ideas then it is reasonable that Fiona does not encourage creative generalizing but chooses to focus attention on the generalization students are supposed to be learning. Fiona's apparent lack of attention to the fact that mathematics needs to be connected and coherent helps to explain why she seems not to notice or be concerned about contradictory definitions of vertex. Meanwhile, a view that mathematics is fixed and static may explain why, when a student points out the discrepancy, she might find it adequate simply to tell students that "it's part of the definition."

MATHEMATICAL KNOWLEDGE FOR TEACHING HIGH SCHOOL GEOMETRY

Patricio Herbst[1]
University of Michigan

Karl Kosko
Kent State University

This paper documents efforts to develop an instrument to measure mathematical knowledge for teaching high school geometry (MKT-G). We report on the process of developing and piloting questions that purported to measure various domains of MKT-G. Scores on the final set of items had no statistical relationship with total years of experience teaching, but all domain scores were found to have statistically significant correlations with years of experience teaching high school geometry. We use this result to propose ways of conceptualizing how instruction-specific considerations might matter in the design of MKT items.

Keywords: Mathematical Knowledge for Teaching; Geometry; High School Education; Assessment

Overview

In his description of paradigms for research on teaching, Shulman (1986a) had called for a focus on teacher knowledge. With particular reference to mathematics, Ball, Lubienski, and Mewborn (2001) responded to Shulman's call by, on the one hand, reviewing research that showed that traditional measures of teachers' content knowledge (e.g., degrees obtained or mathematics courses taken) had not shown to make a difference on students' learning and, on the other hand, arguing that the kind of teacher knowledge needed to focus on was a particular kind of mathematical knowledge, mathematical knowledge for teaching (MKT). This MKT is knowledge of mathematics used in doing the work of teaching and it includes but also goes beyond the pedagogical content knowledge that Shulman (1986b) himself had proposed. The theoretical and empirical work on Ball's brand of MKT that followed such proposal has been vast, showing among other things that the possession of MKT can be measured, that MKT is held differently by teachers and non-teachers, that MKT is held differently by teachers of higher grade level experience than those of lower grade level experience, that it makes a difference in students' learning, and that scores on MKT correlate with scores on an observation measure of good teaching (Hill, Schilling, & Ball, 2004; Hill, Rowan, & Ball, 2005; Hill et al., 2008). The work on constructing measures of MKT has been concentrated mostly on the mathematical knowledge of elementary and middle school teachers (Hill & Ball, 2004; Hill, 2007); a more recent effort has developed MKT items in algebra (Mark Thames, personal communication, 6/15/11). The purpose of this paper is to report on a parallel effort to develop an instrument that measures mathematical knowledge for teaching high school geometry. Our effort has attempted to follow the theoretical conceptualization of MKT and item development procedures of Ball and Hill's group. The paper provides pilot data that compares high school teachers with and without experience teaching geometry in terms of their possession of mathematical knowledge for teaching geometry, and it uses these results to raise some questions about the content specificity of the notion of mathematical knowledge for teaching.

A crucial element in our development of items to measure the mathematical knowledge for teaching high school geometry has been Ball, Thames, and Phelps (2008) conceptualization of the different domains of mathematical knowledge for teaching. According to Ball et al. (2008), the mathematical knowledge used in teaching can be conceptualized as the aggregation of knowledge from six domains. These domains include Common Content Knowledge (CCK), which is the mathematical knowledge also used in settings other than teaching, including for example knowledge of canonical methods for solving the problems teachers assign to students. The domains also include knowledge that is specific to the work of teaching. Thus Specialized Content Knowledge (SCK) is knowledge of mathematics used particularly in doing the tasks of teaching, such as, for example, the knowledge a teacher needs to use in writing the problems they will assign to students or figuring out "whether a nonstandard approach would work in general" (Ball, et al, 2008, p. 400). A third domain, KCT, or Knowledge of Content and Teaching is defined as a combination of knowledge of teaching and knowledge of mathematics and includes the knowledge needed to decide on the best examples and representations to use for given instructional objectives. And KCS, or Knowledge of Content and Students, includes a blend of knowledge of mathematics and of students' thinking, such as the capacity to predict what students might find confusing or what kind of errors students might make when attacking a given problem. In our effort to construct measures of mathematical knowledge for teaching high school geometry, we developed items that purport to measure each of those four domains CCK, SCK, KCT, and KCS. Ball et al. (2008) also include Horizon Content Knowledge (HCK) and Knowledge of Content and Curriculum (KCC), but our work has not included those domains.

Ball and Hill's Learning Mathematics for Teaching project has developed items that measure the different domains of MKT and that has included, over time, attention to different content strands, including number and operation, patterns, functions and algebra, and geometry. These instruments have also included items that purport to measure mathematical knowledge for teaching middle school mathematics as well as for teaching elementary school mathematics. The extensive item development has yielded numbers of validated items that can be put together into forms that assess MKT for particular content strands. But there has not been, as of yet, a systematic development of items to measure MKT in different content strands or deliberate theoretical consideration about how content-strand differentiation might interface with the domains of MKT (Heather Hill, personal communication, 2/8/12). In particular, how would the specific practice of teaching particular mathematics courses be considered and featured in the process of designing measures of the mathematical knowledge for teaching those courses? In this paper we present our beginning attempts to conceptualize such instruction-specificity within the framework of MKT, by reporting on our development of an instrument to measure the mathematical knowledge for teaching high school geometry.

Our interest in MKT originated from our attempts to contribute to a theory of mathematics teaching that accounts for what teachers do in teaching in terms of a combination of, on the one hand, individual characteristics of practitioners and, on the other hand, practitioners' recognition of the norms of the instructional situations in which they participate and of the professional obligations they must respond to (Herbst & Chazan, 2011). While our earlier work focused completely on the conceptualization and empirical grounding of the latter, the present effort was part of a larger project in which we'd develop measures of the constructs that we had contributed (particularly *norms* and *obligations*) as well as measures of other constructs that would give us measures of individual resources. The conceptualization and disciplined approach to measuring MKT spearheaded by Ball and Hill (Ball et al, 2008; Hill and Ball, 2004) provided us with important guidance for the development of MKT measures. Hence, we developed multiple choice items following the definitions of the domains provided by Ball et al. (2008).

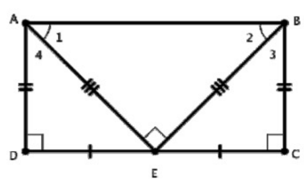
Development of MKT-Geometry

Our item development process covered a relatively wide range of topics from the high school geometry course. We consulted curriculum guidelines in various states and on that basis sought to develop items dealing with definitions, properties, and constructions of plane figures including triangles, quadrilaterals and circles, parallelism and perpendicularity, transformations, area and perimeter, three-dimensional figures, surface area and volume, and coordinate geometry. Those topics by themselves were good enough a guide to create items of Common Content Knowledge. But the definitions of the MKT domains, particularly the definition of Specialized Content Knowledge, calls for items that measure knowledge of mathematics used in the tasks of teaching. To draft these items we found it useful to create a list of tasks of teaching in which a teacher of geometry might be called to do mathematical work. The list included elements like designing a problem or task to pose to students, evaluating students' constructed responses, particularly student-created definitions, statements, explanations, and arguments, creating an answer key or a rubric for a test, and translating students' mathematical statements into conventional vocabulary. As we sought to draft these items, we noted that those tasks of teaching could call for different kinds of mathematical work depending on specifics of the work of teaching geometry. For example, the task of designing a problem would involve a teacher in different mathematical work if the designed problem was a proof problem versus a geometric calculation. While the former might involve the teacher in figuring out what the givens should be to make sure the desired proof could be done, the latter might involve the teacher in posing and solving equations and checking that the solutions of those equations represented well the figures at hand. Thus while a list of generic tasks of teaching was useful to start the drafting of items, this list appeared to grow more sophisticated with attention to tasks that are specific of different instructional situations in geometry teaching (Herbst, 2010).

The tasks of teaching were also useful in drafting items that measured knowledge of content and teaching. To draft these items we used as a heuristic the notion that the item should identify a well-defined instructional goal and the possible answers should name mathematical items that, while correct in general, would be better or worse choices to meet the specified goal. For example, teachers often need to choose examples (and justifications) for the concepts (viz. statements) they teach. While different examples (viz. different justifications) might be mathematically correct, they might not all be pedagogically appropriate to meet particular instructional goals: One example may be better than others as a first or canonical example while another example may be better as an illustration of an extreme case; one argument may require less prior knowledge and thus be more appropriate when students don't know many of the properties of the figure at hand, while another argument may illustrate how all the properties of a figure interrelate.

Finally, to create items that measured knowledge of content and students, we were attentive to the definition provided by Ball et al. (2008) and sought to draft especially items that tested for knowledge of students' errors. As in the case of other domains, there were specifics of the high school geometry class that shaped the items we developed. Thus, while we did create items that probed for teachers' knowledge of students' misconceptions about geometric concepts (e.g., angle bisector), we also created items that probed for their knowledge of students' misconceptions about processes or practices that are specific to geometry—such as the notion that empirical evidence is sufficient proof or that definitions are exhaustive descriptions.

While proving a claim on the board about the figure below, Joe wrote "1 + 2 = 90." Ms. Staples ponders how to correct that statement. Of the following, what is the best alternative?



A	Do nothing. The statement is correct as is.
B	Add the degree symbol so that the statement reads 1 + 2 = 90°.
C	Replace what Joe wrote; write instead that "m∠A + m∠B = 90°".
D	Replace what Joe wrote; write instead that "m∠EAB + m∠EBA = 90°".

After teaching her students the base angles theorem (which states that base angles of an isosceles triangle are congruent), Ms. Wellington is pondering what example she could give to illustrate how this theorem can help find new information. Which of the following would be the best example?

A	If you have a triangle that you know is isosceles and you know two of the sides are 8 and 10, then the third side will be 8 or 10.
B	If you have a triangle that you know the sides have length 8, 10, and 12 you know it does not have two angles that are congruent.
C	If you have an isosceles triangle and two of its angles are 30 you can calculate the third angle by subtracting 60 from 180.
D	If you have a kite and draw its minor diagonal, the kite is divided into two isosceles triangles and those have two congruent angles each.

Figure 1: Example of an SCK-Geometry Item (left) and KCT-Geometry Item (right)

Our research group drafted and revised an initial set of questions including 13 CCK, 20 SCK, 26 KCT, and 16 KCS questions; this drafting and revision process relied among other things on general guidance and comments on specific items by Deborah Ball, Hyman Bass, Laurie Sleep, and Mark Thames.[2] The questions drafted took the form of multiple-choice items, as well as multiple-response items within a single question (e.g., a single stem with 3–4 yes/no questions following). These items were submitted to a process of cognitive pretesting (Karabenick et al., 2007), by way of interviewing teachers and asking them to comment on what they thought each item was asking. Data from the cognitive interviews was also used to examine the content validity of the items, as well as improving such validity. Items were revised to improve interpretability and validity. A revised set of items was pilot tested with inservice secondary mathematics teachers from the same Midewestern state between July and October of 2011. Ten questions from each domain were uploaded into the LessonSketch online platform and completed by participants who took them either by coming in person to a computer lab (37 participants) or by responding to the items online from their homes or workplace (10 participants). For the purposes of this chapter, all data reported is pooled from both samples (n = 47). Participants were predominantly Caucasian (96.4%) and female (56.4%). Participants varied in the amount of mathematics teaching experience (M = 13.02, SD = 7.30), mathematics content courses (M = 10.78, SD = 4.46), and mathematics pedagogy courses (M = 3.04, SD = 2.54). Additionally, 67% of participants had taught Geometry for 3 years or more. Participants completed other questionnaires including one in which they reported on their years of experience teaching secondary school mathematics and teaching high school geometry. Our goal was to use the pilot to select five questions from each domain, as well as additional public-release items.

Item analysis for the MKT-Geometry test was conducted separately for each domain (CCK, SCK, KCS, KCT). We also used the pilot data to select the public-release questions (see Figure 1). In examining the fit of items for each domain, we used biserial correlations (Crocker & Algina, 2006) to measure item discrimination or how well the items discriminated between higher scoring test-takers and lower scoring test-takers. Crocker and Algina (2006) note that in performing classical item analysis such as the one we present here should "…have 5 to 10 times as many subjects as items" (p. 322). Since we conducted item analysis per MKT domain, this suggests a sample of approximately 50 participants (5 × 10 items per domain).

The item analysis of all 10 CCK questions yielded an initial Cronbach's alpha coefficient of .54. We used low biserial correlations (below .30) as one indicator for possible item removal. This resulted in the removal of 3 questions and an acceptable level of internal reliability
(α = .64). The final set of seven questions had biserial correlations ranging from .30 to .48, suggesting sufficient item discrimination. Additionally, item difficulty, in the form of percentage of the sample selecting the 'correct' answer, ranged from 30% to 83%.

We applied the same process to the study of the 10 questions that purported to measure the SCK domain. Item analysis resulted in the removal of three questions. The internal reliability of the remaining questions was found to be sufficient (α = .68), with item difficulties ranging from 19% to 96%. These results suggest both sufficient item discrimination and range of difficulty levels. Item analysis for the KCT domain led to removal of 3 items with a Cronbach's alpha of .57 with item difficulties ranging from 17% to 60%. Item analysis of the ten KCS items resulted in the removal of 3 items. Item difficulties ranged from 17% to 74% (α = .62).

Table 1: Composite Scores and Descriptive Statistics

Domain	M	SD	N	α
CCK – Geometry	0.68	0.22	48	0.64
SCK – Geometry	0.64	0.19	48	0.68
Subject Matter Knowledge of Geometry (CCK & SCK)	0.66	0.18	48	0.74
KCT – Geometry	0.39	0.24	47	0.57
KCS – Geometry	0.44	0.25	47	0.62
Pedagogical Content Knowledge of Geometry (KCT & KCS)	0.41	0.21	47	0.66
MKT – Geometry	0.54	0.18	47	0.84

Table 2: Correlations Between MKT-G Domain Scores

	CCK	SCK	KCT	KCS
CCK	-			
SCK	.44**	-		
KCT	.41*	.59**	-	
KCS	.68**	.55**	.48**	-

*$p < .05$, **$p < .01$

Items chosen through item analysis were used to compute scores for each domain (CCK, SCK, KCT, and KCS) shown in Table 1 above. Correlations between the domain scores are presented in Table 2, and suggest moderate to strong relationships between the different domains. These results show similar trends to those found by Hill et al. (2004) for CCK and KCS, which suggest that the different domains are, to a degree, interrelated. Thus, we interpret the findings from Table 2 similarly in that such relationships make sense, as it would be unusual for a teacher with higher KCS or KCT scores to have significantly lower CCK and SCK scores.

Following the notion proposed by Ball et al. (2008) that some of the MKT domains (notably KCS, KCT, and Knowledge of Content and Curriculum) operationalize the notion of Pedagogical Content Knowledge while the other MKT domains (CCK, SCK, and Horizon Content Knowledge) operationalize Subject Matter Knowledge, we created two additional scores: PCK-G which aggregates scores in KCT and KCS and SMK-G which aggregates scores in SCK and CCK. These are also summarized in Table 1.

Relationships Between MKT-G Scores and Teaching Experience

Our interest in MKT contributes to a larger project that investigates the influence that individual factors (such as mathematical knowledge for teaching) and socialization to the work demands of teaching a particular high school course (in this case, high school geometry, as indicated by teachers' recognition of instructional norms and professional obligations) have in the decisions that a teacher would make. A question we posed to the pilot data is what is the relationship between mathematical knowledge for teaching geometry and experience teaching the high school geometry course. Therefore, we correlated scores for each domain with teachers' years of experience teaching high school, but also with teachers' years teaching mathematics in general. These results are presented in Table 3.

Results indicated a statistically significant and positive relationship for each domain examined. These results show that the more years of experience a participant had teaching high school geometry, the higher their scores were for each domain. While that relationship was statistically significant for years of experience teaching geometry, such a relationship was not found to be statistically significant, or particularly meaningful in size for most measures, when looking at years of experience teaching mathematics in general. Therefore, these results suggest that while teaching experience may affect MKT-Geometry scores, it is the particular experience of teaching the geometry course. To the extent that mathematical knowledge for teaching is the knowledge of mathematics used in the work of teaching, the results lead to ask how the specifics of the instructional work a teacher does in a course matter in the mathematical knowledge for teaching the teacher has.

Table 3. Correlations Between Experience-Type and Score

	Years Teaching Geometry	Years Teaching Mathematics
CCK-G	.32*	.03
SCK-G	.31*	.11
SMK-G	.37**	.08
KCT-G	.36*	.27
KCS-G	.37*	.13
PCK-G	.42**	.23
MKT-G	.43**	.17

$p < .05$, $**p < .01$

Discussion and Conclusion

In our earlier and parallel work we have argued that the particular nature of the didactical contract (Brousseau, 1997; Herbst & Chazan, in press) for a course creates conditions of work that make the teaching of geometry different than the teaching of other mathematics courses, including algebra. The data shown above seems to suggest that teachers of geometry have more mathematical knowledge for teaching geometry, while the difference does not seem to be accountable to general experience teaching secondary mathematics. While at one level one might not find that result surprising, the fact that three of the four domains of mathematical knowledge for teaching we tested for (SCK, KCT, and KCS) are defined as mathematical knowledge used in the work of teaching helps raise questions for future inquiry.

As we noted above, the current conceptualization of MKT has not addressed content differentiation within domains. A natural way of thinking about differentiation could be the topical content of the item—items drawing on knowledge from different branches of mathematics might aggregate into different scores. But that approach seems to apply well only to differentiation within the domain of Common Content Knowledge. To the extent that the other domains are defined in relation to the work of teaching, it is plausible that differentiation within each domain will require considerations of the specifics of the teaching involved. The results from this study suggest that the teaching of high school geometry may entail specific mathematical knowledge demands.

In particular, SCK is defined as the knowledge of mathematics used in doing the tasks of teaching. One could expect that some of those tasks will not be course specific: The task of creating a grading system, for example, involves a teacher in making a mathematical model that feeds from grades in individual assignments; but there is no reason for this mathematical work to be different for teachers of different high school courses. Other tasks of teaching, however, while amenable to generic statement (e.g., choosing the givens of a problem for students), may involve practitioners in different mathematical work depending on the specifics of the task (e.g., choosing the numbers for a word problem in algebra involves different mathematical work than constructing a geometric diagram to include in a geometry worksheet). Are those differences merely differences in mathematical strand (algebra vs. geometry) or do they also reflect differences in the instructional situations (Herbst, 2006) to which those tasks contribute?

We suggest that the management of instructional situations involves teachers in singular mathematical work. An instructional situation has been defined (Herbst, 2006) as a frame for exchanges between types of mathematical work that students will be doing and the knowledge claims that a teacher can make on their behalf based on their accomplishing that work. The teacher's management of instructional situations includes in particular the choosing of the various tasks that constitute that work, the observation of the proceeds (what students actually do), and the effecting of exchanges between such observed actions and the knowledge at stake (identifying at least for herself but possibly also publicly to the class how what students have done indicates their knowledge of what is at stake). While the definition of these tasks of teaching is general, the mathematical knowledge called forth in doing them would be different across different courses, as long as the specific exchanges were different.

A case in point that helps argue that instructional situations matter comes from one SCK question in our instrument. This was a multiple-response question with two items; the stem spoke of a teacher needing to choose algebraic expressions for the sides of an isosceles triangle where the students would be expected to find the lengths of the sides of the triangle after solving an equation. Each item provided expressions for the three sides and asked whether or not they were appropriate expressions. A quick examination of the responses to the item indicated that teachers with more or less years experience teaching geometry (≥ 3 years and < 3 years, respectively) did not respond much differently for the item where the equation could not be solved. However, the two types of teachers' responses did show differences for the item where the equation could be solved: the less experienced teachers tended to answer that the expressions were appropriate while experienced teachers that they were not. In fact, the numbers obtained after solving the equation would not work to represent the sides of a triangle in that the triangle equality would not hold for those numbers. We conjecture that the experienced teachers' familiarity with the instructional situation of "calculating a measure" (Herbst, 2010) mattered in their decision to check that the expressions would yield sides with positive lengths and that they would satisfy the triangle inequality. Our conjecture is not that the non experienced teachers did not know the triangle inequality, but that they did not know it mattered in this task of teaching, possibly because they only saw the problem as an exercise in algebra rather than also as an exercise in triangle properties. More generally, we conjecture that tasks of teaching that are subservient to instructional situations specific to a given course of studies might involve teachers in mathematical work that teachers who are experienced in managing those situations would know better how to do. We suggest that considerations of the nature of the instructional situations in a course could lead to analogous differentiation within the domains of KCT and KCS as well.

Endnotes

MATHEMATICS TEACHERS INVESTIGATING REASONING AND SENSE MAKING IN THEIR TEACHING

Lindsay M. Keazer
Michigan State University
keazer@msu.edu

The purpose of this study was to generate an understanding of the experiences of mathematics teachers examining recommendations for Reasoning and Sense Making (NCTM, 2009) and investigating them in their practice. Narrative inquiry incorporates the voices of teachers and illustrates the phenomenon studied through narratives of participants' experiences. This paper presents the findings through four analogies that convey abbreviated narratives of teachers' experiences enacting recommendations for Reasoning and Sense Making.

Keywords: Standards; Teacher Education/Professional Development; High School Education

Recent recommendations for improving the nature of teaching and learning mathematics across the United States can be traced back to 1980 with the National Council of Teachers of Mathematics (NCTM) publication of *An Agenda for Action* (NCTM, 1980). In subsequent years, NCTM published a series of standards documents (1989, 1991, 1995, 2000) to clarify new goals and curricular recommendations for mathematics education. When evaluating the state of mathematics classrooms, discourse within the field often focuses on the deficits, making broad generalizations pointing to a gap between the state of mathematics classrooms throughout the nation and the classroom environments promoted by these recommendations. Hiebert (1999), for example, declared that "the same method of teaching persists, even in the face of pressures to change," (p. 11). Similarly, the Conference Board of the Mathematical Sciences (1975) asserted that "teachers are essentially teaching the same way they were taught in school," (p. 77) referring to the lack of impact of the earlier "new math" reform movement of the 1960s.

A contributor to the gap between curricular recommendations and classroom practice is the complexity of learning to teach mathematics differently. The changes proposed by reform efforts such as the NCTM standards have the underlying assumption "that teachers will change their world view of mathematics, mathematics teaching, and mathematics learning" (Shaw & Jakubowski, 1991, p. 13). Even when such changes are desired or instigated by the teacher, many have described difficulties they encountered as they attempted them in their own teaching (e.g., Ball, 2000; Cady, 2006; Chazan, 2000; Heaton, 2000). In short, making changes to one's teaching is a complex process.

To add to the conversation surrounding teachers' responses to NCTM recommendations, this study sought to develop an understanding of the experiences of mathematics teachers attempting to enact recommendations for mathematics teaching from *Focus in High School Mathematics: Reasoning and Sense Making* (NCTM, 2009). This document proposed that "reasoning and sense making are the foundations of the NCTM Process Standards" (NCTM, 2009, p. 5), and should be incorporated into "every mathematics classroom every day."

A collaboration of seven mathematics teachers was formed by recruiting teachers interested in investigating their practice and incorporating recommendations into their teaching. The purpose of this study was to learn about the experiences of mathematics teachers as they investigated NCTM recommendations for *Reasoning and Sense Making* (NCTM, 2009) and attempted to make changes in their practice through informal teacher action research. Particularly I focused on five aspects of the experience: conceptions of reasoning and sense making, actions that the teacher took in their teaching, challenges, opportunities, and the teacher's interpretations of the results of their actions. Teacher action research was conceptualized as a self-critical inquiry into one's practice with the goal of improving practice as well as developing a better understanding of that practice (Carr & Kemmis, 1986). Stenhouse (1975) promoted applying curricular recommendations to the formation of one's action research inquiry, suggesting that "the crucial point is that the proposal is not to be regarded as an unqualified recommendation but rather as a provisional specification claiming no more than to be worth putting to the test of practice" (p. 142).

Teachers represented six high schools and ranged from 0 to 11 years of teaching experience (mean of 3.5). They agreed upon the theme of *Reasoning and Sense Making* as the focus of their work together. We met regularly throughout the school year, a total of nine times. Teachers initially read and discussed *Reasoning and Sense Making* and began to focus their action research inquiries in individual ways by selecting specific actions to take in their practice to incorporate their interpretation of the recommendations. Teachers learned informally about the methods of action research through PowerPoint presentations, reading excerpts of methods handbooks, and narrative examples of teacher action research. I created a library of practitioner readings that were related to their goals, from which they selected additional readings. Meetings served as a time for them to discuss readings and share their goals, challenges, and successes.

Data Analysis

During this study a variety of data sources, or *field texts* (Clandinin & Connelly, 2000), were collected to generate an understanding of teacher's experiences. See Figure 1 for an illustration of the data sources that inform this analysis.

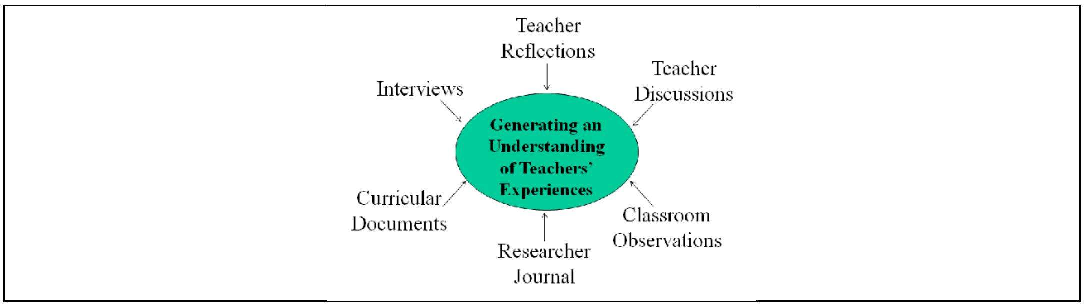

Figure 1: Data sources that inform the research question

This study used narrative inquiry to investigate the ways teachers incorporated recommendations into their practice. Narrative inquiry was selected to allow the voices of teachers to be heard and expand our understandings of "what the experience is like." Clandinin and Connelly (2000) describe narrative inquiry as "a way of understanding experience. It is a collaboration between researcher and participants, over time, in a place or series of places, and in social interaction with milieus" (p. 20). Narrative researchers illustrate a phenomenon studied through creating unified, coherent narratives that convey the meaning of their experiences working together. The method of analysis is emplotment and narrative configuration (Polkinghorne, 1995), in which data snapshots are pieced together to develop a plot. This requires a synthesis of the data rather than separating it into its constituent parts.

As data was collected, I continuously reviewed it. After all data was collected, I organized the data pieces pertaining to each teacher into chronological order in spreadsheets. I coded data pieces according to the aspects of the experience previously identified: conceptions of reasoning and sense making, actions that the teacher took in their teaching, challenges, opportunities, and the teacher's interpretations of the results of their actions, plus the additional category of contextual information. Coded data for each teacher was then reorganized into condensed spreadsheets according to category. I continuously reviewed these consolidated spreadsheets until recurring ideas and connections developed to synthesize the information into the "plot" of the narrative. Then the process of writing of *interim texts* (Clandinin & Connelly, 2000) or smaller drafts of the research text, was an important element of the emplotment and narrative configuration. Through repeatedly experimenting with the writing process by writing interim texts, and then sharing those texts with the teachers, I eventually produced the final research texts. More details about the analysis will be shared in the presentation.

Findings

The analysis revealed the complexity of each teacher's experience. Teachers varied in their past experiences as a mathematics teacher, and in the awareness they held of the ways they influenced student's opportunities to reason and make sense of mathematics. Teachers also varied in the actions they took to adapt their teaching in response to the recommendations. Their action research foci varied from improving their questioning strategies, curriculum, role in discussion, prompting students' justification, prompting writing about mathematics, and incorporating student creativity into the doing of mathematics. As I developed narratives of the teachers' experiences, it became apparent that within the different journeys, subtle similarities existed. I compared the plotlines of narratives that held similarities to clarify my understanding, and I examined the differences across groups. As I read and reread my data, I tested different categorization schemes in my own sense making process to understand the ways I grouped teachers' narratives. Two aspects of their experiences emerged that provided a way to categorize their narratives. The first aspect was their level of *awareness*—both at the time they entered our collaboration and the development of their awareness over time—of the ways that they influenced students' opportunities to engage in reasoning and sense making. The second aspect was their evolution, or development in any direction, of the ways they acted on this awareness by developing *strategies* to promote students reasoning and sense making.

These two aspects, teachers' *awareness* and their *strategies*, were intertwined within each teacher's experience. Particularly, teachers' *awareness* of the ways they impacted students' engagement in reasoning, and their *strategies* for fostering students' reasoning, evolved in response to each other over time. Evolution in teachers' awareness was only recognizable when teachers self-reported new things they had come to realize about their teaching. Evolution in teachers' strategies was more easily identifiable, through teachers sharing new strategies they were developing and through my own observations during classroom visits. As I made sense of differences in teachers' journeys, I generated four analogies to represent their journeys. There isn't sufficient space to present the narratives of teachers' experiences here, but I will offer a glimpse through the four analogies: a linear function, a piecewise function, a step function, and a scatterplot. The independent variable in this mathematical relationship is the time spent studying one's teaching practice. The dependent variable is the evolution of strategies to support students' engagement in reasoning and sense making. While these analogies attempt to illustrate teachers' experiences over the seven months we collaborated, this was a brief stretch amidst their longer journey as a mathematics teacher. In the proceeding sections, I introduce each analogy and provide illustrations from the data of the teachers that they represent.

A Linear Journey

Teachers Peter and Alexis both entered the collaboration having already problematized many aspects of mathematics teaching that *Reasoning and Sense Making* sought to change. Both talked openly about the problematic consequences of teaching mathematics through providing a list of procedures, consequences they had seen firsthand. Peter used humor to tell stories illustrating the negative effects of students' reliance on procedures or the teacher's authority, instead of reasoning and sense making. "I really want my students to start critically thinking. I swear that I could say, 'Your lesson today is to learn that 5 + 8 = 22.' And they will just write 5 + 8 = 22, and not even think a thing about what they're actually writing, whether it even makes sense at all" (12/9/10, meeting 3). Peter talked often about how "we're fighting a decade's worth of ingrained math," after seeing indications that his students were well practiced at learning mathematics *without* reasoning. As Peter and Alexis read *Reasoning and Sense Making*, they agreed wholeheartedly with the proposition of the document that teaching mathematics through steps and procedures did not produce positive student learning outcomes.

Along with identifying certain teaching practices as discouraging to students' reasoning and sense making, Peter and Alexis began their action research with a similar awareness of the ways that their role as teacher influenced student's engagement in reasoning and sense making. Both agreed with the philosophy of the recommendations and shared ways they had already made improvements to their teaching that aligned with recommendations. For instance, Alexis shared:

> I don't teach the $\frac{y_2-y_1}{x_2-x_1}$ formula to find slope. I use t-charts and put six graphs up on the board when I want to start teaching them about slope. … So [the students] figured out when you put it in y=mx+b form, where that [slope] number was coming from. And they realized, you know, if it was negative it went left, positive went right. … And so, we look at all the graphs, and we talk about the change in y over the change in x, and how it goes up and over, and where those numbers came from, and then we just call it change in y over change in x. (11/16/10, meeting 2)

Despite examples of shifts away from a focus on procedures, upon reading *Reasoning and Sense Making* both Peter and Alexis saw themselves as guilty of reliance on practices that did not promote students reasoning and sense making. They both identified room for growth to align their teaching with these recommendations. While their described approaches varied, they each developed their own ways to "transfer the deliverance of my lesson to my students" (Peter, 2/22/11, reflection). Peter focused on removing opportunities for students to rely on his authority instead of their own reasoning, through habits he developed such as "keeping silent," "firing students' questions back at the class," and "going along with wrong ideas." Alexis focused on developing her questioning; restructuring lessons so that students uncovered the mathematical ideas through class discussions facilitated by her questions.

To illustrate the similarities among their journeys and the differences between their journeys and those of others, I draw on the analogy of a linear function (see Figure 2). While Peter and Alexis faced challenges, I conceptualized their evolution of strategies as being fairly linear when compared with that of others. They conceptualized a vision for their teaching and developed their strategies to move continuously towards their goal. Their awareness of their own impact on students' opportunities to engage in reasoning and sense making facilitated a steady progression in the direction of their vision.

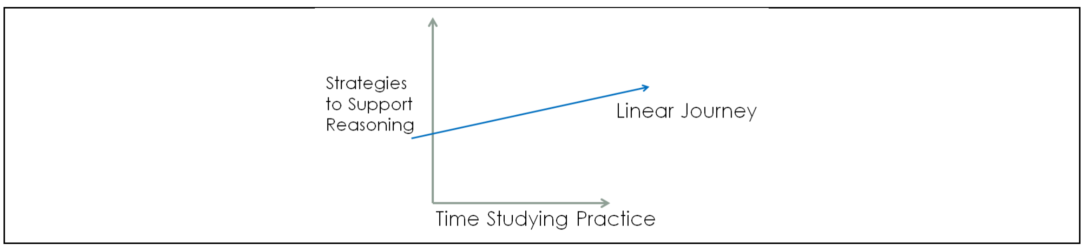

Figure 2: The analogy of the linear function

A Piecewise Journey

Teachers Logan and Melinda both expressed interest in the theme of *Reasoning and Sense Making* as they joined the study, but they did not cite examples of ways that their teaching methods influenced students' opportunities to engage in reasoning and sense making. They hoped to learn more strategies to foster reasoning and sense making as a result of their collaboration in the group.

After reading the recommendations, both Logan and Melinda formulated goals that were related to improving their classroom discussions. Both were interested in changing the structure of lessons to move away from direct instruction by incorporating questions and using student-generated ideas to move a lesson forward. Both identified their initial changes in their teaching as successful based on their students' responses. However, at different points during the school year, each teacher experienced frustration as they encountered students responding to their questions with increasing silence. When their best efforts were met with resistance from students, they became discouraged and wondered if some of their students were not capable of reasoning.

One day after observing Melinda teaching an Algebra lesson, she asked if I would teach the same lesson to the next class walking in. I agreed, and this proved to be a valuable opportunity to foster her thinking about her teaching. After watching me teach her lesson, and noticing the ways her students responded to my questions, she said, "I thought the problem was that my students couldn't reason. But now I see that I was just asking the wrong questions." After that episode, I observed noticeable differences in the questioning that Melinda used. Rather than questioning patterns that resembled those described as "funneling" (Wood, 1998), her questioning changed to resemble more closely the pattern described as "focusing" (Wood, 1998). For example, previous questions had directed students towards a particular procedure such as "Which fraction should we use? What if we use this one? Can we cross anything out?" Her new questioning tended to be more open to allow students to determine their own solution methods, such as "How can you find the side length of a square with an area of five?" and "Steve subtracted and then divided. Do we have to do it in that order?" The following year, Melinda continued to e-mail to share ongoing successes she saw as a result of long-term use of her new questioning strategies.

A similar experience happened in Logan's action research. He became discouraged for several months during the spring semester, and began to wonder if the juniors and seniors in his "intro" level Algebra II courses were capable of reasoning. After persuading him to allow me to teach one of his lessons, I attempted to make an "existence proof" that his students *could* reason mathematically. The following is an excerpt of his reflection:

> When watching Lindsay teach my class, I noticed how she was able to get everyone involved. She was calling on students who had not volunteered to share an idea in months. I have made a point to call on each and every student in my class since then. I also do not let students get away with just saying, "I don't know." They were actually saying, "I don't want to think right now," so I have to make them tell me something that they do know. (5/6/11, final reflection)

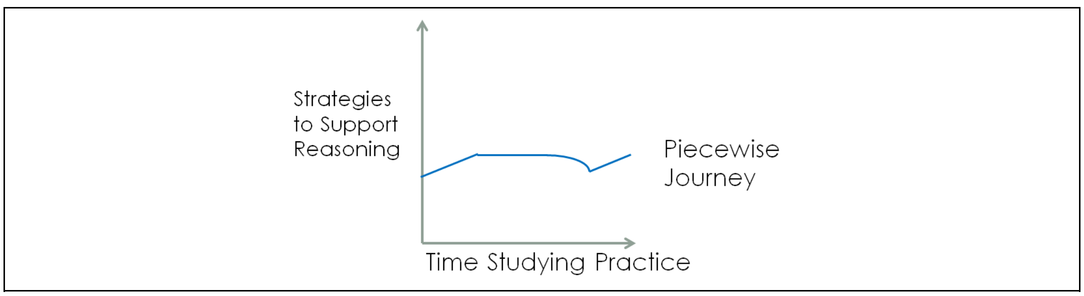

Figure 3: The analogy of the piecewise journey

To illustrate the similarities among Logan and Melinda's journeys, I draw on the analogy of a piecewise function. While Logan and Melinda initially saw short-term improvement in their students' engagement in reasoning and sense making, both also experienced a plateau. They overcome the obstacle when they developed a heightened awareness of ways they impacted students' opportunities to reason. A new awareness of their teaching prompted the development of new actions to support student's reasoning and sense making.

A Step Function Journey

Sarah, a fourth year teacher of high school geometry and algebra, shared that she had not previously considered the importance of fostering reasoning and sense making opportunities until reading these recommendations. The authority of the document convinced her of the importance of developing such practices in students to prepare them for their future. Beginning with suggestions pulled from the document, through trial and reading other practitioner articles, she narrowed the focus to asking more questions and requiring students to justify all ideas. These changes increased the amount of student talk in Sarah's classroom, opening up opportunities for students to "surprise" her with their mathematical ideas. Through studying her teaching, these unexpected incidents became learning opportunities that increased her awareness of how to support students' reasoning and sense making.

> You remember the Algebra class where they wanted to use synthetic division? *(laughing)* I was so caught off guard because I've never thought of using that method [in that context] before in my *life*. I

was like, "Okay let's go with it." But I was really surprised. And I should've been more calm about it… because then they wanted to know what "my way" was. But it totally caught me off guard. (5/18/11, final interview)

Each new unexpected finding fueled further development of her actions. One thing she learned from her students was the value of allowing them to determine their own solution path:

Before, I wouldn't let them [solve problems] the way that they wanted to. … I think a lot of times I would just be like, "Well didn't you see this method," instead of just letting them do it their way. I think its okay now just to let them do it a different way, even if it's the hard route. Just let them be, because that's the way they understand. Giving them that freedom. (5/18/11, final interview)

The analogy of a step function illustrates Sarah's experience (see Figure 4). Each step in the function represents actions she tested in her teaching and subsequently learned from, resulting in new knowledge and a heightened awareness of strategies to support students reasoning. The heightened awareness facilitated her in developing her actions further, represented by the next step in the function. Sarah's experience was unique from the others by the pattern of repeated instances of surprise that resulted in new awareness that fueled developments to her action strategies.

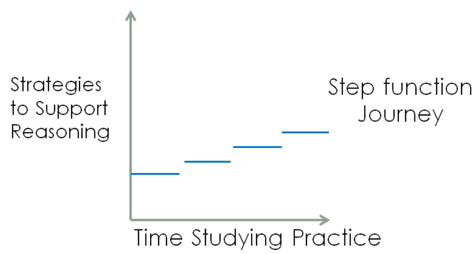

Figure 4: The analogy of the step function

A Scatterplot Journey

Claudia and James were in their first year of teaching, and both juggled many new responsibilities. It took them more time to develop the focus of their actions, and their initial actions changed frequently as they experimented with a variety of different strategies. Claudia reflected on these early months and discussed the challenge of trying to focus her actions:

With it being my first year and everything, I didn't know what my teaching style was and how I wanted to change or improve it... I kept kind of trying the different things I heard people talking about, thinking, "Is this what I need to work on? Is this something that interests me?" (4/28/11, meeting 9)

Both teachers eventually narrowed their efforts to posing open-response prompts on assessments. This approach to incorporating reasoning was more like an add-on to their teaching than a part of their everyday routine. James explained in a written reflection why he picked a subtle approach:

I would love to hold classroom discussions and ask questions where students learn from their mistakes, discuss problems with one another, and problem solve when they do not get the correct answer (Eggleton et al., 2001). That type of classroom environment is one that I envision for the future, but I do not believe my classes are ready for such radical changes all at once. To me, writing seems like a natural and subtle way for students to convey their reasoning and sense making. (1/12/11, reflection)

Both teachers also dealt with school-wide pressures to raise students' scores on the state-wide algebra exam. With the many other things vying for their attention, Claudia and James at times would "forget" their focus. Over time Claudia and James recognized the need to incorporate reasoning beyond assessments and into their mathematics lessons. They each tried fostering reasoning through occasional student-centered activities. However, limitations in time and resources hindered them from incorporating activities on a daily basis. Each saw room for improvement and made plans to continue their actions in subsequent small steps in the future.

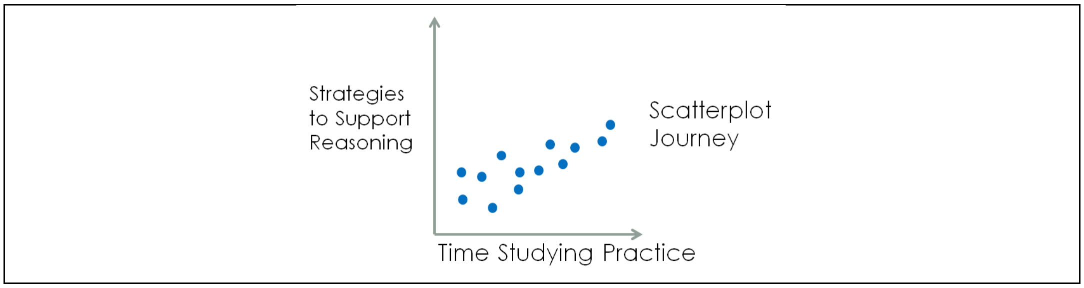

Figure 5: The analogy of the scatterplot

Their journey is illustrated by the analogy of a scatterplot with a positive correlation which became stronger over time. This analogy is distinct from the others as it illustrates the variety of seemingly disconnected actions that Claudia and James tested in their practice but also indicates a progression towards developing more focused and refined strategies.

Conclusion

While each teacher focused their efforts to foster reasoning and sense making in unique ways, the elements they chose to take up and test in their practice were a reflection of those that held meaning for them in the context of their teaching. Common gains among all teachers were a heightened awareness of the ways they impacted students' opportunities to engage in reasoning. Given the trend to focus on the deficit between NCTM recommendations and mathematics classroom practices, this research expands the discourse by illuminating the experiences of teachers attempting changes in their practice. Past research on mathematics teacher change has measured changes in practice along continuums or stages that gauge the degree to which teachers' instructional practices adhere to preconceived change objectives (e.g., Fennema et al., 1996). Alternatively, this study approached teacher change by seeking to understand the complexity of teachers' attempts at change from their perspective. Narrative inquiry offers a valuable perspective to the discourse surrounding mathematics teacher change, validating the knowledge and experiences of teachers and seeking to learn from them.

Parents, K–8 teachers, and 4th–8th grade children participated as equals in math-focused learning communities through the Math and Parent Partners (MAPPS) program. Pre/post testing and qualitative interviews revealed that the learning communities served as a platform for improvement in mathematical knowledge for teaching of participating teachers. Moreover, teachers learned about parents' knowledge and strategies, a construct analogous to Knowledge of Content and Students that we describe as "Knowledge of Content and Parents."

Keywords: Mathematical Knowledge for Teaching; Teacher Knowledge; Informal Education

Background and Research Questions

Student achievement lags in many economically disadvantaged schools. Two factors associated with this achievement gap include inadequate teacher knowledge and low parental involvement (Hill, Rowan, & Ball, 2005; Jackson & Remillard, 2005). A school district in the Southeast partnered with the local university to boost student achievement in Title I schools through Math and Parent Partners (MAPPS) parent-teacher learning communities in mathematics (MAPPS, 2009). We asked,

> Does parental involvement in a standards-based mathematics program such as MAPPS carried on at Title I K–8 schools improve student understanding and achievement in mathematics? Secondarily we asked, how might this improvement occur? In particular, do parents and teachers in MAPPS develop mathematical knowledge for teaching?

Students were found to improve standardized test scores significantly over a three-year period (Knapp, Jefferson, & Landers, in press). However, this paper focuses on factors that may have prompted the student improvement. In particular, we describe *teachers'* development in mathematical knowledge for teaching as they participated in MAPPS learning communities.

Theoretical Framework and Literature Review

Hill, Rowan, and Ball (2005) reported a study in which teachers' *mathematical knowledge for teaching* (MKT) was linked to student achievement in first and third grade. Moreover, they found that teachers in economically disadvantaged schools tended to possess lower MKT. The framework of mathematical knowledge for teaching (MKT) relates to the knowledge and habits of mind needed to teach mathematics well (Ball, Thames, & Phelps, 2008). In the framework, MKT includes six constructs of which we focused on the following four in investigating the Math and Parent Partners learning communities. Common content knowledge (CCK) is basic, lay-person knowledge of the mathematical content. Specialized content knowledge (SCK) is the way the mathematics arises in classrooms, such as for building representations. Knowledge of content and students (KCS) indicates a teacher's knowledge about how students think in mathematical contexts. Knowledge of content and teaching (KCT) indicates a teacher's knowledge of advantageous representations or teaching sequences. MKT encompasses both content knowledge (CCK & SCK) and pedagogical content knowledge (KCS & KCT).

Studies have additionally shown that parent involvement in their children's education is linked with children's academic outcomes (D'Agostino, Hedges, Wong, & Borman, 2000; Epstein, 1994; Kellaghan, Sloane, Alvarez, & Bloom, 1993). As Henderson and Mapp (2002) stated, "The evidence is consistent, positive and convincing: families have a major influence on their children's achievement. When schools, families, and community groups work together to support learning, children tend to do better in school, stay in school longer, and like school more" (p. 7). Low-income parents may be untapped resources for the mathematical achievement of their children. Henderson, Mapp, Johnson, and Davies (2007) asserted that districts serious about closing the achievement gap would have to address the school culture gap that expects parents to remain relatively uninvolved in their children's mathematics learning. Although parental involvement may be linked to student achievement, parents are often not accessed as resources for helping children learn mathematics in standards-based school environments (Jackson & Remillard, 2005; Perissini, 1998). In this paper, we describe a study of a parental involvement program that engaged parents and teachers in mathematics learning communities.

Participants and Context

The Math and Parent Partners (MAPPS) program equips families to act as mathematical resources for their children and for schools. MAPPS curriculum was developed with National Science Foundation funding to engage K–8 parents in exploring with peers the concepts and skills behind the mathematics that their children are learning in schools (see http://mapps.math.arizona.edu/). Currently, the MAPPS program serves sites in six states and the Virgin Islands. One MAPPS site, located in the Southeast and the focus of this article, worked toward improving the mathematical knowledge for teaching (Ball, Thames, & Phelps, 2008) of both parents and teachers in Title I schools within its school district. All parents, teachers, paraprofessionals, and children from selected schools were invited to participate. The local university partnered with MAPPS and the school district to offer Mini-courses for parents and teachers, while young children participated in related mathematical activities and games. Children in 4th-8th grade accompanied their parents in the Mini-course classes. Mini-course sessions convened two hours per week for eight weeks. Over the course of three years, eight separate 8-week Mini-courses, centered on the National Council of Teachers of Mathematics' (NCTM) (2000) content and process standards, were offered. These Mini-courses were hosted by the University's Office of Continuing Education, and instructors were graduate students in mathematics education who were also practicing teachers.

8-week Mini-course Title	NCTM Content Standard Addressed
Thinking About Numbers (offered two times)	Number & Operations
Thinking About Fractions, Decimals, and Percents (offered 3x)	Number & Operations
Thinking in Patterns (offered once)	Algebra
Geometry for Parents (offered once)	Geometry and Measurement
Data for Parents (offered once)	Data Analysis & Probability

Figure 1: Math for parents Mini-course curriculum

In all, 115 children, 59 parents, and 33 teachers from primarily four Title I elementary schools attended at least one Mini-course on a regular basis. Nearly twice that many participants attended sporadically. Approximately 75% of attendees were single parents, and those that attended the Mini-courses did so with one to three children. Most of the parents had graduated from high school with some technical training, and they typically held low-income jobs. Attendees were approximately 40% Caucasian, 40% African-American, and 20% Hispanic. Teachers who attended faithfully received stipends and professional learning units.

MAPPS Mini-courses engage parents in doing mathematics using hands-on materials, working in small groups to solve problems, and presenting their solutions to the whole group as outlined by the NCTM process standards (NCTM, 2000). Both content knowledge and pedagogical content knowledge are intertwined into the instruction for parents (Ball, Thames, & Phelps, 2008), with pedagogical considerations made relevant by Mini-course instructors depending on grade levels of participating children.

To illustrate the intervention and details of the MAPPS program, we describe a learning activity from the two-hour Week Eight session from the Fractions, Decimals, & Percents Mini-course (see Figure 1). For the task, participants were to have shaded a given percentage of various grids for homework from the previous session. The first grid, a bar divided into fifths, required 60% to be shaded (see Figure 2). Participants had to figure out what percent each fifth represented for the entire grid to equal 100%, and they discussed their findings at the beginning of the session.

Shade 60% of this grid.

Figure 2: MAPPS homework task

A father and his 6^{th} grade daughter found that each rectangular fifth must be 20%. The father held up his hand to demonstrate his fingers as the rectangle saying, “Each finger is 20, so we shaded three of them to make 60, see (pointing to his fingers) 20, 40, 60.” Later in the session, parents, teachers, and children made percent strips that they then compared to the fraction and decimal strips made during previous sessions. At the end of each task, group members reported their various solutions and strategies to the entire class. Sometimes the *children* presented unique strategies allowing parents and teachers to learn from the children, and visa versa.

Data Analysis

To assess the impact of the MAPPS Mini-courses, parents and teachers took pre/post tests on mathematical knowledge for teaching (Hill, Schilling, & Ball, 2004) and pre/post attitude surveys (Tapia, 1996). Pre/post tests and surveys were administered before and after each 8-week Mini-course. A focus group of parents, teachers, and children also participated in 95 pre/post interviews. Interviews lasted approximately 15 minutes, and questions were such as these: (1) Have you learned anything about mathematics that you did not know before? Explain. (2) Have you learned anything in MAPPS that helped you help your child or students with math? Explain. Interviews were coded for evidence of improved student understanding, achievement, and factors that might affect that improvement, such as the elements of mathematical knowledge for teaching: CCK, SCK, KCT, SCK (see Table 1). After coding the interviews and pre/post surveys, we tallied the 59 codes to identify the salient areas of participant growth as well as factors prompting that growth. We looked for clusters in the data each year, producing primary and secondary results for each year. At the end of the study, we compressed codes and identified themes based on the primary and secondary codes. Themes arising from the coding process included strengthened teacher content knowledge, improved teacher Knowledge of Content and Teaching, and benefits of the learning community.

Table 1: Teachers’ Results from 34 Teacher Interviews

Code	Freq	Description of Result
Primary:		
Knowledge of Content and Teaching (KCT)	56	
Content Knowledge SCK(16) CCK(6) *GLM(6)	28	Primarily SCK for teachers *GLM-General learning of mathematics reported that could not be identified as CCK or SCK
Enjoyment of/Valuing MAPPS	40	High value placed on program.
Secondary:		
Learning Community	23	The learning community was valued.
Broader impact of program	10	Program impacted non-MAPPS students.
Student learning/achievement	8	

Results and Discussion

We present interview data from several teachers to amplify our coding process and themes that emerged. Examples of codes are in bold. Teacher A, a primary teacher, shared the following:

AK: Well can you just talk to me about how the program went for you?
Teacher A: Well, coming in as a teacher, it really helped me see, uh…just a little more in depth look at the math. Because math isn't one of my strengths, I will tell you, it's not one of my strengths. So I came out to actually deal with like ideas, like fractions, and really at my own pace, kind of look at what is it, what is a fraction.
AK: …Can you give me a specific one [example] that maybe you understood superficially and you could teach it, but now you understand it in a different way?...
Teacher A: One of my favorite ones was when we talked about fractions. She gave us strips and she said, "Okay, fold this strip into one third; fold it into one eighth, …twelve. Fold your strip into twelfths. Eighths and thirds." And first, when you wanted to make the equal sections you kind of thought well this is going to be my stopping point. For that line, which is what we put on our strips as the stopping point. It's the space between that makes that one third. Just that space. Even with measurement, when they looked at the ruler, you know they have all the little increments between 1 and 2, but she kind of let me see that that space. It's not as important as what the numbers are, it's that space, the little spaces between the numbers that, I hadn't really [considered].

In this Mini-course, Teacher A developed **Specialized Content Knowledge (SCK)** when she learned what was mathematically significant about a fractional increment using fraction strips. She came to understand the content more deeply as it arises in a classroom. Moreover, she and other teachers stated that after attending the MAPPS Mini-course on fractions, decimals and percents, that the MAPPS materials became their handbook for teaching the unit on fractions in their classrooms. After attending MAPPS, this teacher and numerous others made the decision to pursue graduate degrees in Elementary Mathematics Education (**Higher Education**).

Another teacher who attended MAPPS described the benefit of the learning community for herself, her parents, and her students.

AK: Is there anything in MAPPS that has helped you to better explain math to kids?
Teacher B:…when we did fractions, decimals, and percents I had so many kids that would not understand that, and so I would literally I would have one child in my room on this side of me and their parent would be right here. And then I would have another one from my room on this side and we would literally work through exactly what we were doing in class with adding and subtracting decimals. We would take the unit cube, and it would be the one whole or the units, rods, and
AK: flats.
Teacher B: flats. And that helps too with the kids when they go home and say, "Well our teacher told us that 5 and 50 are the same." And the parents are going, "No," you know.

This episode exemplifies the parent-teacher interaction enshrined in the **learning community**. The teacher could see first-hand the disconnect between school learning and home learning. It became evident to her that children appeared to understand the concept in class, but they were unable to verbalize their misconceptions adequately to their parents who did not know about the base-10 block representation for decimals. She realized that students were making confusing comments such as, "Our teacher told us that 5 and 50 are the same," to the parents. The experience allowed the teacher to develop **Knowledge of Content and Students (KCS)** about student misconceptions, in this case not understanding that 5 rods were the same as 50 unit cubes. The MAPPS session amplified the student and parent misunderstandings for the teacher, and at the same time, helped the parent to develop **Specialized Content Knowledge (SCK)** about how base-10 blocks can represent decimal operations.

Teacher B additionally expressed that the MAPPS instructors modeled good explanations for her and helped her be reflective. Other teachers stated that MAPPS helped them learn connections between mathematical topics such as fractions, decimals, and percents. Paraprofessionals and substitute teachers who participated also reported that MAPPS equipped them to assist with instruction in mathematics. Finally, the MAPPS environment helped teachers add rigor to their teaching practice. Teacher A stated, "I think I wasn't really going in depth as much as I could." She learned to facilitate conceptual understanding at a deeper level than had been afforded through teaching fractions by rote.

The qualitative result that teachers improved their content knowledge was substantiated by MKT test results. Significant changes were noted when the first Mini-course to the last Mini-course scores were compared (n=20; p=.052). The content knowledge tests were designed such that a well-prepared elementary teacher would get 50% of the questions correct (Hill, Schilling, & Ball, 2004). Although the test scores improved significantly, the average scores did not rise above this 50% benchmark. This data suggests that teachers involved in the program were in need of further instruction in mathematics for teaching and highlights the importance of the result that the MAPPS parent-teacher learning communities built teachers' **confidence** as mathematics learners and emboldened some to attend graduate school in mathematics education.

The next aspect of mathematical knowledge for teaching that developed for both parents and teachers during MAPPS was Knowledge of Content and Teaching (KCT). Teachers reported learning to model problems with tasks and manipulatives, instead of relying as heavily on direct instruction and drill. We considered this shift to be KCT because teachers were expanding their repertoire of effective examples and teaching sequences that they over and over reported taking back to their classrooms, sometimes as an entire grade level (**broader impact**). An interview displayed a teacher learning about the instructional advantage of a dynamic representation to help her teach subtraction with regrouping.

Teacher B: The other thing that I used that they showed us talked about the virtual manipulatives, was the website where you can, there are the little unit cubes, the rods, and the flats…

AK: The base ten blocks?

Teacher B: Yeah and you can drag them over and show and the kids can go up to the active board and manipulate those around and they just loved that because I needed a tool when I was teaching the kids even just when we were learning subtraction with regrouping.

Teacher B went on to explain that her students were confused when using the concrete base-10 blocks and that her static drawings were inadequate. However, after attending MAPPS, she engaged students in a MAPPS task using the virtual base-10 blocks. She said, "But I pulled that website up, and I could just move it right around. And it was just so convenient, and it was easy for them to see because it was color coded too where my little drawings were crude…" Thus, this teacher developed **KCT** related to choosing effective examples and representations.

We found that although some teachers had access to manipulatives, they were unaware of how concrete manipulatives could undergird young children's understanding of mathematics content. A special education teacher said, "Since MAPPS, I've done a lot more work with manipulatives. I make a point to go to the manipulatives quickly and then the abstract." He additionally said, "To approach it [content] rather than drill it and kill it that [MAPPS activity] was a problem solving model that I wouldn't help them with except you know I would get them over humps and stuff. But it was a way to get them to think and to realize, 'Oh I get it, I get it,' and the light bulb [would] click on. You could see it happening, and it was really good." This teacher began using MAPPS activities exclusively for Saturday school instruction. This school's standardized mathematics test scores rose from 64.3% passing in 2008 to 81.3% passing in 2011.

Aside from improved, purposeful manipulative and task use the classroom, Knowledge of Content and Teaching in general improved, as evidenced by teacher statements such as this: "It [MAPPS] gave me ways to bridge that gap between what I know and really making it something that they know." Teacher learning continued to develop after MAPPS, as teachers reported adapting materials to other grade levels and mathematics content areas from year to year.

Teacher C: I think I learned as much from it as the parents did.

RL: And that is what it does for you.

Teacher C: I don't think I learned as much as I did *until I brought it back into my classroom* [emphasis added].

Thus, although teacher learning did occur during MAPPS, there seemed to be a delayed amount of learning that took place. Teachers adapted MAPPS tasks to their own grade levels and state standards, and in the process of enacting the tasks in their own classrooms, or collaborating about the tasks with their colleagues, they furthered their Knowledge of Content and Teaching.

In addition to strengthening teachers' mathematical knowledge for teaching, the learning community afforded by MAPPS strengthened parent-teacher relationships as well. Bonding formed because teachers got to know parents in a different way than in the negatively-connoted position of power, telling parents what to do or not to do in regards to their children. Teachers and parents enjoyed a level playing field in which all were learning for the desired end of helping children (**Enjoyment of/Valuing MAPPS**). One teacher said, "When they saw me get excited about something, they were like, 'Wow, she didn't know this. We're learning this together.'"

Moreover, parents appreciated teachers' extra effort to help children learn, and teachers came to view parents as dedicated individuals, invested in the academic success of their children. The light-hearted nature of the Mini-courses drew families and teachers back for not only more mathematics learning, but relationships fueled by a desire to learn mathematics. Even 4th-8th grade children participated as equal learners of mathematics content, often presenting solutions or strategies that parents and teachers learned from. The casual, non-threatening learning environment served as a relationship-building environment. Finally, teachers helped each other make the tasks and rigor relevant to their respective classrooms. The MAPPS learning community forged a Parent-Teacher-Child triangle of knowledge and respect (see Figure 3).

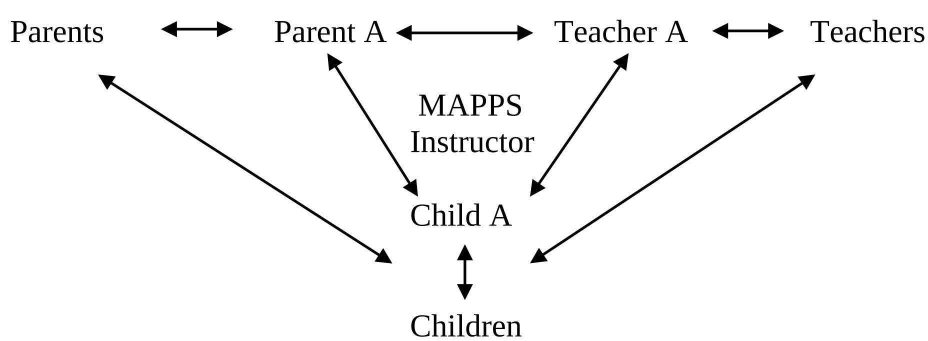

Figure 3: MAPPS learning community

A notable benefit of the learning community was *teachers learning about parents'* knowledge and strategies, a construct we call "Knowledge of Content and Parents." An interview evidenced this.

RL: Tell me, how did you feel about working in groups with other parents and other teachers?
Teacher D: It enlightened me a lot. I didn't know that they didn't know so much of the vocabulary. I had no clue. They really had no clue of how to talk about manipulatives and use them. They didn't know what that meant when their children came home and discussed it.

Just as Teacher B learned that parents didn't understand how to use manipulatives to teach decimal operations when the child said, "5 and 50 are the same," this teacher learned that parents did not possess the *vocabulary* related to the manipulatives. Another teacher explained that she learned about parents by listening to them talk with their children about mathematics. The MAPPS environment allowed teachers to see *why* parents struggled to assist their children with mathematics. Moreover, teachers learned about parent content knowledge and strategies as parents and teachers collaborated to solve problems. Teachers also listened to parents present their strategies, such as when the parent presented his strategy of finding 60% of the fraction grid (see Figure 2). We believe that this *content-focused teacher learning about* *parents' knowledge and strategies,* or *Knowledge of Content and Parents,* is analogous to Knowledge of Content and Students and is also an aspect of Schulman's (1987) category of teacher knowledge, "knowledge of educational contexts" (p. 8).

Through the clinical experience of the MAPPS learning community, teachers gained Mathematical Knowledge for Teaching and Knowledge of Content and Parents. As such, teachers learned what misconceptions parents had, that parents did not know about many manipulatives commonly used in the classroom, and that parents lacked vocabulary needed to connect manipulatives to conceptual understanding of content. Furthermore, teachers learned about parents' content knowledge, problem-solving strategies, explanations to their children, and desire to help their children. Thus, the parent-teacher mathematics learning community provides a unique professional development environment for teachers. Teachers learn both mathematics for teaching and how to access parental involvement in a way that enhances student learning. This study implies that Knowledge of Content and Parents can and should be taught through parent-teacher mathematics learning communities. Further research is needed on the nature of Knowledge of Content and Parents and its relationship to student achievement in mathematics.

This research investigates the question of what growth, if any, is shown by teachers in identifying the components of children's reasoning using an upper and lower bounds argument for a fraction task. Specifically, it reports on assessment outcomes from design-based research in teacher education that measures teachers' identification of children's reasoning from studying videos. We describe the nature of the instructional intervention as well as the video-based assessment used as a pre and post measures for identifying children's mathematical reasoning, and report on the nature of teacher growth in recognizing components of children's arguments.

Keywords: Reasoning and Proof; Teacher Education–Inservice/Professional Development; Rational Numbers; Design Experiments

Introduction

The research presented here comes from an ongoing, interdisciplinary research and development project[1] at a large public university. Work includes the development of a digital repository that provides open access to a seminal video collection of children's mathematical reasoning that accumulated through a quarter century of research on the development of mathematical thinking and reasoning in students.[2] Videos from the repository have been used to conduct design research in teacher education, specifically for the purpose of examining how the opportunity to study videos may help teachers augment their abilities to recognize mathematical reasoning as it emerges from children's explanations and justifications of their problem solving. Instructional interventions for teachers were created for implementation in courses or workshops, typically based on one of two models (Palius & Maher, 2011). We report here on a different kind of intervention model that was created specifically for implementation in the context of online learning with digital resources.

Theoretical Perspective

Learning occurs in complex contexts and it is important that it be studied in the way it naturally occurs (Brown, 1992; Greeno & MAP, 1998; Spiro, Feltovich, Jacobson, & Coulston, 1992). However, teachers and those preparing to be teachers do not ordinarily have the opportunity to study in detail the learning of individual students in classrooms. Collections of video offer a rich source of data for careful analysis and reflection on children's learning. Choosing subsets of videos from large collections can provide a rich resource for addressing particular research questions. Our work and the work of others have demonstrated that there is much to gain from studying episodes of children's learning from videos (Cobb, Wood, & Yackel, 1990; Maher & Davis, 1995; Fenemma, Carpenter, Franke, Levi, Jacobs, & Empsom, 1996; Tirosh, 2000). Further, video offers an excellent medium for teachers' development of what Bransford et al. (2006) refer to as "adaptive expertise," that is, an ability to spontaneously and flexibly identify, critically evaluate, and respond in appropriate ways to instances of children's learning. It is from this perspective that our study was designed.

Yackel and Hanna (2003) discuss the importance of reasoning and proof in mathematics learning and their functions of verification, explanation, and communication. They point to the need for mathematics educators to be able to support students' development along the continuum from reasoning, explaining, and justifying towards articulation of formal proof, as well as to the need for teachers to create a classroom atmosphere that support such development (Yackel & Hanna, 2003). Mathematics teacher education, therefore, is faced with the challenge of helping teachers to attend to emerging forms of reasoning as children express justifications using their own language. Making use of episodes and transcripts of video data of children's reasoning from a major collection, we sought to investigate whether teachers could build the mathematical knowledge for recognizing components of children's reasoning. Specifically, the question that guided our research was whether and to what extent teachers successfully identified components of children's reasoning using an upper and lower bounds argument for a fraction task.

Methodology

As part of the design research in teacher education, three of the authors developed a new, online course in mathematics education, entitled *Critical Thinking and Reasoning*, to be taken as an elective by graduate students. Its purpose was to focus teachers' attention to how children reason about fraction ideas through study of videos children's reasoning, while engaged in problem solving with fraction tasks (Yankelewitz, Mueller, & Maher, 2010). Research literature connected to the video content was assigned as readings to comprise course units around which online discussions were focused. As a component of the design research, we examined teachers' attention to children's reasoning before and after the intervention. For this report, we investigate the nature of teacher growth in identifying upper and lower bounds reasoning in children from videos.

The first implementation of the course was during a semester with 12 students participating in the research. The second iteration was done as a four-week summer session course with 10 students participating in the research. Both courses contained a unit that focused specifically on children's mathematical reasoning about the fractions task in the video assessment. Specifically, students were assigned to study two videos, *Fractions, Grade 4, Clip 1 of 4: David's upper and lower bound argument* (http://hdl.rutgers.edu/1782.1/rucore00000001201.Video.000054465) and *Fractions, Grade 4, Clip 4 of 4: Designing a new rod set* (http://hdl.rutgers.edu/1782.1/rucore00000001201.Video.000054751). The reading assignment from the unit was a book chapter that discussed children's mathematical exploration that leads toward proof-like reasoning, which included the example of David's upper and lower bounds argument (Maher & Davis, 1995). The prompt for group online discussions was open-ended and suggested that attention be paid to forms of children's arguments and the evidence they provide, as well as consideration of what may be evidence of understanding or evidence of obstacles to the children's understanding of the mathematics. Students were assigned to small groups for engaging in online discussions about the videos they were viewing and the related literature.

Consistent with methodology of the larger research project, participants were administered pre and post-tests to measure change from before to after the intervention. We focus here on a video-based assessment for identifying children's mathematical reasoning on a particular task in the fractions strand. The assessment video includes footage from research conducted in an after-school enrichment program for 6th graders in an urban community, where children engaged in many of the same tasks that were explored by children in the 4th grade classroom study (Maher, Mueller, & Yankelewitz, 2009). It contained short clips of children working in groups on a task to find a Cuisenaire rod in the set that could be given the number name one-half when the blue rod has been given the number name one. It also contained short clips of children explaining their solution ideas with rod models as justification to the whole class (Maher, Mueller, & Palius, 2010).

The children in the assessment video offered various explanations for why they found that there is no rod in the set that can be called one half when the blue rod is called one. Some of the explanations took the form of reasoning by cases; however, one of the arguments took the form of reasoning by upper and lower bounds (Yankelewitz, Mueller, & Maher, 2010). More than one child's discourse contributed to the articulation of this argument form, which, along with the mathematical sophistication of the argument, made it particularly interesting as focal point of analysis after coding the assessment data. That is, we were curious about the extent to which teachers would recognize that children were expressing in their own language that the solution for half of Blue is bounded by the Yellow and Purple rods, with Yellow being the least upper bound and Purple being the greatest lower bound (i.e., that there is no rod in between them).

A highly detailed rubric was developed by our research team in order to code the data by the components of the arguments that were articulated by the children in the assessment video. The assessment prompted study participants to describe as completely as they can the reasoning that the children put forth, whether each argument offered by children is convincing, and why or why not are they convinced. Participants were provided with a transcript for the video and were not restricted in the amount of time spent working on the assessment. The assessment prompt also informed participants that their responses would be evaluated by the following criteria: recognition of children's arguments, their assessment of the validity or not of children's reasoning, evidence to support their claims, and whether the warrants they give are partial or complete.

Two researchers scored assessment data with 90.4% inter-rater reliability. For the upper and lower bounds argument, there were four components of the children's reasoning that could combine in three different ways to be a complete argument (a, b, and c; a, b, and d; or a, b, c, and d):

a. The Yellow rod is (1/2 of one White rod) longer than half of Blue; (AND)
b. Purple is (1/2 of one White rod) shorter than half of Blue; (AND)
c. There is no rod with a length that is between Yellow and Purple; (OR)
d. The White rod is the shortest rod and the difference between the Yellow rod and the Purple rod is one White rod.

Participant responses that did not mention any of the above components or that mentioned only one or two of them were deemed to be incomplete. The coded data were analyzed quantitatively.

Results

Analysis of the video assessment data yielded the following results with regard to the upper and lower bounds argument. Tables 1a, 1b, and 1c describe the distributions of pre-assessment argument components, showing results for the two classes combined and then disaggregated by the two implementations of the course. In Table 1a, we note that 13 of the 22 students in the combined courses provided an incomplete argument description in the pre-assessment, while 8 of these 13 students provided none of the 3 essential argument components (a, b, and c or d) of a complete upper and lower bounds argument. A total of 11 out of 13 excluded argument component a; 12 out of 13 excluded argument component b; and 10 out of 13 excluded either argument component c or d. Table 1b shows that 8 of 12 students in the intervention provided an incomplete argument description in the pre-assessment; 5 of these 8 students provided none of the 3 essential components (a, b, c or d) of a complete argument description. A total of 3 out of 8 excluded argument component a; 7 out of 8 excluded argument component b; and 6 out of 8 excluded either argument component c or d. Table 1c shows that 5 of 10 students in the summer course intervention provided an incomplete argument description in the pre-assessment; 3 of these 5 students provided none of the three essential components (a, b, c or d) of a complete argument description. A total of 4 out of 8 excluded argument component a; 5 out of 5 excluded component b; and 4 out of 5 excluded either component c or d.

In summary, the pre-assessment results indicate that 59% of the students in the two courses did not provide a complete upper and lower bounds argument description on the pre-assessment. Of the students with an incomplete argument description, over 75% from the two combined courses failed to describe each of the three essential upper/lower bound argument components.

Table 1a: Distribution of Pre-Assessment Argument Components: Two Courses Combined

Students with Incomplete Argument			Students with Complete Argument		
Components	Count	Frequency	Components	Count	Frequency
None	8	0.6154	a, b, c	4	0.4444
a	1	0.0769	a, b, d	2	0.2222
c	1	0.0769	a, b, c, d	3	0.3333
d	2	0.1538			
a, b	1	0.0769			
Total	13	1.0000	Total	9	1.0000

Table 1b: Distribution of Pre-Assessment Argument Components: Semester Course

Students with Incomplete Argument			Students with Complete Argument		
Components	Count	Frequency	Components	Count	Frequency
None	5	0.625	a, b, c	2	0.25
c	1	0.125	a, b, d	1	0.50
d	1	0.125	a, b, c, d	1	0.25
a, b	1	0.125			
Total	8	1.000	Total	4	1.00

Table 1c: Distribution of Pre-Assessment Argument Components: Summer Course

Students with Incomplete Argument			Students with Complete Argument		
Components	Count	Frequency	Components	Count	Frequency
None	3	0.6	a, b, c	2	0.4
a	1	0.2	a, b, d	1	0.2
d	1	0.2	a, b, c, d	2	0.4
Total	5	1.0	Total	5	1.0

Tables 2a, 2b, and 2c describe the distributions of post-assessment argument components, showing results for the two classes combined and then disaggregated by the two implementations of the course. In Table 2a, we note that of the 10 of the 22 students in the combined courses provided an incomplete argument description in the post-assessment, while only 1 of these 10 students provided none of the three essential argument components (a, b, and c or d) of a complete upper and lower bounds argument. A total of 4 out of 10 excluded argument component a; 4 out of 10 excluded component b; and 7 out of 10 excluded either component c or d. Table 2b shows that 6 of 12 students in the intervention provided an incomplete argument description in the post-assessment. Of these 6 students, at least one the three essential components (a, b, c or d) were provided. Three of the 6 students excluded argument component a; none excluded component b; and 5 out of 6 excluded either argument component c or d. Table 2c indicates that 4 of 10 students in the summer course provided an incomplete argument description in the post-assessment, 1 of these 4 students provided none of the three essential components a, b, c or d of a complete argument description. A total of 2 out of 4 excluded argument component a, 3 out of 4 excluded argument component b, and 2 out of 4 excluded either argument component c or d.

Table 2a: Distribution of Post-Assessment Argument Components: Two Courses Combined

Students with Incomplete Argument			Students with Complete Argument		
Components	Count	Frequency	Components	Count	Frequency
None	1	0.1	a, b, c	4	0.3333
b	2	0.2	a, b, d	3	0.2500
d	1	0.1	a, b, c, d	5	0.4166
a, b	4	0.4			
a, d	1	0.1			
a, d	1	0.1			
Total	10	1.0	Total	12	1.0000

a, b	3	0.5000	a, b, d	2	0.3333
b, d	1	0.1667	a, b, c, d	2	0.3333
Total	6	1.0000	Total	6	1.0000

Table 2c: Distribution of Post-Assessment Argument Components: Summer Course

Students with Incomplete Argument			Students with Complete Argument		
Components	Count	Frequency	Components	Count	Frequency
None	1	0.25	a, b, c	2	0.3333
d	1	0.25	a, b, d	1	0.1667
a, b	1	0.25	a, b, c, d	3	0.5000
a, d	1	0.25			
Total	4	1.00	Total	6	1.0000

In summary, the post-assessment results indicate that 45.5% of the students in the two courses combined were not able to provide a complete upper and lower bounds argument description, compared to 59% on the pre-assessment. Of the students with an incomplete argument description on the post-assessment, 40% failed to describe each of the components a and b, and 70% failed to describe component c or d. This is in contrast to over 75% who failed to describe each of the three argument components on the pre-assessment.

Table 3 classifies the pre-assessment argument descriptions into three categories: (1) a Complete Argument description containing components a, b, and c or d; (2) a No Components description which lacks all three essential argument components; and (3) a Partial Argument description which contains at least one essential argument component but lacks all three. The respective frequencies for the two combined courses are: 40.9% Complete Argument, 36.4% No Argument Components, and 22.7% Partial Argument.

Table 3: Upper-Lower Bound Pre-Assessment Argument Frequencies

Pre-Assessment Argument Components	Combined Courses		Semester Course		Summer Course	
	No.	Freq.	No.	Freq.	No.	Freq.
Complete Argument	9/22	40.9%	4/12	33.3%	5/10	50.0%
No Components	8/22	36.4%	5/12	41.7%	3/10	30.0%
Partial Argument	5/22	22.7%	3/12	25.0%	2/10	20.0%
Total Number Students	22	100%	12	100%	10	100%

Table 4: Post-Assessment Transition Frequencies

Pre-Assessment	Post-Assessment	Combined Courses No.	Combined Courses Transition Frequency	Semester Course No.	Semester Course Transition Frequency	Summer Course No.	Summer Course Transition Frequency
NONE		N=8		N=5		N=3	
	No Growth	1/8	12.5%	0/5	0%	1/3	33.3%
	Partial Growth	6/8	75%	5/5	100%	1/3	33.3%
	None to b	2		2		0	
	None to ab	4		3		1	
	Complete	1/8	12.5%	0/5	0%	1/3	33.3%
	None to abcd	1		0		1	
PARTIAL		N=5		N=3		N=2	
	No Growth	1/5	20%	0/3	0%	1/2	50%
	d to d	1		0		1	
	Partial Growth	2/5	40%	1/3	33.3%	1/2	50%
	a to ad	1		0		1	
	d to ad	1		1		0	
	Complete	2/5	40%	2/3	66.7%	0/2	0%
	ab to abd	1		1		0	
	c to abc	1		1		0	

Table 4 provides the post-assessment transition descriptions and frequencies. For example, the 4th data row of Table 4 indicates 2 students in the combined courses exhibited a pre-to-post argument description transition of “No Components” on the pre-assessment to a post-assessment description with only the argument component “b” (transition labeled as “none to b”). In examining the transition frequencies for the combined courses in Table 4 we note the following: (1) 75% of students with no upper and lower bounds argument components on the pre-assessment provided a partial upper and lower bounds argument description on the post-assessment and 12.5% provided a complete argument description, and (2) 40.0% of students with a partial argument on the pre-assessment provided a complete upper and lower bounds argument description on the post-assessment. In the semester course, it is important to note that 2/3 of the students with a partial argument description on the pre-assessment transitioned to a complete argument description on the post-assessment. This is in contrast to the summer course, where one half of the students with a partial pre-assessment description exhibited no growth on the post-assessment and the other half exhibited only partial growth.

Conclusions and Discussion

The effectiveness of using video examples in online courses to stimulate the growth of teachers’ ability to recognize and describe upper and lower bounds arguments of students is evidenced by the fact that 2/3 of the semester course students transitioned from a partial to a full upper and lower bound argument description on the post assessment, and 2/3 of the summer course students transitioned from a recognizing no components of the upper and lower bounds argument description to a partial or complete argument description. Some teachers recognized the yellow rod as an upper bound and the purple rod as a lower bound, but did not attend to the detail of the child’s argument that there was no rod in between, so that the yellow rod was the smallest upper bound and the purple rod was the largest lower bound. Although there was some growth in teachers’ recognition of components of children’s arguments after studying the videos, there is still a need for improvement. The research suggests that a video-based approach for teacher education has the potential to be effective, but that a single-unit intervention may not be adequate for developing satisfactory adaptive expertise with regard to this particular form of reasoning. Future studies might include interventions that give greater attention to the variety of arguments, partial and complete, that children naturally develop in the process of problem solving so that there may be increased opportunities for teacher evaluations of the validity of the arguments posed. With regard to online courses, research also is needed to investigate the role of threaded discussion as a tool to develop adaptive expertise in recognition of children's emergent mathematical reasoning and what kinds of scaffolds may serve to stimulate group discussions that address important aspects of the process as can be observed through studying video data.

AT THE CROSSROADS OF MATHEMATICAL VOCABULARY, WRITING, AND THE SECONDARY MATHEMATICS TEACHER

Sharon K. O'Kelley
Francis Marion University
sokelley@fmarion.edu

Although much research has been done citing the benefits of using writing in mathematics lessons, little has been done that examines teachers' responses to writing about mathematics and how those responses may shape teacher attitudes about using writing in the classroom. In this study, I examined the experiences of six teachers as they explored mathematics in a graduate class in secondary mathematics education and prepared written reports for Internet publication. After analyzing their work and their responses on questionnaires and in interviews, I found that several of the participants struggled with using the technical vocabulary of mathematics in their writings and that some of them had differing beliefs about the use of the vocabulary. Based on these findings, I recommend that mathematics educators use activities that challenge teachers to view vocabulary as mathematical content and that hone their skills in using it in their writings.

Keywords: Teacher Education–Preservice; Teacher Education–Inservice/Professional Development; Teacher Knowledge; Teacher Beliefs

Objective

During their careers, teachers will frequently transition between being a student and being a teacher. It is a necessary move that offers teachers the chance to experience for themselves the lessons they want their students to learn. As mathematics educators, we bear the burden of insuring that those moments the teachers spend as students are filled with rich, thought-provoking experiences that provide them with the knowledge they will need to help their students learn. This need for teachers to have rich experiences as students is particularly important in the area of mathematical language and writing in which teachers are asked to navigate yet another transition—when they are asked to transition from using informal language in writing about mathematics to using the formal language of mathematics.

For many years now, mathematics educators and researchers have promoted the use of writing in the mathematics classroom. In 1977, Geeslin reported on the benefits of using writing in mathematics "as a learning device for the student" (p. 113). In 1989, the National Council of the Teachers of Mathematics (NCTM) suggested in its *Curriculum & Evaluation Standards* that "all students need extensive experience…writing about…mathematical ideas" (p. 140). Since those early years, much research has been done noting the benefits of using writing in the mathematics classroom (Porter & Masingila, 2001), but there is evidence that suggests these recommendations have not been embraced by a majority of secondary mathematics teachers. In a national survey of secondary mathematics teachers conducted in the United States in 2000, 55% of those teachers surveyed indicated that they never use reflective writing in their classrooms (Weiss, Banilower, McMahon, & Smith, 2001).

As intuitively expected, Flores and Britain (2003) suggested that mathematics teachers are likely not to use writing in their lessons "unless they have had the experience themselves of writing in relation to mathematics" (p. 112). However, this suggestion seems to overlook the nature of the experience and creates a question about how teachers respond to writing about mathematics. Before we as mathematics educators can help preservice and inservice mathematics teachers transition to an effective use of writing in their classrooms, we must first understand how teachers themselves respond to the writing in terms of what they can do and what they believe. Principally, we need to know how they respond to writing about mathematics when they are acting from the perspective of a student. In this study, I endeavored to explore and examine those responses. In this paper, I report on one area of the study in which I focused on how the participants responded to writing in terms of the language they used and what they believed about the type of language they should use.

Theoretical Framework

I conducted this exploratory study from the view that to effectively write about mathematics, teachers and students must give attention not only to accurate descriptions of concepts and procedures but also to the proper use of mathematical language. Arguably, students do not have a competent understanding of mathematics unless they are fluent in its language which Ball and Sleep (2007) characterized as "both mathematical content to be learned and [a] medium for learning mathematical content" (p. 19). Essentially, to write about mathematics in a manner which showcases understanding, students must first have a working knowledge of mathematical language.

The language of mathematics is often defined as the mathematics register. Foley (2008) characterized the mathematics register as "the formal academic approach to mathematical speaking and writing" (p. 1). Schleppegrell (2007) separated the mathematics register into two categories: multiple semiotic representations and grammatical patterns. Multiple semiotic representations address symbolic notation, oral and written language, graphs, and other visual displays. Grammatical patterns cover technical vocabulary, dense noun phrases, and "implicit logical relationships" (p. 141). In this paper, I focus on elements drawn from both categories. I specifically focus on the use of technical vocabulary within the written language of mathematics.

In terms of using the technical language of mathematics in the classroom, teachers can often feel two opposing forces at work within themselves: the urge to use students' informal language in order to be relevant and the need to foster the development of the technical vocabulary of mathematics. Jill Adler (1997) characterized this delicate balancing act as one of the "dilemmas of mediation" (p. 235) in which mathematics teachers have the burden of "shaping informal, expressive and sometimes incomplete and confusing language, while aiming towards the abstract and formal language of mathematics" (p. 236). How teachers balance this tension, however, is often influenced by what they believe about the use of mathematical language in the classroom.

In this study, the word *belief* is being used in a broad sense to encompass the idea of *attitude* which Philip (2007) defined as "manners of acting, feeling, or thinking that show one's disposition or opinion" (p. 259). Although there are distinctions between the two concepts, it can be argued that belief and attitude are deeply connected and that what people believe does influence how they act and what they say. In teacher education, beliefs play an important role in how preservice and inservice teachers approach their training and what they glean from it. Cooney (1998) stated that mathematics educators must consider such beliefs in order to "create activities that encourage teachers to wonder, to doubt, to consider what might be, to reflect, and most important, to be adaptive" (p. 332). In this paper, I focus on those beliefs about the use of the technical language of mathematics that seemed to influence how the participants in the study wrote about the mathematics.

Methodology

In this qualitative study, I examined the responses of five preservice teachers and one inservice teacher in a graduate course in secondary mathematics education as they completed 11 explorations of various mathematical topics using technology. After completing the explorations, they posted their findings on the Internet in written reports called "write-ups." In addition to preparing these formal reports, I asked the participants to take notes while they explored the mathematics and to complete a written reflection after they finished each activity. My objective was to have three forms of writing to which the participants could respond: formal, informal, and reflective. In this paper, I focus on their responses to the formal writing or to the write-ups they prepared for Internet publication.

Maxwell (2005) noted in his book *Qualitative Research Design: An Interactive Approach* that "the typical way of selecting setting and individuals" (p. 88) is "purposeful selection" (p. 88). He described this method as "a strategy in which particular settings, person, or activities are selected deliberately in order to provide information that can't be gotten as well from other choices" (p. 88). In an effort to collect unbiased data, I solicited participation from a class in secondary mathematics education in which writing about mathematics was frequently used but was not a focus of instruction. In so doing, I diminished the risk that the biases of the instructor about writing in mathematics were frequently passed on to the participants. Throughout the study, I also endeavored to refrain from offering my opinion about writing in mathematics, about what the participants had to say, or about the quality of their work. My objective was to study the responses of the participants in an atmosphere as free as possible from instructor or researcher bias.

The semester-long class met weekly for three hours, and after a brief introduction of the relevant topic by the instructor, most of the class time was devoted to individual explorations of mathematical topics at computers. Students prepared their Internet reports based on 11 activities covering topics in algebra, geometry, data analysis, precalculus, and calculus. These activities presented a wide range of tasks that students could explore using software such as Geometer's Sketchpad (Version 4.07) and Graphing Calculator (Version 3.5). In each activity, students were given several tasks from which they could choose one to explore and about which they could write a report. For example, in one activity they could choose to describe what happens to the graph of a quadratic equation in standard form when the value of *a, b,* or *c* is varied as the other two values are held constant in the equation. Students were free to work through the activities at their own pace and post their reports to the Internet at any time throughout the semester.

At the first class meeting, I requested that all master's level students in a class of 31 complete the initial questionnaire. Twenty-three students signed a consent form and 18 students returned their responses via email or at the next class meeting. From these 18 students, I asked 10 if they would agree to participate based upon their responses to the questionnaire. My goal was to ask participants to volunteer who offered differing opinions on the use of writing in the mathematics classroom. Throughout the semester-long class, I tracked the participants' progress with the write-ups by checking their Internet postings, informally speaking with each participant during class, and by conducting formal interviews of each participant at the beginning, midpoint and end of the semester. At the end of the semester, I also asked the participants to complete a post-questionnaire about their experiences with the various writings in the class.

Near the end of the study, I determined that four of the participants had finished less than half of the write-ups. This lack of progress meant that they would complete the bulk of the course in two weeks which ran counter to an initial request I had made at the first meeting that they work at a steady pace throughout the semester to insure they had an adequate amount of time for reflection. In good faith, I could not compare their work with those who had steadily worked their way through the course and were primarily done with the course at the end of the study; therefore, I eliminated these four participants from the study. After data collection, I began the analysis of the data collected from the six remaining participants: Gwen, Amy, Claire, Grace, Lisa, and Kim.

During the analysis phase of my study, I performed two different types of examinations. During the first examination, I studied all notes, interview transcriptions, questionnaire responses, and written reflections to categorize participant responses according to various topics such as background, experiences with the course and the writings, and their beliefs about writing in mathematics. This categorization allowed me to situate the participants according to their various experiences. I prepared a report for each participant in outline form which addressed these topics. After I completed a report for each participant, I carefully examined each report noting emerging themes across the documents about participant responses to writing in mathematics. Once I identified these themes, I reexamined all the data, making note of any new evidence to support or contradict these major ideas. During the second type of examination, I studied each write-up posted on the Internet to determine the soundness of the mathematics used and the quality of the writing in terms of style, grammar, and language usage. In this paper, I specifically focus on two themes which emerged from these two examinations: the quality of the participants' use of technical vocabulary in the write-ups and the participants' differing beliefs about the use of technical vocabulary when writing about mathematics.

Results

Several participants struggled with the use of technical vocabulary in their write-ups. In one write-up, Grace described ellipses as "tall up and down" or "long left to right" rather than as *vertical* or *horizontal*. In another write-up, she characterized the areas of triangles as congruent. Kim characterized the graph of an inverted parabola as a "negative" graph. Gwen described the number of "humps" in the graph of a parametric equation. Amy described graphs as merging “after the domain of –3 [and] 3” which she seemed to want to mean that the graphs merged after the points with the *x-coordinates* of –3 and 3 (see Figure 1). However, her phrasing technically means that the domain consisted only of –3 and 3 which is not a true statement. Although a knowledgeable reader could reasonably infer what these participants intended when they used these words and phrases, the use of mathematical vocabulary in the write-ups ranged from informal at best, imprecise on average, and incorrect at worst. For example, the word *congruent* is customarily used in reference to two geometric figures that have the same size and shape. The concept of area, as Grace used it, is typically not included in that description.

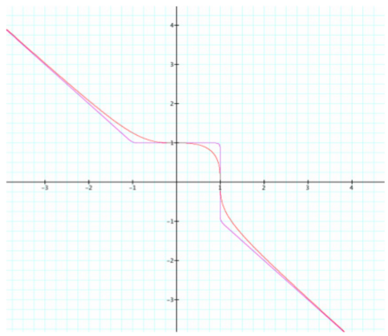

Figure 1: Amy’s merging graphs

The use of technical vocabulary also brought out differing beliefs and attitudes in three of the participants. Claire stated in the second interview that she had recently learned about the mathematics register in one of her graduate classes and implied that the lesson had helped her to become more aware of the language she was using in her write-ups. She implied it was important that the readers understood the technical language she was using in the write-ups so they could make sense of her explanations. Kim, however, expressly stated that she wanted to avoid the use of technical language. During the second interview, she offered the opinion that she thought her write-ups were “mathematically written” but were not like a textbook which seemed to be what she wanted. She stated during the interview that she believed textbooks contain “just too much mathematical language” and implied that she wanted to “use just normal conversational language.” In the final interview at the end of the study, she noted again that she “wanted to make sure that [her] words were universal.”

In contrast to Kim, Amy showed a desire to use technical vocabulary in her writing, but she noted on several occasions that she struggled with the language. During the second interview, she commented that “a lot of why I can’t communicate mathematically [is] sometimes I don’t know the language.” She clarified the comment by stating that she had a problem with “using the right math terminology” but conceded that doing the write-ups up to that point had helped her to build her mathematical vocabulary. She commented that completing the write-ups was helping her “think about the math language and how should I write this or how should I explain what’s going on with this in words….” It was not entirely clear, however, that Amy believed that the mastery of the vocabulary was part of the mathematical content she needed to know. She stated in the final interview that “my…my problem isn’t math, it’s writing about math or writing, I think, about anything period….” When asked if she would have preferred to have done oral rather than written presentations, she stated that she would have preferred the oral presentations because it would have been easier for her to “show you why versus trying to explain in words why.”

Discussion and Conclusions

Although researchers have claimed for many years that writing is a beneficial tool to help students learn mathematics, a gap exists in the research which informs us about how teachers respond as students to writing about mathematics. In this study, I sought to examine the responses of preservice and inservice teachers as they engaged in an intensive exploration of various mathematical topics and published their written findings on the Internet. In this paper, I focus on participant response in terms of technical vocabulary. The results of this study tend to suggest that preservice and inservice teachers struggle with the use of mathematical language in terms of vocabulary and that they also have varying beliefs about the role technical vocabulary should play in writing about mathematics.

Ball and Sleep (2007) described mathematical language as “mathematical content to be learned” (p. 19). Viewed from this perspective, this study shows that several of the participants were deficient in this area of their mathematical content knowledge in varying degrees. For example, Grace knew how to describe the orientation of the ellipse as “tall and long” but she did not reach for the content word *vertical*. In effect, she did not take her informal language and translate it into mathematical content. At the other end of the spectrum, Amy’s struggle with the use of mathematical language showed a clear deficiency in mathematical understanding. In other words, she could not use the content word *domain* properly in her writing because she did not appear to fully understand the concept.

The study also tends to show that not all of the participants agreed with the notion that mathematical language is mathematical content as demonstrated by their attitudes or their “manners of acting, feeling, or thinking…” (p. 259). After learning about the mathematics register in one of her graduate classes, Claire embraced technical vocabulary as part of mathematical content and endeavored to make her writing precise and technically correct. Kim, on the other hand, expressly fought against it. Kim desired that her writings contain what she called “universal” language. For her, there seemed to be no “dilemmas of mediation” (Adler, 1997) between formal and informal language but instead a belief that technical language is an unnecessary obstacle to understanding mathematics. Amy seemed to share a similar opinion. Although Amy frequently acknowledged her struggles with knowing the vocabulary of mathematics, she nevertheless declared at the end of the study that she knew the mathematics but had problems expressing it in writing. This stance seems to imply that she believed someone could know the mathematics without being able to use its technical language in writing.

When we as mathematics educators ask secondary teachers to use writing in their classrooms, we sometimes assume that they believe in the use of technical vocabulary in writing about mathematics and that they have mastered the skill themselves. However, this study indicates we must first consider the importance of teachers’ beliefs about the use of technical language in writing about mathematics. We must do as Cooney advised and “create activities that encourage teachers…to consider what might be…and most important, to be adaptive” (p. 332). Specifically, we need to develop lessons that directly challenge both preservice and inservice teachers to confront their beliefs about the role of technical language in mathematics and that encourage a consideration of mathematical language as an integral part of mathematical content knowledge. The simple inclusion of lessons about the mathematics register may raise awareness for some teachers such as Claire experienced in one of her classes. Next, we need to provide guidance and practice through activities and assessments designed to help teachers transition from the use of informal language in their writing to the effective use of the formal language of mathematics. We also need to raise their awareness that a misuse of technical vocabulary in writing may indicate that teachers do not fully understand the mathematical concept behind the terms. In providing these types of activities, we better equip teachers to navigate the “dilemmas of mediation” (Adler, 1997, p. 235) which they will face in their own classrooms.

The results of this study also suggest an area in need of further research. We need studies devoted to how teacher beliefs about the use of technical vocabulary in writing may influence their teaching. Specifically, we need to probe the depths of how those beliefs may influence how teachers structure their lessons, what they expect from their students in terms of language use, and how those decisions and expectations influence student learning. In pursuing such research, we provide a connection to practice that informs both the researcher and the practitioner in the ways language use in writing may shape what students learn and do not learn in their mathematics classes.

The most important transition educators make is between the roles of student and teacher. It is a transition that occurs frequently during one’s career from the preservice phase to the inservice stage, to advanced schooling, and then on to years of professional development. It is during those times when teachers are in the role of students that we as mathematics educators must make the most of their experiences. Essentially, we cannot ask teachers to teach what they have not experienced themselves as students. This is particularly true in the area of mathematical language and writing. Teachers at all stages in their development need a rich, thorough experience of using the technical vocabulary of mathematics in their writings. By participating in activities and lessons focused on the use of technical vocabulary in writing about mathematics, they have a chance to confront their beliefs and work on their skills. In essence, we as mathematics educators help them navigate the transition from the use of informal language to the use of the formal language of mathematics. By providing these rich experiences, we also increase the odds that these students will become master teachers who feel more comfortable with writing about mathematics and, in turn, are more likely to use writing in their classrooms. Ultimately, we create teachers who can effectively guide their students in becoming fluent in the use of mathematical language in writing about mathematics.

The purpose of the study was to examine how teachers enhance their knowledge of rational numbers focused on modeling problem tasks using multiple representations. The professional development summer institute and the follow-up Lesson Study (Lewis, 2002) throughout the academic year focused on engaging teachers in rational numbers and proportional reasoning problem solving tasks, exploring pedagogical strategies, utilizing mathematics tools and technology, and promoting connections in the elementary and middle school curricula. This research report has two aims: (1) identify ways in which focusing on modeling rational numbers with multiple representations impacted teachers' understanding of rational numbers and proportional reasoning concepts; and (2) examine what strategic competence (NRC, 2001) looks like in teachers as they learn to model rational numbers concepts using multiple models.

Keywords: Modeling; Rational Numbers; Teacher Development; Professional Development

Theoretic Framework

Strategic competence has been defined as the "ability to formulate, represent, and solve mathematical problems" (NRC 2001, p. 116). The National Research Council define "mathematics proficiency" as having five strands that include strategic competence along with conceptual understanding, procedural fluency, adaptive reasoning and productive disposition. This study uses the term strategic competence as a competence we want to develop in teachers and expand the definition to include specific criteria in AMTE's standards for Pedagogical Knowledge for Teaching Mathematics, which include the ability to "construct and evaluate multiple representations of mathematical ideas or processes, establish correspondences between representations, understand the purpose and value of doing so; and use various instructional tools, models, technology, in ways that are mathematically and pedagogically grounded" (AMTE, 2010, p. 4). Modeling mathematics and developing representational fluency are key mathematics practices emphasized in the common core standards for math (CCSSI, 2010).

Research on rational numbers has also shown that representational fluency is critical in developing a conceptual understanding of the topic (Lamon, 2007; NRC, 2001). Representational fluency, the ability to use multiple representations and to translate among these models, has been shown to be critical in building students' mathematical understanding (Goldin & Shteingold, 2001; Lamon, 2001). The Lesh Translation Model highlights the importance of students' abilities to represent rational numbers in multiple ways, including manipulatives, real life situations, pictures, verbal symbols and written symbols (Lesh, Cramer, Doerr, Post, & Zawojewski, 2003). Translations among the different representations assess whether a student conceptually understands a problem. Such abilities to be able to translate within and among multiple representations indicates an aspect of strategic competence. Some of the ways to demonstrate translation among representations in mathematics is to ask students to restate a problem in their own words, to draw a diagram to illustrate the problem, or to act it out. In teaching and learning, representations can play a dual role, as instructional tools and learning tools. As Lamon (2001) states, representations can be "both presentational models (used by adults in instruction) and representational models (produced by students in learning), which can play significant roles in instruction and its outcomes" (p.146). Another way to think about representations is that they allow for construction of knowledge from "models *of* thinking to models *for* thinking" (Gravemeijer, 1999). The *Principles and Standards for School Mathematics* (NCTM, 2000) emphasizes that representations serve as tools for communicating, justifying, sense making and connecting ideas by stating, "Representations allow students to communicate mathematical approaches, arguments, and understanding to themselves and to others. They allow students to recognize connections among related concepts and to apply mathematics to realistic problems" (p. 67).

Research Questions

This study explored the following research questions:

1. How does focusing on modeling rational numbers with multiple representations impact teachers' understanding of rational numbers and proportional reasoning concepts?
2. How do teachers exhibit strategic competence, in terms of the ability to construct, use and evaluate multiple representations and models of mathematical ideas and establish correspondences between representations?

Methods

Sixteen elementary and middle grades teachers from grades 3–8 met for a one-week summer institute and continued as school-based Lesson Study teams during the academic year. A majority of the teachers (78%) taught in Title One schools that served underrepresented and underserved populations. The daily topics included reasoning up and down, direct and inverse thinking, unitizing, and, ratios and proportional thinking. For this research report, we focused our analysis in the summer content institute and the lesson study data sources to demonstrate the progression of development in teachers' strategic competence as they emerged from the critical incidents as reported in teachers' reflections and instructors' memos and field notes and artifacts.

Data Sources

The data sources included teacher reflections, posters of solution strategies, videotapes of the class sessions, instructors' memos and field notes.

Teacher daily reflections from content institute. Teachers reflected daily on the problem solving tasks and wrote about new strategies and representations that were shared in class by other teachers. The teacher reflections focused on the understanding, reactions, and feelings of the individual teachers. The purposes of the daily reflections were to elicit responses in teachers focused on rational number problems which asked teachers to explain their thoughts and solution strategies; identify any differences in their own understanding, approaches, and thinking which resulted from the day's activities; and, illuminate any modifications to their teaching content and approach which they intend to employ.

Artifacts from class sessions–Poster proofs and concept map posters. The data collected, teacher reflections, posters of solution strategies, videotapes of the class sessions, and field notes, was focused on the development of conceptual knowledge, not procedural skill. Each group discussed the problem, and recorded their thought processes on large poster paper. The poster proofs were used to explain their reasoning, their discussions, their mistakes, and their conclusions with the class. Others in the class could comment or ask questions. These poster proofs used to document teachers' progression of ideas.

Video class sessions and instructors' memos. The researchers collected instructors' memos each day to serve as a record of the professional development. Researchers also took photographs and video recorded daily sessions focused on teachers' sharing their representations, class discussions, and studying teachers' work and collaborative poster proofs.

Through the use of multiple data sources our goal was to capture, teachers' strategic competence, namely: (a) the connection between teachers' content knowledge and the use of representations;

(b) teachers' use of mathematics models, tools and technology and pedagogical strategies; and
(c) teachers' rationale for choosing tools and representations to represent their thinking. The researchers included the faculty and knowledgeable others who recorded their observations in a consistent format that helped us analyze and identify evolving themes and misconceptions.

Data Analysis Procedure

Critical Incident Analysis (Tripp, 1992, 1994) was used to analyze key events that evoked teachers to reflect on their math knowledge for teaching rational numbers and their teaching practices. Tripp (1992, 1994) defines critical incidents, which emerge through the critical reflection process, in the following way: *"Incidents happen, but critical incidents are produced by the way we look at a situation: a critical incident is an interpretation of the significance of an event. To take something as a critical incident is a value judgment we make, and the basis of that judgment is the significance we attach to the meaning of the incident."* Tripp also describes critical educational events are catalysts for transformative development of both students and teachers. As researchers, we took inventory of critical incidents that occurred throughout the content institute and the Lesson Study and collected the data sources from those episodes to analyze them for their meaning, relate the incidents to a broader analysis to understand how those critical incidents developed teachers' strategic competence.

Findings

Critical Incident 1: Letting Go of Formulas and Modeling Division of Fractions: What's All These Partitive, Quotitive Models?

A challenge that teachers encounter in their curriculum is having to model division of fraction. This requires understanding of the partitive and quotitive model of division. It was evident in many of our teachers that they had learned math rules without conceptual understanding and were challenged to reason about the mathematics they were teaching. To understand modeling division of fractions it is necessary to appreciate the different meanings such as measurement division, sharing, finding a whole given a part, and missing factors etc. Two different conceptual models that often evolve in modeling fractions include a fair-share (partitive) or measurement (quotitive) model. In the fair-share partitive model, the goal is to share out the same number of object to a fixed number of groups. On the other hand in a measurement quotitive model, a measurement unit is chosen and is repeated as many times to yield the quantity being measured. While the former leads to an invert and multiply algorithm, the latter leads to a common denominator algorithm. One of the instructors focused her module on this notion of division of fractions and in helping teachers model story structures that represented partitive and quotitive models. She writes in her instructor's memo:

> *I did see discussions between models of division that showed that participants did not have two equally robust models of division that they could use in their models. There was a debate between two participants that suggested that one participant had a model of division that was partitive, but the table-mate was showing a quotitive model. I hope that through modeling division problems tomorrow they will have the opportunity to figure out each division model from a set of problems. Having participants use manipulatives to model quotitive and partitive expressions challenges their views of division. (Excerpt-instructor's memo Day 3)*
>
> *The next thing I learned today is that having participants use manipulatives to model quotitive and partitive expressions challenges their views of division. For example, students who were comfortable with modeling $34 \div 14$ were stumped by $45 \div 2$. However, the reverse was also true: participants comfortable with $45 \div 2$, could not figure out a way to model $34 \div 14$. It is fascinating to me that this occurred at most tables, and I think it is something that could be followed up on. From a teaching point of view, setting up the confusion over division models and then resolving them by naming the modeling process made it much easier to teach the idea of partitive and quotitive. The participants knew that there was something "fishy" going on, but couldn't name it, and therefore couldn't work*

with their models. I know that many want to skip teaching these ideas explicitly, but I think it is an essential understanding in learning to model rational number operations, and more importantly, learning to teach students modeling! (Excerpt-instructor's memo Day 4)

These excerpts from the instructor's memo were revealing of how this class activity elicited a relearning experience for teachers. One teacher commented in her reflection, "I am grappling with the process of modeling the process of dividing by a fraction. Since I learned to multiply by the reciprocal over forty years ago, and it has always worked that way, I have never questioned that process really works. I still don't fully get it. But I will continue to examine the model until I "get it!" Other teachers also echoed their awareness of being too reliant on learned procedures and how they needed to let go of the formulas to relearn the conceptual models of operation with rational numbers. "I need to constantly use the manipulatives or I revert back to my happy place with algorithms."

Critical Incident 2: Developing Conceptual Maps and Poster Proofs with Multiple Models

The conceptual posters were used to document teachers' progression of ideas. In addition, posters showed how people in a group approached problem solutions in a variety of ways. The reflections gave insight into how the individual teachers were feeling about the sessions but they also documented how they were adding new models on to their conceptual maps for rational numbers. In class sessions, groups were required to strategize solutions by at least three of the five possible representations. The teams would affix their poster proofs to the wall, but, before verbal explanations from the teams, the class would do a "gallery walk," a walk around the room stopping to look at and to analyze each poster then they would take time considering different representations. Several themes were present in the majority of the reflections about the poster proofs. These were: the importance of clarity in the models, seeing the connection between the various models, the advantage of building multiple models, the benefit of collaboration, and recognizing that there are multiple valid approaches to problem solving, which leads to viewing student work with new eyes. Several teachers reported "Aha" moments concerning ideas about rational numbers, which they had formerly accepted but now actually understood, giving them a feeling of liberation. A teacher wrote, "I wish more classroom teachers fostered an environment where students can struggle with problems and work together to solve problems. Struggling through and listening to strategies of others has really opened up my thinking." As the teachers' conceptual knowledge deepened, the teachers began to question their own knowledge and assumptions. Classroom discussions of problems and sharing solution strategies was seen as a valuable approach both to clarify problems as well as to develop their conceptual thinking.

The teachers rediscovered the use of a ratio table to solve a problem called the Robot and Cars problem. Teachers reported that the reasoning up and down strategy helped them to break problems into chunks and build on those chunks. One teacher wrote that she would use reasoning up and down to help her students focus on what they already know and then guide them in building on that knowledge. Several teachers remarked on the importance of labeling processes so that students have a clear picture of how the concepts tie together; this leads to the development of conceptual understanding and the internalization of concepts and processes for the students. The teachers recognized the crucial importance of thinking about the question before crunching numbers. Additionally, as can be seen in the posters, the teachers gained an appreciation for the validity of multiple approaches to problem solution (see Figure 1).

One of the teacher's reflection commented on how the poster proofs allowed for colleagues to share different models of proportional reasoning. *"Even though people have different approaches on problem solving. Not one person thinks alike. The robot/hrs/cars problem had multiple ways to get the answer. Some were very basic and others more complex."*

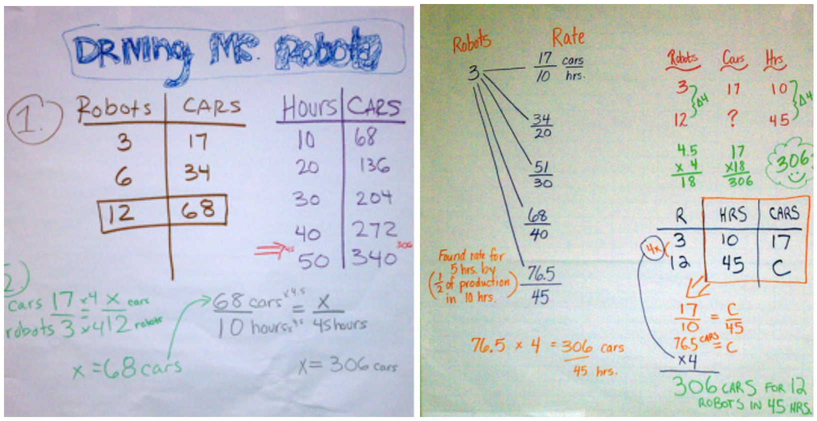

Figure 1: Using a ratio table and counting vs. finding multipliers

Mistakes and confusion allowed the teachers to use mathematical reasoning and arguments to do side-by-side comparisons of solutions, or just talk through comparisons of solutions to find where they did not match up. Then, the teachers would strategize to determine not only how to proceed but also to determine why one method did not work. For example, "1 robot can make 1 car in 1 hour" does not mean "2 robots can make 2 cars in 2 hours." Teachers discussed why a simple "multiply through" technique did not work. Teachers benefited from these discussions in several distinct ways. First, they began to see that real problems involving rational numbers are not simply plug-and-play exercises; they are multi-layered challenges, which require analysis, sound reasoning, and understanding of the relationships among quantities. Second, they recognized the profound importance of conceptual understanding as a baseline for strategizing approaches to problem solving. And, third, they gained an acute appreciation for the frustration of their students who apply incorrect procedures and cannot understand why their answers are incorrect. Several teachers mirrored that idea in their writings. Lastly, another teacher reflected, *"I am also starting to think differently about analyzing student work. When problems have the opportunity of yielding a variety of correct answers, it is important to consider what the student is doing and what math they can do and understand."*

Critical Incident 3: Using Lesson Study to Observe How Students Modeled a Problem

One critical class episode during the summer institute surrounded a problem called the *Mango Problem*. The problem is as follows: *One night, the King went down into the Royal kitchen, where he found a bowl full of mangoes. Being hungry, he took 1/6 of the mangoes. Later that same night, the queen was hungry, found the mangoes and took 1/5 of what the King had left. Still later, the first Prince awoke, went to the kitchen, and ate ¼ of the remaining mangoes. Even later, his sister, the Princess, ate 1/3 of what was then left. Finally, the youngest Prince woke up hungry and ate ½ of what was left, leaving only 4 mangoes for the kitchen staff. How many mangoes were originally in the bowl?* Teachers initially had difficulty approaching this problem because they were fixated on the whole being one mango or figuring out a formula. The researcher noted how the instructor reminded the teachers to "letting go" of rules and figure out ways to approach problems through modeling without getting fixated on the numbers. Video analysis revealed a group of teachers, Sunny, Jane and Al act out their solution. As they acted out the scenario, they asked questions like, "Is a mango the whole or are 4 mangoes the whole?" "What role are the fractions playing?" They started to wrestle with the idea of their previous math task called the Candy Bar and Circle Problem, which focused on the varying definitions of the "whole" and they had to negotiate and determine different meaning of fractions of that whole. Some teachers were observed having obstacles because they started with one mango as the whole; but, halfway through started to think as 4 mangos as the whole. This indicated a misconception that the teachers seemed to have about part-whole vs part-part interpretation. In addition, we observed teachers solving problems by working backwards using the manipulatives. The idea of unitizing that involves mentally constructing quantities in different chunks appeared to be somewhat problematic even for teachers. Although this group seems to be quick to catch on, they seem to be having problems truly grasping the concepts and applications of unitizing.

Because we noted this episode to be a critical incident, we were interested to see how this group of teachers who planned a Lesson Study (Lewis, 2002) with the *Mango Problem* would elicit models from their students. For the *Lesson Study Reflections,* we asked teachers to reflect on the process of developing and refining a research lesson, creating assessments items, and analyzing students' learning. The formal reflection assignment included teachers' evaluation of instructional strategies that promoted rational numbers and proportional reasoning through modeling, teachers' analysis of student thinking and what was learned from the process of collaboratively planning, teaching, observing and debriefing with colleagues. One of the Lesson Study teachers taught the mango problem to her 5th grade students and commented on the multiple models and representations that were used in her class.

> *Students approached the task in numerous ways. Some students tried to employ algorithmic approaches base on their current knowledge. This strategy often highlighted misconceptions they were having in regard to the relationships of fractions. Students would add all the numerators and then add on the number of mangos that remained. Others drew pictures or a model of 6/6 and took 1/6 away, but got stuck with where to go next. Others used the unifix cubes and represent this model the same way and were not sure how to proceed either. Still others quickly drew a model of 6/6 and identified the last box as having three mangos in it. They saw at that point that because fractional parts are of equal size all the boxes would have three mangoes in them. From there, they eliminated 1/6, 1/5,1/4, etc. recognizing that each time they took away one-sixth their whole changed. Drawing seemed to be the strategy that worked the best.*

Her reflection continued with an analysis of her students' work and how she asked her students to use their models of understanding the problem to justify their answers. This teacher reflected upon this Lesson Study and reported that the planning of the *Mango Lesson* helped bring deeper understanding of the importance of unitizing or the changing of the unit as one proceeds through a task. In addition, it solidified the meaning of fractional parts being of equal size. The planning session, also, brought to the forefront for her the multiple approaches that could be utilized by students to solve the task. Developing pictorial representations and then discussing the processing behind each solution with a collegial group allowed her to see thinking that was different from hers and yet valid. They looked at the process of working backwards and the relationship of parts to the whole. Collaboratively discussing misconceptions with her lesson study group also aided her in developing open-ended guiding questions to assist students in navigating through the task if and when they get stuck while modeling the task.

Discussion and Conclusion

Our study operationalized the notion of teachers' strategic competence using the NRC's (2001) description "as the ability to formulate, represent, and solve mathematical problems" and AMTE's standard (2010), "as the ability to construct and evaluate multiple representations of mathematical ideas or processes, establish correspondences between representations, and understand the purpose and value of doing so; and use various instructional tools, models, technology, judiciously, in ways that are mathematically and pedagogically grounded".

In our analysis we observed that teachers needed multiple opportunities to construct and evaluate multiple representations of mathematics ideas. In the critical incidence described above, teachers recognized that certain models afforded different opportunities for mathematizing. For example, the ratio table allowed teachers to bring out the ideas of reasoning up and down and highlight the multiplicative structures in proportional reasoning. In addition, the notion of "establishing correspondences between representations" came up a lot as an important theme when making connections between tabular, numeric and graphical approaches to representing a problem. *"Because I am so comfortable with mental math and using numbers, I find it arduous to think in terms of manipulatives and pictures. However, I can see the* *value of hands-on manipulatives for my math students. Today I used a ratio table and Kathy showed me how to "pull apart" a ratio so that I could manipulate it more easily."*

During the lesson study, the planning and debriefing phases revealed teachers pedagogical dilemmas with the "use various instructional tools, models, technology, judiciously, in ways that are mathematically and pedagogically grounded." For example, teachers who presented the mango problem wrestled with the pedagogical dilemmas of determining which manipulatives should be available for students and what model of fractions would be important in the lesson.

Most importantly, we gathered from their multiple reflective entries, teachers' sense of "understanding the purpose and value of doing so (representing and connecting representations). Teachers reflected on how the opportunity to struggle with problems in order to develop deep understanding of rational numbers. While many teachers expressed frustration with the homework problems as well as the in-class problems, they also recognized that their frustration led them to think about rational numbers in ways which they had not employed previously. This led to deeper understanding. Several teachers reported that they now "get" rational numbers and are gaining appreciation for the connections between concepts; they attribute this to the experiences of struggling through the investigative problems without the crutch of plug-and-play procedures. Teachers questioned each other's thinking and would not allow unsubstantiated assumptions. The focus was on mathematical reasoning, not the answer. We repeatedly heard teachers asking each other, "please explain that again, I don't understand where you are going with this" or "why would that be reasonable way to solve this?" Knowing that numerous approaches to problem solution were both possible and valid freed the teachers to concentrate on the soundness of their approaches, resulting in the teachers being able to develop more profound understanding. Participants valued the learning process and the opportunity to collaborate with other mathematics educators in translating their learning into practice. This study contributes to the growing body of knowledge on documenting how professional development serves as a catalyst for change in teachers as they reflect on developing their strategic competence for teaching and modeling rational numbers concepts in elementary and middle grades.

This paper reports on a design experiment within a professional development context purposefully planned to teach teachers about students' mathematics thinking and learning. We examine the factors to which participating elementary teachers attributed student mathematics success or failure when engaging with the projects' professional learning tasks.

Statement of the Problem

In his attempt to explain how people think, Schoenfeld (2011) put forth the following claim: "People's decision making in well practiced, knowledge-intensive domains can be fully characterized as a function of their orientations, resources, and goals" (p. 182). Defining orientations as including a myriad of concepts such as dispositions, beliefs, values, tastes, and preferences, Schoenfeld explained that orientations shape what we perceive, the meaning we make of what we see as relevant, the goals we establish in a particular situation, and the resources we bring to bear to achieve those goals. Further, he claimed that in mathematics classrooms, teachers' actions were shaped by their orientations toward mathematics, students, learning and teaching.

Using the broad definition of orientation that Schoenfeld put forth, our study examines elementary teachers' orientations toward students' mathematics. More specifically, we attend to teachers' attribution as one aspect of orientation and examine the following question: *to what factors do elementary teachers' attribute students' mathematical work when working on professional learning tasks designed to teach them about students' mathematics thinking and learning?* The project consisted of a design experiment within a professional development setting purposefully planned to teach teachers' about students' mathematical thinking and learning. This design experiment allowed for the study of changes over time in teachers' attributions for students' mathematical successes and failures. The initial conjecture under investigation stated that learning about students' mathematical thinking would add a new attribution to teachers' repertoire, thus changing the array of attributions available for teachers to use as they examined student work within the professional learning tasks used in the professional development. As a first step in the investigation of this conjecture, the various factors teachers used in the professional development to attribute students' successes or failures were documented.

We begin this paper by briefly reviewing the literature that defines the theoretical framework of our study. Then, we present our research methodology, describing the professional development setting in which we work. Next, we define the attribution factors we observed in our professional development and share examples of how these attributions were present in our work with elementary teachers. We conclude with a set of next steps for our research.

Framework

Thompson, Phillip, Thompson, and Boyd (1994) first used the concept of orientation to describe what they called a calculational and a conceptual approach to teaching mathematics. The authors incorporated teachers' knowledge, beliefs and values within the concept of orientation and, much like Schoenfeld (2011), proposed that these orientations shape teachers' images, views, intentions, and goals for mathematics instruction. Magnusson, Krajcik, and Borko (1999) included orientation as a component of teachers' pedagogical content knowledge. They considered that teachers' orientation influenced instructional practice by shaping teachers' knowledge and beliefs about curriculum, students, teaching, and assessment. Phillip (2007) noted teachers' orientations were operationalized through attention to teachers' language and actions.

When analysing teachers' language in a professional development organized around student work, Kazemi and Franke (2004) reported a shift in the ways teachers attended to the details of student mathematical thinking. They explained that in the initial meetings of the professional development group, teachers focused their analysis of student work on students' mistakes, could not provide detailed explanations on how students completed the problem posed to them, and were surprised that the problem posed was difficult for the students. However overtime, teachers conversations became more detailed regarding the work their students were doing and teachers able to note various levels of sophistication in students' mathematics reasoning.

Sowder (2007) cited various examples of professional development projects in mathematics that used student thinking to promote teacher learning and noted that these projects often provided teachers with opportunities to examine student work. As indicated in Little (1999), the sustained and systematic study of student work provides one of the most powerful and least expensive opportunities for teacher learning.

When working with teachers in professional development that offered opportunities to examine student work, we observed that an important aspect of teachers' orientation toward students was the ways in which they talked about students' successes or failures in completing the mathematics tasks under examination. The attribution aspect of teachers' discourse turned our attention to attribution theories as one facet of teachers' language when examining student work.

Bar-Tal (1978) defined attributions as the inferences made about the causes of one's own or someone else's behaviours. Weiner (1985) noted that attributions were classified in relation to its locus of causality (internal or external) as well as stability (fixed or not) and controllability (who can change it). Classification of attribution along these dimensions usually leads to the examination of ability, effort, luck or the difficulty of the task as the causes for one's successes or failure.

Middleton (1999) noted that teachers' attributions of their students' successes and failures were reflected in the ways teachers interacted with their students during mathematics instruction. Examining pre-school settings, Dobbs and Arnold (2009) claimed that teacher's attributions of the students' behavior shaped the teacher's behavior toward the child, which in turn often elicited the expected behavior from the child, having a self-fulfilling prophecy effect.

Because our work is in professional development settings, we extend the discussion of the role of teachers' orientations and attributions in instruction to professional development settings. We consider that teachers' orientations toward students' mathematics play a fundamental role in teachers' engagement with professional learning tasks, with teachers' attributions of students' successes and failures shaping professional conversations around student work used in these learning tasks.

Methods

Professional Development

Our work with teachers is based on the concept of learning trajectories (LTs). When Simon (1995) coined the expression "hypothetical learning trajectory," he indicated that teachers create representations of the "paths by which learning might proceed" (p. 135) when students progress from their own starting points toward an intended learning goal. He named these trajectories hypothetical because each student individual learning path was not knowable in advance. However, he suggested that these learning paths represented expected tendencies and that commonalities across students allowed teachers to develop expectations about how learning might proceed.

Over time, the concept of LTs has developed to go beyond the notion that teachers have expectations about how learning might proceed to include an empirical search for the highly probable sets of levels through which students progress as their learning of specific mathematics topics evolve. Thus, current work on LTs uses research on student learning from clinical interviews and large-scale assessment trials to seek clarification of the intermediate steps students take as learning proceeds from informal conjectures into sophisticated mathematics.

Recently, research on LTs has progressed from an agenda for studying student learning to an agenda for research on teaching. Daro, Mosher, and Corcoran (2011) called for the translation of LTs into "usable tools for teachers" (p. 57). They indicated the need to make these trajectories available to teachers so that they can guide classroom instruction.

Research Design

The overarching purpose of our research is to understand the ways in which teachers come to learn about one particular LT as a representation of students' mathematics in the context of a professional development setting. Inasmuch, we examine both teacher learning and the set of professional learning tasks that support their learning experiences. As we teach teachers' about students' mathematics through the concept of LTs, teachers' orientations toward students shape the ways in which teachers engage with the professional learning tasks proposed to them, with teachers' attributions playing an important role in their discourse.

We use a design experiment methodology within a school-based professional development setting to accomplish our research goals. Design experiments are "iterative, situated, and theory-based attempts simultaneously to understand and improve education processes" (diSessa & Cobb, 2004, p. 80). They are used to develop "a class of theories about both the process of learning and the means that are designed to support that learning" and they "entail both 'engineering' particular forms of learning and systematically studying those forms of learning within the context defined by the means of supporting them" (Cobb, Confrey, diSessa, Lehrer, & Schauble, 2003, p. 9).

In order to analyze the data, we engaged in a grounded theory approach to data analysis (Strauss & Corbin, 1989). In doing so, we coded our data (field notes and group discussion transcripts) using open coding, which enabled us to create concepts from raw data. In addition to creating data-driven codes, we also used theory and research goals to help create several of the codes. Once all of the codes were created, we then engaged in axial coding in order to make connections between the initial codes. This allowed us to create larger categories or themes (see results section for categories). In line with the grounded theory approach to data analysis, we used the constant comparison method in that we were comparing various project data sources including field notes and group discussion transcripts as well as the research literature (Glaser & Strauss, 1967). The constant comparison method allows for the creation of emerging categories in the data analysis and the refinement of these categories as they are contrasted with new project data. Various sources of data are used for the ongoing analysis and for triangulating information (Miles & Huberman, 1994) in search of both confirming and disconfirming evidences.

Context and Participants

The professional development comprised of both a summer institute and academic-year monthly meetings. These two components of the intervention were designed with different goals in mind. The summer institute offered teachers opportunities to learn about the LT and develop an appreciation for the role of the trajectory in understanding student mathematics. In contrast, the academic-year monthly meetings focused on establishing connections between the trajectory and instructional practices. The two components of the professional development totalled 60 hours of face-to-face, whole group interactions over one school year.

The professional development was offered in partnership with one elementary school in a mid-size urban area in the southeast of the United States. The school had approximately 600 students, 35% Caucasian, 29% Hispanic, 25% African American, 7% Asian, and 4% other; 54% of the children qualified for free or reduced lunch. Teachers at the school volunteered to participate and all professional development meetings were conducted at the school, in times selected based on convenience to the teachers. Of the 24 teachers who started the professional development in July 2010, 21 completed the program one year later in June 2011. The initial group of teachers included six Kindergarten teachers, three

Grade 1, five Grade 2, three Grade 3, two Grade 4, and one Grade 5 teacher. Four teachers taught multiple grade levels.

Results

Teachers' attributions of students' mathematics emerged very early on in the professional development, calling our attention to its importance for our work. Here, we offer one example from a professional learning task posed to teachers in the beginning of the professional development to demonstrate how teachers' attributions shaped discourse in the professional development setting.

The task we are using as an example engaged teachers in watching videos of clinical interviews with students from different grade levels solving similar mathematical problems. Teachers were asked to describe the ways in which each child solved the problem, conjecture about each student reasoning for that particular solution, consider the sophistication of the various strategies, and examine what surprised them about each student work. In the discussion that followed, despite the facilitator's effort to focus the discussion on what each child did and why, teachers' discourse focused mostly on whether what each child did aligned (or not) with what teachers' thought a student at that grade level was expected to do. That is, they attributed what the children did to grade level. The information about each child's grade level, offered to teachers as part of the context for the clinical interviews, became the center of the discussion as if grade level defined for the teachers what a child could or could not do mathematically. Thus, in the case of this particular task, teachers' attributions for students' work shaped the discussion around the professional learning task.

Through the examination of teachers' discourse when asked to engage with a collection of professional learning tasks, we documented the various attributions teachers' brought forth. In what follows, we present each attribution, a short working definition for it, and two or three quotes that exemplify how the attribution was represented in our data.

1. *Ability*: Considers personal traits of students and characteristics that define the student as fixed qualities related to students' aptitude in mathematics. Often times, teachers use achievement to consider students' abilities, attributing students' performance to an innate capacity.

   "We had evaluated this student and we were convinced there was a learning disability. The work was really low. But we were working on tangrams and this student put the 7 shapes into a square; he did immediately, first one to have done it and did it quickly."

   "I had a lot of math genius and they can figure things out when they are so young."

2. *Effort*: Refers to the level of student attention and engagement with a particular task at a particular moment. It indicates that performance does not always represent a fixed characteristic of the student, but depends on how carefully or how speedy that particular student progressed through the work at a particular moment.

   "Well, he just zipped through all this, so, no wonder…"

   "He worked on this so carefully."

   "In my mind, this kid just wasn't paying attention to me while I was teaching and he played connect the dots."

3. *Luck*: Includes the idea that what students do has no intentionality behind it. Also implies that students do things that have no real explanation for what or why they did something, or knew what they were doing.

   "I thought she was just guessing and she was just lucky."

   "When questioned how did you know, that is when I realized she really randomly chose to give each one two pieces. It was not that she had the number fact or she understood."

4. *Difficulty of task*: Expresses the notion that what students do is determined by the clarity or lack of clarity of the question posed to them. Has an embedded idea that there is a perfect way to ask a question so that students would not make a mistake.

   "The proctor asked her to put things together and then divide them, so, she shared differently because the proctor asked a different question."

   "When we teach a group of students and over half of them make the same mistake, then we have to go back and look at the way we presented it and ask ourselves…is it some fault in the way the question was presented?"

5. *Grade level*: Includes the notion of development and the expectations teachers have for students' performance given normalized definitions for what the generic student should be able to do at certain point in his or her development. Indicates that grade level groups students at similar developmental levels.

   "I taught Kindergarten and I would have guessed she would share using one for you, one for you, one for you; what she did was more advanced because she counted two plus two plus two."

   "I had expected the third grader to not share dealing it one by one."

6. *Cultural context*: Indicates that teachers take into account the experiences students bring with them from their own lives. Includes outside school understandings and explanations that students generalize to the academic context.

   "She just shared and she thought "it is fair because we each got some", and that is because of how we use the word share in the real world. She thought we both have some so we have shared."

   "I think that was a problem for a lot of these kids, dishing out the whole birthday cake (to fair share it). I just wonder if you called it something else besides a birthday cake if they would have seen the whole differently."

7. *Teaching*: Implies that what students do depends on what teachers have presented to them. Depending on whether or not a teacher has already taught a particular topic to the students, teachers expect students to know a topic taught. On the other hand, it indicates that teachers consider that students have no way of knowing a topic not yet taught.

   "Sometimes students can say something even when we had not taught it, like, this is ½ of 10 so that part has to be 5 as well. It seems simplistic, but I don't know how they would have known that already."

   "It used to be that students would do what teachers taught and we would follow it. But now students generate their own ideas and can do it in a way that is different from my own. They know how to come with the right answer by themselves."

Next Steps

In this paper, we documented seven different factors brought forth in the context of our professional development as teachers attributed students' mathematics successes or failures when examining student work. These attributions go beyond ability, effort, luck and difficulty of tasks to also include grade level, cultural context and teaching. They represent teachers' orientation toward students, and indicate the knowledge, dispositions, beliefs, and values teachers activated to examine student work in the context of our professional learning task.

In continuing our research, our conjecture is that the array of attributions available for teachers examining student work will change as teachers learn about student mathematics represented by LTs. Thus, we will examine whether our professional development on LTs added a new attribution to teachers' repertoire, one that includes recognition of students' mathematics successes and failures in relation to the level represented in LTs. This attribution recognizes that students' mathematics requires interactions between internal and external factors such as previous knowledge and opportunities to learn. Further, this attribution is not fixed and both students and teachers are responsible for changing it. We also conjecture that as the professional development unfolds and teachers come to better understand LTs, they will use the learning trajectory attribution more often. Examining these conjectures are the next step in the development of our work.

This article is a report on the findings of a case study that focuses on a first grade teacher's noticing of children's understanding of linear measurement along a learning trajectory, extending Jacobs and her colleagues' framework (Jacobs, Lamb, & Philipp, 2010). It documents what the teacher noticed in terms of attending to and interpreting student strategies in four different contexts during her participation in a lesson study. The findings indicate that the teacher was overall more successful in attending to student strategies than interpreting mathematical understanding reflected in the strategies when she used a learning trajectory as a tool to notice student understanding. More interestingly, we found that her level of noticing differed depending of the role that she took in the process of lesson study.

Keywords: Learning Trajectories (or Progressions); Teacher Education–Inservice/Professional Development; Teacher Knowledge)

Understanding children's mathematical thinking is one of the key factors for teachers to provide effective instruction. More specifically, teachers' knowledge about how children's thinking progresses over time and what conceptual mile stones indicate is critical to support children's mathematical learning. The National Research Council (NRC, 2001) asserted, "Familiarity with the trajectories along which fundamental mathematical ideas develop is crucial if a teacher is to promote students' movement along those trajectories" (p. 370). Many research studies (e.g., Cobb et al., 1991; Confrey, Mojica, & Wilson, 2009; Gearhart & Saxe, 2004; Schifter, 1998, 2001) investigated teachers' instruction that builds on children's mathematical thinking and its progression in the domain of numbers and operations, and some studies reported improvement in student learning by building on children's thinking (Carpenter, Fennema, Peterson, Chiang, & Loef, 1989; Fennema et al., 1996; Jacobs, Franke, Carpenter, Levi, & Battey, 2007; Villaseñor & Kepner, 1993).

Several groups of researchers (Barrett & Clements, 2003; Barrett et al., 2012; Sarama & Clements, 2009) have documented children's thinking and learning trajectories in the domain of measurement, more specifically linear measurement. A study by Barrett and his colleagues (Barrett, Jones, Thornton, & Dickson, 2003) discussed benefits of instruction when teachers design tasks and questions that recognize where students are in the learning trajectory and help move children to a more sophisticated level. However, more research studies are needed to document how teachers make sense of a learning trajectory and how it may impact their teaching. This initial study may help to fill this gap through a case study of a first grade teacher who participated in a professional development program that focused on knowledge of children's thinking about linear measurement through the use of a learning trajectory. The teacher was supported in her effort to put the knowledge into practice through a lesson study.

To capture how teachers use their knowledge of a learning trajectory of linear measurement in practice, we used *noticing* (Mason, 2002) as a main framework. Noticing allows us to highlight the nature of knowledge that teachers need to actively respond to complex and challenging environment in practice. Teachers may have knowledge on children's thinking, but if it is not active they may not notice it in practice, which in turn will result in difficulty in taking appropriate instructional actions to improve it. In mathematics education, Jacobs and her colleagues (Jacobs, Lamb, & Philipp, 2010) recently studied what teachers notice in terms of children's mathematical thinking in the domain of whole numbers and operations with a goal of unpacking teachers' in-the-moment decision making. They defined the professional noticing as a set of skills including how they attend to children's strategies, how they interpret mathematical understanding reflected in the strategies, and what decisions teachers make to respond to the understanding in the strategies. Jacobs et al. analyzed what teachers noticed in children's strategies presented in a video clip and also a collection of students' written work during their professional development activities. They then compared teacher noticing with different levels of teaching and professional development experiences. They concluded that teachers' noticing expertise grew with teaching and professional development experiences, which indicate that this expertise can be learned and supported through professional development. Although Jacobs' study provides a framework on how to analyze teachers' noticing of children's thinking, the question of how teachers' noticing in a professional development context is related to teaching context still remains unanswered. In this study, we aimed to extend Jacobs' study to an actual classroom, and to put a step closer to teachers' in-the-moment decision making.

This study examines teachers' noticing in the context of lesson study as a part of a professional development program. The context of lesson study allows teachers to develop *knowledge-in-practice*, which Cochran-Smith and Lytle (1999) described as the practical knowledge of teaching "embedded in practice and in teachers' reflections on practice" (p. 250). Sowder (2007) discussed lesson study as an example of learning-in-practice because "in lesson study teachers deliberate on the practices they observe with others." Fernandez and Yoshida (2004) described lesson study as a well-defined common practice in Japanese schools. This process involves three processes and three additional processes that some groups follow. The first three processes are for teachers and professionals in the community to collaboratively plan a study lesson, to observe the lesson study in action, and to discuss the lesson. Sowder (2007) pointed out that the first two steps are not new to U.S. teachers, although they rarely involve other teachers, but the last step is uncommon. Ball (2002) and Lewis (2000) discussed that these processes allow teachers to attend to and learn what each child understands, organize instructional tasks based on mathematics, and make adjustments as needed. Three additional processes that are optional are to revise the lesson, to teach the new version of the lesson, and to share reflections about the new version of the lesson. Our study situates teacher's noticing of children's understanding of linear measurement concepts along a learning trajectory in the context of all six processes of lesson study.

The purpose of this study is to contribute in making sense of teachers' learning of children's thinking in the domain of linear measurement. More specifically, we aim to examine one teacher's noticing through a case study in the context of a lesson study, which supported teachers' learning and use of a learning trajectory as tool to make sense of children's understanding. Our research question is:

- How do teachers use a learning trajectory as a tool to notice students' measurement understanding in the context of lesson study? In their noticing, how do teachers attend to and interpret students' strategies?

Methods

Participant

Here we report a case study that focuses on one teacher, Ms. Smith, from a larger study involving 24 teachers. At the time of the study, Ms. Smith was teaching first grade with 16 years of teaching experience. Ms. Smith taught at a K–4 elementary school. The school was classified as a Title 1 school, where 34% of the students were qualified for free or reduced lunch, and 59% were minority.

Professional Development

The aim of the larger study was to introduce teachers to a learning trajectory on length measurement and support their use of it in assessing students and designing instructional tasks. All of the participants were from an urban school district in the Midwest. The teachers participated in two summer professional development conferences for a total of ten days. During the first professional development, which lasted six days in June, the teachers were introduced to the Length Learning Trajectory developed by Sarama and Clements (2009). The teachers learned about each level of the trajectory and student understanding at each level. They designed assessment tasks using the trajectory and also tested their tasks with children from a local summer program. The second professional development, which lasted four days in August, introduced the concept of lesson study.

The teachers worked together in six groups of four to develop lesson plans. Ms. Smith's lesson study group designed a lesson to develop students' understanding of linear measure focusing on non-standard units. The teachers in Ms. Smith's lesson study group designed a lesson about a postman delivering mail. The students were asked to measure and compare routes on their classroom floor using cutouts of the postman's foot.

Prior to the first instruction of the lesson, each teacher was asked to interview six students of varying abilities from their classroom using length tasks he or she designed or tasks given during the summer professional development. Following the interviews, each group of teachers participated in the processes of teaching or observing the lesson, and discussing the lesson. Based on the discussion, the teachers revised the lesson and iterated the processes four times. In this process, each teacher was asked to re-interview his or her six students following the classroom lesson. The teachers were asked to write reflections for each iteration of the lesson study as well as reflections on pre- and post-student interviews. These reflections prompted the teachers to describe the tasks or lesson posed, discuss student responses and thinking in relation to the learning trajectory, and prescribe future instructional tasks for the students.

Data

In this study, we analyzed video and journal accounts of Ms. Smith's reflections for the second and third iterations of the lesson. Ms. Smith taught the second iteration of the lesson and observed the third iteration. We transcribed the videotapes of the second lesson that Ms. Smith taught and the post lesson discussions of the second and third lessons that she participated in. The journal accounts included her reflections of the lessons and discussions as well as the pre- and post-student interviews. This provided us with four main data sources: Ms. Smith's report of pre-lesson interviews with the six students, her reflection of her own teaching, post-lesson interview with the six students, and Ms. Smith's reflection of third iteration of the lesson taught by another teacher in her group.

Data Analyses

Each of the four main data sources was analyzed with attention to two of the professional-noticing skills from Jacobs, Lamb and Philipp (2010), including *attending* to student strategies and *interpreting* children's understanding. With regard to attending to student strategies, we used two codes of showing or not showing evidence when we analyzed her reflections on pre- and post-student interviews. If she was able to provide mathematically significant details on how a student measured or used tools to measure then it was coded as showing evidence of attending to student strategies. We used three codes, attending to individual student strategies, attending to group strategies, or not showing evidence when we analyzed her reflections on discussions or lessons during the lesson study. This two-tier coding scheme was used because in the interview context, Ms. Smith worked with the students one-on-one, and in the lesson study context she worked with a classroom of students. We decided to use the additional code for the data from the lesson study context to account for the difference in the nature of the contexts.

With regard to interpreting student strategies, we used three codes including robust evidence of interpretation, limited evidence of interpretation, or lack of evidence of interpretation. We used the same set of codes for both contexts. When Ms. Smith made specific comments about her interpretation of mathematics in students' strategies, it was coded as robust evidence. When Ms. Smith made general comments of mathematics in student strategies, it was coded as limited evidence. When Ms. Smith provided little to no comments of mathematics in student strategies, it was coded as lack of evidence. For instance, her comments focusing on other issues within her classroom such as her teaching style, improving teaching, or student behavior were coded as lack of evidence.

Results

In this section, we share Ms. Smith's noticing of children's understanding of linear measurement from the four different contexts. We describe our observation of her noticing with sample statements from her reflections.

Ms. Smith's Noticing in the Context of Pre-Lesson Student Interviews

In the pre-student interviews, Ms. Smith interviewed six students one-on-one and described their responses to each of the three tasks. After describing the student response to the task, Ms. Smith provided her interpretation of their responses.

Attending to student strategies. Ms. Smith's reflections showed evidence of attention to student strategies for each of the six students. When describing student strategies, she noted how individual students responded to the task with very detailed descriptions of the strategy. She typed up about one-page descriptions of each student. Consider Ms. Smith's following statements that showed evidence of attention to student strategies:

> With the *Length Comparer* activities, she lined up the first two objects and identified them correctly as a big one and a small one. Then she took the five objects and lined them up in correct order but there were not all starting at the same zero point.

In the statements, Ms. Smith captured mathematically important details. Specifically, she included descriptions about how the student compared the length of multiple objects and made a mathematically significant note that the student did not line them up with the same starting point.

Interpreting students' understanding. Ms. Smith exhibited limited evidence of interpretation of students' understanding. Her statements showed her intention of interpretation but they were rather broad and general. The following is an example of showing limited evidence of interpretation:

> In the Indirect Length Tasks, he was able to identify the shorter and taller of two fixed objects…he took the thread and measured the first cabinet and saved his place on the string. When he held it up to the longer cabinet, he said it was longer because it was longer than his arms… I would place student 6 in the Indirect Length activities.

Ms. Smith provided detail descriptions of what the student did to compare the height of two cabinets, but she concluded that the student's strategy would be at level 6 without providing evidence or justifying why she came to the conclusion.

Ms. Smith's Noticing in the Context of Teaching

Attending to children's strategies. When her group met after she taught the postman "Bob" lesson as the second of the four iterations of the lesson, Ms. Smith shared what children's strategies she noticed during the lesson. Unlike her detailed descriptions of individual student's strategies in the context of pre-student interview, Ms. Smith provided description of strategies that she noticed a group of students used:

> Most of them just slid the foot [paper cutout] along counting as they went. Some of them slid it longer than other ones. … Students seem to be at the beginning of the end-to-end trajectory. They were moving their foot [paper cutout] along the street [marked on the floor] and counting as they went. Some were actually putting a finger down to mark their place but most were just moving it in jerky, supposedly iterated movements.

Although she thought that children's strategy of sliding the foot cutout to measure lengths of delivery routes was invalid, Ms. Smith provided a detailed description of the strategy including, the motion that children took, length of the motion, and jerkiness of it. However, she did not discuss which students used the strategy, but rather said "most of them," referring to a large of group of students. We found that in her journal account Ms. Smith also reported her observation of the whole class, instead of individual students. We coded her noticing of students' strategies as attending to group strategies.

Interpreting children's understanding. Ms. Smith demonstrated lack of evidence in interpreting student understanding during the discussion following the teaching and in her written reflection. In both contexts, she focused on student behaviors unrelated to mathematical understanding or aspects of the lesson related to her teaching. The following are examples of Ms. Smith's responses to children's understanding:

> I was pleased with how the lesson flowed. The students were enthusiastic…. In retrospect, I guess I needed to model that a little more thoroughly…. I expected some of the students to use this as a time to play more than focus on the learning part of what they were doing and this is precisely what happened.

Ms. Smith's Noticing in the Context of Post-Lesson Student Interview

Attending to children's strategies. After teaching the lesson, Ms. Smith was also asked to re-interview the six students she initially interviewed and reflect on what they said about how they attempted the task and learned from the lesson. During the second interview, Ms. Smith showed evidence of attending to student strategies for only one student. For the other five Ms. Smith did not comment on how the student attempted the task. Ms. Smith did not reference her findings from the initial interview. Again she wrote about each student individually but this time she only wrote a few sentences and rarely referenced students' mathematical strategies. In this reflection she shifted from making specific comments about students' understanding to commenting about general behavior and teaching and learning. These are several of her comments from her post-interview with students.

> JH said it was fun. She said she had worked as a team with her friend who helped her measure the lines…TD did not iterate. He said he had compared it to driving and counted up that way as he moved his foot.

Interpreting children's understanding. In the post-lesson interviews, Ms. Smith demonstrated lack of evidence of interpreting student understanding. Miss Smith mainly focused on non-mathematical student behavior and she did not try to link student's individual behaviors to the levels in the trajectory following the lesson.

Ms. Smith's Noticing in the Context of Classroom Observer

Attending to children's strategies. As an observer Ms. Smith demonstrated evidence of attention to individual student strategies. Ms. Smith commented during the reflection that she was able to watch several students closely as she followed them around the classroom as they attempted to measure the length of several paths. In this instance, Miss Smith considered individual students within the group and the mathematical strategies that they used to measure a line.

> The team that I followed used their fingers to mark where they needed to move the foot forward from and count. One girl was more accurate with this than others… One of the boys didn't iterate, instead he just moved his foot along and counted… At one point they realized that it did not matter if they started at one end or the other when counting"

Interpreting children's understanding. Following the lesson, Ms. Smith demonstrated robust evidence of interpreting student strategies. Ms. Smith discussed with the group that that she had considered why the students were measuring in different ways and had formed a hypothesis based on student reasoning. She was able to link interpretations to specific student behaviors. In the post-discussion, she reflects on one student's struggles with measuring the path and she attributes this to his understanding of the number line.

> *Ms Smith*: I got the feeling that they were confusing how they were measuring with the foot. The student (that demonstrated) that came up with the incorrect answer was thinking of that first foot placement not as something he would count but he was using that as a starting off point and that is why their answer is less than the other. Instead of saying its one, two, three (moving her hand along a line). He started here, and you know how we teach the first step is one, two, three so he ended up

saying its three…it is kind of how you teach the number line counting to the kids at the start of the year. So, that's one observation I made on that initial thing. Trying to look at what the kids were thinking in their minds.

Discussion

In this case study of Ms. Smith, several themes emerge. First, there is evidence that when Mrs. Smith was introduced to a learning trajectory, it provided her with a language to describe student thinking. The findings indicates that Ms. Smith was able to use the learning trajectory to focus on student strategies, share knowledge about students with other teachers, and reflect on student strategies and responses. Ms. Smith was able to use appropriate mathematical language from the trajectory to communicate her understanding of students. Although Ms. Smith was not always proficient in using the trajectory, in several instances, she was able to correctly link student strategies with the appropriate level in the learning trajectory.

A second finding that emerged was that the lesson study provided a context that allowed the researchers to see differences in Ms. Smith's ability to notice student strategies. During the lesson study process Ms. Smith was able to take on several roles apart from her normal role as classroom teacher. Throughout the lesson study, Ms. Smith's noticing varied depending on the role that she took in the processes. Ms. Smith was more successful in attending to student noticing when she assumed the role of interviewer or observer. It may have been easier for her to observe and record student behavior because her focus was solely on one student at each interview. In the observer role during the third iteration of the lesson study, Ms. Smith focused on a small group of several students, instead of a whole class. Her attention to students' thinking may have been better because she was not responsible for student learning or classroom management. It seemed that this role of the observer allowed her to direct her focus to a few students for the entire class period and pay closer attention to their strategies and responses. When Ms. Smith taught the lesson, she did not attend to student strategies as well as in other contexts. This could be because the complexity of a classroom environment made it difficult for Ms. Smith to notice details of students' strategies or recall them in reflection.

Third, there seems to be connection between attending to student strategies and interpreting student understanding. When Ms. Smith provided more clear evidence of individual student strategies, she was more successful at interpreting student strategies. When Ms. Smith was able to attend to individual student strategies in the assumed role of interviewer or observer, she was able to interpret mathematics reflected in the strategies. We wonder if her close attention to individual strategies allowed an access to more concrete examples, which in turn helped her interpretations of student thinking. When Ms. Smith taught, she had difficulty attending to individual student strategies. In that context, she provided limited interpretation of student thinking and instead the focus was on her teaching or children's non-mathematical responses.

Lastly, we note the challenge of prompting teachers to use a learning trajectory as a longitudinal tool to assess children's progression over time. In the initial interview, Ms. Smith was able to use the trajectory to evaluate what level of the trajectory she thought students exemplified. However, we observed no evidence of her making connections of the information she gained from the pre-lesson student interviews to reflecting on the same students' thinking in a classroom lesson, and then to the post-lesson student interviews, although we had called on teachers to do so. It makes us wonder if she thought of the trajectory as an assessment tool prior to the lesson and not a tool to help promote student growth before, during, and following the lesson.

This case study of Ms. Smith provided us with a preliminary but very complex picture of what and how teachers notice children's thinking and how they use a trajectory to assess and make sense of student thinking. The results signify that the act of teacher noticing using a learning trajectory may become increasingly more complex when teachers move from observing and analyzing one or two students to working with an entire classroom. Further studies need to be conducted to analyze how classroom teachers develop in their ability to notice using a learning trajectory and how teachers connect knowledge of individual student strategies to classroom instruction. The findings and themes that emerged in this initial study gave us a glimpse of the multiple factors involved in improving teachers' noticing using a learning trajectory and provide a direction for future research.

PROSPECTIVE TEACHERS' CONCEPTIONS OF PROOF

Zulfiye Zeybek
Indiana University
zzeybek@indiana.edu

What types of mathematical justifications do pre-service elementary teachers find convincing? To investigate this question, a task-based interview which was designed to elicit arguments of what students find convincing was administered to two female students who were enrolled in a geometry course at a large Midwestern university. These arguments were categorized according to the proof schemes crafted by analyzing different studies dealing with proof. A qualitative analysis of the data revealed that the two pre-service elementary teachers (PSTs) who were interviewed have difficulties in following or constructing formally presented deductive arguments and in understanding how deductive arguments differ from inductive arguments. They also held explicit misconceptions about proving (or disproving) statements such as: "a couple of examples constitute proof" or "one counterexample is not sufficient to disprove a statement."

Keywords: Inductive Argument; Deductive Argument; Proofs; Preservice Elementary Teachers

Introduction

It is difficult to overstate the importance of proofs in mathematics. If you have a conjecture, the only way that you can be completely sure that it is true is by presenting a valid mathematical proof. However, the mathematics education community worldwide is facing the challenge of improving students' abilities to prove and to reason mathematically at all grade levels. Despite the fundamental role that proof and refutation play in mathematical inquiry (Lakatos, 1976) and the growing appreciation of the importance of these concepts in students' mathematical education (Hanna, 2000; Reid, 2002), students hold various misconceptions not only about proof, but also about refutation (Chazan, 1993; Simon & Blume, 1996).

Several studies have reported that formal deduction among students who have studied secondary school geometry is nearly absent (Burger & Shaughnessy, 1986; Dreyfus, 1999; Chazan, 1993). Many students accept inductive arguments as valid mathematical proof (Martin & Harel, 1989; Chazan, 1993) or they fail to recognize that using a larger set of examples still does not constitute proof (Knuth, Choppin, & Bieda, 2009). In addition, students have difficulty in understanding that a valid proof confers the universal truth of a general statement; thus mathematical proof requires no further empirical verification (Fischbein, 1982; Martin & Harel, 1989; Chazan, 1993). Some students believe that counterexamples do not really refute; instead they tend to treat valid counterexamples to general statements as exceptions that do not really affect the truth of the statements (Balacheff, 1988). Similarly, Simon and Blume (1996) show that many students think that giving one example is not enough to refute an argument.

Despite students' current lack of knowledge, as well as interest, in proof and proving, the topic is central to mathematics, so it should be a key component of mathematics education (Bell, 1976; Hanna, 2000; Martin & Harel, 1989). Not only is proof at the heart of mathematical practice, it is an essential tool for promoting mathematical understanding (Martin & Harel, 1989; Hanna, 2000; Knuth, 2002). Stylianides (2007) has shown that young children can make legitimate mathematical arguments and even formal arguments that count as proof. He claims that proof should be part of students' mathematical experiences even in early elementary grades (Stylianides, 2007). Similarly, Harel and Sowder (1998) argue that instructional activities that educate students to reason mathematically about situations are crucial to students' mathematical development, and that these activities must begin at an early age. Thus, calls for improvement in mathematics education in the U.S. have increasingly emphasized the importance of proof and reasoning by recommending that reasoning and proof should be a part of the mathematics curriculum at all levels from pre-kindergarten through grade 12 (NCTM, 2000).

The purpose of this paper is to describe pre-service elementary teachers' attempts to construct proofs and also to examine different arguments regarding proofs in order to better understand their conceptions of proof. The following research questions guided the study:

- How do pre-service elementary teachers support claims, warrants, and backings as elements of their argumentations?
- What are pre-service elementary teachers' conceptions of proof?

The Framework

Various studies that include a description of proof schema ideas at both pre-college and college levels are evaluated with an effort to craft the framework used in this study (see Table 1). Hanna (1989) argues that proofs can have different degrees of validity and still gain the same degree of acceptance. To document different types of mathematical justifications attempted by each participant, mathematical arguments constructed to examine pre-service teachers' conception of proof are assessed according to a hierarchy of levels of mathematical justifications explained in the framework.

While many studies have focused primarily on distinctions between the inductive and deductive justifications (Chazan, 1993; Martin & Harel, 1989; Morris, 2002), some researchers have posed questions such as: What might make one example or empirical justification stronger than another? Or can all mathematical arguments be categorized as inductive or deductive? As a result, they have divided inductive and deductive justifications into further subcategories (Balacheff, 1988; Harel & Sowder, 2007; Simon & Blume, 1996; Quinn, 2009) and proposed another type of justification along with inductive and deductive justifications (Harel & Sowder, 1998; Simon, 1996). The framework crafted for this study focuses not only on the distinction between the inductive and deductive justifications, but also further subdivides those categories as well as includes the justifications that are neither inherently inductive nor deductive.

Many researchers define several stages or levels in which students' reasoning skills vary in terms of the justifications they are able to produce (Bell, 1976; Simon & Blume, 1996; Quinn, 2009). Harel and Sowder (1998, 2007) categorize those levels into three classes in their taxonomy—the external conviction proof scheme class, the empirical proof scheme class, and the deductive proof scheme class—with some subschema for each class. Similarly, Balacheff (1988) describes two main categories—pragmatic justifications and conceptual justifications—which play complementary roles. The first justification type (pragmatic justification) is divided into three subcategories: naïve empiricism (justification by a few random examples), crucial experiment (justification by carefully selected examples), and generic examples (justification by an example representing salient characteristics of a whole class of cases) and the second justification type (conceptual justification) into two subcategories as "thought experiment" and "symbolic calculation." Weber and Alcock (2004), on the other hand, focus only on deductive reasoning and divide deductive justifications as syntactic proof scheme (manipulating correctly stated definitions and facts in a logically valid way) and semantic proof scheme (use instantiations of the mathematical objects to which the statement applies to suggest and guide the formal inferences) which aligns with Hanna's (2000) distinction of proofs that prove and proofs that also explain.

The framework used in this study summarizes the proof schemes explained above, by merging those categories—from external to analytic—along with different levels in which provers demonstrate different level of mathematical justifications. The framework outlines various strong background work, thus, provides a powerful as well as useful tool for an analytical assessment of PSTs' conceptions.

Table 1: Types of Mathematical Justifications

Level 0		Responses that do not address justification.
EXTERNAL	**Level 1**	**Appeals to external authority** • ***Authoritarian proof*** : depends on an authority such as a teacher or a book • ***Ritual proof*** : depends on the appearance of the argument • ***Non-referential symbolic proof***: depends on some symbolic manipulation, often without reference to the symbols' meaning
Level 2		***Naïve reasoning, usually with incorrect conclusions.*** Although provers use some deduction, the arguments start with an analogy or with something that provers remember hearing, often incorrectly. Provers generally reach an incorrect conclusion or, if they reach a correct conclusion, they have used the wrong assumptions.
EMPIRICAL	***Inductive Frame***	**Level 3A*: Naïve Empiricism:*** an assertion is valid from a small number.
		Level 3B: ***Crucial Empiricism*** deals more explicitly with the question of generalization by examining a case that is not very particular. If the assertion holds in that case, it is validated.
	Rudimentary Transformational Frame	**Level 3C:** ***Perceptual Proof:*** Provers make inferences that are based on rudimentary mental images that are not fully supported by deduction.
Deductive frame expressed in terms of particular instances		
TRANSFORMATIONAL	**Level 4**	***Generic Example:*** Deductive justification that is expressed in terms of a particular instance (examples might be used to generalize the rules, but unlike an empirical proof scheme, the general rules are predicted based on the inference rules.) Simon (1996) defines transformational proof schemes an enactment of an operation (or set of operations) on an object (or set of objects) that allows one to envision the transformations that these objects undergo and the set of results of these operations.
Deductive frame that is independent of particular instances		
ANALYTIC	**Level 5**	• ***Syntactic:*** a verification of a statement is evaluated according to ritualistic features. • ***Semantic/Conceptual:*** a judgment is made according to causality and purpose of argument.

Method

Participants

Two pre-service elementary teachers, Sara and Dacey (pseudonyms), volunteered to participate in this study. Both of the participants had enrolled in a Geometry-content course designed for elementary majors at a large Midwestern university. Both participants satisfied the course requirements and passed the course with a grade of B or above.

Data Sources

The study uses a qualitative approach, mainly participant classroom observation and task-based interviews to investigate pre-service elementary teachers' conceptions of proof. Every class in which the participants were enrolled was audiotaped and notes were taken by the author of this study.

Each participant was interviewed individually for about an hour in a semi-structured manner using an interview script consisting of three phases. The interviews took place near the end of the semester, in each case. Thus, the interviewees were expected to have learned most of the course topics and have had some practice justifying different statements by the time the interviews took place.

Phase 1. During this phase, each student was presented the written tasks A, B, and C, described below. The PSTs were asked to explain in their own words what the statements said, and to decide whether the statements were always, sometimes, or never true and how they would know. And then, they were asked to produce a justification in cases where they believed the statements to be true.

Phase 2. After letting the participants try to justify the statements by themselves first, the participants were presented with four brief arguments for both Task A and B, varying in terms of level of justification, one after the other, and asked to think out loud as they read each one, to judge the correctness, and to say to what extent each argument was convincing.

Phase 3. Having seen and thought about all four arguments, one after the other, the students were provided "Always," "Sometimes," "Never" cards and asked to assign the appropriate card to each argument presented. For instance, if the participants thought that the conclusion derived from one of the arguments would always hold true then they needed to put an "Always" card on the argument.

The data collected consisted of the audiotaped interviews, the interviewer's notes and the students' work on the "proof" sheets provided during the interview.

Interview Tasks

The interview tasks were designed to provide, first, an indication of pre-service elementary teachers' competence in constructing proofs, and then, an overview of their views as to what constituted a proof. The interview tasks included three types of items (from familiar to unfamiliar) to probe pre-service teachers' views of proof from a variety of standpoints.

Task A. This task was adopted from the course textbook. Thus, it was expected that by this time of the year, the interviewees were familiar with it and could reproduce the proof on their own. The task appears on the sheet presented to the participants as follows:

> A kite is a quadrilateral with two distinct pairs of adjacent sides that are equal in length. Given the definition, justify whether or not the following statement is true. "*In a kite, one pair of opposite angles is congruent*."

Task B. The same structure as in Task A was used to construct Task B. This task was adopted from Chazan (1993), but it was modified such that four arguments, varying in terms of level of justification, were added to present to the participants. The task appears as follows:

> Justify whether or not the statement is true: "*In any triangle, a segment joining the midpoints of any two sides will be parallel to the third side*."

Task C. Task C was a non-familiar case to the participants. Thus, it was expected that this task might be challenging for them. This task was adopted from Simon and Blume (1996). The task appears as follows: Find the area of the shape below.

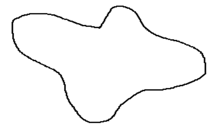

Figure 1

Arguments for interview tasks. The theoretical framework explained before (see table 1) governed the choice of arguments included in both of task A and B. Arguments for task A and B were characterized as empirical, subdivided as Naïve Empiricist with a small number of cases (Arguments 1 labeled as Level 3A) and Crucial Empiricism with an extended number of cases including non-particular cases (Arguments 2 labeled as Level 3B), argument requiring concrete demonstration or explanation written in everyday style (Arguments 3 labeled as Level 4), and a deductive proof, written in a formal style (two-column) (Arguments 4 labeled as Level 5). For task C, the following method was presented to the participants:

> "*If you take a piece of string and measure the whole outside of the area and then pull that into a shape like a rectangle, you can easily calculate the area of the figure*." Justify whether or not the above method will work to find the area of the figure.

Results

Sara's Proof Scheme

When Sara was presented task A, she attempted to dissect the kite into two triangles in order to use triangle congruency to justify the statement. However, because she drew a diagonal that produced two isosceles triangles instead of a diagonal that produced two congruent triangles, she failed to proceed from there to justify the statement. Even though, she started to use some deduction such as congruent triangles that she remembered hearing from her class, she failed to reproduce it correctly. Similarly, she attempted to use what she learned about parallel lines in her class to justify the statement in task B. However, she failed to proceed from using her previous knowledge to construct a justification. Thus, her proof scheme was coded as Level 2 (Naïve Reasoning) for both task A and B.

Even though Sara failed to construct a proof, she correctly distinguished the deductive arguments from the inductive arguments when she was presented the arguments for both task A and B. Sara understands that a couple of examples do not qualify as proof. She was aware that the conclusion that was arrived at from direct measurements of specific cases was approximate and that the generalization which was arrived at without examining every possible case might be highly probable but not certain. Additionally, Sara understands the role of justification in mathematics: that is, to provide an argument that holds for every case. She knows that providing examples will hold only for those specific examples and she chooses "Sometimes" for argument 1 and 2 and "Always" for argument 3 and 4. Thus, her proof scheme was coded as Level 5 in phase 2 and 3 for both tasks.

Dacey's Proof Scheme

Dacey, on the other hand, did not attempt to reproduce the proof she learned in her class for task A. Instead, she tried to justify the statement by saying that if two sides are equal, then the angles between them are going to be equal since where those sides will meet will be the same. Dacey did not attempt to provide examples nor attempted to use logical deduction to justify the statement. Rather, her attempt to prove the statement in Task A was driven by her perceptual observation of the figure provided to her. Thus, her proof scheme for this task was coded as Level 3C based on the framework. When Dacey was presented task B and asked to decide whether or not the statement was correct, she quickly concluded that the statement was correct, because, as she explained, the instructor recently showed the same statement and justified why it was correct in the class. However, because Dacey did not understand why the statement was correct or how to justify that it was correct in class, she failed to reproduce the proof. Dacey remembered that the proof included corresponding angles, but she could not proceed from using corresponding angles to conclude that the statement is true. Her response for this task was coded as Level 2.

Dacey found arguments 3, 2 and 1 more convincing than argument 4. She claimed that seeing actual measurements or illustrations was more convincing than providing a logical argument. She insistently claimed that arguments 4 were not convincing for her at all.

Task C was an unfamiliar case; none of the participants had experienced this type of task in their classrooms. Thus, both participants struggled with the task and neither of them could come up with a method to find the area of the figure presented. After they presented the method, their answers also differed. Even though Sara confirmed the method would work, after more thought she realized that there might be two rectangles with the same perimeter and different areas or vice versa. However, she also concluded that being able to refute argument (the method in this case) requires more than one counter example. Dacey, on the other hand, was certain that the method would work and she justified her conclusion by stating that if the outside of two shapes are equal so must the inside.

Conclusion and Discussion

The findings outline a mixed picture of what constitutes proof in the eyes of those two pre-service elementary teachers. When asked to define proof, it was clear that pre-service teachers had some experience of proof and were using this to inform their judgments about what constituted a good proof. They had experience of seeing a proof being performed and were quoting these as examples of what was required. However, despite their experience of seeing proofs in their classrooms, both participants failed to produce a proof for task A and B. This result aligns with Senk's (1989) argument that students need to be at higher levels in order to perform a proof than to be able to follow a proof. In addition, Healy and Hoyles (2000) provide evidence that students are better at choosing correct mathematical proofs than at constructing them.

In this study, even though Sara failed to apply her understanding of logical necessity to construct a proof, she was aware of the fact that inductive conclusions as in arguments 1 and 2 provide probable conclusions while, in deductive inference, the prover reaches a conclusion that is certain. Additionally, Sara exhibited different levels when she was asked to prove the statement by herself than when she was asked to evaluate different arguments constructed by others. Even though she failed to prove the statements, she recognized and selected the deductive arguments correctly.

Dacey, on the other hand, relied on examples as her primary means of justification for task A and B. She consistently justified the generalizations by stating that it worked for all the cases tested. She did not realize the limitations of such reasoning. Stylianides (2007) argues that considering empirical arguments as proof is a threat to students' opportunities to learn how to prove a proposition. Thus, one can argue that Dacey might lead students to believe that two examples would qualify as proof in her future classroom. Balacheff (1988) distinguishes between two large categories of proofs that students produced—pragmatic proofs and conceptual proofs. Pragmatic proofs are those having recourse to actual action or showings, and by contrast, conceptual proofs are those which do not involve action and rest on formulations of the properties in question and relations between them (p. 217). As in Balacheff' s definition, Dacey stated that actual action or showing was more convincing than the one which did not involve action.

This study reveals that students' levels of mathematical justification are not static. Rather, students might demonstrate different levels on different tasks depending upon their familiarity with the tasks. Fischbein (1982) argues that students choose to believe in something that seems more natural to them, subjectively, intuitively as an intrinsic property of the object. Nothing in the direct experience of the student needs such an explanation and leads to intuition. It was clear that Dacey was intuitively convinced that the outside of the shape also determines the inside in Task C. Thus she believed that if the perimeters of two shapes are equal, then the areas should be equal as well, so the method should work.

Implications and Suggestions

This study reveals that the participant PSTs do not always see the need of justifying a statement if the statement is intuitively appealing to them. In addition, they referred to the authority (the math teacher in this case) a couple of times to support their answers. Thus, it would be necessary to develop the shift of authority from teacher and textbook to the whole class. A classroom environment where mathematical ideas are not only constructed individually but also socially as students participate in meaningful activities (Cobb, Wood, Yackel, & McNeal, 1992; Yackel & Cobb, 1996) has the potential of generating mathematical justifications among prospective teachers.

I believe that a balance between visual reasoning and deductive reasoning seems to be a direction to pursue—discussing with students the role that examples play in proving statements in mathematics (Knuth, Choppin, & Bieda, 2009) while also creating learning opportunities for students to encounter both inductive and deductive proofs, so that students may develop not only a deeper understanding of proof but also a deeper understanding of the underlying reasons for using deductive proofs (Knuth, 2002).

If the goal is to help students develop a strong understanding of proof—especially in a deductive manner—teachers should assess students' current knowledge (common difficulties or misconceptions) in order to help them gradually refine their knowledge (Harel & Sowder, 2007). The framework used in this study may be a useful tool for teachers not only for assessing students' development in order to seek ways in which to help students gradually refine their perceptions but also for examining their perceptions of the nature of proof.

"AFTER ALL, MATH WAS ONLY NUMBERS, RIGHT?" TRANSITIONS IN TEACHERS' BELIEFS ABOUT EQUITY

Mathew D. Felton
The University of Arizona
mdfelton@math.arizona.edu

In this paper I examine the beliefs about equity of a cohort of 14 upper elementary teachers participating in their first year of a 5-year project aimed at developing elementary mathematics teacher leaders. Teachers' responses to a beliefs survey and their written reflections indicate a greater recognition of the role of equity in the teaching and learning of mathematics.

Keywords: Equity; Teacher Beliefs

There is a growing body of work focused on explicitly incorporating issues of equity, social justice, and diversity into mathematics teaching. One body of work focuses on using mathematics as a tool for analyzing inequity in our society (M. V. Gutiérrez, 2009). Related work focuses on issues of power surrounding the role of mathematics in our society (R. Gutiérrez, 2007). A second body of work emphasizes the role of culture and out-of-school experiences in the learning of mathematics, such as building on students' home and community Funds of Knowledge (González, Andrade, Civil, & Moll, 2001) or teaching mathematics in culturally responsive ways (Leonard & Guha, 2002). A third body of work focuses on mathematics as a fundamentally cultural activity emphasizing the accomplishments of groups around the world and throughout history (Zaslavsky, 2001) or on how socially significant constructs—such as race—are partially constructed in and through mathematics (Martin, 2009; Tate, 1994).

There is also a growing field of research focused on preparing prospective teachers to grapple with these issues in their teaching of mathematics (e.g., Rodriguez & Kitchen, 2005). While there are some exceptions (e.g., Wager, 2012), there has been minimal work in mathematics education examining how practicing teachers learn to incorporate the social and political nature of mathematics described above into their teaching practice. In this paper I examine transitions in a cohort of 14 elementary teachers' beliefs about the social and political dimensions of mathematics teaching and learning during one semester near the beginning of their participation in a 5-year grant focused on developing greater leadership in elementary mathematics education.

Theoretical Framework

I use the term "equity" to cover the broad range of perspectives focusing on the social and political nature of mathematics detailed above. I draw on the *What, How,* and *Who* (WHW) framework of mathematics (for more detail see Felton, 2010a, 2010b). The WHW considers:

- *What* messages are sent through the teaching of mathematics. Specifically,
  - mathematics is *co-constructed* with other important social constructs such as race, gender, culture, etc., and
  - mathematics can and should be a tool for *social analysis* by examining complex real world issues, and more specifically, social and political issues.
- *How* mathematics *concepts* and real world *contexts* are related in mathematics teaching. Specifically, we can:
  - use real world contexts as a tool for learning about mathematical concepts, or
  - use mathematics as a tool for learning about real world contexts.
- How people (the *Who*) relate to the mathematics we teach. Specifically,
  - mathematics can serve as a *mirror* reflecting back, or
  - as a *window* into broader perspectives (R. Gutiérrez, 2007).

Methods

Description of Program and Course

The Arizona Master Teachers of Mathematics (AZ-MTM) is an NSF Noyce grant to work with a single cohort of 14 upper elementary teachers over a 5-year period to develop leadership in elementary mathematics education. AZ-MTM focuses on developing teachers' knowledge of content, pedagogy, equity, and leadership. The grant has two primary strands: (1) each semester the teachers take a course at The University of Arizona taught by a mathematics educator focused on a particular content theme, such as Numbers and Operations, and (2) the teachers participate in professional development opportunities focused on teacher leadership.

This paper documents the teachers' participation in the mathematics education course taught by the author during the Fall 2011 semester. This was the first semester that the entire 14 teachers participated in the grant (8 of the teachers began the grant the previous semester). The course focused on (1) children's learning of whole numbers and early algebra, and (2) an introduction to issues of equity through readings and discussions (e.g., Felton, 2010b; M. V. Gutiérrez, 2009; Leonard & Guha, 2002; Martin, 2009; Tate, 1994; Zaslavsky, 2001).

Data Sources and Analysis

There are two data sources used in this paper. First, the teachers completed a beliefs survey designed around the themes of the WHW framework at the beginning and end of the semester. Second, I analyzed the teachers' responses to their final written reflection assignment in the course in which they were asked to (a) consider how their definition of mathematics has changed, (b) describe their views of equity and how they have evolved over the semester, (c) reflect on what they had learned during the semester, and (d) reflect on an interview project they completed. The teachers' reflections were coded for instances of *transitions*—a stated change from a past belief to a present belief. I coded the beliefs were based on the WHW framework and I engaged in open coding to capture new themes raised by the teachers (Strauss & Corbin, 1998).

Results and Discussion

Beliefs Survey

I focus on two instances of change across the pre and post surveys. One survey prompt stated "no matter how mathematics is taught it sends messages about…" followed by several sub-prompts. The number of teachers who selected "agree" or "strongly agree" for each sub-prompt is shown in Table 1. As can be seen, there were fairly consistent increases in agreement with the idea that mathematics sends messages about our social world. Thus, the course appears to have been successful in shifting many of the teachers' reported beliefs about the relationship between mathematics and important social constructs.

Table 1: Teachers Who Agree That Math Teaching Sends Messages About . . .

Sub-prompt	Pre	Post
Society in general	9	13
Race/ethnicity	5	10
Gender	5	10
Socioeconomic background	5	11
Culture	9	11
Social/political issues	6	11

A second pair of prompts stated "it is impossible to separate mathematics and politics in school" and "mathematic and politics should remain separate in school." Table 2 shows the number of teachers who selected "agree" or "strongly agree" for these two prompts (the results from the first prompt are reversed due to the phrasing). While many of the teachers indicated that mathematics and politics *can* be separated in school, a smaller number felt that it *should* be separated. Moreover, both prompts showed a substantial decrease from the pre to post survey.

Table 2: Teachers Who Agree That Math and Politics *Can* and *Should* Be Separated in School

	Pre	Post
Can be Separated	10	6
Should be Separated	6	3

Final Reflections

I identified three types of transitions in the teachers' reflections. *Adding* a new belief occurred when the teachers indicated that they had not previously thought about issues of equity as can be seen in the following quote.

> This semester I've thought more about math and equity with regard to how math is taught in schools. For a long time, I've looked at equity and social justice issues with regard to instruction in literacy, but I've never really thought about it in math, besides how math is taught. After all, math was only numbers, right? At the beginning of the semester, I started thinking more about how math was taught and not necessarily the messages behind what content was taught. Now, I think there is so much behind both how and what we teach in math.

Replacing a past belief occurred when a teacher indicated a change from a prior belief to a new belief about equity. The following quote provides an example of this.

> My views of equity…. [have] changed from the beginning of the class. I believed equity was just being fair to students in class and making sure all students had equal opportunities in class…. Although, I do know those things are important I know being fair means so much more. All the articles we read and discussed allowed me to see equity in an entirely different light. Even though I do understand it, I am not too sure how to fix it.

Finally, there was one instance of a teacher *expanding* on a previous belief. In the quote below the teacher describes how her prior valuing of "real world applications" was expanded to include more explicit connections to the political and social issues of students' lives.

> Prior to the readings and discussions I've never thought there was a place for politics in math, or even in the classroom at all. I'm always looking for real world applications to help students understand mathematical concepts, so why not include the real goings-on in their lives.

Conclusion

The results above indicate that the course served as a powerful introduction to issues of equity in the teaching and learning of mathematics. The teachers showed shifts in their beliefs about whether mathematics sends messages about our social world and about the relationship between mathematics and politics in the classroom. In their written reflections the teachers exhibited transitions in their thinking about equity over the course of the semester. One common theme across the quotes above, and across many of the reflections, was a lack of specificity in the teachers' beliefs about equity and uncertainty about how to address equity in their practice. On their final reflection 8 of the 14 teachers indicated that they had not considered issues of equity in the past and/or that one or more ideas in the course were new to them. Considering the diverse range of perspectives on equity in mathematics education and the newness of these ideas to many of the teachers, it is not surprising that they often provided vague or uncertain responses regarding their own beliefs about equity. This indicates the need for additional opportunities to grapple with these ideas. Future research in this area should focus on how teachers' beliefs evolve over extended periods of time and across differing contexts, including their classroom teaching.

CONSTRUCTING A MODEL ELICITING ACTIVITY FOR MATHEMATICS TEACHERS: SUPPORTING TEACHERS IN THE COMMON CORE ERA

David M. Glassmeyer
University of Northern Colorado
david.glassmeyer@unco.edu

Model Eliciting Activities (MEAs) are powerful tools for teachers that support their knowledge development in ways that productively and proactively impact their practice. However, the upcoming Common Core State Standards (CCSS) will redefine the knowledge base required for teachers in the classroom, and the large role that the teacher education programs must serve in order to support the CCSS. This study details the construction of an MEA designed to develop mathematics teachers' models of quantitative reasoning, one of the standards for mathematical practice given by the CCSS. An online summer course was the focus for the MEA, where secondary teachers completed a mathematics education course in master's program. By documenting the development process as well as conducting observations of the implementation of the MEA, the author will describe the MEA and suggest improvements based on this data.

Keywords: Design Experiments; Instructional Activities and Practices; Teacher Education–Inservice/ Professional Development

Introduction and Literature Review

With the impending incorporation of the Common Core State Standards (CCSS), K-12 mathematics education in the United States will change. In addition to laying out what content each grade is expected to cover, the CCSS include eight standards for mathematical practice, which are expected proficiencies with longstanding importance in mathematics education. These reform efforts place added pressure on mathematics teacher education, as teacher expectations shift. At the same time, research on mathematics teacher educators is lacking, especially concerning how professional development aligns with the CCSS educational reform goals in ways that productively impact teacher practice (Confrey & Krupa, 2010; Krupa, 2011; Sztajn, Marrongelle, & Smith, 2011.

A models and modeling approach to professional development has received increased attention by mathematical educators due to this perspective's ability to challenge teachers to develop ways of thinking that productively impact teacher practice while simultaneously documenting the development for research purposes. This approach uses Model Eliciting Activities (MEAs), which are tasks that engage teachers in thinking about realistic and complex problems embedded in their practice in order to foster ways of thinking that can be used to communicate and make sense of these situations (Doerr & Lesh, 2003; Lesh & Zawojewski, 2007). Model eliciting activities contribute to teacher development by encouraging teachers to think more deeply about student thinking, engage in mathematics, and reflect on prior held beliefs about problem solving (Chamberlin, Farmer, & Novak, 2008; Schorr & Koellner-Clark, 2003; Schorr & Lesh, 2003). These studies have implemented successful MEAs for teachers, but there is a need for additional activities given the recent demands the CCSS have placed on professional development (Confrey & Krupa, 2010; Garfunkel et al., 2011).

In response to that specific research need, this study documents the construction of a teacher MEA focusing on the quantitative reasoning standard for mathematical practice. Specifically the research questions were: (1) what is the process of developing a teacher MEA about quantitative reasoning; and (2) what are challenges specific to the design of an MEA that must be implemented within a professional development course conducted online during the summer? This study could be classified as an instrumental case study (Stake, 1995), with the creation of the MEA being the event under analysis that incorporates contextual factors in ways that convey understanding in other contexts. Aspects of a holistic case study are incorporated, since literature-based artifacts and feedback from mathematics educators, mathematicians, and teacher MEA experts were incorporated in the construction of the MEA.

Methods

The setting for this study was a mathematics education course for 23 secondary teachers in a master's program. The course was offered online during the summer, lasting four weeks, and met synchronously online four times a week. During each of these three hour meetings, the instructor, a mathematics educator, led class discussions with PowerPoint and application sharing. The teachers were also split into smaller groups for additional discussion. Audio and video transfer allowed communication to occur in real-time and facilitated group work despite the geographical distance between teachers in the course. Asynchronous technology such as email and Blackboard was used for file transfer and assignment submissions.

This course was titled Quantitative Reasoning in Secondary Mathematics and used aspects of a models and modeling perspective to promote teacher development of quantitative reasoning. The main course objectives included teachers being able to understand the meaning of quantities, quantitative relationships, and quantitative reasoning. They also needed to be able to identify each in secondary mathematics curriculum and deepen their understanding of secondary mathematics content involving quantities and quantitative reasoning; and be able to develop model-eliciting activities to support and document the development of student understanding and reasoning. The course reading list was comprised of articles focused on MEA development and quantitative and mathematical reasoning for students. The MEA which I describe in this proposal constituted 50% of the course grade, with the other 50% coming from task analyses.

The theoretical perspective I used for this study is a models and modeling perspective, as described by Lesh and colleagues. In addition to having a powerful lens for examining professional development, a models and modeling perspective also provides guidelines for the methods that support significant findings given the current research question. Given these methods, a models and modeling perspective offers a framework for understanding teachers' models, their development, and provides a mechanism for analyzing and piecing together findings, which may help future studies that investigate the implementation of the MEA (Koellner-Clark & Lesh, 2003; Hiebert & Grouws, 2007; Silver & Herbst, 2007; Sriraman & English, 2010).

Data collection sources include documents from the development of the MEA and feedback from other faculty members familiar with the teachers in the course, the setting, and teacher MEAs. Multiple versions of the MEA were developed to conform to the MEA guidelines established by literature, the setting restrictions, and input from these individuals. The faculty members used is summarized in Table 1, along with rationale for why their input was considered valuable in the development process. The course used for this study begins in June. At this time observations will be conducted document how the MEA was used and how it can be further improved. Interactions with the teachers enrolled in the course and participants in the table during and after the implementation of the MEA will provide data for a measurable response of the research question.

Table 1

Pseudonym	Position	Position/Expertise
James	Mathematics Educator	Instructor of the Quantitative Reasoning Course
Michael	Mathematician	Instructor of previous content courses within the master's program
Nikkea	Mathematician	Principal Investigator of the grant, familiar with the teachers and previous content instructor within the master's program
Jennifer	Mathematics Educator	Familiar with the master's program, and published multiple studies on MEAs for teachers
Germaine	Mathematics Educator	Expert researcher and theorist on MEAs and models and modeling perspectives

Preliminary Results

The purpose of the MEA is to reveal the way teachers think about quantitative reasoning tasks. Teachers' models of quantitative reasoning tasks can be evidenced by their development of a task that, from the teachers' perspective, captures quantitative reasoning skills of their students. The studied MEA for teachers is purposeful, sharable, and reusable, and also upholds the five principles stated in literature to guide the design of activities within teachers' practice (Doerr & Lesh, 2003; English, 2003); these include the reality, multilevel, multiple contexts, sharing, and self-evaluation principle. These principles as well as the purposeful, sharable, and reusable aspects of teacher MEAs were used to first structure the development of the MEA.

The version of the MEA implemented in the course included 5 iterations of the task, each prompted by feedback, where teachers work in groups of three. This process, outlined in Table 2, was determined by the guidelines in literature and input from the individuals detailed earlier. The rationale behind the development of the MEA was included to provide evidence that this data collection task meets the five principles of a quality teacher MEA, and that it upholds the final product is purposeful, shareable, and reusable. These components also allow the researcher to examine how teachers' interpretations, reasoning, and expressions develop during the iterations of the MEA. Details on how the MEA developed will be included in the presentation of this research, as well as results from the implementation of the MEA that occurs this summer.

Table 2

Assignment Name	Short Description of Components
Pre-Assignment	Document including initial models of QR, QR tasks, QR course
Version 1	Four documents including (a) Quantitative Reasoning Task; (b) Facilitator Instructions; (c) Assessment Guidelines; (d) Decision Log
Instructor's Feedback	Instructor's comments and suggestions to Version 1.
Version 2	Updated Version 1 in response to the instructor's feedback.
Teachers' Feedback	Groups swap Version 2 and offer comments and suggestions
Version 3	Updated Version 2 in response to the teachers' feedback.
Undergraduate Work	Student work after completing QR task (part (a) of Version 3)
Version 4	Updated Version 3 in response to student work, plus evaluation of student work.
Post-Assignment	Models of QR, QR tasks, relation to Continuous Math Course.
K12 Implementation	Each teacher implements the QR task (part (a) of Version 4) in classroom
Version 5	Updated Version 4 in response to student work, plus evaluation student work.

Implications

The development of this activity contributes to both research and teaching methods. Teacher MEAs are designed to promote development as well as documentation, the construction of such an activity would have benefits to other researchers in the field of mathematics teacher education, as the design of the activity could be shared and reused in similar contexts (Lesh & Doerr, 2003; Lesh & Lehrer, 2003). The selection of quantitative reasoning, a vital component of mathematics education that is receiving increased attention by the CCSS, increases the demand to make this specific MEA. Documenting the MEA development process can be helpful to other mathematics educators designing professional development (Pope & Mewborn, 2009).

EXAMINING WHAT IN-SERVICE ELEMENTARY TEACHERS NOTICE WHEN PRESENTED WITH INSTANCES OF STUDENTS' MATHEMATICAL THINKING

Whitney Grese Hanna
University of Houston
wdgrese@uh.edu

This report presents the findings of a study that was designed to investigate what in-service elementary teachers notice when watching video clips of task-based interviews of elementary mathematics students. Four second-grade teachers met with the researcher to watch these video clips and discuss their thoughts in reaction to them. Sessions were conducted without any prior professional development on noticing. They were video recorded and videos were analyzed for emerging themes. Over the course of the study, teachers displayed an ability to notice students' mathematical thinking to varying degrees of sophistication.

Keywords: Mathematical Knowledge for Teaching; Teacher Education–Inservice/Professional Development

Introduction

How does such a common word, like *noticing,* become powerful? What is it about the word that carries weight among teacher educators today? *Noticing*—also called *professional vision* (Goodwin, 1994)—happens when a teacher takes in his or her surroundings and is able to determine what is worth paying attention to, and what can be disregarded depending on the current purpose. Then they must integrate this information about the students with their own knowledge of the content.

This study examines what in-service elementary teachers notice about students' mathematical thinking without any direct professional development to guide them. By determining a baseline level of noticing, it is possible to examine avenues for developing teachers' abilities to identify, interpret and analyze students' thinking and subsequently use that thinking to guide their instruction. Recent research indicates that teachers who develop the ability to examine students' thinking with the aid of video are better able to respond to and make use of that thinking when it arises in a lesson (Cohen, 2004), in line with reform mathematics thinking. This report shares the findings of a video-based study that was conducted during the fall semester of 2011 at an urban, Title one, public elementary school in the United States.

Literature Review

When teachers can see exactly what students know, they can develop appropriate plans of action to ensure that everyone in the classroom reaches their full potential as a learner. Teachers with well-developed noticing skills are able to respond to students, and use the students' thinking to guide learning. Reform mathematics initiatives and curricula encourage teachers to work closely with students to understand and use student thinking to guide learning experiences in the classroom (National Council of Teachers of Mathematics [NCTM], 2000).

Teachers' knowledge of content and pedagogy is closely tied to their noticing skills. Because many elementary teachers are at a disadvantage as evidenced in their lack of confidence in their own mathematical knowledge (Ball, 1990), one can infer that it must be difficult for them to notice students' mathematical thinking. Teachers may be able to identify—to notice—an area of misunderstanding that a student exhibits without knowing how to remedy the confusion.

Teacher noticing as a field of study is gaining ground in three main areas of mathematics education (Sherin, Jacobs, & Phillipp, 2011): teaching by responding and adapting to what happens in the classroom; ongoing learning by teachers; and deconstructing teaching practice into essential elements for practice and improvement. The second focus responds to the idea that teachers can learn to be better "noticers" of their own practice in order to grow as professionals. They can learn to identify the particulars of students' mathematical thinking in a classroom setting, or to see the ways that they should change a lesson to better impact student learning. The seminal author on this topic is John Mason (2002), whose book *Learning to Notice: Researching Your Own Practice* has been a guide for many education researchers interested in this field.

Methods

As part of her work, the researcher serves as a math specialist for K–6 teachers at an urban public school supporting teachers' mathematics instruction, planning, and professional development. One of the ongoing professional development projects with the second grade teachers involved watching video clips of students solving math problems in a one-on-one interview setting. The teachers watched the clips and responded to them in an adaptation of a video club (Sherin & Han, 2004), a kind of professional learning community where video serves as the medium for launching discussions about teaching and learning. The goal of the project was to determine what the teachers were noticing about the video clips without guidance from the researcher, in order to better formulate future professional development around noticing students' mathematical thinking. As such, the sessions were dominated by teacher discussion, with little guidance or commentary from the researcher. Sessions were video recorded to capture the teachers' conversation and interaction, as well as to match specific video clips to teachers' comments.

Sherin and Han (2004) define video clubs as "meetings in which groups of teachers watch and discuss excerpts of videotapes from their classrooms" (p. 163). In order to determine what teachers notice about students' mathematical thinking when faced with it directly, the design of this study purposefully eliminated many of the elements that other noticing studies have included. Rather than having teachers bring in clips from their own classrooms, which would likely contain many elements unrelated to student thinking, video clips where student thinking is paramount were provided. The video clips used in this study come from a project conducted at San Diego State University, led by Randolph Philipp, Ph.D. The study, called IMAP (Integrating Mathematics and Pedagogy), was funded by the National Science Foundation and the Department of Education from 1999–2002.

Aligned with research done by Elizabeth van Es on video clubs (van Es, 2011), teachers' responses were examined and categorized into levels of noticing and an overall session level was determined. For instance, if teachers commented on students' confusion but then also made comments about specific mathematical thinking that took place, the session would be categorized as a Level 2, or Mixed, level of noticing (see Table 1 below—modified from van Es, 2011, p. 139).

Table 1: Levels of What Teachers Noticed

	Level 1 *Baseline*	*Level 2* *Mixed*	*Level 3* *Focused*	*Level 4* *Extended*
What teachers notice	Notice students' confusion or clarity about the math task	Begin to attend to students' mathematical thinking	Attend to students' mathematical thinking	Attend to the relationship between students' mathematical thinking and possible pedagogical strategies or learning experiences
Sample teacher comment	"She doesn't understand place value." "He's really got it."	"He added on." "She groups by tens and ones."	"You can tell how flexible his understanding of tens and ones is by…"	"I wonder if she's had many opportunities to build the quantities with Base-10 blocks so she can see how the place value relationships work."

Findings

At the outset of the study, the researcher expected to hear many comments that could be categorized as Level 1 comments, in which teachers would remark about a student's confusion or understanding without much else added to it. Indeed, many of these comments were made. They stated exactly what a student did, saying, "He counted up and ignored the manipulatives," and they questioned another student's understanding, remarking, "Maybe that was just a guess?" However, even in the first session, teachers made comments that showed their attention to students' mathematical thinking. After one student showed an invented subtraction method, one teacher said, "He found the easiest way to make the biggest number possible, and then added on…it really shows he knows place value—he can trade the tens out." This comment shows the beginnings of an attention to students' thinking, bringing them to Level 2 on the continuum, Mixed Noticing. Their comments didn't stay focused on students' thinking, but instead often led back to their own classrooms—"That's really inefficient. I wouldn't want my kids to do it that way."

By the second video club session, the teachers were more consistently noticing students' thinking, operating at a Level 3, or Focused level of noticing. They often wondered what experiences students were bringing to the interviews, whether the way they solved problems were related to their teachers' expectations of how they should work. "Could she solve it in her head, but her teacher makes her use the algorithm, so that's what she does here?" one teacher asked. Another teacher reacted to a student's use of the traditional subtraction algorithm to solve 1000 – 4 by saying, "I want my students to think about number combinations so that they immediately think about putting that four with a six to make a ten." By getting a glimpse into the minds of these children, the teachers were thinking more critically about their own instructional practice. What they failed to do was think about how the specific student thinking displayed could be addressed with particular teaching strategies. How, for instance, would Elizabeth get her students to think about those number combinations that make ten?

In the third and fourth sessions, teachers continued to notice students' thinking. When a student struggled to connect the subtraction algorithm to the Base-10 blocks with which he had also solved a problem, the teachers noted that, "the five is not a fifty for him, and the zero isn't part of a hundred, so he really thinks he's taking five from nothing." They wondered how they might help him make that connection, and discussed lessons and activities they might use to develop a better understanding of place value. This was a clear example of Level 4, Extended Noticing. However, after another clip where a student clearly misunderstood what the numbers in the traditional algorithm represented, Kate commented that she felt students should be taught to add this way before they learned about larger numbers. She made this comment without recognizing the lack of understanding of quantity that the student had displayed. This missed opportunity to notice was telling—her understanding of student thinking is fragile.

Discussion

In general, the teachers participating in this study clearly showed their ability to notice students' mathematical thinking. Their comments showed a range of noticings, from basic retellings of what students in the video clips had done, to beginning identifications of what students are thinking mathematically, to eventually talking about instructional strategies to develop students' understanding of basic number concepts. Teachers were able to notice students' thinking at the most sophisticated level of the framework, Extended Noticing, some of the time. This occurred within a group discussion and without guidance from the researcher.

What is less clear is how much high-level noticing was taking place on an individual level. Due to the presence of a more experienced teacher who had a strong knowledge of the school's mathematics curriculum, it is possible that the other teachers' lack of noticing abilities were sometimes masked. Since no written data collection took place, this cannot be confirmed. Future studies should include a written component to be completed before discussion in order to analyze individual noticing abilities.

It should also be noted that the small size of the video club group makes generalization about teacher noticing impossible. Other groups might show more or less sophisticated noticing of students' thinking. With a larger group of participants, it would be possible to examine teachers' noticing abilities relative to their level of classroom experience, understanding of mathematics concepts, depth of pedagogical content knowledge, and many other factors.

Continued research on teachers' noticing of students' mathematical thinking might investigate the following topics: how does collaborative noticing compare or contrast with noticing in the absence of peers; how does noticing progress over significant periods of time; what strategies can professional developers utilize to increase teachers' noticing abilities; how can the simple framework in this study be further augmented? Research on teacher noticing is a field that is rich with possibility. This study provides a single focus.

ELEMENTARY TEACHERS' UNDERSTANDING OF COGNITION BASED ASSESSMENT LEARNING PROGRESSION MATERIALS FOR MULTIPLICATION AND DIVISION

Ryan M. Harrison
University of Wisconsin Eau Claire
harrisrm@uwec.edu

Michael T. Battista
The Ohio State University
battista.23@osu.edu

Research-based learning progressions (LP) of children's mathematical development represent a valuable resource to help teachers make sense of children's thinking, and research on teachers' use and understanding of such materials is needed. This study investigated teachers' understanding of the Cognition Based Assessment (CBA) LP materials for multiplication and division concepts. Data sources included clinical interviews based around teachers' use of the CBA LP materials while analyzing student work episodes. Analysis of teachers' understanding of the CBA materials consisted of grounded theorizing and retrospective analysis. This paper reports on one key finding; as the complexity of either the CBA LP level, or a student's mathematical reasoning, so did the inconsistency and variation in teachers' interpretations of the student thinking.

Keywords: Learning Trajectories (or Progressions); Teacher Knowledge

Introduction and Literature Review

Teachers' knowledge of mathematical content and children's mathematical thinking have been identified as critical elements related to teachers' ability to effectively teach mathematics (Peterson, Carpenter, & Fennema, 1989). According to the National Research Council (2007), "Learning progressions are descriptions of the successively more sophisticated ways of thinking about a topic that can follow one another as children learn about and investigate a topic" (p. 214). The LP conceptualization has provided a way to encapsulate research-based findings about not just how children think about specific mathematical topics, but how learning about those topics develops (Battista, 2007; Daro, Mosher, & Corcoran 2011; Maloney & Confrey, 2010). Research-based learning trajectories/progressions of children's mathematical development are a valuable resource for teachers to help make sense of children's thinking, and research on teachers' use and understanding of such materials is needed.

Although there is a significant amount of research in the LP realm, limited research has investigated teachers' learning about research-based learning progressions. Research indicates that teachers need a solid understanding of the mathematics they teach, the common conceptions children hold about mathematics, and how to help children make connections to increasingly sophisticated mathematical ideas (Fennema & Franke, 1992). Research also shows that teachers struggle with exactly these things, but professional development focused on children's thinking can help them improve in these areas (Jacobs, Lamb, & Philipp, 2010).

Methodology

Because research on teachers' understanding of learning progressions is in an exploratory stage, qualitative and descriptive research can explicate some of the core issues in this area. Although quantitative methodology is not uncommon in the research design of projects focused on designing learning progressions, the available research on teachers' learning of learning progressions is largely qualitative in nature (Bardsley, 2006; Wilson, 2009). Quantitative counts of qualitative trends and patterns are included to help encapsulate ideas that emerged in the data.

The larger project that this research is a subset of is CBA2—Cognition Based Assessment, Phase 2 (An Investigation of Elementary Teachers' Learning, Understanding, and Use of Research-Based Knowledge about Students' Mathematical Thinking). CBA2 began in 2006, with the goal to investigate how elementary teachers make sense of and use research-based knowledge about the development of students' reasoning about particular mathematical topics.

Participants for this study included 17 elementary teachers responding to as many as four samples of student work (a total of 65 teacher episodes of student work analysis are included in the study), in the state of Ohio or Michigan, who were involved in the CBA2 research project. By utilizing transcribed clinical interviews, detailed descriptions, grounded theories, and brief vignettes of teachers' understanding of CBA learning progressions were developed.

CBA2 researchers collected a significant amount of data from participating teachers from 2006–2010. The data described for the current inquiry represents a portion of the collected data from the CBA2 project. Interview protocols consisted of episode(s) of student work and subsequent questions. Of interest in this paper were teachers' responses to the question: What CBA level of sophistication do you think the student's strategy is?

Data analysis utilized a retrospective approach as described by Steffe and Thompson (2000) which calls for the use of videotaped interviews, and individuals' written work in order to build an historical account of the individuals' actions and interactions. Data was analyzed and re-analyzed in ways that can explicitly support or disconfirm the evolving theories and hypotheses. This retrospective analysis informed the continuation of model building, hypothesis generation, and analytic category construction.

Results

Recognizing and understanding children's mathematical thinking in terms of CBA levels is an important component of making sense of the CBA LP materials. We investigated teachers' ability to do this when students' reasoning exactly matched a CBA level, or not, and when students' reasoning was simple and complex. Here is the relevant portion of the CBA MD LP:

Level 3. Operates on Numbers by COMBINING/SEPARATING (without Counting or Skip-Counting)

3.1 Recalls Facts	*3.3 Uses Distributive Property to Decompose Numbers by Place-Value into 2 Partial Products*
3.2 Uses Number Properties	*3.4 Uses Distributive Property to Decompose Numbers by Place-Value into 4 Partial Products*

In identifying CBA levels, sometimes teachers focused more on perceptually salient characteristics than on the technical, and conceptually more precise, definitions given in CBA documents. As an example, in evaluating RR's reasoning on the following problem, T2 relies heavily on keywords describing the number of partial products computed, as opposed to recognizing the precise place-value decomposition of these partial products.

Task: 46×5. RR: 20 times 5 is 100. Another 20 times 5 is 200. Plus 6 times 5 is 230.

T2: [T2 had used CBA MD materials]

(Reads problem with RR's strategy) See that's interesting. Because, there is no 3 parts [in the CBA levels]…but they broke it up into 3 parts almost, so that's kinda interesting. The difference between them is that they broke down the 200 into smaller parts, and maybe that is because it is a single digit on the other number, so they couldn't break it down any further. I would definitely put them at least at an MD 3.3, but I would say that they…well I would pursue whether they were at the 4 part level.

T2's interpretation of *partial products* focused on the number of concrete computations in the decomposition, but does not explicitly include mention of the distributive property or the specific place value nature of the partial products as described in CBA levels 3.3 and 3.4. Although T2 indicates that the students' strategy might not exactly match the description of level 3.3 when she states, "The difference between them is that they broke down the 200 into smaller parts," she does not explicitly recognize or articulate the fact that it is not representative of the technical definition of place-value partial products in CBA (in this case, 2 place value partial products would mean 46×5 would be computed as 40×5 plus 6×5).

Even so, T2 understands that RR's reasoning is at Level 3. She also seems to understand that RR's reasoning is some type of legal decomposition into parts (although she does not mention the distributive property). She might even consider RR's decomposition based on place value because RR decomposes 46 into 20 + 20 + 6 – which has tens parts and a ones part. This understanding brings her to consider Levels

3.3 and 3.4. At this point, she examines the number of parts in the decomposition, because that is what distinguishes Levels 3.3 and 3.4. And finally, taking almost a rubric scoring approach, she says that RR is "at least at an MD 3.3 [level]." We hypothesize that because use of non-place-value distributive property decomposition is one of many strategies discussed in Level 3.2, T2 does not recognize RR's reasoning as such.

Looking at overall teacher responses to four samples of student work can help to frame the discussion for this type of teacher use of the CBA MD materials. CBA teachers were asked to evaluate students' mathematical thinking about multiplication on the following three tasks.

Task 1. There are 6 soccer teams in a tournament. Each team has 12 players. How many players are there altogether? SX: 12, 24, 36, 48, 60, 72 [raising one finger after each number]. So, there's 72 players.

Task 2. 46×5 RR: 20 times 5 is 100. Another 20 times 5 is 200. Plus 6 times 5 is 230. QR: 40 times 5 is 200; 6 times 5 is 30. So it's 200 plus 30 equals 230.

Task 3. 45×23 Sally: 45 times 10 is 450. 45 times another 10 is 450; that's 900. 45 times 3 is 120, plus 15. So it's 1020 plus 15, or 1035.

Task 1 describes a less complicated strategy involving iteration (skip-counting) of a two-digit number. This strategy is a relatively simple strategy to recognize based on perceptually salient actions, as the CBA MD level of "skip-counting all" always involves a student writing or saying all multiples in the skip count sequence without decomposing numbers in any way.

Task 2 has two samples of student thinking. QR's strategy represents using the distributive property to decompose 46 by place value parts into 2 partial products. Much like the "skip-counts all," CBA MD level 3.3 always involves decomposing one factor by place value and the distributive property to create 2 place-value partial products. RR's strategy, however, represents using a non-place-value distributive-property decomposition, one of many strategies included in Level 3.2. Because students at this level do not use strict place value decomposition of numbers, their decompositions can take unique forms based on particular students' comfort with certain numbers. For this reason, level 3.2 might be challenging for teachers to learn at a conceptual level because there are many variations; indeed, in the language of research on concept learning, level 3.2 is a superordinate category and might be more difficult to learn than level 3.3, which is at the basic level.

Task 3 represents a fairly complicated episode of student thinking about multiplying a 2-digit by 2-digit multiplication problem. In consideration of the CBA MD levels, Sally's thinking is quite complex, as it involves instances where Sally decomposes by place value (40 times 3 is 120, plus 15…where Sally decomposes 45×3 into 40×3 and 5×3 implicitly), and instances where Sally does not decompose strictly by place value (45 times 10 is 450 and another 10 is 450; that's 900…where Sally decomposes 45×23 into 45×10 and 45×10 instead of simply 45×20). Sally's thinking is best described as applying 2-partial products twice (Level 3.3), with further decomposition of one of the partial products using a non-place value decomposition (Level 3.2). Because Sally's reasoning is a combination of CBA MD levels 3.2 and 3.3, this episode represents a situation in which it would be expected that teachers would struggle to make sense of her thinking by matching it to CBA descriptions and examples of student work.

Quantitative Summary

A quantitative summary of teacher responses indicated that episodes of student thinking the directly matched a single-strategy encompassing CBA level were correctly identified more often. Those situations requiring deeper analysis of student thinking, or matched a level describing several possible strategies showed higher variation in teachers' determination of students' CBA level. Below are the counts of teacher responses to each episode. Although the sample sizes are small, this exploration of teachers' interpretations of various complexity of children's thinking supports the idea that mathematical and cognitive complexity of the CBA levels as well as complexity of student thinking both play a role in teachers' ability to appropriately level students within the CBA MD framework.

Table 1: Student Work and CBA Complexity Comparison

SX and QR (less complex work and CBA levels)	Percent Completely Consistent	Percent Partially Consistent	Percent Inconsistent
Total of Teachers with CBA MD use	89.3% (25/28)	7.1% (2/28)	3.6% (1/28)
Total of Teachers with **No** CBA MD use	77.8% (7/9)	11.1% (1/9)	11.1% (1/9)
Total of ALL Teachers	86.5% (32/37)	8.1% (3/37)	5.4% (2/37)

Sally and RR (more complex work and CBA levels)	Percent Completely Consistent	Percent Partially Consistent	Percent Inconsistent
Total of Teachers with CBA MD use	47.6% (10/21)	42.9% (9/21)	9.5% (2/21)
Total of Teachers with **No** CBA MD use	0% (0/7)	28.6% (2/7)	71.4% (5/7)
Total of ALL Teachers	35.7% (10/28)	39.3% (11/28)	25% (7/28)

Discussion

There is no doubt that with any LP materials, or any materials intended to help teachers with the process of teaching, certain aspects of the materials will be related to more complex components of mathematics or children's thinking about mathematics. As was anticipated, CBA teachers struggled far more to effectively characterize student work that was more complex and that represented more complex CBA levels, or did not fit into the CBA level descriptions in a straightforward way. One interesting finding in the data was that teachers with experience using the CBA MD materials seemed to more effectively choose CBA aligned levels than teachers without use of the CBA MD materials on the student work sample that was most complex.

The CBA materials can be understood at varying levels of conceptual understanding. Obviously, it would be ideal for teachers to develop a formal conceptual understanding of CBA levels. Understanding the conceptual and computational delineations between each level could allow teachers to have fine-grained knowledge about children's mathematical thinking that could serve to inform instructional decisions. This could be especially important for a teacher working with a student one-on-one who is struggling to make progress, for whom conventional instruction does not seem to benefit. However, teachers do not always have the time or flexibility to work with their students individually to utilize CBA to its fullest. Therefore, using CBA more efficiently, in manners that lead to identifying big-picture conceptualizations of children's thinking (potentially using less formal and more fuzzy conceptions of CBA) could serve a valuable purpose as well, especially for whole-class LP use.

SUPPORTING TEACHER LEARNING THROUGH DESIGN RESEARCH

Teruni Lamberg
University of Nevada, Reno
Terunil@unr.edu

This study reports on a design research approach used to support elementary teachers to use reformed approaches in teaching mathematics. Findings from a three-year Math and Science partnership grant are presented. Specifically, the impact on content/pedagogical content knowledge and student learning are presented in addition to the mechanisms for supporting teacher learning. A theoretical framework for designing professional development aimed at using reformed approaches is presented.

Keywords: Teacher Education–Inservice/Professional Development

Theoretical Framework

Studies have found that content focused professional development is the most effective form of professional development to support student achievement (Hill, Rowan, & Ball, 2005). Content focused professional development should provide teachers with pedagogical content knowledge for effective teaching (Ball, 1991; Schulman, 1986, 1987). Pedagogical Content knowledge integrates content knowledge and knowledge of how students learn math. In other words, it requires understanding how students think and learn. Once the teacher has an understanding of how the student is thinking, then the teacher has to challenge the student's current thinking in order to facilitate new learning. This requires carefully selecting tasks, posing problems and figuring out what representations can help this student make sense of the problem.

Unfortunately, most teachers do not teach for conceptual understanding. The TIMSS (1999) Study points out that a typical American teacher relies on teaching students' strategies and formulas as opposed to conceptual understanding. The Common Core State Standards for Mathematics (CCSSI, 2010) point out that students not only should learn procedures but also develop conceptual understanding of mathematical ideas. The NCTM standards recommend that students should develop these understanding through a problem solving approach that builds on student reasoning. This means that professional development must support teachers to teach for mathematical understanding through a problem solving approach advocated by NCTM and the Common Core State Standards for Mathematics.

Designing professional development that provides teachers with content and pedagogical content knowledge is a challenge. This is particularly the case when teachers are using more traditional or procedural approaches in teaching. Therefore, simply having students take more math content courses are not effective (Hill, Rowan, & Ball, 2005). We need to consider ways we can shift their practice from teaching mathematics as procedures to focus on students understanding mathematical concepts.

A design research (Lamberg & Middleton, 2009; Kelly, 2003; Cobb, diSessa, Lehrer, & Schauble, 2003; Collins, Joseph, & Bielaczyc, 2004) approach is useful for designing professional development. This is because it allows us to generate conjectures on how teachers might learn, design tasks, try these tasks and modify subsequent tasks with teachers. When using a design research approach, tasks are designed based on theoretical principals from prior research (Lamberg & Middleton, 2009, Kelly, 2003; Cobb, diSessa, Lehrer, & Schauble, 2003; Collins, Joseph, & Bielaczyc, 2004). The theory provides an overarching framework for the design team to generate tasks, select and validate alternative designs (DiSessa & Cobb, 2004). However, when tasks are used with teachers, they may make sense of the tasks differently than the intention of the design team (Collins et al., 2004). The goal of design research is to understand why teachers interpreted the tasks differently. In addition, the process in which learning happens is also documented. The underlying focus of a design experiment is to understand the *process* or *mechanisms* that promote development of one state of learning to another (Lesh & Kelly, 2000). Therefore, we investigated how to support teacher learning through a design research approach in addition to its impact on teacher knowledge and student achievement.

Methods

We received funding for three years from a Math Science Partnership grant to provide teacher professional development. A design research approach was used to design tasks and implement professional development to support teacher learning during the first two years. In the third year, a lesson study approach was used. Thirty-seven teachers from 5 school districts in a large rural area participated. The project team consisted of a mathematician, a math educator, regional professional development trainers and a math consultant from the state department. The teachers participated in three week long institutes with 6 follow-up sessions during the academic year. We used the following cyclical design approach to work with teachers. Conjectures were generated; tasks were designed, and implemented in professional development sessions. Ongoing adjustments were made based on what was happening during the session, and a retrospective analysis of data took place to modify, confirm and generate new conjectures.

The data to measure the impact of this professional development included a teacher pedagogical content knowledge pre and posttest. The mean of the gain scores of the pre and post tests were compared. Student achievement was measured using a pre and post math content test. The percentage of growth of students gain scores was measured over three years. Data that were collected to examine professional design decisions and its impact included videos of professional development sessions, field notes, video analysis of teacher professional development data, field notes from and professional development team meetings. The qualitative data was analyzed using Strauss and Corbin constant comparative method (2001). The following framework was used to make sense of teacher learning and sense making. Specially, we examined how teachers interpreted the tasks, the professional development activities that supported the sense making and the context in which the professional development took place. An interpretive framework listed below was used as an analytic lens for making sense of the learning of teachers.

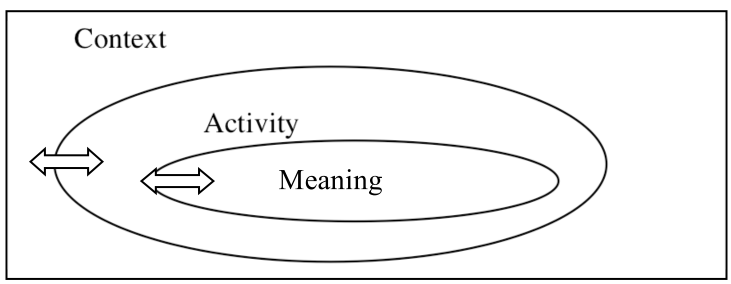

Figure 1. Interpretive framework to make sense of teacher learning

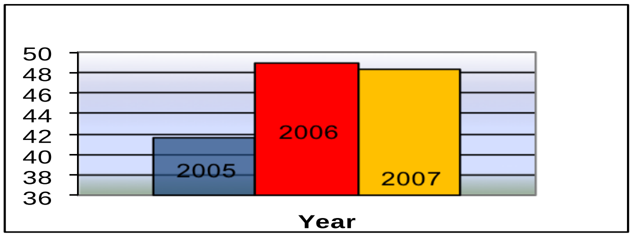
Results

The data revealed that not only teacher pedagogical content knowledge increased, but also teachers changed their teaching practices towards more NCTM reformed practices. In addition, student learning was impacted as indicated in the gain scores of the pre and posttest.

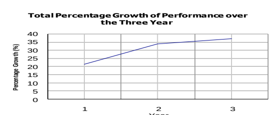
Mean of Teacher Pedagogical Content test



Teacher's pedagogical content knowledge significantly increased from year 1 to 2. Year three pretty much stayed the same. It is interesting to note that a design research approach was used the first two years, while the third year we used a different approach.

Comparison of Percentage growth of Student Gain Scores

	Percentage Growth (%)		
Grade	*Year One*	*Year Two*	*Year Three*
3rd	87.1	110.1	102.1
4th	33.7	42	41.9
5th	15	21.7	33.5
6th	20.6	45.4	40.9
7th	7.3	8.5	-1.1
8th	2.2	0.3	N/A
Total	21.5	33.8	37



Student achievement data also reveals that learning increased. The data presented in the chart above represent a comparison of the percentage of gain score that occurred each year across three years. The following framework captures the three phases of professional development that took place to support shifts in teachers' practices. Professional development tasks were designed around these three phases in teacher development.

Phase I: Teachers experience thinking about mathematics conceptually.
Raise awareness of student reasoning and how students learn.
Examining norms of how a lesson is structured – Supporting a problem-based approach to teaching.

Phase II: Interconnections between lessons-sequencing – *Building on student thinking and supporting mathematical connections*

Phase III: Reflection on student learning and teaching – *Refine teaching*

Discussion

The study is significant because it elaborates how a design research approach can be a useful approach for making design decisions to develop effective professional development. Furthermore, this study demonstrates that design research approach had the most impact on teacher knowledge and teaching. This was because we adapted the PD based on the needs of the teachers. Whereas the third year, we had laid out the PD plan and followed the plan of lessons study. Therefore professional development must not only provide activities for teachers to do but should be adapted based on teacher learning. A design research approach is useful for making these decisions. In addition, effective professional development not only pays attention to teacher learning but also examines shifts in teacher's classroom practice to make changes.

Hill, Cohen, and Ball (2005) point out that the most effective professional development pays attention not only to providing teachers' content knowledge but also pedagogical content knowledge. However they point out there is very little research that says what this should look like. The phases outlined in the framework above provide a starting point for future professional development work. Phase I points out that teachers should experience mathematics conceptually through a problem solving approach. If teachers don't understand what problem solving is, they are unable to transfer this way of thinking to their students. Teachers also examined student reasoning and how it related to understanding. During Phase II, teachers began to use a more problem solving approach to their teaching; however we discovered that even though they had made changes in their practice, they were not sequencing lessons. Therefore, during the second phase we focused designing experiences for teacher to reflect deeply on how lessons are interconnected mathematically. The third phase involved refining the first two phases and implementing in the classroom. These phases can be a starting point for designing future professional development for teachers.

TEACHER SUCCESS: DEEP LEARNING AND PRACTICE

Hea-Jin Lee
Ohio State University–Lima
lee.1129@osu.edu

This study explores the effectiveness of a hybrid professional development model in supporting a teacher's success in their professional learning and practice. The findings present the impact of the program on teachers' practice, beliefs about math, perspective about themselves, as well as the nature of the virtual interactions, including frequency and content of virtual communication. Furthermore, the study investigates the depth of learning and variables influencing the depth of learning. The conceptual discussion includes potentials and limitations to be considered in further dialogue, development, and research in designing and evaluating a hybrid program for teacher success in deep learning and practice.

Purpose of the Study

Ongoing professional development is critical in teacher success. By "teacher success," we mean the improvement of a teacher's understanding of mathematical content and practice within their classroom. Teacher quality is closely related to student achievement. Gains in student achievement cannot be made without ongoing professional development. The research question that guided this study was "How should a professional development program support teacher success in their professional learning and practice?"

Theoretical Framework

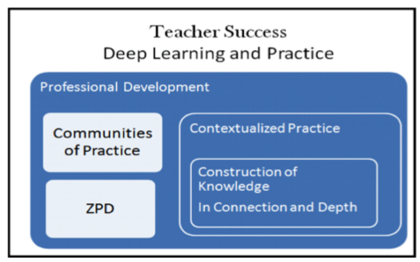

Figure 1: Theoretical framework

Figure 1 illustrates the theoretical framework for teacher success in deep learning and practice through a blended professional development involving contextualized practice and active construction of knowledge. Since Dewey, the social nature of all human learning and the role of communication skills and abilities in the human development process are the most often discussed concepts in higher education (Feldman, 2000; Heinze & Procter, 2005). Learning in Communities of Practice, networks of practitioners, relies on communication between individuals and occurs as interaction among practitioners takes place (Heinze & Procter, 2005; Kahan, 2004). Communities of Practice involve "creating a Zone of Proximal Development with capable peers. There is no one on the stage who is the knowledge source, but all individuals have an equal right to share their experience, and their stories are valuable contributions to the community" (Heinze & Procter, 2005, ¶ 3).

Mere interaction among participants, however, does not guarantee meaningful cognitive engagement or facilitate meaningful learning and understanding. Garrison, Anderson, and Archer (2000) provide a model of a community of inquiry, the integration of cognitive, social, and teaching presence. A community of inquiry involves more than a social community and interaction among participants: "Interaction directed to cognitive outcomes is characterized more by the qualitative nature of the interaction and less by quantitative measures. There must be a qualitative dimension characterized by interaction that takes the form of purposeful and systematic discourse." (Garrison & Cleveland-Innes, 2005, p. 135)

Rovai (2002) found a "positive significant relationship between a sense of community and cognitive learning" (p. 328). Even though researchers recognize various views in defining learning communities, there are common themes that link the definitions and uses. Professional development programs should provide opportunities for participating teachers to "learn mathematics around specific content and teaching situations that may arise in practice" (Brown & Benkenp, 2009, p. 56), as well as opportunities to implement/practice their learning in their own context. The key concerns, therefore, are to ensure peer exchange of ideas and information (Hammond, 1998); the creation and assimilation of knowledge (Thomas, 1992); and providing a climate of accelerated change in which participants need to access up-to-date knowledge and apply new skill flexibly in changing circumstances (Hargreaves, 1994). The learning community should be more than a forum for the exchange of information. It must evolve in response to the diverse needs of learners and the communities in which they work.

Methods: Data Collection and Analysis

This study analyzed data from the *Teaching Algebra in Context, Community, and Connections (TACCC)* project funded by the Improving Teacher Quality Program in 2010–2011 and 2011–2012. The professional development program of this study was designed to improve student mathematics knowledge and attitude by (1) increasing teacher content knowledge, and (2) improving instructional skills to teach mathematics concepts in an environment rich in context, community, and connections. The major activities of the project consisted of three components: face-to-face workshop courses, online conversations between face-to-face meetings, implementation, and sustaining a professional community. Teachers explored how algebra is taught at different grade levels, is related to other math content, and applies to our daily life. The workshops were conducted through discussions; collaborative group work; hands-on activities; problem-solving opportunities; and presentations by participants. Table 1 summarizes the two projects and the data collected for the study.

Table 1: Participants and Data Collection

Project Year	Online support system	Participants (MS teachers)	Data				
			No. of online Postings	Pre-survey	Post-Survey	Interviews	Observation notes/reflection
Group 1 (2010-2011)	Desire2Learn	29	1149	Yes	Yes	Yes	Yes
Group 2 (2011-2012)	Online Social Network (MSP2)	22	1002	Yes	Yes	Yes	Yes

Surveys, interviews, and filed observation notes were analyzed, and mean scores were compared. The written document data were analyzed in two ways: (1) purpose and content, and (2) depth of learning. The final codes were developed after two analyses. The depth of learning was analyzed using the Gerbic and Stacey (2005) model. Gerbic and Stacey proposed a generic framework for the content analysis of deep and surface learning that can be used both for face-to-face and various online learning environments. The discussion threads in each online assignment were used as the unit of data collection and analysis. All of the postings among the 51 participants were analyzed and coded. Three coders were trained and checked for inter-rater reliability at the end of training by using a sample set of coding. SPSS was used for the quantitative elaboration of online posting data, and chi-square tests were used to examine the relationship between two categorical variables.

Results

Changes in Opinions about Mathematics and Classroom Practices

Overall, most of the group revealed a high level of comfort with innovative instructional practices on the pre-survey. Teachers' responses (2010–2011) pointed to increases in their use of inquiry-based instructional practices and alternative assessment. They had also expanded their professional development activities at their schools and online. Teachers from the 2011–2012 program expressed the desire to continue their growth as math instructors who were equipped with a wide range of strategies that would address the needs of their students. Their responses on the follow-up survey demonstrated their progress. Comparisons of the teachers' pre- and post-responses to questions about the frequency of their use of inquiry-based instructional practices and involvement in various professional development activities revealed significantly higher use in several areas.

A descriptive analysis on teachers' beliefs about mathematics and their perspectives about themselves will be shared during the presentation. In summary, with regard to teachers' opinion about themselves, teachers from the 2010–2011 program show significant changes in their confidence about their preparation to answer students' questions. Responses indicated that teachers were more comfortable about their skills in mathematics at the year's end. Teachers in 2011–2012 show numerous significant improvements about their understanding of effective strategies for teaching math and confidence about ways to help their students learn math. They were more knowledgeable about how to turn students on to math and gave more value to the role of effective math teaching.

Teachers altered their beliefs about math during the course. The 2010–2011 group of teachers gave responses on their confidence level in preparing to answer students' questions that indicated that teachers were more comfortable about their skills in mathematics at year's end. They came to value working on problems that do not have a precise answer. They increasingly viewed strategies as a way to help students learn math. Finally, they were less likely to view math as a solitary activity. This is consistent with the results of another survey in which participants were significantly more likely to have students working in groups. The 2011–2012 group of teachers was significantly less likely to agree that only certain people could do well in math and to view math as a solitary activity. They gave greater value to students working hard to learn math, to taking a longer time if needed to learn math concepts, and working on problems that do not have a precise answer.

Depth of Learning

In order to measure participants' depth of learning, messages posted for four online assignments were analyzed: (1) Book Reading Discussion and Assignment, (2) Video Critique, and (3) and (4) Discovery Lesson Creation, which required creation of lessons and implementation, and commenting on the work of peer teachers.

Descriptive Analysis: The average number of postings per assignment and individual teachers' total and average postings will be compared within the group and between the two groups.

Purpose of Messages and their Content: In addition to communication frequency, our study analyzed the data to find the purpose of messages and their content. Our codes were founded in Gareis and Nussbaum-Beach (2007), Interstate New Teacher Assessment and Support Consortium (1992), and Joint Committee on Standards for Educational Evaluation (1988) and finalized after two initial analyses. The final codes were: Reflection, Sharing experience, Issues/Problems, Questions/Suggestions, Instructional ideas, Concerns regarding students, Guided advice, Simple agreement, and Acknowledgement. Sample messages and descriptive comparisons between groups and within group will be presented during the presentation.

Depth of Learning: The Gerbic and Stacey (2005) model was used to analyze teachers' depth of learning. According to Gerbic and Stacey's analytical framework, deep learning is defined in this study as the ability of learners to demonstrate critical thinking skills by (a) looking for meaning in course content; (b) relating course topics to prior knowledge and real world examples; (c) interpreting content through synthesis, analysis, and evaluation; and (d) utilizing internal motivation to learn (2005, p. 55). Surface learning is defined as a learning approach where learners simply dwell inside (a) a reproducing approach; (b) course boundaries; (c) an unthinking approach; (d) fear of failure; and (e) are extrinsically motivated (2005, pp. 55–56). The depth of learning is divided into two categories, deep learning and surface learning, with four subcategories in deep learning and five subcategories in surface learning. It was noted that online communication mechanisms help teachers not only to develop critical thinking skills and deepen their learning of teaching, but also to demonstrate their abilities to teach mathematics in different ways. The study further investigated variables that are related to the depth of learning. Chi-square test results for the relationship between the level of discussion threads and the depth of learning, the relationship between discussion topics versus the depth of learning, and the relationship between the online support system and the depth of learning will be presented during the presentation.

Discussion

This study investigated the effectiveness of a hybrid professional development program and online communications. By year-end, it was evident that participants had made an effort to make their classrooms more student-centered and inquiry-based. Students were doing more group work and the teachers had begun requiring students to explain their answers and to respond to “why” inquiries if their explanations were not sufficiently clear. Overall, teacher participants increased their math content knowledge and improved their instructional skills. Furthermore, teachers enthusiastically described changes that they have made in their classrooms to enrich their students’ math learning.

With regard to the effectiveness of the online part of the program, there were some trivial findings and unexpected outcomes that can provide insight to mathematics teacher educators. Most face-to-face discussions centered on the activity or mathematics problems that were presented in class; whereas online discussions reflected on and shared experiences in their own classrooms. The content of online discussions made no distinction between different assignments. The main focus of discussions was sharing their experience about teaching mathematics instead of focusing on what they were required to discuss. It would be important to investigate how different online discussion topics and assignments contribute to teachers’ active learning and participation. Another interesting finding was the differences in the total number of messages for each assignment. First-year teachers had more to share when they were asked to reflect on book readings or video-taped best practices than to exchange their own ideas and experiences about planning and implementing a discovery-based lesson. What teacher educators can learn from this finding is the sequential order of the online professional development program. Practitioners also need plenty of time to become acquainted with the website and technology that the online PD uses.

TEACHERS' KEY DEVELOPMENTAL UNDERSTANDINGS FOR MEASUREMENT FRACTION DIVISIONS

Soo Jin Lee
Montclair State University
leesoo@mail.montclair.edu

Jaehong Shin
Korea National University of Education
jhshin@knue.ac.kr

Contemporary research on mathematical knowledge for teaching (MKT) has predominantly been conducted under the framework suggested by Ball and her colleagues (Ball, Hill, & Bass, 2005; Ball, Thames, & Phelps, 2008). Recently, alternative perspective of MKT is proposed by Silverman and Thompson (2008), which centers on key developmental understandings or KDUs (Simon, 2002, 2006). The preliminary analysis of 14 middle grade teachers' reasoning with fraction division problems indicates that 'common partitioning operations' and 'three-levels-of-units structure', would be essential KDUs for measurement fraction divisions. The study extends previous research on KDUs for fraction operations (Simon, 2006; Lee & Shin, 2011; Lee & Shin, 2012) by investigating teacher knowledge through a semester-long professional development.

Keywords: Mathematical Knowledge for Teaching; Rational Numbers

Purpose of the Study

Since Shulman's (1986) proposal of pedagogical content knowledge, in mathematics education, Ball and her colleagues (Ball, Hill, & Bass, 2005; Ball, Thames, & Phelps, 2008) have used the phrase *mathematical knowledge for teaching* to emphasize knowledge teachers use when solving problems that arise in practice. Research on teacher knowledge (e.g., Hill, Schilling, & Ball, 2004) on this line shows that there is a positive correlation between teacher knowledge and student achievement. They have also stressed the conceptual demands of teaching mathematics by defining MKT as a special kind of knowledge, which the 'man on the street' does not need in their work. Nonetheless, further research is needed to elaborate mathematical knowledge for teaching particular topics (Izsák, 2008) and to reveal, "what it is, and how one might recognize it, and how it might develop in the minds of teachers." (Silverman and Thompson, 2008, p. 499). The Silverman's and Thompson's perspective of MKT is grounded in the idea that "teachers teach what they know" (Thompson, 1994, p.3), where "to know" means to have a scheme of meanings (i.e., mathematical ways of knowing and mathematical ways of understanding) that express themselves in action. In their view, powerful mathematical knowledge for teaching involves pedagogical understandings that are grounded in significant, coherent personal understandings, and they cited Simon's (2002, 2006) key developmental understandings (KDUs) as a type of powerful personal understandings. The purpose of this paper is to extend previous research on MKT and to investigate a particular topic (measurement fraction division) in detail by delineating KDUs of fraction divisions.

Theoretical Framework

In a measurement fraction division problem in the form of $a/b \div c/d$, one may ask oneself "How many groups of *c/d* are in *a/b*?" The fundamental operation one might use to find an answer to the problem is a *unit-segmenting operation* (Steffe & Olive, 2010). This entails the operation of segmenting the dividend by the divisor. To elaborate, consider the problem of grouping a pile of fifteen books by three. One could use three as a segmenting unit to divide the composite unit, fifteen and measure the fifteen by threes. While it is enough for one to reason with only two levels of units[1] in such a simple problem situation, our claim is that one who has flexibilities with forming and transforming three-levels-of-units structures could better adapt his or her reasoning to more complex problem situations, especially, those where one needs to reason with fractions. We use the term *common partitioning operations* (Steffe & Olive, 2010) to refer to the partitioning operations that one uses when one's goal is to coordinate the common number to be used in partitioning. This operation entails various partitioning operations that support one to achieve the goal of coordinating the common number (on an actual bar or mentally). When one uses common partitioning operations, one could find commensurate fractions[2] for the dividend and the divisor using a co-measurement unit.[3] For instance, to solve the problem $\frac{2}{3} \div \frac{1}{7}$ using a number line model, one can use common partitioning and measure two-thirds of a unit stick using one-seventh of the stick by finding 1/21 as a co-measurement unit for both one-third and one-seventh. Using the co-measurement unit as a base, one could find commensurate fractions, fourteen-twenty first for two-thirds and three-twenty first for one-seventh as in Figures 1a and 1b.

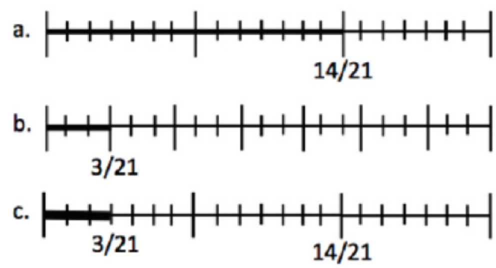

Figure 1: Determining 2/3 ÷ 1/7

(a) A three-level structure of 2/3. (b) A three-level structure of 1/7.
(c) Two three-level structures of 2/3 and 1/7.

Therefore, finding commensurate fractions entails reasoning with three-level structures. One coordinates two three-level structures to determine the quotient for 2/3 ÷ 1/7 as in Figure 1c. One may also calculate a common denominator between the divisor and the dividend quantities and then represent one's reasoning using drawn quantities. As long as one can clearly explain the co-measurement unit and commensurate fractions for the divisor and the dividend quantities, we include calculating the common denominator beforehand as part of common partitioning operations. In these cases we stated that the person made a conceptual association between procedural knowledge and common partitioning operations.

Methods

Professional development on rational numbers was offered to 14 middle grades teachers in an urban district. In this paper, we consider six of those teachers including three seventh grade and three sixth grade teachers. The course met once per week for three hours at a time across 14 weeks. All meetings were videotaped using two cameras and combined into a single restored view (Hall, 2000). The primary data for this analysis included two class meetings focused on measurement fraction division. In these two class periods, the teachers engaged with several tasks that relied on number line and area model representations as well as discussions about using those representations for fraction division. This analysis also relied on data from three interviews with the teachers about their answer selections on pre and post-course assessments. From the assessment, we only focused on two fraction division items: One using an area model to illustrate quotative division of fractions, and the other using a number line item. Each interview asked participants to explain how they selected their response on the multiple-choice items. These interviews were also videotaped. From the restored view, we created lesson graphs, a document that parsed the lessons and the interviews into episodes. From the lesson graphs, we memoed teachers' mathematical reasoning to identify the two primary categories, then we coded the lesson graphs using an emergent set of categories to generate hypotheses that were then united into comprehensive accounts.

Results

From the initial analysis of teachers' knowledge of quotitive division, we observed positive correlation between a sequence of problems and teachers' struggles to make sense of the problems using the drawn representations. The three sequences were (1) When the divisor partitions the dividend evenly; (2) When the divisor does not partition the dividend evenly; (3) When the divisor is bigger than the dividend. No matter what sequence the problem falls in, common partitioning operation with three-levels-of-units structures appeared as KDUs for measurement fraction division. The teachers' coordination of two three-levels-of-units structures activated more sophisticated partitioning operations and supported teachers making sense of more complex fraction division situations. While the teachers could use two levels of units across each measurement fraction division sequence to determine the quotient using drawings of quantities they chose, those teachers could not use more sophisticated partitioning operations to activate unit-segmenting operations. In addition, when the teachers established part-whole reasoning between the two quantities, their ability to use the measurement unit as the referent unit was critical, and it was impossible without the teachers' coordination of two three-levels-of units structures.

Conclusion

Conceptual analysis of teachers' knowledge at this grain size allows us to develop a stronger understanding of teachers' capacities to reason about fraction division in detail. By building on understanding of teachers' mathematical concepts and operations in the ways illustrated here, we propose that a richer understanding of teachers' understandings was identified, which could be used for developing stronger professional learning opportunities for teachers.

Above all, the present study indicates that the knowledge components found in the previous research literature about children's fractional knowledge appeared in the participating teachers' mathematical activities with fraction problems, and further turned out to be essential for their mathematical thinking in the context of division problems. Further, we began to realize that the development of teachers' knowledge (might or necessarily) differ from that observed in children even though applying the results from research with children could be a viable way to start. Teachers are already well equipped with procedural knowledge and they are likely to have more sophisticated number sequences already developed.

To elaborate, some participating teachers' common partitioning operations were evoked by their strategy of finding a common denominator between two given fractions. While the teachers brought forth common partitioning operations by themselves, they believed they used an algorithm. They were referring to the algorithm in finding a common denominator for two fractions, which was a procedural strategy that they usually used in fraction addition or subtraction problems. It is plausible that some of the teachers could have already been equipped with procedural knowledge that was associated with (mental) operations for common partitioning operations because they have revisited the content over and over. However, we think this may cause serious problems when the teachers go back to their classrooms because they may implicitly demonstrate common partitioning operations, but outwardly teach an algorithm to their students. This conclusion also has an implication for designing effective professional development program in which teachers could explicitly become aware of the associations they make between the procedural algorithm and the key mathematical operations embedded in it.

Endnotes

[1] Simply saying, levels of units denote the number of units available to a problem solver prior to actual solving activity. For instance, a child with two levels of units might be embarrassed with the division problem "How many fours in twenty?" because the available units for the child are only 'one' and "twenty."

[2] We use the term, *commensurate fractions* (Steffe & Olive, 2010) to describe when one uses drawings of quantities to figure out, in conventional terms, equivalent fractions.

[3] A *co-measurement unit* is defined as a measurement unit for commensurable segments, that is, segments that can be divided by a common unit without remainder (Olive, 1999).

Introduction

The purpose of this paper is to describe a research project that investigated school improvement in mathematics in two Canadian provinces. Nine schools were selected based on their interest in improving mathematics education at their school, and various contexts such as public and private schools, rural and urban schools, and size of schools. This report will provide researchers, teachers and administrators with strategies and tools to make change to mathematics programs within elementary schools. Further, elementary school administrators can use the findings to help teachers and support staff to use a professional development strategy to improve teaching of mathematics within their school.

Theoretical Framework

Peer coaching is professional development strategy for educators to consult with one another, to discuss and share teaching practices, to observe one another's classrooms, to promote collegiality and support, and to help ensure quality teaching for all students. In peer coaching, usually two teachers share conversations, and reflect on and refine their practice. Their relationship is built on confidentiality and trust in a non-threatening, secure environment in which they learn and grow together; therefore, peer coaching is usually not part of an evaluative system.

The primary goal of peer coaching is to provide positive feedback to instructors, most of who regularly receive negative comments from students on teaching evaluations. Peer coaches also provide support and companionship for their partners (Joyce & Showers, 1982). Finally, peer coaching may improve student learning because good instructors teach their students more effectively (Weimer, 1993). Evidence of the positive effects of such in-service learning on teacher implementation of math education reform and student achievement is accumulating (e.g., Loucks-Horsley et al., 2003; Schifter & Simon, 1992; Smith, 2000).

Method and Data Sources

This project explores the effectiveness of teacher peer coaching teams and describes strategies used to enhance mathematics teaching in elementary schools. To this end, teachers met to determine which dimensions to focus their discussion, negotiate improvement goals, devise strategies to implement the goals, observe teaching and provide feedback.

The method is exploratory case study (Yin, 2009) combining qualitative methods (interview and observations) with quantitative measures (survey and continuum scores, provincial test results). The participants are principals and teachers in elementary schools selected to represent a range of contexts (particularly traditional and reform teachers). Participants completed the Ten Dimension Mathematics Continuum (McDougall, 2004), met in pairs with another teacher, discussed the survey and continuum results, identified two dimensions for discussion and focus, negotiated improvement goals and implemented innovative teaching strategies.

Teachers observed each other while researchers sat in the classroom taking field notes. The teachers were interviewed before, during and after each math lesson to elicit the teacher's intentions and reflections on the lessons observed. The interview guides for teachers and principals were based on guides developed for earlier studies (McDougall, 2004; Ross, McDougall, Hogaboam-Gray, & Le Sage, 2000).

We interviewed the Principal and three teachers in each of the five schools. We selected the teachers from the staff list so that we have one primary teacher, one junior teacher and a resource teacher. The principal and teachers had an opportunity to indicate that they do not want to participate in the project. Each interview was about 45 minutes in length. They were audiotaped and transcribed.

Peer-Coaching Sessions

Teachers formed pairs, and each pair met during a pre-observation conference in which each teacher was given a form containing several initial questions and other questions to assist their observation of the dimension that the teacher who was being observed had identified. The discussion during the conference was guided by these questions, including, what are you planning to do today in the classroom? What did you do in the past in this topic? What would you like me to observe? The teachers met to select the dimensions on which they wanted to focus the discussion, negotiate goals for improvement, and devise strategies to implement goals, observe teaching, and provide feedback.

During the pre-observation conference, the observing teacher asked probing questions so that they could find out more about the teacher's goals for the lesson, which Dimension would be focused on and what parts of their teaching they wanted the observer to pay close attention to. During the lesson, the observer would take notes.

After the lesson, the pair met for a post-observation conference to discuss the lesson and the observing teacher would share their observations on the lesson, specifically on the areas that the teacher asked them to focus on. Judgments about the teacher were withheld unless the teacher asked for suggestions for improvement. During the discussion, the teacher was asked to share their thoughts about the lesson, what they learned from the experience and once feedback was given, prompted to reflect on what they would change/do differently the next time and what area(s) of improvement they would like to focus on during the next session.

Data Analysis

The data analysis included an initial exploratory review of the data and a constant comparison analysis (Miles & Huberman, 1994) of interview transcripts, field notes, observation notes, and feedback from participants. Computer qualitative research software, nVivo8, was used to assist in the analysis of the data. The initial coding scheme was based on the characteristics of mathematics reform and was elaborated based on the emerging themes. The use of codes such as context, diversity, peer coaching, professional development, distributed leadership, and each of the Ten Dimensions of Mathematics Education (McDougall, 2004) helped to further illustrate the richness of the data.

Findings

When asked about the benefits of peer coaching, many teachers revealed that they have more opportunities for reflection and gain valuable feedback from their peer coach, which they found have strengthened their collegiality and increased their personal and professional growth.

Many teachers mentioned the level of comfort that they have with a peer observing them in the classroom. As part of the peer coaching process, teachers interact through coaching, discussing, and sharing thoughts and information with each other. This process creates more informal and formal conversations between teachers and as well as opportunities for collaboration. One teacher stressed the need to discuss and brainstorm ideas with his peer before implementing constructivism and incorporating manipulatives in the class.

Teachers found that, as the observer, they have more insights into what other teachers are doing in their classrooms and benefit from visual understanding of how students react and learn in the class. From the perspective of an observer, a teacher declared, “it was good to just watch the students and how they were learning” (Weeping Willow, T2, Reflection) and another stated that it is “interesting to see where and what others are doing in terms of classroom management and teaching” (Weeping Willow, T4, Reflection).

Teachers also felt that, through discussing and receiving feedback from their coach, they became more oriented and focused in their teaching. For example, one teacher explained, “It is useful to have a process in place to help me focus on specific aspects of my teaching I want to improve—otherwise I am often caught up in ‘juggling’ everything” (White Oak, T8, Reflection) and another stated, “It was a chance to really focus myself on key aspects of what I was trying to do” (White Oak, T8, Reflection).

Peer Coaching – Challenges

When asked about the challenges that the peer coaching model presented, the participants frequently spoke about themes that were prevalent in their everyday teaching. One of the challenges that teachers faced was time. They believed they felt a pressure to do their job well given the amount of time that they had to spend preparing and teaching their lesson, so when asked to engage in peer coaching sessions, teachers found it difficult to schedule the session into their routine.

Some teachers found that it was challenging to get other teachers participating in the process. One teacher shared that recruiting her colleagues to engage in this model of professional development “might take some convincing. I think the newer teachers are more onboard than some of the ones that have been around for awhile” (Alder, T2, Interview, January 24, 2008).

One of the main components of the peer coaching process is having colleagues observe each other teach. This component gave rise to many fears and concerns by the participants. Many teachers had initial concerns about having an observer in the classroom. This observer could have been a member of the research team, another teacher or an administrator.

A colleague at the same school echoes the importance of a well working partnership. She says that, “It is important to be] sensitive when giving feedback. [And you] need to have someone who can accept honest feedback” (White Oak, T4, Reflection).

In addition to the challenge of having a colleague watch their teaching practice, teachers found it a challenge when they realized that their lesson was not going exactly as planned. A teacher said her challenge was “realizing that at times I had not thought certain things all the way through—and suddenly I was on the spot!” (White Oak, T8, Reflection).

Significance of the Study

Many teachers who were being observed mentioned the level of comfort that they have with a peer observing them in the classroom. Some teachers felt comfortable and appreciated having the other set of eyes to give them feedback. Being observed in the classroom is taken as a great opportunity to improve teaching since it is hard to come up with things that need improvement when teachers shut the door and teach in isolation.

Similarly, observers in the classroom gain pedagogical techniques and teaching strategies, such as how to react to weak students, how concepts and skills are introduced and how to be 'hands-on' to assist students' learning. Some teachers even visualize what tomorrow's lessons will look like based on observation. In addition, teachers further understand how learning occurs and how to take interventions with individual students. By observing their peers, teachers realize the different challenges that each age group poses and the different strategies that they should adjust and work with.

The peer coaching process strengthens collegiality and creates opportunity for collaboration. Many teachers consider collegial collaboration as mutual respect. This good rapport allows teachers to explore one another's ideas or opinions, to encourage each other, observe each other, share sources and across-share in different grades.

Many teachers find that timely feedback and constructive suggestions are beneficial to their professional development. Teachers value the feedback that they receive as it helps them focus on specific aspects of their teaching rather than juggling everything. As a consequence, teachers become more open and flexible to try new lessons and to tweak lessons for particular students' needs. Many teachers appreciate feedback that gives them ideas on what could be worked on, other ways to look at a problem and how to vary strategies.

Traditional methods of professional development may be ineffective in promoting teacher's continual learning as well as the transfer of knowledge into practice. Sustaining changes and improvements in teachers' instructional practices is a challenge that educational stakeholders are facing today. Peer coaching may be one answer for teachers who wish to improve their teaching in a supportive, non-threatening environment.

TO FOIL OR NOT TO FOIL

Margaret J. Mohr-Schroeder
University of Kentucky
m.mohr@uky.edu

Mnemonic devices have been around for thousands of years and are commonly used in mathematics classrooms to help students remember formulas, units, operations, etc. One of the most common mnemonic devices is the acronym, FOIL (First Outer Inner Last). This study takes a closer look at the acronym FOIL, how a group of preservice elementary and middle school mathematics teachers used it, and its possible implications for classroom instruction.

Keywords: Algebra and Algebraic Thinking; Teacher Education–Preservice; Mathematical Knowledge for Teaching; Teacher Knowledge

Introduction

KFC = Kentucky Fried Chicken = Keep Flip Change (Dividing Fractions)

KHDMDCM = King Henry Danced Merrily Drinking Chocolate Milk = Metric Units

ND = Notre Dame or Nice Dog = Numerator before Denominator

PEMDAS = Please Excuse My Dear Aunt Sally = Order of Operations

IPRT = I am PReTty = Simple Interest Formula

May I have a large container of coffee? = Pi to 7 decimals (word lengths are digits) = 3.1415926

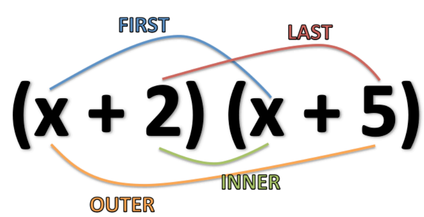
5 tomatoes = 5 to (m)ate oe(s) = 5 2 8 0 feet in a mile

FOIL = First Outer Inner Last = Multiplying a binomial times a binomial

Walk into a freshman level college mathematics classroom and ask the students what is the one thing they remember from high school mathematics. What do you think the result will be? The responses will probably vary, but if your students are anything like mine were, they will overwhelmingly say “FOIL” or “that FOIL thingy.” When I walked into my first college algebra class back in Spring 2003, I wanted to get a better gauge on my students. I didn’t have a pretest prepared for them; I thought I would just verbally quiz them to see where they were and where I needed to start. I left after the first day and thought, where do you start when they answer FOIL? I taught several more entry-level college mathematics classes and each and every time, the resounding answer for the most memorable thing from high school mathematics was FOIL.

First, Outer, Inner, Last, or FOIL, is a mnemonic device to aid in multiplying two binomials together. FOIL is the acronym for the steps:

“First” terms are multiplied together
“Outer” terms are multiplied together
“Inner” terms are multiplied together
“Last” terms are multiplied together



The result is then simplified, if necessary, but most commonly adding the resulting middle terms together.

It is a tool for secondary students to use in order to not forget to distribute all of the terms when multiplying binomials together. It is limited in its use as it only works for the multiplication of two binomials.

Objectives of the Study

The purpose of this study was to explore preservice teachers' use of the mnemonic FOIL (First Outer Inner Last) when answering questions about multiplying binomials and factoring trinomials into binomials and its implications for K–12 classrooms.

Perspectives

The above examples are common mnemonic devices found in the mathematics world. Mnemonics are devices, operations or procedures used to improve memory. Although mnemonics can be found in nearly every content area imaginable, they have more of a "home" in special education. Mnemonics is one of the most highly touted and commonly used intervention strategies in Special Education. Learning disabled (LD) students are the most common to receive this type of intervention strategy because semantic memory difficulty is a common characteristic of LD students (Scruggs & Mastropieri, 1990).

Mnemonics have been around for thousands of years (cf. Yates, 1966) and have seen positive results amongst the Special Education Community, especially in mathematics (Manalo, Bunnell, & Stillman, 2000; Mastropieri & Scruggs, 1989; Scruggs & Mastropieri, 1990). There are several types of mnemonic devices including: Keyword method (i.e., "of" means multiply, see Schoenfeld, 1982), Pegword method, Acronyms (i.e., FOIL, HOMES, PEMDAS), Reconstructive Elaborations, Phonic mnemonics, spelling mnemonics, number-sound mnemonics, and "Yodai" methods (cf., Higbee & Kunihira, 1985; Kilpatrick, 1985).

Other than the occasional response to an article, a majority of the research articles related to mnemonic devices and/or acronyms lie within the Special Education realm. This is problematic given that K–12 classrooms use mnemonic devices on a regular basis beginning early in elementary school with the keyword method. Mnemonic devices, especially acronyms, become more prevalent in the middle and high school classrooms as students are taught little tricks to help them remember algorithms foundational in numeracy and algebra.

The mnemonic device, FOIL, is a common term found in many current algebra textbooks beginning as early as middle school, through beginning college mathematics courses, and can even be found in middle and secondary mathematics methods textbooks for preservice teachers. It is often thought that FOIL is a newer term in the mathematics world, coming along after the "New Math" movement. Contrary, you can a reference and picture of FOIL in Shute's (1956) *Elementary Algebra* book and even further back is Betz's (1931) *Algebra for today, second course* (p. 150) in text and picture reference. As this was not Betz's first book text, it's more than likely the case that FOIL had been written about before this.

Methods

This study was part of a larger concurrent triangulation mixed-methods study in which preservice middle grades teachers' mathematics knowledge for teaching was investigated. Preservice teachers were given questions based on items from 6th–8th grade math content standardized assessments. The questions were broken down into four different subject areas, one of which was Algebra. This study focuses on two particular questions from the Algebra assessment taken by 158 preservice middle grades teachers pursuing Mathematics/Science Specialist degrees and who were enrolled in the middle-grades specialist undergraduate degree program at a large public university. These two items were related to each other and common in current Algebra curricula: the multiplication of two binomials, and the factoring of a trinomial into two binomials.

(1) Multiply the expression: $(3x - 5)(2x - 8)$
Answer: _________
Explanation of Answer: _______
Explanation to someone who didn't understand: __________

(2) Factor $y^2 + 3y - 18$ into two binomials.
Answer: _________
Explanation of Answer: __________
Explanation to someone who didn't understand: ___________

Data were analyzed qualitatively using constant comparative analysis (Denzin & Lincoln, 2000).

Results and Discussion

Results indicate that a majority of preservice teachers were able to correctly answer both questions, but relied heavily on the term FOIL to explain their answer to the first question and as an instructional technique for explaining it to someone who did not understand. A lack of the phrases "distributive property" and "multiplication of each term" among the explanations was noted:

- I just used FOIL to multiply it out and then I added like terms.
- I came to this answer by foiling or multiplying the two parentheses together. By doing this I get 6x^2-24x-10x+40. Then combining like terms I get 6x^2-34x+40, which is my answer.

In the second item, there was a tendency to misuse mathematical vocabulary and procedures in explanations of solutions. Instead of explaining how they factored their solution or talking about various methods of factoring, a majority of students used several variations of FOIL. Again, there was noted a lack of mathematical vocabulary akin to this content, especially the distributive property:

- y is squared so it needs to be in both parentheses. Then use FOIL.
- The solution is (y – 3)(y + 6) because when you FOIL these two factors together it gives you y^2+3y-18. FOIL is just a way of multiplying the two factors together without leaving out a part.

Across item two explanations, the most common method of arriving at a solution was to work the FOIL method backwards:

> I did the FOIL method backwards in a way. I know y^2 is y times y so that will be the first portion of each binomial. Then I thought about the factors of 18 and picked on that when subtracted would equal 3.

FOIL is a process that is supposed to aid students in using the distributive property to multiply two binomials together. However, from these examples, one can see that participants memorized the procedure and may not understand what they are doing. FOIL is taught as early as 6th grade and ingrained into students' minds throughout high school and even into college. There are alternative procedures for teaching the multiplication of binomials that the participants are taught during the middle-grade program at the site of this study, including algebra tiles. However, there was no mention of these methods.

Implications

In a heightened era of assessment and teacher evaluation, it is critical to continue to address the mathematical content needs of preservice and inservice teachers. In the late 1980s, the National Center for Research on Teacher Education found elementary and secondary teachers were unable to explain their reasoning or why the algorithms they used worked (RAND, 2003). Instead, they exhibited a rule-bound sense of understanding, similar to what was exhibited in this study by the preservice middle school mathematics teachers. This rulebound sense of understanding reflects the nature of teaching and the curriculum teachers experienced in elementary and secondary schools (RAND, 2003). Through sustained professional development and preservice teacher mathematics and education coursework, inservice and preservice teachers should have exposure to mathematics and mathematics methods that force them to explain their reasoning and begin to understand how and why algorithms they use work. There should be a strong emphasis placed on the importance of using correct mathematics vocabulary (e.g., distributive property instead of "FOILing") and conceptually understanding that vocabulary (e.g., distributive property).

PROPORTIONS, RELATIONS, AND PROPORTIONAL RELATIONSHIPS: ONE TEACHER'S NAVIGATION BETWEEN PROFESSIONAL DEVELOPMENT AND PERSONAL KNOWLEDGE

Chandra Hawley Orrill
University of Massachusetts Dartmouth
corrill@umassd.edu

James Burke
University of Massachusetts Dartmouth
james.burke@umassd.edu

In this paper, we report an exploratory study considering how one teacher made sense of professional development related to proportions. We consider this from the perspective of knowledge in pieces, paying attention to the organization of the teacher's knowledge as it related to the structure of the content in the PD. Implications for the design of PD are discussed.

Keywords: Teacher Knowledge; Teacher Education–Inservice/Professional Development; Number Concepts

Purpose

Professional development for teachers has led to disappointing results in terms of teacher learning (e.g., Garet et al., 2011). Further, studies of teacher knowledge have proven ineffective for determining teacher effectiveness as measured by student outcomes (e.g., National Mathematic Advisory Panel, 2008). Some researchers have posited that the constructs that matter for teacher knowledge are unique to teaching, such as pedagogical content knowledge (Shulman, 1986), and efforts to measure those constructs and correlate them to student learning have led to somewhat more promising results (e.g., Baumert et al., 2010; Hill, Rowan, & Ball, 2005). This shift in thinking about teacher knowledge opens opportunities for researchers to further examine what teachers need to know and how they develop their knowledge.

In this study, we consider how a teacher understood proportions after completing a professional development (PD) course that included 9 hours (3 sessions) of instruction on proportions. For our analysis, we used a content-mapping strategy to create visual representations of the concepts discussed in PD and the content discussed in a clinical interview with the teacher. Our research sought to explore how this teacher made sense of the content in the PD by comparing.

Theoretical Framework

We rely on the knowledge-in-pieces epistemology (diSessa, 2006). Knowledge in pieces asserts that each of us has a variety of fine-grained understandings that work in concert with each other to make sense of complex situations. Thus, for any given problem situation, we are likely to invoke some number of these pieces to create a more complex, synergistic knowledge. Thus, learning can be seen as (a) developing more fine-grained knowledge pieces, and (b) refining existing pieces so they have more connections between them, allowing a more coherent understanding. Learning occurs when a perturbation causes the learner to reassess an understanding in ways that lead to new understandings or new connections among existing understandings. For example, if a student only understands fractions as *n* pieces of an *m*-sized whole, (e.g., 3 pieces of a 4-piece cake is ¾) that student cannot use that understanding to make sense of 7/4. The student needs to both add a new piece of knowledge about fractions and reassess the existing piece of knowledge to better understand how and when it is appropriate. The development of expertise from this perspective involves building connections and refinements that allow appropriate pieces of knowledge to be invoked in various situations. In our study, we consider the connections between ideas that were discussed in the PD and the ways those did or did not translate to the teacher's understanding of proportional reasoning.

Methods

For this study we interviewed Walt, a 6th grade teacher with six years of teaching experience. He participated in our 14-week PD designed to strengthen teacher's mathematics knowledge by engaging in open-ended exploratory tasks involving mathematical reasoning. Walt was one of 14 participants in the course, which was led by an advanced doctoral student with a strong mathematics background and prior teaching and PD experience.

The three PD sessions that focused on proportions were video recorded with two cameras to capture the speaker(s) and any written work. These were combined using a picture-in-picture technique. A 90-minute clinical interview on proportional reasoning with Walt was conducted and videotaped 10 months after the PD. Walt was asked to engage in a number of proportional tasks that featured sample student reasoning and hypothetical interactions in professional development. This interview was also videotaped using two cameras.

To understand how content was organized and discussed for Walt and in the PD, we created content maps (Empson, Greenstein, Muldonado, & Roschelle, in preparation) from the videos. To do this, we considered relationships among lexical content to compare what mathematical language is explicitly linked within the two situations. Phrases representing concepts or objects became nodes of our maps. When we noted Walt using two words in similar ways, we recorded that connection as a line connecting the nodes. When Walt described a relationship, we recorded the description of the relationship as an annotation to the line (e.g., a proportion *can be* set-up).

In the case of the PD, this mapping showed our analysis of the whole-class discussions about proportions in which Walt participated. For Walt's clinical interview, this mapping showed our observations of Walt's use of language while reasoning about proportional situations.

We analyzed within these maps for notable groupings and absences of connectedness in concepts important for proportional reasoning. We then compared the PD mappings to Walt's interview mapping.

Results

Our analysis uncovered fundamental differences between the ways in which the content was organized in the PD and the ways in which Walt made sense of the content. Due to space limitations, we focus on only two key aspects of knowledge organization in this paper: representations of proportions and the definition of proportion.

Representations for Proportions

In the PD, one key element of all three proportions classes was the use of representations for making sense of proportional situations. These sessions included not only discussion of different representations (e.g., double number lines, graphs, tables, etc.), but also how they could be used to support thinking about the relationships rather than providing illustration of pre-calculated answers. By the third proportion class, the discussion included how the representations were related to each other. In the PD, the representations discussed were generated and introduced by the participants, but the facilitator took the role of engaging the participants in seeing connections between and among the representations as well as considering how the representations of directly proportional relationships, particularly for graphs, varied from those of inverse proportion and linear relationships.

Despite actively engaging in these sessions, Walt seemed not to rely on knowledge of representations in his own proportion problem solving. In our interview, Walt described only three representations: the equation, graphs, and a drawing that could be used as a build up strategy in which a ratio was expressed by a certain number of x's in the numerator to match the value of one quantity and a number of x's in the denominator to match the value of the other quantity. Walt explained that this drawing could be iterated to determine the "missing value" in a proportion.

The limited discussion of graphs in the interview mirrored our observation from PD that Walt demonstrated a general lack of fluency with the representation. For example, in PD he commented that he never learned about slope. In the interview, he drew a proportional relationship with the axes reversed, leading him to note that the graph was not representing his intended idea, but also leaving him without the resources to fix it. In the PD, he instead relied on symbolic notation, which in the interview also, in his words, failed to represent his idea. He did not invoke any knowledge of other representations during the interview.

Definition of Direct Proportion

In the PD, direct proportion was defined in terms of relationships. For example, it was described as division, a constant product, a constant rate, and a relationship. Further, after three weeks of refining the definition, the community definition in PD was that proportions were two equal ratios and that the equality could only be maintained through a multiplicative relationship. The PD also highlighted that a direct proportion could be expressed as $y = kx$ or as $y/x = k$ and that the graph of a proportion is a straight line that goes through the origin.

In our interview with Walt, we found that his definition of proportion seemed split. He had a set of ideas related to "relationships" between numbers and a separate set of ideas related to "proportion." The connection between these was not explicated. His definition for relationships seemed bound by the concrete world. He described them as connected sets of units of certain size. For example, a 2 : 5 ratio was, to him, a 2-unit connected to a 5-unit that he described with statements like, "2 is to 5", "2 is 5" and "2 equals 5, in a way." He was able to conceive of these units increasing (e.g., doubling) or decreasing (e.g., halving) through build-up or iteration strategies and he was able to reason about them in ways that attended to the quantity (Thompson, 1994). He also dismissed the importance of composed unit reasoning, focusing instead on one value in a proportion increasing at a time. In contrast, his definition for proportion was grounded in calculation. He said that proportions were "equal ratios" which he elaborated to be equivalent fractions in which the ratio stayed equal while it increased proportionally. He also talked about proportions in terms of filling in missing values, multiplying, and sometimes dividing. For Walt, contextualized understanding was separated from procedural knowledge of the content.

Discussion

In our analysis of these data, we considered Walt's learning from the perspective of knowledge in pieces. While the PD offered opportunities for teachers to development understanding of the concepts through connection making and through the introduction of new ideas, we found that Walt's activation of proportional knowledge did not generally reflect the PD. It appeared that the definition of proportion and the use of a variety of representations were not evoked when Walt was faced with questions that required him to reason proportionally and make sense of student reasoning. We suggest this is a result of two different issues.

First, the PD offered a socially negotiated opportunity for exploring ideas related to proportions, however, it may not have scaffolded Walt's connection making. While he clearly had considerable understanding about proportions, particularly his understanding about "relationship," those understandings were not supported by use of the representations from the PD. Further, his definition for "proportion" lacked the mathematical focus of the PD. The PD may not have provided the right perturbations to support Walt's connection making. Alternatively, Walt's limitations with graphing may have led him to overlook aspects of the representation discussion that were accessible to him because he perceived the representations to be outside his zone of development.

Second, aspects of the PD remained tacit that perhaps should have been made more explicit. While the facilitator asked many questions to help participants see connections between and among ideas and to promote precise mathematical description, there was no meta-discussion about these moves. Perhaps discussion should have included more insight into the reasons for asking connection-making questions. Further, more opportunity for reflection or concept mapping may have helped fit the knowledge pieces together more. Such metacognitive moves may be necessary for creating a coherent body of understandings.

In short, further research needs to be conducted to understand the relationship between professional development and teachers' knowledge. By understanding how professional development supports or fails to support the development of connected understandings, we situate ourselves to be more successful in supporting teachers in the development.

Acknowledgments

STORIES OF MATHEMATICAL PROBLEM SOLVING IN PROFESSIONAL LEARNING COMMUNITIES

Joy A. Oslund
University of Michigan
oslund@umich.edu

Mathematics teacher educators often engage teachers in solving and discussing mathematics problems relevant to the school curriculum. This paper reports on elementary teachers' discourse as they shared solutions to a mathematics problem in professional learning communities. Teachers employed narrative structures as they shared their mathematical work. A structural analysis of the narratives suggests questions, insights, and conjectures about how teachers learn mathematical knowledge for teaching in and from such discussions. Since narrating is a natural way for teachers to discuss mathematical experiences, it makes sense to understand how narrative functions in such contexts to open opportunities for learning. Implications for future research are suggested.

Keywords: Mathematical Knowledge for Teaching; Teacher Education–Inservice/Professional Development; Teacher Knowledge

Purposes and Perspectives

Mathematics professional developers have employed professional learning communities (PLCs) to embody new understandings of cognition and foster changes in practice (e.g., Arbaugh, 2003; Crespo, 2006). However, there are few studies of teachers' discourse practices in PLCs. Researchers have begun to study important elements of discourse in PLCs, such as how teachers take up ideas from literature (Herbel-Eisenmann et al., 2008), render stories of classrooms (e.g., Crespo, 2006; Horn, 2005), and challenge one another's ideas (e.g., Males et al., 2010). Such work focuses primarily on how teachers talk about pedagogy and teaching practice.

Engaging teachers in solving and discussing math problems is also part of many PDs (e.g., Crespo, 2006; Schifter, 1998). Such work seeks to move teachers toward the deep, flexible knowledge of mathematics that is essential for effective teaching (Ball, Thames, & Phelps, 2008). Experienced teachers are uniquely poised to work toward nuanced understandings of relevant mathematics (Feimen-Nemser, 2001); however, little is known about how teachers engage in discussing mathematics. Teachers in one study talked about mathematics in more tentative, exploratory ways than they talked about teaching (Crespo, 2006). This is important because common challenges with PLCs include fostering inquiry and critique. Another study found that preservice teachers' discussions of mathematics problems influenced their conceptions of mathematics and themselves (Schifter, 1998). This is important because mathematics teaching is intertwined with identity (e.g., Drake, 2006). Understanding how discussions of mathematics problems create opportunities to learn is informative to the design and facilitation PLCs.

This paper reports on data collected when teachers in eight PLCs were sharing solutions to estimation problems. Estimation is crucial for academic mathematics and everyday situations; many contexts constrain the possibility of an exact answer (e.g., measurements are never exact) or do not require exactness (Bell & Bell, 2002; Usiskin, 1986). Estimation is often uncomfortable for learners, who may prefer certainty. It was historically taught as discrete procedures (primarily rounding) with correct answers (Reys, 1986; Trafton, 1986). However, other strategies are often more efficient than rounding, including front-end (focusing on left-most digits), clustering (assigning a common value for several numbers that are close together), compatible numbers (using values that add to a nice number like 10 or 100), and special numbers (rounding to numbers that are easy to compute) (Reys, 1986). Estimating encourages number sense, mental flexibility, and confidence (Bell & Bell, 2002).

The purpose of the analysis was to point to places in teachers' discourse about mathematics problems that potentially inform our understanding of *how* and *why* teachers learn mathematics knowledge particular to the practice of teaching when solving problems and sharing their solutions.

Methods

This paper reports on part of a design research project (Cobb, Zhao, & Dean, 2009) on elementary teacher PD that seeks to foster teachers' mathematical knowledge for teaching and skill with teaching mathematics and mentoring novices (Moss, Boerst, & Ball, 2010). Eight PLCs (five to ten teachers each) meet bi-monthly to investigate records of practice as well as solve and discuss mathematics problems. The purpose of the PD is to engage teachers in collaborative assessment of their own and others' teaching to develop a shared language. Four facilitators with experience as successful elementary teachers, teacher educators, and field instructors lead the groups. The curriculum consists of semester-long units, each focused around a high-leverage content area and a high-leverage teaching practice. Facilitators video- and/or audio-record all sessions and collect teachers' written work.

I analyzed excerpts from a session on computation that included discussion of estimation problems. Teachers solved five problems then shared their work. I report only on discussion of estimating the sum of the following numbers: 392, 1547, 84, and 3198. Facilitators chose the problem to engage teachers in discussing multiple estimation strategies, context, and place value.

I transcribed the segments of the recordings where the teachers discussed the estimation problems. I noted the estimation strategies teachers named (e.g., rounding). I noticed that when teachers shared their work they always employed a basic narrative structure. Therefore, I re-examined the transcripts to identify *estimation stories*, which are the focus of this paper.

Once I had identified estimation stories, I conducted a structural analysis of each one (Riessman, 1993), adapting Labov's (1972) narrative structures. In this paper, I focus on the complicating action and evaluations in the stories. The complicating action of a story—its action or sequence of events—is the only necessary story structure. Evaluation serves as justification for telling the whole story or for elements of the story. It may be present as a separate evaluation section or embedded in other narrative structures.

Results

A diverse array of narratives emerged as the teachers shared their strategies. A few narratives included only complicating actions, as seen in Molly's story. (The stories that follow indicate the complicating action with *italics* and evaluations with **bold**):

> *All I did was round it to either a ten, ten hundreds or a thousands place*. *And then add quickly*. Yeah.

Others were more complex, intertwining evaluation with various other structures, as seen in Estelle's story:

> ***Three hundred and ninety two is closer to four hundred*** *(implying that she rounded to four hundred)*, **even though I could've gone three ninety**. *And then* ***one thousand five hundred and forty-seven, forty-seven is less than fifty*** *so I just kept it at fifteen hundred*. *And eighty-four,* ***I don't know why****, I went to a hundred,* ***'cause it is over fifty in the tens place*** *(laughs)*. **I guess that's why I did it instead of going, yeah. I screwed up.** But any way. *Three thousand one hundred and ninety eight, I went to thirty two hundred,* ***because a hundred and ninety eight is closer to two hundred than it is to thirty one hundred****.* And I came up with fifty one hundred, **if I added that correctly, which I don't even know right now.** So that's what I did.

Estelle embedded evaluation into the complicating action and provided additional evaluation statements. She started by evaluating the number three hundred and ninety two in relationship to four hundred, implying a justification of her decision to round to four hundred, thus embedding evaluation into the complicating action. However, she then suspended the story's action and further evaluated that decision, saying, "I could've gone three ninety."

There were only a few estimation stories that, like Molly's, did not originally include the evaluation structure. In most of these cases, when the facilitator prompted for more information, the storyteller provided evaluation. For example, Molly told the above story and then paused to indicate that the story was complete. Then the facilitator stepped in:

Facilitator: And so, can you talk a little bit about that, what made you decide, in terms of place value, what were you looking at?
Molly: **In third grade I was taught this and so** (laughs)=
Teachers: (laughing, talking over one another)
Molly: =**I went with what I knew. Place value**. *I just looked to the right of the number, the largest number. I went to the right to see if it was five or above. Flip it up, or down, or stay the same.*

Teachers often added evaluation to narratives (both those that were originally evaluated or unevaluated) after being prompted by the facilitator or other teachers, even when the prompt did not ask for an evaluation. Consider the interaction around Jeni's estimation story:

Jeni: *I rounded to the hundreds with every one except the last one* ***because I wanted to leave fifty****. I just went four plus fifteen is nineteen. Plus another one, twenty. Plus thirty* is fifty hundreds. (Pauses, as if she is finished with her story.)
Facilitator: How did you, I didn't catch that.
Jeni: *I rounded to the hundreds with everyone except four, the last one, I just took the hundreds.*
Facilitator: You took the hundreds.
Jeni: Yeah, well, **three ninety two was closer to four hundred**.

In this interaction, facilitator asked Jeni to repeat, then echoed Jeni. However, Jeni responded by providing evaluation.

I noted a number of thematic and topical patterns in the narrative structures as well. For example, in the evaluation structures of the narratives, the most common themes were feelings or aesthetics (e.g., "It just looks a little bit better"), the ease or difficulty of a procedure (e.g., "I was just trying to think about making it easier to do in my head"), judgments about numbers (e.g., "a hundred and ninety eight is closer to two hundred"), recollections of social interactions (e.g., "I heard you say 'estimate'"), and evaluations of the quality of decisions (e.g., "I screwed up").

Discussion

Narrating is a sense-making activity and means for consolidating and transforming learning (Goodson & Gill, 2011; Ochs & Capps, 2001). Therefore, it makes sense that the teachers narrated their work; they were not simply communicating their work to others, but organizing it to make sense of the mathematics and themselves.

A task that is common to all storytellers is that of justifying and convincing, and the disposition to do those things is one that is also important to mathematical practice. Although elegance and economy of syntax are often privileged in the communication of mathematical solutions, more complex narratives make teachers' thinking more visible and therefore open to probing by the facilitator and other teachers. While previous work found that more robust and reflective narratives provide the most opportunities for the storyteller's learning (Goodson & Gill, 2011), it is interesting to think about the tension between the discursive norms for mathematical justification and narrative. This tension has implications regarding the interplay between teachers' ways of knowing and communicating mathematical knowledge for teaching.

This preliminary theoretical and analytical work has only investigated the first session in the project where teachers solved problems and discussed solutions. Further questions remain, including whether teachers tell increasingly robust narratives over time and what specific facilitator moves impact teachers' narratives of their mathematical work.

This paper discusses the role of technology and embodiment theory for the teaching of graphing trigonometric functions to promote students' understanding of time as a component axis in Cartesian graphs for periodic movements. The embodiment theory will be discussed not only as our framework but also as a possibility in helping teachers to better understand students' thinking about. This is an ongoing research that is occurring in Brazil. We follow a design based research methodology including three cycles, the first one, presented here, shows the development of applets taking in account the notion of fictive motion. We conclude arguing that technology may transform a fictive motion in factive one.

Keywords: High School Education; Technology; Embodiment Theory; Fictive Motion

Introduction and Problem

The purpose of this study is to *discuss the role of technology and embodiment theory for the teaching of graphing trigonometric functions to promote students' understanding of time as a component axis in Cartesian graphs for periodic movements.*

Research on that theme revealed that there are many different problems regarding understanding functions and graphs of trigonometric functions, even among teachers (Quintaneiro, 2010; Weber, 2005; Kendal & Stacey, 1997; Costa, 1997). Weber (2005) findings indicate that the students who were taught in the lecture-based course developed a very limited understanding of these functions, while students who received an instruction based on the process-object perspective developed a deeper understanding. Quintaneiro (2010) investigated the appropriation of formal definition of sine and the sine function among teachers, observing that offering different ways of representing these notions were crucial to enable students' to access formal definitions.

We start this study investigating teachers' meaning production for graphs involving periodic phenomena. The investigation took place in Brazil with 10 mathematics teachers. We began posing the following problem:

> *Sketch a Cartesian graph showing distance x time of a person seated in a capsule/chair of a Ferris Wheel. Knowing that the person seats for 4 turns of the wheel.*

Two responses called our attention because their analysis let us raise a few hypotheses about how teachers thought about trigonometric functions.

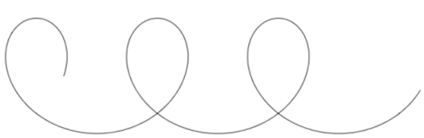

Figure 1

Figure 2

Studies such as, Quintaneiro (2010) and Weber (2005), as well as other research on the teaching or learning trigonometry, do not provide interpretations for these answers. In general, these studies focus on understanding of mathematical objects, by their formal definitions. Moreover, for us it seems that researchers, in this area, often take more into account what is missing in students' or/and teachers' answers and less what they are actually saying, talking or drawing.

Theoretical perspectives lead us to different interpretation. In the next section we briefly present our theoretical lens. After that we present our analysis of these responses, based on the notion of fictive motion. And as a conjecture in this cycle of the larger research, we will present, computer applications, applets that may help in promoting a deep reflection and understanding about periodic phenomena and their graphics.

Theoretical Perspective

We share a premise with others that work with embodiment theory that mind and body are not separable as proposed by Descartes' work. According to Damasio (1996) a human being interacts with the environment as a whole, the interaction is not exclusively of the body or of the mind. Edwards (2011) points out that "embodiment theory offers an answer to the question of how meaning arises and of how thought is related to action, emotion and perception. Embodiment theory proposes that meaning and cognition are deeply rooted in physical, embodied existence" (p. 1). Since we are interested in meaning production for periodic phenomena we assume this theory. Lakoff and Johnson (1999) stated that our conceptual system is directly related to the way we think and act.

For mathematicians a concept is a definition, but to someone who is learning mathematics a concept is something rather different. We adopted Rosch (1999) ideas that concepts are one aspect of the study of categorization, one of the basic functions of living beings, "concepts are open systems by which humans can learn and invent new things" (p. 61).

Due to constraints of space we do not present works on digital representations, to name a few Luis Radford that looks at graphs as semiotics constructions, the use of graphic calculators and sensors as proposed by James Kaput and Roschelle, and Ricardo Nemirovsky.

Ramscar, Matlock, and Boroditsky (2010) argue that more abstract domains can be understood through analogical extensions of domains based on experience. They describe a series of studies that indicate the following: (a) people's understanding about the time comes to thinking about concrete experiences of movement in space, (b) the way people think about the time can also be influenced by a nonliteral type of motion called fictive motion.

We agree with the fact that engaging in reflection about movement is crucial to change the way we think about the time. Concerning the problem of our research, we anticipate that this point seems to be fundamentally important, once we intend to engage study participants in thinking about movements determined by computing experiences that are designed to allow "visualization" of movement through time.

Matlock (2004) indicates that the presence of an actual motion isn't necessary to process such movement, and concludes that the processing of the fictive motion includes mental simulation of movement. Barsalou (2009) indicates that simulation is typically located on the experience and that we conceptualize insight gained in frequent experience with the world body and mind, as captured by multimodal patterns,

Relationship Between Fictive Motion and Charts in Periodical Phenomena

We conjecture that the ideas associated with understanding of graphs, relating to the movements of periodic phenomena, may be related to how we understand the "passage of time" in these movements. We also agree with other works such as Nunez (1999) and Font, Bolite, and Acevedo (2010) that the understanding of time flow utilizes ideas and inferences grounding in experience with the physical world, and, even unconsciously, associated with a horizontal translation of a self or a thing.

On the responses (Figures 1 and 2) the problem of the wheel we found different ways of meaning production to the required graphing in a time vs. distance representation; mainly approaching the graph as if it were only the trajectory. Moreover, we believe this response is related to a cognitive simulation of motion (in the sense the Matlock 2004), when used in a horizontal translation of the replacement time, because the graph was obtained as if it were a "path of bicycle tire" (see Figure 3). The graphs in Figures 3 and 4 show the route given by a particle that is a uniform circular motion, where the center of the circular motion is in a uniform rectilinear motion.

Considering the bold circle rolling on a plane without slipping, then the curve described by a point on this circle is called a cycloid. In this case the rose curve is long cycloid. What we want highlight is that this curve is obtained by the trajectory of a point that undergoes a translation composed with a rotation. In Figure 4, the red curve represents the path of the red chair, and the difference is that in the case of Ferris wheel the rotation can occur in the counterclockwise.

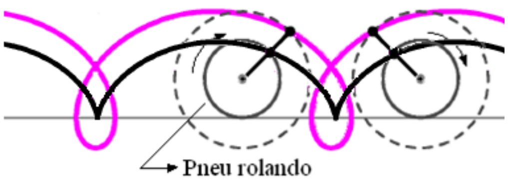

Figure 3

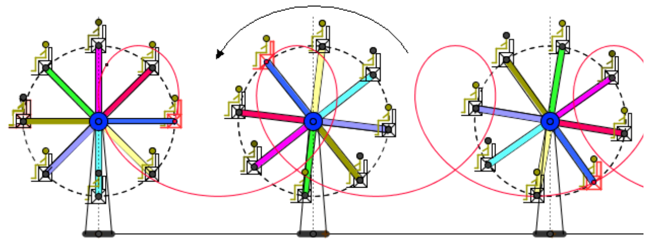

Figure 4

Taking into account the need for a horizontal translation to obtain this type of curve, we conjecture that it is necessary for a teacher/student to make a cognitive simulation, i.e., a person should simulate a horizontal movement of the wheel instead of looking for time flowing, although this is a fictive motion because there is no such movement. This fact fortifies our conjecture that there is a relationship between fictive motion and graphic involving periodic phenomena. Thus, converge with the ideas of Ramscar brought in the previous section, that people can recruit concepts acquired experience of the physical world, horizontal displacement, to give sense of more abstract concepts like time.

Given our theoretical perspective, thinking about different curves and different situations may further the development of different elements for categorization and, consequently, may bring life to a richer set of experiences for those immersed in these type of problems. We then start developing applets, thinking in helping physical and mental simulations of these periodic phenomena.

Developing Applets

Based on our framework, in order to be able to analyze the impact of using these applets we also had to create possibilities for exploration that promoted discussion, gestures, verbalization and sketches. Some questions included arguing about fictive motion, a movement that at least until it was materialized, were not physically there. We developed two applets[1] that may enable the animation of fictive motion "Ferris Wheel" and "Piston," which are still being improved. One can see in the applet "Ferris Wheel," for example, a Ferris wheel, as in Figure 4, moving (horizontal translation) in the time axis. Our hypothesis is that with this translation the technology can transform a fictive motion in a factive one. This fact enables discussion and reflection about cognitive simulation that could be difficult to conceive without technology. These facts characterize these applets as simulators according to Barsalou (2009).

Final Considerations

For us, there is a strong connection between the role of technology and embodiment theory for the teaching of graphing trigonometric functions to promote students' understanding of time as a component axis in Cartesian graphs for periodic movements. Due to space constrains we did not present the different responses that led to rich discussions and the development of other applets. We will bring that for presentation.

We emphasized the problematic of our investigation as well as possible discussions on periodic phenomena, involving the idea of fictive motion and the use of computational resources. It is worth noting how our theoretical perspective supported the considerations that led to the development of applets. The features we have chosen try to explore more about our experiences in the world of motion, namely our repertoire of movements and self movement, the applets do not only display static figures, but took advantage of dynamics representations.

Finally, we observed that this presentation reveals part of a larger research, and the applets are being used with graphic calculators and sensors to promote, students and teachers, to build a repertoire of experiences that may function to further conceptualizations based on situations of periodic phenomena.

A CASE FOR CHINESE LESSON STUDY

Thomas E. Ricks
Louisiana State University
tomricks@lsu.edu

The predominant version of lesson study described in the literature and attempted by U.S. educators is still the Japanese form. Chinese lesson study may be a softer introduction—or even a possible substitute—for U.S. teachers challenged by the cultural and logistical demands of sustained Japanese lesson study.

Keywords: Chinese Lesson Study; Japanese Lesson Study; Professional Development; Reform

The purpose of this article is to describe Chinese lesson study and advocate for its use. The Japanese form is the most common type attempted in the U.S.; unfortunately, current U.S. school climates are generally not conducive to adopting this more rigorous and demanding form of lesson study. Chinese lesson study (Fraser, Allison, Coombes, Case, & Linder, 2006) could be a happy medium for teachers interested in grass-root, practice-based professional development that do not have access to the resources necessary to enact Japanese lesson study. After briefly describing the Japanese and Chinese forms, I argue that Chinese lesson study: (1) will make an excellent form of professional development in and of itself, and (2) may also provide crucial training for those teachers wanting to eventually attempt the more demanding Japanese form.

Japanese Lesson Study

Japanese lesson study has been proposed as a model of effective professional development that could be imported into U.S. schools. Japanese lesson study involves the collaborative planning by teachers of a lesson designed to address specific student-centered goals The lesson is then taught in an actual classroom, with close observation by the other lesson study teachers to verify the effectiveness of the designed lesson in reaching the lesson study goals (Lewis, 2000; Lewis & Tschudia, 1998). Japanese lesson study is an experiment in practice that turns teachers into researchers-in-action. Stigler and Hiebert (1999), the ones who introduced the U.S. to Japanese lesson study, described its 8 sequential parts: (1) defining the problem, (2) planning the lesson, (3) teaching the lesson with observation and debriefing, (4) evaluating the lesson, (5) revising the lesson, (6) teaching the revised lesson to another class, (7) further evaluation and reflection with other teachers, and (8) sharing the results.

Despite being a powerful form of professional development, Japanese lesson study clashes with the current U.S. school climate of (1) time constraints (Darling-Hammond et al., 2009; Wei et al., 2009), (2) teachers as consumers not generators of professional knowledge (Fernandez, Cannon, & Chokshi, 2003; Hiebert, Gallimore, & Stigler, 2004), and (3) the "persistence of privacy" (Little, 1990). Teachers' isolation, often reinforced by entrenching school cultures and norms, is damaging to the profession of teaching (Ball, Lubienski, & Mewborn, 2001) and prevents teachers from becoming reflective practioners (Schön, 1983). Overcoming this isolation culture is very difficult (Grossman, Wineberg, & Woolworth, 2001).

Chinese Lesson Study

Chinese lesson study is another form of lesson study that may provide a solution for U.S. educators wishing to adopt lesson study. Like Japanese lesson study, the Chinese versions respect the central role that researching an actual lesson plays in teachers' professional development. Chinese lesson study is not yet well-known to the U.S. professional development field; the reason for this may be that mainland China has only recently emerged from self-imposed isolation during the Cold War—now, as China embraces the global village, U.S. educators have been able to visit and document Chinese versions of lesson study.

There are two principal forms of Chinese lesson study: (a) the model lesson, and (b) exemplary lesson development.

The first version of Chinese lesson study is when a school or district invites a regionally recognized "master teacher" to teach a mathematics lesson to a random class of students. During the lesson, usually held in an auditorium, the school or district teachers sit and watch the "master teacher" teach the class of students, whom she or he has never interacted with prior to this lesson. As a side note, this practice of teaching on-the-spot an unfamiliar class of students challenges basic U.S. assumptions about teachers needing to "know" their students before being able to effectively teach them. This "fishbowl" arrangement of observing teachers looking in on an actual lesson provides a chance for practicing teachers to: (1) watch a "master" at work, (2) closely observe students, (3) talk quietly with colleagues about issues that arise during the lesson, and (4) witness excellent instruction—See! It is possible to do it! These are not activities afforded to teachers during the act of teaching. Teachers have a chance to step back and reflect on this model lesson from a vantage point not possible during the rapid decision-making of instruction. After the model lesson is concluded, the students are dismissed, and the master teacher has a chance to debrief with the observing teachers. In a way, the observing teachers have become students at the feet of a master.

Exemplary lesson development. The second version of Chinese lesson study is exemplary lesson development—sometimes called "keli": A teacher will prepare his or her best lesson on a particular topic, and teach this lesson to his or her own class, with invited colleagues watching (Huang & Bao, 2006). After the lesson the students are dismissed, and all of the teachers engage in a debriefing discussion. The presenting teacher has an opportunity to talk about the lesson, especially the reasoning behind its design. Afterward, other teachers can make comments, critique, or ask questions of either the teacher or other participants. Often, invited district or regional observers will offer their advice and insight. The debriefing meeting ends with the teachers breaking out into small groups to further discuss the lesson in detail. The presenting teacher then continues to refine the lesson to make it even better, and will eventually teach it again with invited colleagues observing. This cyclic process can be repeated again, with the goal of developing an exemplary lesson that can be shared in a report detailing the research process and product (Huang & Li, 2009).

Keli occurs in the context of a group of teachers and outside educators (school, district, or regional levels) or researchers from nearby universities that form a research group. They identify a central goal for improvement related to the national standards and then move through three phases of (1) demonstrating existing practice by teaching a lesson; (2) reflecting, revising, and re-teaching the updated lesson; and (3) further reflecting, revising, re-teaching, and disseminating their lesson (Huang & Li, 2009). The lesson can either be individually or collectively planned. But the activity of reflectively revising through systematic practice is closely connected to having recognized excellent teachers participate in this process.

Chinese lesson study occurs in the well-established framework of Chinese educational professional development, which includes school and city-based research activities, regional and national teaching competitions, and a rigorous promotional system that identifies these excellent teachers and encourages them to work with less-advanced colleagues (Huang & Li, 2009). The Chinese highly value the role these excellent teachers play in developing knowledge and guiding the research groups. Although knowledgeable others do play a role in Japanese lesson study, the Chinese version emphasizes the role these "experts" play in working closely with groups of teacher who are actively studying how to be better teachers in the context of their own practice (Fernandez, Cannon, & Chokshi, 2003; Huang & Li, 2009).

Both the Chinese and Japanese versions of lesson study share common features that make lesson study such a powerful professional development activity. They both enable the teacher to be a researcher, essential to improving one's practice (Stigler & Hiebert, 1999); they both allow for structured collaboration; they both focus on issues of practice, principally lessons; they both aim at student learning both in the goal orientations and in the collection of measures of student learning demonstrate that evidence is a central measure of the success of lesson study.

Despite their similarities, I believe that Chinese lesson study has a greater chance of being initially adopted by U.S. teachers than the more demanding Japanese form. In particular, Chinese lesson study places great emphasis on experts participating as co-partners in the research process; experts would fit better with current U.S. professional development climates where teachers are not yet used to taking the initiative and being researchers of their own practice. Additionally, the flexibility of the Chinese version means that teachers new to lesson study can adopt the less rigorous types. Attendance at model lessons could be a great way to encourage even the most resistant teachers to consider researching practice. Watching a master teacher successfully teach a random class of students demonstrates that reform teaching is possible; further, deprivitization of practice has begun. As teachers become more accustomed to observing, critiquing, and reflecting on others' practice, they can be encouraged to open their own lessons up for peer scrutiny. This can be done in ways that the teachers feel comfortable, perhaps with only a small group of departmental colleagues (or even just one!). When prepared, a revised lesson can be taught again to another class. Over time, this continual attempt to research one's practice will provide tangible rewards and a sense of confidence in one's teaching.

This article has proposed Chinese lesson study as a softer introduction—or perhaps even a simpler alternative—for schools overwhelmed by the demands of sustained Japanese lesson study. Chinese lesson study offers an intriguing solution; model lessons by recognized expert (or veteran) teachers can begin to deprivatize mathematics teaching practice (Little, 1990). As teachers grow comfortable observing, discussing, critiquing, and reflecting on others' practice, they can begin to participate with experienced colleagues in small study groups to develop their *own* exemplary lessons. As their confidence grows, they can invite other teachers and administrators, even parents, university personnel, and state officials, to observe their successful—and polished—lessons. Additional teachers may see the fruits of such collaboration and wish to join in on the small teacher study groups. In this way, some of the barriers to implementing practice-based research can be overcome, opening up the possibility for more intense Japanese lesson study for the daring. Or teachers may wish to stay with Chinese lesson study; either way, teachers would begin studying localized teaching in an attempt to improve their students' learning.

INTERDISCIPLINARY ALGEBRA CURRICULUM MODEL

Susan Staats
University of Minnesota
staats@umn.edu

This presentation proposes a model for designing interdisciplinary curriculum to supplement College Algebra courses. Interdisciplinary curriculum is often implemented in a team-taught format—effective but expensive and complex to implement, limiting the number of students who experience interdisciplinary challenges. This model makes content and learning goals drawn from a partner discipline explicit and limited, so that a mathematics teacher is responsible for a manageable amount of material in class. A sample curriculum module that unites financial mathematics with psychologist Erik Erikson's theory of life stage development is discussed. Reflection on the teaching experiment and on student reactions is guided by research in interdisciplinary curriculum design, mathematical modeling, and universal instructional design.

Keywords: Post-Secondary Education; Curriculum; Modeling

Interdisciplinary education is a high-impact practice for early undergraduates, but implementing it can be a daunting prospect. Interdisciplinary education often requires significant organizational changes such as learning communities, team teaching or longitudinal programs that allow for strong disciplinary grounding and gradual development of integrative skills (Boix Mansilla, Miller, & Gardner, 2000; Lattuca, Voigt, & Fath, 2004; Wentworth & Davis, 2002). Full support for interdisciplinary education is complex, expensive, and it requires an enormous commitment from institutions and instructors.

The disciplinary insulation that makes this work challenging may be particularly strong in mathematics. Mathematics curriculum is often defined more rigidly than in other fields (Grossman & Stodolsky, 1995). Mathematics faculties often have limited professional interactions with faculty in other disciplines (Ewing, 1999). At times, even the philosophical basis of mathematics is held in contrast to the integrative goals of interdisciplinary education (McGivney-Burelle, McGivney, & Wilburne, 2008; Siskin, 2000). These curricular boundaries impede the adoption of deeply interdisciplinary curricula in mathematics classes (Staats, 2007). This presentation proposes a model for designing supplemental interdisciplinary curriculum that addresses the dilemmas of expense, disciplinary expertise, and organizational sustainability.
